SCOPE

An electromagnetic emissions test has been performed on the Savi Technology, Inc. models 645 and 646 Tags pursuant to Subpart C of Part 15 of FCC Rules for intentional radiators and Subpart B of Part 15 of FCC Rules for receivers. Conducted and radiated emissions data has been collected, reduced, and analyzed within this report in accordance with measurement guidelines set forth in ANSI C63.4-1992 as outlined in Elliott Laboratories test procedures.

The transceiver above has been tested in a simulated typical installation to demonstrate compliance with the relevant FCC performance and procedural standards.

Final system data was gathered in a mode that tended to maximize emissions by varying orientation of EUT, orientation of power and I/O cabling, antenna search height, and antenna polarization.

Every practical effort was made to perform an impartial test using appropriate test equipment of known calibration. All pertinent factors have been applied to reach the determination of compliance.

The test results recorded herein are based on single type tests of the Savi Technology, Inc. models 645 and 646 Tags and therefore apply only to the tested samples. The samples were selected and prepared by Eugene Schlindwein of Savi Technology, Inc.

OBJECTIVE

The primary objective of the manufacturer is compliance with Subparts B and C of Part 15 of FCC Rules for the radiated and conducted emissions of intentional radiators and receivers. Certification of these devices is required as a prerequisite to marketing as defined in Part 2 the FCC Rules.

Certification is a procedure where the manufacturer or a contracted laboratory makes measurements and submits the test data and technical information to the FCC. The FCC issues a grant of equipment authorization upon successful completion of their review of the submitted documents. Once the equipment authorization has been obtained, the label indicating compliance must be attached to all identical units, which are subsequently manufactured.

STATEMENT OF COMPLIANCE

The tested samples of Savi Technology, Inc. models 645 and 646 Tags complied with the requirements of Subpart C of Part 15 of the FCC Rules for low power intentional radiators and the requirements of Subpart B of Part 15 of the FCC Rules for receivers operating between 30 MHz and 960 MHz.

Maintenance of FCC compliance is the responsibility of the manufacturer. Any modification of the product which may result in increased emissions should be checked to ensure compliance has been maintained (i.e., printed circuit board layout changes, different line filter, different power supply, harnessing or I/O cable changes, etc.).

EMISSION TEST RESULTS

The following emissions tests were performed on the Savi Technology, Inc. models ST-644 and ST-645 Tags. The actual test results are contained in an exhibit of this report.

LIMITS OF CONDUCTED INTERFERENCE VOLTAGE

The limits detailed in FCC Rules Part 15 Section 15.207 for the conducted interference voltage on AC power leads do not apply to the 640 series of tags as they are powered from internal batteries and cannot be powered, directly or indirectly, from the AC mains.

LIMITS OF RADIATED FIELD STRENGTH - RECEIVER

The EUT tested complied with the limits detailed in FCC Rules Part 15 FCC Rules Part 15 Section 15.109(a) for a receiver.

The following measurement was extracted from the data recorded during the radiated electric field emissions scan and represents the highest amplitude emission relative to the specification limit. The actual test data and any correction factors are contained in an exhibit of this report.

30 – 900 MHz, Receive Mode LO @433.72 MHz, ST-644

Frequency MHz	Level dBuV/m	Pol v/h	Class B		Detector Pk/QP/Avg	Azimuth Degrees	Height Meters	Comments
			Limit	Margin				
867.618	44.1	h	46.0	-1.9	QP	60	1.0	EUT Upright

30 – 900 MHz, Receive Mode LO @433.72 MHz, ST-645

Frequency MHz	Level dBuV/m	Pol v/h	Class B		Detector Pk/QP/Avg	Azimuth Degrees	Height Meters	Comments
			Limit	Margin				
867.560	41.8	h	46.0	-4.2	QP	75	1.0	EUT on its side

BANDWIDTH

The EUT tested complied with the limits detailed in FCC Rules Part 15 Section 15.231(c). The 20dB bandwidth was 455kHz.

DUTY CYCLE CALCULATION

The maximum duty cycle permitted for all signals is 10% (refer to the Theory of Operations for details) when measured over any 100ms period. This corresponds to a minimum average duty cycle correction factor of -20 dB to be applied to peak readings to calculate the average level of the signal.

PERIOD OF OPERATION

All transmissions consist of a pulse train of 10ms pulses, 1 pulse every 100ms (duty cycle = 10%). The pulse train transmission lasts for less than 1 second and there is a silent period of the longer of 30 times the transmission period or 10 seconds between successive transmissions, thereby meeting the timing requirements of 15.231(e). Refer to the Theory of Operations for more details. Timing plots are attached to the test data.

LIMITS OF RADIATED FIELD STRENGTH -INTENTIONAL RADIATOR

The EUT tested complied with the radiated field strength limits detailed in FCC Rules Part 15 Section 15.231(e) and 15.209 in the case of emissions falling within the frequency bands specified in Section 15.205.

The following measurement was extracted from the data recorded during the radiated electric field emissions scan and represents the highest amplitude emission relative to the specification limit. The actual test data and any correction factors are contained in an exhibit of this report.

30 – 4500 MHz, ST-644

Frequency MHz	Level dBuV/m	Pol v/h	15.231(e)		Detector Pk/QP/Avg	Azimuth degrees	Height meters	Comments
433.878	91.6	V	Limit	Margin	Pk	130	1.3	EUT upright

30 – 4500 MHz, ST-645

Frequency MHz	Level dBuV/m	Pol v/h	15.231(e)		Detector Pk/QP/Avg	Azimuth degrees	Height meters	Comments
433.878	91.7	V	Limit	Margin	Pk	79	1.1	EUT upright

MEASUREMENT UNCERTAINTIES

ISO Guide 25 requires that an estimate of the measurement uncertainties associated with the emissions test results be included in the report. The measurement uncertainties given below are based on a 95% confidence level and were calculated in accordance with NAMAS document NIS 81.

Measurement Type	Frequency Range (MHz)	Calculated Uncertainty (dB)
Conducted Emissions	0.15 to 30	± 2.4
Radiated Emissions	30 to 1000	± 3.2

EQUIPMENT UNDER TEST (EUT) DETAILS**GENERAL**

The Savi Technology, Inc. 640 series of RFID Tagging devices are designed to identify the container to which they are attached when used as a part of the Savi Control System. There are three models that make up the 640 series – ST- 644, ST-645 and ST-646.

All three use the same rf circuitry on PCB CCA 810-02900-00, but they use different stuffing options to enable auxiliary functions. These stuffing options do not affect the rf circuitry. The ST-644 does not use any options. The ST-645 and ST-646 use stuffing options to connect to a small daughter card that connects to a sensor. The magnetic coil sensor for the ST-645 detects if a bolt has been removed to trigger an alarm transmission. The ST-646 uses an optical sensor is used to detect if a cable is cut.

All of the 640 series use Lithium cell batteries for power (the ST-645 uses two cells, the others only one).

Only models ST-644 and ST-645 were submitted for testing. The model ST-646 sensor is not yet available. It is anticipated that data for the ST-646 would be submitted at a later date to file for a Permissive Change to the FCC ID KL7-640T-V1.

Normally, the EUT would be mounted to a container or similar piece of equipment. The EUT was treated as tabletop equipment during testing to simulate the end user environment.

The ST-644 sample was received on June 18, 2002 and tested on June 18, June 19 and June 20, 2002. This sample had the components for the ST-644 and ST-645 installed in all of the stuffing options but did not have the sensor attached. The ST-645 sample was received and tested on September 4, 2002.

The EUTs tested consisted of the following component(s):

Manufacturer/Model/Description	Serial Number
Savi Technology, Inc. 644 Tag	644005
Savi Technology, Inc. 645 Tag	none

ENCLOSURE

The EUT enclosure is primarily constructed of Injection molded ABS plastic. It measures approximately 15.7cm long by 4.3cm wide by 3cm high.

SUPPORT EQUIPMENT

No support equipment was used during emissions testing.

EXTERNAL I/O CABLING

The 640 series of tags do not have interface ports that would connect to external cables.

EUT OPERATION

The EUT was either set to transmit continuously or to receive-only during testing.

TEST SITE**GENERAL INFORMATION**

Final test measurements were taken on June 18, June 19 and June 20, 2002 at the Elliott Laboratories Open Area Test Site #2 located at 684 West Maude Avenue, Sunnyvale, California. The test site contains separate areas for radiated and conducted emissions testing. Pursuant to section 2.948 of the Rules, construction, calibration, and equipment data has been filed with the Commission.

The FCC recommends that ambient noise at the test site be at least 6 dB below the allowable limits. Ambient levels are below this requirement with the exception of predictable local TV, radio, and mobile communications traffic. The test site contains separate areas for radiated and conducted emissions testing. Considerable engineering effort has been expended to ensure that the facilities conform to all pertinent FCC requirements.

CONDUCTED EMISSIONS CONSIDERATIONS

Conducted emissions testing are performed in conformance with ANSI C63.4-1992. Measurements are made with the EUT connected to the public power network through nominal, standardized RF impedance, which is provided by a line impedance stabilization network, known as a LISN. A LISN is inserted in series with each current-carrying conductor in the EUT power cord.

RADIATED EMISSIONS CONSIDERATIONS

The FCC has determined that radiation measurements made in a shielded enclosure are not suitable for determining levels of radiated emissions. Radiated measurements are performed in an open field environment. The test site is maintained free of conductive objects within the CISPR defined elliptical area incorporated in ANSI C63.4 guidelines.

MEASUREMENT INSTRUMENTATION**RECEIVER SYSTEM**

An EMI receiver as specified in CISPR 16-1 is used for emissions measurements. The receivers used can measure over the frequency range of 9 kHz up to 2000 MHz. These receivers allow both ease of measurement and high accuracy to be achieved. The receivers have Peak, Average, and CISPR (Quasi-peak) detectors built into their design so no external adapters are necessary. The receiver automatically sets the required bandwidth for the CISPR detector used during measurements.

For measurements above the frequency range of the receivers, a spectrum analyzer is utilized because it provides visibility of the entire spectrum along with the precision and versatility required to support engineering analysis. Average measurements above 1000MHz are performed on the spectrum analyzer using the linear-average method with a resolution bandwidth of 1 MHz and a video bandwidth of 10 Hz.

INSTRUMENT CONTROL COMPUTER

The receivers utilize either a Rohde & Schwarz EZM Spectrum Monitor/Controller or contain an internal Spectrum Monitor/Controller to view and convert the receiver measurements to the field strength at an antenna or voltage developed at the LISN measurement port, which is then compared directly with the appropriate specification limit. This provides faster, more accurate readings by performing the conversions described under Sample Calculations within the Test Procedures section of this report. Results are printed in a graphic and/or tabular format, as appropriate. A personal computer is used to record all measurements made with the receivers.

The Spectrum Monitor provides a visual display of the signal being measured. In addition, the controller or a personal computer run automated data collection programs which control the receivers. This provides added accuracy since all site correction factors, such as cable loss and antenna factors are added automatically.

LINE IMPEDANCE STABILIZATION NETWORK (LISN)

Line conducted measurements utilize a fifty microhenry Line Impedance Stabilization Network as the monitoring point. The LISN used also contains a 250 uH CISPR adapter. This network provides for calibrated radio frequency noise measurements by the design of the internal low pass and high pass filters on the EUT and measurement ports, respectively.

FILTERS/ATTENUATORS

External filters and precision attenuators are often connected between the receiving antenna or LISN and the receiver. This eliminates saturation effects and non-linear operation due to high amplitude transient events.

ANTENNAS

A biconical antenna is used to cover the range from 30 MHz to 300 MHz and a log periodic antenna is utilized from 300 MHz to 1000 MHz. Narrowband tuned dipole antennas are used over the entire 30 to 1000 MHz range for precision measurements of field strength. Above 1000 MHz, a horn antenna is used. The antenna calibration factors are included in site factors programmed into the test receivers.

ANTENNA MAST AND EQUIPMENT TURNTABLE

The antennas used to measure the radiated electric field strength are mounted on a non-conductive antenna mast equipped with a motor drive to vary the antenna height.

ANSI C63.4 specifies that the test height above ground for table-mounted devices shall be 80 centimeters. Floor mounted equipment shall be placed on the ground plane if the device is normally used on a conductive floor or separated from the ground plane by insulating material from 3 to 12 mm if the device is normally used on a non-conductive floor. During radiated measurements, the EUT is positioned on a motorized turntable in conformance with this requirement.

INSTRUMENT CALIBRATION

All test equipment is regularly checked to ensure that performance is maintained in accordance with the manufacturer's specifications. All antennas are calibrated at regular intervals with respect to tuned half-wave dipoles. An exhibit of this report contains the list of test equipment used and calibration information.

TEST PROCEDURES**EUT AND CABLE PLACEMENT**

The FCC requires that interconnecting cables be connected to the available ports of the unit and that the placement of the unit and the attached cables simulate the worst case orientation that can be expected from a typical installation, so far as practicable. To this end, the position of the unit and associated cabling is varied within the guidelines of ANSI C63.4, and the worst-case orientation is used for final measurements.

CONDUCTED EMISSIONS

Conducted emissions are measured at the plug end of the power cord supplied with the EUT. Excess power cord length is wrapped in a bundle between 30 and 40 centimeters in length near the center of the cord. Preliminary measurements are made to determine the highest amplitude emission relative to the specification limit for all the modes of operation. Placement of system components and varying of cable positions are performed in each mode. A final peak mode scan is then performed in the position and mode for which the highest emission was noted on all current carrying conductors of the power cord.

RADIATED EMISSIONS

Radiated emissions measurements are performed in two phases as well. A preliminary scan of emissions is conducted in which all significant EUT frequencies are identified with the system in a nominal configuration. At least two scans are performed from 30 MHz up to the frequency required by the regulation specified on page 1. One or more of these is with the antenna polarized vertically while the one or more of these is with the antenna polarized horizontally. During the preliminary scans, the EUT is rotated through 360°, the antenna height is varied and cable positions are varied to determine the highest emission relative to the limit.

A speaker is provided in the receiver to aid in discriminating between EUT and ambient emissions. Other methods used during the preliminary scan for EUT emissions involve scanning with near field magnetic loops, monitoring I/O cables with RF current clamps, and cycling power to the EUT.

Final maximization is a phase in which the highest amplitude emissions identified in the spectral search are viewed while the EUT azimuth angle is varied from 0 to 360 degrees relative to the receiving antenna. The azimuth, which results in the highest emission, is then maintained while varying the antenna height from one to four meters. The result is the identification of the highest amplitude for each of the highest peaks. Each recorded level is corrected in the receiver using appropriate factors for cables, connectors, antennas, and preamplifier gain. Emissions, which have values close to the specification limit, may also be measured with a tuned dipole antenna to determine compliance.

SPECIFICATION LIMITS AND SAMPLE CALCULATIONS

The limits for conducted emissions are given in units of microvolts, and the limits for radiated emissions are given in units of microvolts per meter at a specified test distance. Data is measured in the logarithmic form of decibels relative to one microvolt, or dB microvolts (dBuV). For radiated emissions, the measured data is converted to the field strength at the antenna in dB microvolts per meter (dBuV/m). The results are then converted to the linear forms of uV and uV/m for comparison to published specifications.

For reference, converting the specification limits from linear to decibel form is accomplished by taking the base ten logarithm, then multiplying by 20. These limits in both linear and logarithmic form are as follows:

CONDUCTED EMISSIONS SPECIFICATION LIMITS, SECTION 15.207 & 15.107(a)

The table below shows the limits for the emissions on the AC power line from an intentional radiator and a receiver.

Frequency Range (MHz)	Limit (uV)	Limit (dBuV)
0.450 to 30.000	250	48

FUNDAMENTAL AND HARMONIC LIMITS 15.231 (b)

The table below shows the limits for both the Fundamental and Harmonic emissions for each frequency band of operation detailed in Section 15.231 (b) for control signals.

Operating Frequency (MHz)	Field strength (microvolts/m)	Harmonics (microvolts/m)
70 - 130	1250	125
130 - 174	1250 - 3750	125 - 375
174 - 260	3750	375
260 - 470	3750 - 12,500	375 - 1250
Above 470	12,500	1250

FUNDAMENTAL AND HARMONIC LIMITS 15.231 (e)

The table below shows the limits for both the Fundamental and Harmonic emissions (that do not fall in restricted bands) for each frequency band of operation detailed in Section 15.231 (e) for data signals.

Operating Frequency (MHz)	Field strength (microvolts/m)	Harmonics (microvolts/m)
70 - 130	500	50
130 - 174	500 - 1500	50 - 150
174 - 260	1500	150
260 - 470	1500 - 5000	150 - 500
Above 470	5000	500

RADIATED EMISSIONS SPECIFICATION LIMITS, SECTION 15.209

The table below shows the limits for the spurious emissions from transmitters that fall in restricted bands.

Frequency Range (MHz)	Limit (uV/m @ 3m)	Limit (dBuV/m @ 3m)
0.009-0.490	$2400/F_{\text{KHz}} @ 300\text{m}$	$67.6-20*\log_{10}(F_{\text{KHz}}) @ 300\text{m}$
0.490-1.705	$24000/F_{\text{KHz}} @ 30\text{m}$	$87.6-20*\log_{10}(F_{\text{KHz}}) @ 30\text{m}$
1.705 to 30	30 @ 30m	29.5 @ 30m
30 to 88	100	40
88 to 216	150	43.5
216 to 960	200	46.0
Above 960	500	54.0

RADIATED EMISSIONS SPECIFICATION LIMITS, SECTION 15.109(a) (RECEIVER)

The table below shows the limits for emissions from the receiver.

Frequency Range (MHz)	Limit (uV/m @ 3m)	Limit (dBuV/m @ 3m)
30 to 88	100	40
88 to 216	150	43.5
216 to 960	200	46.0
Above 960	500	54.0

SAMPLE CALCULATIONS - CONDUCTED EMISSIONS

Receiver readings are compared directly to the conducted emissions specification limit (decibel form) as follows:

$$R_r - B = C$$

and

$$C - S = M$$

where:

R_r = Receiver Reading in dBuV

B = Broadband Correction Factor*

C = Corrected Reading in dBuV

S = Specification Limit in dBuV

M = Margin to Specification in +/- dB

- * Broadband Level - Per ANSI C63.4, 13 dB may be subtracted from the quasi-peak level if it is determined that the emission is broadband in nature. If the signal level in the average mode is six dB or more below the signal level in the peak mode, the emission is classified as broadband.

SAMPLE CALCULATIONS - RADIATED EMISSIONS

Receiver readings are compared directly to the specification limit (decibel form). The receiver internally corrects for cable loss, preamplifier gain, and antenna factor. The calculations are in the reverse direction of the actual signal flow, thus cable loss is added and the amplifier gain is subtracted. The Antenna Factor converts the voltage at the antenna coaxial connector to the field strength at the antenna elements. A distance factor, when used for electric field measurements, is calculated by using the following formula:

$$F_d = 20 * \log_{10} (D_m/D_s)$$

where:

$$F_d = \text{Distance Factor in dB}$$

$$D_m = \text{Measurement Distance in meters}$$

$$D_s = \text{Specification Distance in meters}$$

Measurement Distance is the distance at which the measurements were taken and Specification Distance is the distance at which the specification limits are based. The antenna factor converts the voltage at the antenna coaxial connector to the field strength at the antenna elements.

The margin of a given emission peak relative to the limit is calculated as follows:

$$R_c = R_r + F_d$$

and

$$M = R_c - L_s$$

where:

$$R_r = \text{Receiver Reading in dBuV/m}$$

$$F_d = \text{Distance Factor in dB}$$

$$R_c = \text{Corrected Reading in dBuV/m}$$

$$L_s = \text{Specification Limit in dBuV/m}$$

$$M = \text{Margin in dB Relative to Spec}$$

EUT Operation During Emissions

The EUT was either set to transmit or standby mode during testing. In transmit mode the device was operating continuously. Correction factors were applied to all peak readings signals related to the transmit signal to calculate the average value of the signal based on a 10% duty cycle as detailed in the Theory of Operations. The Theory of Operations also includes plots showing the duty cycle of the system.

Radiated Emissions

Test Specifics

Objective: The objective of this test session is to perform final qualification testing of the 645 Tag with respect to the specification listed above.

Date of Test: 9/4/2002

Test Engineer: Chris Byleckie

Test Location: SVOATS #2

Config. Used: 1

Config Change:

EUT Voltage: internal batteries

General Test Configuration

The EUT was located on the turntable for radiated emissions testing.

On the OATS, the measurement antenna was located 3 meters from the EUT.

Note, **preliminary** testing indicates that the emissions were maximized by orientation of the EUT and elevation of the measurement antenna. **Maximized** testing indicated that the emissions were maximized by orientation of the EUT, elevation of the measurement antenna, and manipulation of the EUT's interface cables.

Note, for testing above 1 GHz, the FCC specifies the limit as an average measurement. In addition, the FCC states that the peak reading of any emission above 1 GHz, can not exceed the average limit by more than 20 dB.

Ambient Conditions:

9/4/2002
Temperature: 23°C
Rel. Humidity: 46%

Summary of Results

Run #	Test Performed	Limit	Result	Margin
1	RE, 433.92MHz fundamental	FCC 15.231(e)	Pass	-1.2dB @ 433.878MHz
2	RE, 433.92MHz Tx Mode, Spurious Emissions	FCC 15.231(e)	Pass	-13.0dB @ 867.840MHz
3	RE, 433.7MHz Rx Mode, LO and Second Harmonic	FCC 15.209	Pass	-4.2dB @ 867.560MHz

Modifications Made During Testing:

No modifications were made to the EUT during testing

Deviations From The Standard

No deviations were made from the requirements of the standard.

Radiated Emissions

Test Specifics

Objective: The objective of this test session is to perform final qualification testing of the 644 (with all options stuffed) with respect to the specification listed above.

Date of Test: 6/20/2002 Config. Used: 1
Test Engineer: Vishal Narayan Config Change: None
Test Location: SVOATS #2 EUT Voltage: internal batteries

General Test Configuration

The EUT was located on the turntable for radiated emissions testing.

On the OATS, the measurement antenna was located 3 meters from the EUT.

Note, **preliminary** testing indicates that the emissions were maximized by orientation of the EUT and elevation of the measurement antenna. **Maximized** testing indicated that the emissions were maximized by orientation of the EUT, elevation of the measurement.

Note, for testing above 1 GHz, the FCC specifies the limit as an average measurement. In addition, the FCC states that the peak reading of any emission above 1 GHz, can not exceed the average limit by more than 20 dB.

Ambient Conditions:

Temperature: 13°C
Rel. Humidity: 69%

Summary of Results

Run #	Test Performed	Limit	Result	Margin
2	RE, 433.92MHz fundamental	FCC 15.231(e)	Pass	-1.3dB @ 433.878MHz
3	RE, 433.92MHz Tx Mode, Spurious Emissions	FCC 15.231(e)	Pass	-13.1dB @ 867.84MHz
4	RE, 433.7MHz Rx Mode, LO and Second Harmonic	FCC 15.209	Pass	-1.9dB @ 867.618433.8188

Modifications Made During Testing:

No modifications were made to the EUT during testing

Deviations From The Standard

No deviations were made from the requirements of the standard.

Timing Verification

The following plots were made to demonstrate the timing of the transmissions from the Savi ST-60X and ST-64X series of tags. The actual tag used during testing was an ST-602, but both tag series use the same firmware. These plots are representative of the transmission timing for both the 640 and 604 series.

The graphs show:

- A 10.1 second interval between successive transmissions;
- A total of four pulses per transmission, each pulse separated by a 90mS period, giving a total transmission time of 310mS;
- An individual pulse width of 10mS.

The timing of the pulses meets the requirements of FCC 15.231(e) as the transmission time is less than 1 second and the silent period is greater than 30 times the duration of each transmission and greater than 10 seconds.

ST-64X-XX Duty Cycle/Bandwidth Plots

ST-64X-XX Single Data Pulse (10 msec)

ST-64X-XX Data Pulse within 100 msec period

ST-64X-XX Data Pulses within 1 second period

ST-64X-XX Data Pulses with 30 second silent period between transmissions

ST-64X-XX Beacon Duty Cycle Plots

ST-64X-XX Single Beacon Pulse (10 msec)

ST-64X-XX Beacon Pulses with 10 second silent period between transmissions

ST-64X-XX: 20 dB Bandwidth Measurement
