6L	1900MHz/Part 24: Frequency Stability

800 MHz : RF POWER OUTPUT

Para. 2.985 (a) and 22.913 (a)

The RF power measured at the output terminals (antenna connector) is plotted against supply voltage variation and temperature variations at the highest levels.

Supply

Exhibit	Voltage (V)	Temperature	TX Freq	Output (W)	Power Level	Analog/Digital
6A2	4.8	Varied	Mid Band	.4 W	0	Analog
6A3	Varied	+25 C	Mid Band	.4 W	0	Analog
6A4	4.8	Varied	Mid Band	.4 W	0	Digital
6A5	Varied	+25 C	Mid Band	.4 W	0	Digital

The measurements were made per IS-137A using a Hewlett Packard 8953DT North American Dual Mode Cellular Test System which includes the following equipment:

HP8958A Cellular Interface
HP6623A DC Power Supply
HP8596E Spectrum Analyzer
HP437B RF Power Meter
HP8901B Modulation Analyzer
HP8903B Audio Analyzer
Thermotron SM-8C Temperature Chamber

EFFECTIVE RADIATED POWER

The following is a description of the substitution method used in accordance with IS-137A to obtain accurate ERP readings at the carrier fundamental frequency:

- (1) EUT measurements are made at 3 m using calibrated antennas and equipment with known cable losses.
- (2) A peak measurement is made by raising and lowering the antenna and rotating the EUT 360 degrees. Horizontal and vertical polarization data is recorded.
- (3) A generator and dipole antenna are then substituted for the EUT. The dipole antenna is a half-wave dipole. If a dipole antenna cannot be used, then the designated antenna is referenced to a dipole antenna.
- (4) Measurements are made through the dipole antenna at known power levels to determine the system calibration factors at a given frequency.
- (5) At frequencies where no calibration data is taken, the value is interpolated between the closest data point above and below the transmit frequency. Calibration data is taken with a half-wave dipole antenna.

Measurements at a distance of 3 m from the source at the highest power level setting:

800 MHz : OCCUPIED BANDWIDTH

Per 2.989 (c), (1) (h) and 22.917 (d)(1) the exhibits presented show the modulations that co-exist in a cellular system:

The method of measuring occupied bandwidth of a US digital cellular is different from the analog FM signal. The traditional method for specifying occupied bandwidth of a FM signal is to use a mask drawn over the spectral plot of the modulated signal. If any point of the modulation signal exceeds the mask a failure is noted.

A different method is used for the US DAMPS system. This is described in the TIA IS 137A document. The method employed in digital applications is to measure average power within a 30kHz bandwidth corresponding to a channel bandwidth for the system. This measurement is used to determine and specify power in neighboring channels relative to the fundamental occupied channel; i.e.: the average power in the adjacent channels is compared to the average power in the fundamental channel for specifying occupied bandwidth.

The power in each channel is an average of all the energy within that channel. This is less than the peak within the channel due to the nature of an average power measurement. This characteristic of measuring average power prohibits the use of a spectral mask. The mask could only be drawn relative to the spectral peaks and would not give an indication of the average power as specified in IS 137A, section 3.4.1.2. Consequently, the only way to accurately measure and specify occupied bandwidth for DAMPS is with special equipment designed to collect all the energy within a specified bandwidth and display the average power of this energy. This can't be done with a simple spectrum analyzer measurement as was traditionally possible for FM only signals.

<u>Exhibit #</u>	<u>Description</u>	<u>Power Level</u>

Thermotron SM-8C temperature Chamber

EFFECTIVE ISOTROPIC RADIATED POWER

The following is a description of the substitution method used to obtain accurate EIRP readings at the carrier fundamental frequency:

- (1) EUT measurements are made at 3 m using calibrated antennas and equipment with known cable losses.
- (2) A peak measurement is made by raising and lowering the antenna and rotating the EUT 360 degrees. Horizontal and Vertical Polarization data is recorded.
- (3) A generator and dipole antenna are then substituted for the EUT. The dipole antenna is a half-wave dipole. If a dipole antenna cannot be used, then the designated antenna is referenced to a dipole antenna.
- (4) Measurements are made through the dipole antenna at known power levels to determine the system calibration factors at a given frequency.
- (5) At frequencies where no calibration data is taken, the value is interpolated between the closest data point above and below the transmit frequency. Calibration data is taken with a half-wave dipole antenna.

Measurements at a distance of 3 m from the source at the highest power level setting:

Frequency (MHz)	Rated Output Power (W)	EIRP (dBm)
1879.98	0.375	25.7

Exhibit 6G2

Exhibit 6G3

800/1900 MHz: MODULATION CHARACTERISTICS

Definition

The transceiver shall be capable of generating $\pi/4$ shifted differentially encoded quadrature phase shift keying signals. The transmitted signal is given by:

$$S(t) = \sum_n g(t-nT) \cos(\phi_n) \cos(\omega_c t) - \sum_n g(t-nT) \sin(\phi_n) \sin(\omega_c t)$$

where $g(t)$ is the pulse shaping function that corresponds to a square root raised cosine baseband filter with roll off factor of 0.35, ω_c is the radian carrier frequency, T is the symbol period, and ϕ_n is the absolute phase corresponding to the n th symbol interval. The symbol rate ($1/T$) is 24.3 k symbols /sec.

The modulation accuracy requirement is specified by setting limits on the RMS difference between the actual transmitted signal waveform and the ideal signal waveform. The ideal waveform is derived mathematically from the specification of modulation shown above. The specified requirement is error vector magnitude.

For this measurement, frequency accuracy shall meet the requirements of Section 3.1 prior to measurement.

The average carrier frequency error is the difference between the average carrier frequency of the actual transmitted waveform and the average signal waveform carrier frequency.

The ideal modulation is defined above. The definition is such that, observing an ideal transmitter through an ideal root raised-cosine receiver filter at the correct sampling instants one symbol apart would result in the sequence of values given by:

$$S(k) = S(k-1) e^{j\{\pi/4 + B(k) \cdot \pi/2\}}$$

where $B(k) = 0, 1, 2, 3$ according to the following table:

X _k	Y _k	B(k)
0	0	0
0	1	1
1	1	2
1	0	3

In the forward channel, $S(k)$ forms part of a continuous data stream. In the reverse channel, the transit bursts from the mobile are truncated by power up and down ramping. In this case, $S(6)$ is the first sample that enters into demodulation, which yields the first two information bits by comparing $S(6)$ with $S(7)$. The last information bits lie in the comparison of $S(162)$ and $S(161)$.

The ideal transmit and receive filters in cascade form a raised cosine Nyquist filter having an impulse response going through zero at symbol period intervals, so there is no inter-symbol interference at the ideal sampling points. The ideal signal sampler therefore, take on one of the eight values defined above, at the output of the receive filter.

This section defines how the output signal from a transmitter is to be evaluated against the ideal signal.

Let $Z(k)$ be the complex vectors produced by observing the real transmitter through an ideal measuring receive filter at instants k , one symbol period apart. With $S(k)$ defined as above, the transmitter is modeled as:

$$Z(k) = [C0 + C1 * [S(k) + E(k)]] * W^k$$

where:

$$k = n/24.3\text{KHz}$$

$$dr = jda$$

$W = e^{dr}$ accounts for both a frequency offset giving "da" radians per symbol phase rotation and an amplitude changes of "dr" nepers per symbol:

$C0$ is a constant origin offset representing quadrature modulator imbalance,
 $C1$ is a complex constant representing the arbitrary phase and output power of the transmitter, and
 $E(k)$ is the residual vector error on sample $S(k)$

The sum square vector error is then:

$$\sum_{k=\text{MIN}}^{k=\text{MAX}} |E(k)|^2 \quad \sum_{k=\text{MIN}}^{k=\text{MAX}} |[Z(k) * W^{-C0/C1} - S(k)]|^2$$

$C0$, $C1$ and W shall be chosen to minimize this expression and are then used to compute the individual vector errors $E(k)$ on each symbol. The symbol timing phase of the receiver output samples used to compute the vector error shall also be chosen to give the lowest value.

The values of MAX and MIN for the reverse channel (mobile station transmitter) are:

$$\begin{aligned} \text{MIN} &= 6 \\ \text{MAX} &= 162 \end{aligned}$$

The RMS vector error is then computed as the square root of the sum-square vector divided by the number of symbols in the slot, (157 in the reverse direction).

Method of Measurement

Connect the mobile station to the Standard Test Source and Modulation Accuracy Equipment. Modulate the Standard Test Source with pseudo-random Data Field bits. The mobile station shall transpond the Data Field bits using the TDMAON command. Use the Modulation Accuracy Measurement Equipment to measure the modulation accuracy of the mobile station.

Minimum Standard

The RMS vector error in any burst shall be less than 12.5%. In addition, the normalized error vector magnitude during the first 10 symbols (20 bits) of a burst following the ramp-up, must have an RMS value of less than 25% when averaged over 10 bursts within a 1 minute interval. The minimum standard for frequency offset is specified in section 3.1.2.2.3 of IS 137. The origin offset in any burst shall be less than -20 dBc.

1900 MHz: OCCUPIED BANDWIDTH

Per 2.989 (c, l, h) the exhibits presented show the modulations that have to exist in a 1900 MHz Cellular System.

All the exhibits listed below are plots where the modulation condition is Psuedorandom Data (48.6 kb/s switched), operating in the DAMPS (TDMA) mode. All plots were taken while transmitting at Power Level 0. Any frequency span not covered at the exhibits below was found to be unaffected by the transmitter/modulation.

The emissions mask is not provided for this exhibit. The method of measuring occupied bandwidth of a US digital cellular is different from the analog FM signal. The traditional method for specifying occupied bandwidth of a FM signal is to use a mask drawn over the spectral plot of the modulated signal. If any point of the modulation signal exceeds the mask a failure is noted.

A different method is used for the US DAMPS system. This is described in the TIA IS 137A document. The method employed in digital applications is to measure average power within a 30kHz bandwidth corresponding to a channel bandwidth for the system. This measurement is used to determine and specify power in neighboring channels relative to the fundamental occupied channel; i.e.: the average power in the adjacent channels is compared to the average power in the fundamental channel for specifying occupied bandwidth.

The power in each channel is an average of all the energy within that channel. This is less than the peak within the channel due to the nature of an average power measurement. This characteristic of measuring average power prohibits the use of a spectral mask. The mask could only be drawn relative to the spectral peaks and would not give an indication of the average power as specified in IS 137A, section 3.4.1.2. Consequently, the only way to accurately measure and specify occupied bandwidth for DAMPS is with special equipment designed to collect all the energy within a specified bandwidth and display the average power of this energy. This can't be done with a simple spectrum analyzer measurement as was traditionally possible for FM only signals.

EXHIBIT

Lower Channel (Channel 2)

Normal bursted operation; data rate 48.6 kb/s, Output power 0.4 Watts, 1850.04 MHz.

612 1 MHz Resolution Bandwidth reference plot.

613 Emission Bandwidth

614 1 MHz span, Center Frequency 1849.99 MHz.

Upper Channel (Channel 1998)

Normal bursted operation; data rate 48.6 kb/s, Output power 0.4 Watts, 1909.90 MHz.

615 1 MHz Resolution Bandwidth reference plot.

616 Emission Bandwidth

617 1 MHz span, Center Frequency 1909.92 MHz.
