Test Setup

Description of test set-up:

The procedure used was ANSI/TIA-603-E-2016 and FCC KDB 935210 D05 Indus Booster Basic Meas v01r02:. A CW tone was input at the frequency where the system gain is the maximum in the pass band, with the nominal input power level. The spectrum analyzer was connected to the output RF port via a 50 Ohm 30 dB attenuator. The maximum hold trace and peak detector was used to capture the output power. The output power minus the input power equals to the booster gain in dB.

The EUT was set to **Operation Mode #1 with configuration Mode #1.**

Test Setup

Description of test set-up:

The procedure used was ANSI/TIA-603-E-2016. Two tones (CW) method was used. The input power to the amplifier was set at maximum drive level by combining the two tones. The two tones were chosen in such a way (1) the third order intermodulation product frequencies are located within the pass band of the DUT and (2) they produce the worst-case emissions out of band.

Based on FCC KDB 935210 D05 Indus Booster Basic Meas v01r03: 2019, the two tone was located on either side of the maximum gain frequency in the passing band, and separated with the available spacing, which is 12.5kHz.

Measurements were performed with modulated -tone at identical input amplitude which produced integrated maximum rated output power.

The EUT was set to **Operation Mode #1 with configuration Mode #1.**

Test Setup

Description of test set-up:

Based on FCC KDB 935210 D05 Indus Booster Basic Meas v01r03: 2019, the system maximum gain and the noise density is measured. Measurements were performed within the EUT's passband.

The noise figure is then calculated by $NF = NP - Gain + KTB \text{ Noise}$; where

NP is in band noise power per Herz,

Gain is measured at the maximum noise frequency with -55 dBm input signal in UL.

KTB Noise is 174dBm/Hz.

The EUT was set to **Operation Mode #1 with configuration Mode #1.**

8 Frequency Stability

The DMU and RU37 are synchronized to the same reference clock. Therefore there is no frequency error after down and up frequency conversion are performed.

The frequency stability check is not applicable to the EUT.

Supplementary test set-up	☒	Measurements were made in semi-anechoic chamber that complies to CISPR 16. Preliminary (peak) measurements. The EUT was rotated 360° about its azimuth with the receive antenna located at various heights in horizontal and vertical polarities. Final measurements (quasi-peak detector below 1GHz and average detector above 1GHz) were then performed by rotating the EUT 360° and adjusting the receive antenna height from 1 to 4 m. All frequencies were investigated in both horizontal and vertical antenna polarity, where applicable.			

Supplementary information	• If the highest internal frequency of the EUT is less than 108 MHz, the measurement shall only be made up to 1 GHz. • If the highest internal frequency of the EUT is between 108 MHz and 500 MHz, the measurement shall only be made up to 2 GHz. • If the highest internal frequency of the EUT is between 500 MHz and 1 GHz, the measurement shall only be made up to 5 GHz. • If the highest internal frequency of the EUT is above 1 GHz, the measurement shall be made up to 6 GHz. • Where the highest internal frequency is not known, tests shall be performed up to 6 GHz.
VERDICT: PASS	

Test Method
This test measures the radiating levels from the EUT, thus evaluating the potential for the EUT to cause radio frequency interference to other electronic devices. Testing was performed in accordance with the test standard(s) referenced in the test summary section of this report. The Equipment Under Test (EUT) was configured based upon the requirements of the applicable test standard. Initially, the primary emission frequencies are identified by positioning a broadband receive antenna three meter from the EUT. A scan was made with an EMC Analyzer, controlled by EMC Test Software, Tile7! with the receiver in the peak mode. The receiver IF bandwidth was 120 kHz and scan step was less than 30kHz. To ensure that the maximum emission at each discrete frequency of interest is observed, the receive antenna is varied in height from one to four meters and rotated to produce horizontal and vertical polarities while the turntable is rotated to determine the worst emitting configuration. Measurements were then made using CISPR quasi peak when the peak readings were within 10dB of the limit line. The numerical results are included herein to demonstrate compliance.

Test Setup
The EUT was placed on a 0.8m non-conducting table above a ground reference plane (GRP).

Measurement data and Plot

Note:

- 1) The test results below show that EUT pass the tests with Class B limit. As Class B limit is more restrictive than Class A limit, consequently the EUT pass the tests with Class A limit.
- 2) Quasi-peak (dBuV/m) = Raw Quasi-peak (dBuV) + Antenna Factor (dB/m) + Correction Factor (dB)
Correction Factor (dB) = Cable loss(dB)
- 3) The emissions that exceed the limit were emitted from the transmitter, which is not required by the standard in this section.

Annex

Annex 1 – Measurement Uncertainties

The tables below show measurement uncertainties of the EMC test set-ups. The reported expanded uncertainties are based on a standard uncertainty multiplied by a coverage factor of k=2, providing a level of confidence of approximately 95%.

Emission tests		Uncertainty	U _{CISPR}
RF Conducted disturbance (mains port) 150kHz – 30MHz	AMN:LIN-120C	dB	3,44dB
	AMN:	dB	
	AMN:	dB	
Radiated Emissions; 30MHz – 300MHz(Horz.)		dB	5,34dB
Radiated Emissions; 30MHz – 300MHz(Vert.)		dB	6,32dB
Radiated Emissions; 300MHz – 1000MHz(Horz.)		dB	5,34dB
Radiated Emissions; 300MHz – 1000MHz(Vert.)		dB	6,32dB
Radiated Emissions; 1000MHz – 6000MHz(Horz.)		dB	5,18dB
Radiated Emissions; 1000MHz – 6000MHz(Vert.)		dB	5,18dB
LF Harmonic current emissions		%	n/a
LF Voltage Fluctuations		%	n/a

Annex 2 - ISO 17025 ACCREDITATION CERTIFICATE

For complete scope of certification use
