3.3 Occupied Bandwidth (FCC Rule § 2.1049)**3.3.1 Measuring Method**

FCC rule 47 CFR 2.1049 requires measurements of the occupied bandwidth which is defined in the same section as "the frequency bandwidth such that, below its lower and above its upper frequency limits, the mean powers radiated are each equal to 0.5 percent of the total mean power radiated by a given emission." To obtain the occupied bandwidth of the radar transmitter, a special program (program list shown below) was loaded to the Hewlett-Packard spectrum analyzer and run by entering the HP-provided POWER BANDWIDTH calculation command [PWRBW].

The result was automatically displayed on the screen on the spectrum analyzer as:

POWER_BW=----- MHz

(1) "Upper Tolerance Frequency measured (at -20°C)", $f(\text{U}) = 9427.0$ MHz

(2) "Lower Tolerance Frequency measured (at $+50^\circ\text{C}$)", $f(\text{L}) = 9409.0$ MHz

(3)-(a)

$f(\text{U}) + \text{max. } f(1.5/T) = 9445.75 \text{ MHz} < f(\text{UAUBW}) = 9460 \text{ MHz} \leq f(\text{UASB}) = 9500 \text{ MHz}$

(3) - (b)

$f(\text{L}) - \text{max. } f(1.5/T) = 9390.25 \text{ MHz} > f(\text{LAUBW}) = 9360 \text{ MHz} \geq f(\text{LASB}) = 9300 \text{ MHz}$

So, both are found within the specified limits.

5.2 Description of the circuits employed for suppression of spurious radiation, for limiting or shaping the control pulse, and for limiting or controlling power

ANTENNA UNIT

TRANSCEIVER MODULE (RTR-074)

Modulator/Block PCB 03P9270

The primary function of the modulator is to produce narrow high tension pulses to drive the magnetron. To produce such pulses, the modulator block incorporates a modulator trigger circuit, a modulating pulse generator and a booster pulse transformer.

The modulator trigger circuit is composed of U851 and associated components. It generates pulses that fire modulator FET Q857. Normally, the circuit is stable with U851 off. The pulse to fire the modulator FET is produced when U851 turns on upon receiving the TX trigger pulse from the display unit. When U851 turns on at the positive-going edge of the TX trigger pulse, it produces a narrow pulse. This narrow pulse is boosted by pulse transformer T851 by the ratio 1:9. The resultant pulse, its level being 2.2 kV, is provided to oscillate the magnetron.

CR856 and CR857 absorb the ringing in the secondary side of T851 while C862 decouples the pulse energy that is liable to occur across the magnetron heater when T851's secondary windings are unbalanced or the load is asymmetric.

Also incorporated in the PCB 03P9270 are the TX HV circuit and magnetron heater power supply circuit. The TX HV circuit provides a high tension of about 300 V to the pulse forming network through CR837, CR838. A DC voltage of 8.0 V is supplied to the magnetron heater through CR836.

Duplexer and Frequency Converter

Since this radar uses a patch array antenna for transmission and reception, an efficient device is required for switching the transmission and receiver. This radar employs circulator U801 (Composed of the circulator and the MIC) for this purpose. It is a passive directional coupler with three ports.

The microwave energy produced by the magnetron enters the circulator from port RF1. It is fed to port RF2 with little loss of energy; port MIC-INPUT at this is isolated. In the same manner, the received signal entering into RF2 is transferred to port MIC-INPUT, isolating port RF1. This

operation of the circulator protects the receiver during transmission and minimizes the loss of the received signal.

A diode limiter, made up of a pair of PIN diodes, is incorporated in the first stage of the MIC (microwave IC). It is a passive switching device which allows the low-level RF signal to pass through and prohibits relatively strong microwave energy, such as the leak from the circulator during each TX cycle or the TX pulses received directly from other radars operating in the proximity, to enter the sensitive receiver circuit.

When a low-level signal is received, the PIN diodes remain in the cutoff state, and the limiter's input impedance matches the characteristic impedance of the receiver allowing the signal to be delivered to the frequency converter of the MIC. When strong microwave energy is received, the PIN diodes are put in the conductive state (or short-circuited) causing the input energy to be attenuated. The strong input is further reduced to about 150 mW by the limiter diode.

The MIC converts 9 GHz RF signal into an intermediate frequency of 60 MHz. It is achieved by mixing the received signal with the local oscillator signal in the frequency converter of the MIC. The built-in local oscillator oscillates at a frequency 60 MHz higher than the magnetron frequency of 9410 MHz.

IF Amplifier Block PCB 03P9321

The converted 60 MHz IF signal from MIC is amplified in the IF amplifier block. The signal detected at the final stage is delivered to the display unit video amplifier.

The 60 MHz IF signal is divided into the tuning block and the amplifier block through C3 and C92.

In the tuning block, IF signal is amplified at Q10 and tuned at T2. CR12 detects IF signal. And its detected voltage is amplified and buffered by U6. The output voltage is used for the tuning indicator and the tuning control.

In the amplifier block, Q1/Q2 is the first amplifier. Q6 is the attenuator switch. The signal from Q6 is fed to the detector/broadband-amplifier U1. The output of U1 is coupled to the video amplifier U2.
