2.0 General Description

2.1 Product Description

The OpenSky M-803 Mobile Radio is a versatile voice and data radio designed for the mobile environment. The M-803 Mobile Radio operates in the 800 MHz SMR and NPSPAC frequency bands. A production version of the M-803 Unit was received on July 1, 2004 in good condition. The purpose of testing is to perform a routine RF Exposure evaluation for five antennas which are being added to the existing filing. Only the OpenSky digital modulation (OTP/ORP which employs a GFSK modulation) software was provided and tested. This radio has been tested and complies with the FCC RF exposure limits for Controlled Exposure.

The EUT has been tested at the request of

Company: M/A-Com

Overview of M-803 Mobile Radio Unit

Applicant	M/A-Com
Trade Name	OpenSky M-803 Mobile Radio
FCC Identifier	BV8M803M
Use of Product	Voice and Data Communication
Type of Modulation	GFSK and FM
Bit Rate	19200 bps
Max. Allowed Deviation	10 kHz
RF Output	25 Watts Rated
The dc voltage applied to and current into the several elements of the final RF amplifying device	Voltage: 12VDC Current: 9A
Frequency Range	806 – 824 MHz and 851 – 869 MHz
Max. Number of Channels	830
Antenna(e) & Gain	3 dBd (5 dBi)
Detachable Antenna?	☒ Yes ☐ No
Receiver L.O. Frequency	921 – 939 MHz
External Input	☒ Audio ☒ Digital Data

2.2 Related Submittal(s) Grants

None.

2.3 Test Facility

Site 2C (Middle Site) is a 3m and 10m sheltered emissions measurement range located in a light commercial environment in Boxborough, Massachusetts. It meets the technical requirements of ANSI C63.4-1992 and CISPR 22:1993/EN 55022:1994 for radiated and conducted emission measurements. The shelter structure is entirely fiberglass and plastic, with outside dimensions of 33 ft x 57 ft. The structure resembles a quonset hut with a center ceiling height of 16.5 ft.

The testing floor is covered by a galvanized sheet metal groundplane that is earth-grounded via copper rods around the perimeter of the site. The joints between individual metal sheets are bridged with a 2 inch wide metal strips to provide low RF impedance contact throughout. The sheets are screwed in place with stainless steel, round-head screws every three inches. Site illumination and HVAC are provided from beneath the ground reference plane through flush entry ports, the port covers are electrically bonded to the ground plane.

A flush metal turntable with 12 ft. diameter and 5000 lb. load capacity is provided for floor-standing equipment. A wooden table 80 cm high is used for table-top equipment. The turntable is electrically connected to the ground plane with three copper straps. The straps are connected to the turntable at the center of it with ground braid. The copper strap is directly connected to the groundplane at the edges of the turntable. The turntable is located on the south end of the structure and the antennas are mounted 3 and 10 meters away to the north. The antenna mast is a non-conductive with remote control of antenna height and polarization. The antenna height is adjustable from 1 to 4 meters.

FCC Site Registration #: 91658

The EUT was activated at full power, and connected to each of the antennas listed in this report. Each antenna was placed at a typical mounting point. At the request of M/A-Com, the roof mounted antennas were connected to an 8"x8" flat metal panel which was 3mm thick. The metal panel the roof mounted antennas were mounted on was grounded to the chassis of the vehicle at the sun visor attachment screw via a 195 cm 14-gauge ground wire. A measurement antenna was connected to a spectrum analyzer, and peak readings of the field strength were taken at various test points outside and inside of the vehicle. Measurement antenna height and polarization were varied at each point to produce the worst-case value. Below are diagrams showing the transmit antenna mounting point and the corresponding test point locations and designations. Note that for this set of antennas, only the trunk @ window and roof mounting points were tested as they fully represent the intended use of these antennas.

The readings at the spectrum analyzer are in dBuV/m. The limits are expressed in mW/cm². An equation that relates these two values is

$$E = 20 \text{ LOG } (1 \times 10^6 (377 \times 10 \times P)^{1/2})$$

where E is the measured voltage in dBuV/m, and P is the power density in mW/cm². The factor 377 is the impedance of free space, a constant. The obtained power density can then be compared to the limits. The power density limit for controlled exposure is f/300, where f is the transmit frequency. The worst case limits are at the lowest transmit frequency, and the measured RF output power of the EUT at the antenna port was maximum at the lowest transmit frequency.

Therefore the lowest transmit frequency of 806.0125 MHz was selected as the worst case frequency and the limit for Maximum Permissible Exposure (MPE) in controlled environments was determined to be 2.687 mW/cm².
