2.0 TEST SUMMARY AND RESULTS

The EUT (Equipment Under Test) is a Booster Amplifier, Model DSP85-L7/PG, manufactured by Westell Technologies, Incorporated. The detailed test results are presented in a separate section. The following is a summary of the test results.

Transmitter Requirements

Environmental Phenomena	Frequency Range	FCC KDB 935210 section	Test Result
AGC Threshold	698-746 MHz	3.2	Pass
Amplifier Bandwidth	698-746 MHz	3.3	Pass
Mean output power	698-746 MHz	3.4	Pass
Amplifier Gain	698-746 MHz	3.5	Pass
Band Edge	698-746 MHz	3.6.2	Pass
Spurious Emissions	30-7,500 MHz	3.6.3	Pass
Frequency Stability	N/A	3.7	Note 1
Field Strength of Spurious Radiated emissions	30-7,500 MHz	3.8	Pass

Note 1: Test not required since the amplifier repeater does not alter the input signal in any way.

The product tested was originally labeled as Model DSP85-L7. The DSP85-L7/PG is electrically identical to the DSP85-L7.

3.0 EQUIPMENT UNDER TEST (EUT) DETAILS

3.1 EUT Description

The EUT is a Booster Amplifier, Model DSP85-L7/PG, manufactured by Westell Technologies, Incorporated. The RF communications link is encrypted in both directions. The EUT was in good working condition during the tests, with no known defects.

The EUT was tested a 120 VAC 60 Hz input power.

The EUT has a gain of 85 dB and a frequency range of 698-716 and 728-746 MHz

The amplifier's rated mean output power (Prated) is 1 watt.

The output signal coupling attenuation is 0 dB

There is no frequency stability since it does not translate frequency.

3.1.1 DC Voltages and Currents of Final Transmitter Stage

Frequency Range	698-716 and 728-746 MHz
DC input Voltage Range	+28 VDC, + 5 VDC (On-Off)
DC current	130mA at 1 Watt

4.0 TESTED SYSTEM DETAILS

4.1 Tested System Configuration

The system was configured for testing in a typical fashion. The testing was performed in conditions as close as possible to installed conditions. Wiring was consistent with manufacturer's recommendations. The identification for all equipment used in the tested system, is:

Tested System Configuration List

Item	Description	Type*	Manufacturer	Model Number	Serial Number
1	Booster Amplifier	E	Westell	DSP85-L7/PG	C6WH61931
2	AC-DC Power supply	S	Westell	UDIT-PSCH-148VMOD	C101EG166393

* Type: E = EUT, S = Support Equipment

4.1.1 EUT Modifications

No modifications were made to the EUT at Radiometrics' test facility in order to comply with the standards listed in this report.

4.2 EUT Operating Modes

The following are descriptions of the operating states of the amplifier. The mode number in the first column will be listed elsewhere in this report.

Mode	Description	Frequency Range
1	Signal Generator to Donor with AWGN Modulation	728-746 MHz
2	Signal Generator to Server with AWGN Modulation	698-716 MHz
3	Signal Generator to Donor with MSK Modulation	728-746 MHz
4	Signal Generator to Server with MSK Modulation	698-716 MHz
5	Signal Generator to Donor CW Signal	728-746 MHz

Test Report for the Westell, Incorporated, Booster Amplifier, Model DSP85-L7/PG

Mode	Description	Frequency Range
6	Signal Generator to Server with CW Signal	698-716 MHz

Modulations used

Modulation	Description
AWGN	Broadband modulation with an occupied bandwidth (OBW) of 4.1 MHz. This is representative of a 5 MHz LTE channel
MSK	Narrowband MSK modulation. It has a Gaussian Filter of 0.3 and a data rate of 270 kbps. This is representative of a GSM-TDMA signal.
CW	Continuous Wave; No Modulation

4.3 Special Accessories

No special accessories were used during the tests in order to achieve compliance.

6.0 RADIOMETRICS' TEST FACILITIES

The results of these tests were obtained at Radiometrics Midwest Corp. in Romeoville, Illinois, USA. Radiometrics is accredited by A2LA (American Association for Laboratory Accreditation) to conform to ISO/IEC 17025: 2005 "General Requirements for the Competence of Calibration and Testing Laboratories". Radiometrics' Lab Code is 121191 and Certification Number is 1495.01. A copy of the accreditation can be accessed on our web site (www.radiomet.com). Radiometrics accreditation status can be verified at A2LA's web site (www.a2la2.org).

The following is a list of shielded enclosures located in Romeoville, Illinois used during the tests:

Chamber A: Is an anechoic chamber that measures 24' L X 12' W X 12' H. The walls and ceiling are fully lined with ferrite absorber tiles. The floor has a 10' x 10' section of ferrite absorber tiles located in the center. Panashield of Rowayton, Connecticut manufactured the chamber. The enclosure is NAMAS certified.

Chamber B: Is a shielded enclosure that measures 20' L X 12' W X 8' H. Erik A. Lindgren & Associates of Chicago, Illinois manufactured the enclosure.

Chamber E: Is a custom made anechoic chamber that measures 52' L X 30' W X 18' H. The walls and ceiling are fully lined with RF absorber. Pro-shield of Collinsville, Oklahoma manufactured the chamber.

A separate ten-foot long, brass plated, steel ground rod attached via a 6-inch copper braid grounds each of the above chambers. Each enclosure is also equipped with low-pass power line filters.

Test Report for the Westell, Incorporated, Booster Amplifier, Model DSP85-L7/PG

The FCC has accepted these sites as test site number US1065. The FCC test site Registration Number is 732175. Details of the site characteristics are on file with the Industry Canada as site number IC3124A-1.

7.0 DEVIATIONS AND EXCLUSIONS FROM THE TEST SPECIFICATIONS

There were no deviations or exclusions from the test specifications.

8.0 CERTIFICATION

Radiometrics Midwest Corporation certifies that the data contained herein was taken under conditions that meet or exceed the requirements of the test specification. The results relate only to the EUT listed herein. Any modifications made to the EUT subsequent to the indicated test date will invalidate the data and void this certification.

10.0 TEST SECTIONS

The following sections are the detailed results in accordance to FCC KDB 935210 D05.

11.0 AGC THRESHOLD

11.1 Applicable Standard

The EUT shall comply with FCC KDB 935210 section 3.2.

11.2 Test procedures

- A signal generator was connected to the input of the EUT.
- A spectrum analyzer or power meter was connected to the output of the EUT using appropriate attenuation as necessary.
- The signal generator was initially configured to produce either of the required test signals (i.e., broadband AWGN or narrowband MSK)
- The signal generator frequency was set to the center frequency of the EUT operating band.
- While monitoring the output power of the EUT, measured using the methods of 3.5.3 of KDB 935210, the input level was increased until a 1 dB increase in the input signal power no longer causes a 1 dB increase in the output signal power.
- This level was recorded as the AGC threshold level.
- The procedure was repeated with the remaining test signals.

11.2.1 AGC Threshold Test Results

Model	DSP85-L7/PG	Specifications	FCC KDB 935210 D05 Sec. 3.2
Serial Number	C6WH61931	Test Date	September 14, 2016
Test Personnel	Richard L. Tichgelaar	Test Location	Station F
Test Equipment	Power Meter (PWM-01)		

The spectrum analyzer was set to Band power measurements using 100 trace average in the RMS peak mode.

The Highlighted cells are the AGC Threshold. This is Level where a 1 dB change in increase in the input signal power no longer causes a 1 dB increase in the output signal power.

Note that there was a 20-dB attenuator between the Generator output and the EUT input.

12.0 OUT OF BAND REJECTION

12.1 Applicable Standard

The EUT shall comply with sections 3.3 of FCC KDB 935210 for passband gain.

12.2 Test Procedures

- A signal generator was connected to the input of the EUT. A spectrum analyzer was connected to the output of the EUT using an external attenuator.
- The swept CW signal was configured with the following parameters:
 - For each band, the analyzer and signal generator was set to a Frequency range $\pm 250\%$ of the passband, for each applicable band.
 - The generator level was set to a level so that the out-of-band rejection is > 20 dB above the noise floor and will not engage the AGC during the entire sweep
 - The Dwell time of each frequency step was at least 10 ms.
 - Number of points was set to at least $\text{SPAN}/(\text{RBW}/2)$.
- The resolution bandwidth (RBW) was set to 1 MHz and the video bandwidth (VBW) was set to 3 MHz.
- The detector was set to Peak, Max-Hold and waited for the spectrum analyzer's spectral display to fill.

Test Report for the Westell, Incorporated, Booster Amplifier, Model DSP85-L7/PG

- e) A marker was placed to the peak of the frequency response and record this frequency as f0.
 f) Two markers, one at the lowest and the other at the highest frequency of the envelope of the spectral display, were placed such that each marker was at or slightly below the -20 dB down amplitude, to determine the 20-dB bandwidth.
 g) The frequency response of the EUT was captured.
 h) The procedure was repeated for all frequency bands applicable for use by the EUT.

12.3 Passband Bandwidth Test Results

Model	DSP85-L7/PG	Specification	KDB 935210 D05 Sec 3.3
Serial Number	C6WH61931	Test Date	October 18, 2106
Test Personnel	Richard L. Tichgelaar	Test Location	Chamber B
Test Equipment	EMI Receiver (REC-21)		

RBW MHz	VBW MHz	Mode	#of Points	Pass band		20 dB Down		Analyzer Reading		
				-250% MHz	-250% MHz	1st Freq. MHz	2nd Freq. MHz	Readin g MHz	F0 MHz	F0 dBm
300k	1M	1	600	692	782	727.7	746.3	18.65	728.9	9.315
300k	1M	2	600	662	752	697.7	716.3	18.65	710.8	9.68

Judgement: Pass; the 20-dB bandwidth did not exceed the nominal bandwidth stated by the manufacturer. Outside of the 20-dB bandwidth, the gain did not exceed the gain at the 20-dB point.

13.0 INPUT VS OUTPUT COMPARISON; WITH OCCUPIED BANDWIDTH

13.1 Applicable Standard

The EUT shall comply with FCC KDB 935210 section 3.4.

13.2 Test procedures

A 26-dB bandwidth measurement was performed on the input signal and the output signal.

- A signal generator was connected to the input of the EUT.
- The signal generator was configured to transmit the AWGN signal.
- The signal generator amplitude was configured to be zero to 0.5 dB below the AGC threshold level.
- A spectrum analyzer was connected to the output of the EUT using an external attenuator.
- The spectrum analyzer center frequency was set to the center frequency of the operational band under test. The span range of the spectrum analyzer was between 2 times to 5 times the occupied bandwidth (OBW).
- The nominal RBW was in the range of 1 % to 5 % of the anticipated OBW, and the VBW was $\geq 3 \times$ RBW.
- The reference level of the instrument was set as required to preclude the signal from exceeding the maximum spectrum analyzer input mixer level for linear operation.
- The noise floor of the spectrum analyzer at the selected RBW was at least 36 dB below the reference level.
- The spectrum analyzer detection function was set to positive peak.
- The trace mode was set to max hold.
- The reference value was determined by: Allowing the trace to stabilize, setting the spectrum analyzer marker to the highest amplitude level of the displayed trace (this is the reference value), and recording the associated frequency as f_0 .

Test Report for the Westell, Incorporated, Booster Amplifier, Model DSP85-L7/PG

l) Two markers, one at the lowest and the other at the highest frequency of the envelope of the spectral display, were placed such that each marker is at or slightly below the -26 dB down amplitude. The 26 dB OBW is the positive frequency difference between the two markers. If the spectral envelope crosses the -26 dB down amplitude at multiple points, the lowest or highest frequency was selected as the frequencies that are the furthest removed from the center frequency at which the spectral envelope crosses the -26 dB down amplitude point.

m) Steps e) to l) were repeated with the input signal connected directly to the spectrum analyzer (i.e., input signal measurement).

n) The spectral plot of the input signal (determined from step m) was compared to the output signal (determined from step l) to affirm that they are similar (in passband and roll off characteristic features and relative spectral locations).

o) The procedure [steps e) to n)] was repeated with the input signal amplitude set to 3 dB above the AGC threshold.

p) Steps e) to o) were repeated with the signal generator set to the narrowband signal.

q) Steps e) to p) were repeated for all frequency bands authorized for use by the EUT.

Judgement: Pass

14.0 MEAN POWER OUTPUT AND AMPLIFIER GAIN

14.1 Applicable Standard

The EUT shall comply with FCC KDB 935210 section 3.5.

In accordance with section 3.5 of KDB 935210 D05, the mean input and output power and the amplifier gain was measured by adjusting the internal gain control of the EUT to the maximum gain for which equipment certification is sought. Any EUT attenuation settings were set to their minimum value.

Input power levels (uplink and downlink) were set to maximum input ratings while confirming that the device is not capable of operating in saturation (non-linear mode) at the rated input levels, including during the performance of the input/output power measurements.

14.2 Test procedures

- a) A signal generator was connected to the input of the EUT.
- b) The signal generator was configured to generate the AWGN (broadband) test signal.
- c) The frequency of the signal generator was set to the frequency f0 as determined from 3.3 of KDB 935210.
- d) A spectrum analyzer was connected to the output of the EUT using an external attenuator.
- e) The signal generator amplitude was configured to be zero to 0.5 dB below the AGC threshold level.
- f) The output power of the EUT measured and recorded; using 3.5.3 KDB 935210 for power measurement.
- g) The EUT was removed from the measurement setup. Using the same signal generator settings, the power measurement was repeated at the signal generator port, which was used as the input signal to the EUT, and recorded as the input power. EUT gain may be calculated as described in 3.5.5 KDB 935210.
- h) Steps f) and g) were repeated with input signal amplitude set to 3 dB above the AGC threshold level.
- i) Steps e) to h) were repeated with the narrowband test signal.
- j) Steps e) to i) were repeated for all frequency bands authorized for use by the EUT.

The mean gain was reported for each authorized operating frequency band and each test signal stimulus.

After the mean input and output power levels have been measured as described in the preceding subclauses, the mean gain of the EUT can be determined from:

Gain (dB) = output power (dBm) – input power (dBm).

15.0 SPURIOUS EMISSIONS

15.1 Applicable Standard

The EUT shall comply with sections 3.6.2 and 3.6.3 of KDB 935210 D05, since it is a Multi-Channel Enhancer.

For a multi-channel enhancer, any intermodulation product level must be attenuated, relative to P, by at least: $43 + 10 \times \log_{10} P$, or 70 dB, whichever is less stringent, where P is the total RF output power of the test tones in watts. Since $43 + 10 \times \log_{10} P$ is less stringent than 70 dB, that limit was used.

Spurious emissions shall be measured using a single test signal sequentially tuned to the low, middle, and high channels or frequencies within each authorized frequency band of operation.

Out-of-band/out-of-block emissions (including intermodulation products) was measured under each of the following two stimulus conditions:

- two adjacent test signals sequentially tuned to the lower and upper frequency band/block edges;
- a single test signal, sequentially tuned to the lowest and highest frequencies or channels within the frequency band/block under examination.

15.2 Test procedures for section 3.6.2

- a) Two signal generators were connected to the input of the Device Under Test (EUT), via a combiner.
- b) The signal generator was set to produce two AWGN signals as previously described (e.g., 4.1 MHz OBW).
- c) The center frequencies were set such that the AWGN signals occupy adjacent channels at the upper edge of the frequency band or block under test.
- d) The composite power levels were set to be zero to 0.5 dB below the AGC threshold level.
- e) A spectrum analyzer was connected to the output of the EUT using an external attenuator.
- f) The RBW = reference bandwidth was set in accordance with the applicable rule section for the supported frequency band (typically 1 % of the OBW or 100 kHz or 1 MHz).
- g) The RBW was set so that the VBW = $3 \times \text{RBW}$.
- h) The detector was set to power averaging (rms) detector.
- i) The sweep time was set so that sweep time = auto-couple.
- j) The spectrum analyzer start frequency was set to the upper block edge frequency, and the stop frequency to the upper block edge frequency plus 300 kHz or 3 MHz, for frequencies below and above 1 GHz, respectively.
- k) Trace averaged at least 100 traces in power averaging (rms) mode.
- l) The marker function was used to find the maximum power level.
- m) The spectrum analyzer trace of the power level was captured for inclusion in the test report.
- n) Steps k) thru m) were repeated with the composite input power level set to 3 dB above the AGC threshold.
- o) The frequencies of the input signals were reset to the lower edge of the frequency block or band under test.
- p) The spectrum analyzer start frequency was reset to the lower block edge frequency minus 300 kHz or 3 MHz, for frequencies below and above 1 GHz, respectively, and the stop frequency to the lower band or block edge frequency.
- q) Steps k) to n) were repeated.
- r) Steps a) to q) were repeated with the signal generator configured for a single test signal tuned as close as possible to the block edges.
- s) Steps a) to r) were repeated with the narrowband test signal.
- t) Steps a) to s) were repeated for all authorized frequency bands or blocks used by the EUT.

On any frequency outside the authorized bandwidth shall be attenuated by at least $43 + 10 \log (P)$ dB. This corresponds to an absolute level of -13 dBm.

15.3 Results for Section 3.6.2

Model	DSP85-L7/PG	Specification	FCC KDB 935210 Sec. 3.6.2
Serial Number	C6WH61931	Test Date	September 16, 2016
Test Personnel	Richard L. Tichelaar	Test Location	Chamber B
Test Equipment	EMI Receiver (REC-21)		

The spectrum analyzer was set to 100 trace average in the RMS mode.

15.4 Test procedures 3.6.3

- a) A signal generator was connected to the input of the EUT.
- b) The signal generator was set to produce the broadband test signal as previously described (i.e., 4.1 MHz OBW AWGN).
- c) The center frequency of the test signal was set to the lowest available channel within the frequency band or block.
- d) The EUT input power was set to zero to 0.5 dB below the AGC threshold level.
- e) A spectrum analyzer was connected to the output of the EUT using appropriate attenuation as necessary.
- f) Set the RBW = reference bandwidth in the applicable rule section for the supported frequency band of operation (e.g., reference bandwidth is typically 100 kHz or 1 MHz).
- g) The VBW was set as $\geq 3 \times \text{RBW}$.
- h) The Sweep time was set to equal auto-couple.
- i) The spectrum analyzer start frequency was set to the lowest RF signal generated in the equipment, without going below 9 kHz, and the stop frequency to the lower band/block edge frequency minus 100 kHz or 1 MHz, as specified in the applicable rule part. The number of measurement points in each sweep must be $\geq (2 \times \text{span}/\text{RBW})$, which may require that the measurement range defined by the start and stop frequencies be subdivided, depending on the available number of measurement points provided by the spectrum analyzer.
- j) The power averaging (rms) detector function was selected.
- k) A trace average measurement with at least 10 traces in power averaging (rms) mode was performed.
- l) The peak marker function was used to identify the highest amplitude level over each measured frequency range. The frequency and amplitude were recorded and captured in a plot.
- m) The spectrum analyzer start frequency was reset to the upper band/block edge frequency plus 100 kHz or 1 MHz, as specified in the applicable rule part, and the spectrum analyzer stop frequency to 10 times the highest frequency of the fundamental emission. The number of measurement points in each sweep was $\geq (2 \times \text{span}/\text{RBW})$, which may require that the measurement range defined by the start and stop frequencies be subdivided, depending on the available number of measurement points provided by the spectrum analyzer.
- n) Trace averages were at least 10 traces in power averaging (rms) mode.
- o) The peak marker function was used to identify the highest amplitude level over each of the measured frequency ranges. The frequency and amplitude were recorded and captured in a plot for inclusion in the test report; and tabular data was provided.
- p) Steps i) to o) were repeated with the input test signals firstly tuned to a middle band/block frequency/channel, and then tuned to a high band/block frequency/channel.
- q) Steps b) to p) were repeated with the narrowband test signal.
- r) Steps b) to q) were repeated for all authorized frequency bands/blocks used by the EUT.

Test Report for the Westell, Incorporated, Booster Amplifier, Model DSP85-L7/PG

On any frequency outside the authorized bandwidth shall be attenuated by at least $50 + 10 \log (P)$ dB. This corresponds to an absolute level of -13 dBm.

15.5 Test Results for Section 3.6.3

16.0 FIELD STRENGTH OF SPURIOUS RADIATED EMISSIONS

16.1 Applicable Standard

The EUT shall comply with section 3.8 of FCC KDB 935210 D05 and FCC Part 2.1053. This test is intended to capture any emissions that radiate directly from the case, cabinet, control circuits, etc., instead of via the antenna output port, and thus would not be captured in conducted spurious emission measurements.

Spurious emissions of zone enhancers shall be suppressed as much as possible. Any emission must be attenuated below the power (P) of the highest emission contained within the authorized band, by at least: $43 + 10 \times \log_{10} P$, or 70 dB, whichever is less stringent, where P is the total RF output power of the test tones in watts. Since $43 + 10 \times \log_{10} P$ is less stringent than 70 dB, that limit was used.

16.2 Test Procedures

Radiated emission measurements in the restricted bands were performed with linearly polarized broadband antennas. The results obtained with these antennas can be correlated with results obtained with a tuned dipole antenna. A 10 dB linearity check is performed prior to start of testing in order to determine if an overload condition exists. Radiated emissions measurements were performed in the anechoic chamber at a test distance of 3 meters. The entire frequency range from 30 to 7500 MHz was slowly scanned and the emissions in the restricted frequency bands were recorded. Measurements were performed using the peak detector function.

The spectrum analyzer was adjusted for the following settings:

- 1) Resolution Bandwidth = 100 kHz for spurious emissions below 1 GHz, and 1 MHz for spurious emissions above 1 GHz.
- 2) Video Bandwidth = 300 kHz for spurious emissions below 1 GHz, and 3 MHz for spurious emissions above 1 GHz.
- 3) Sweep Speed slow enough to maintain measurement calibration.
- 4) Detector Mode = Positive Peak.

The transmitter to be tested was placed on the turntable in the standard test site, or an FCC listed site compliant with ANSI C63.4. The transmitter is transmitting into a non-radiating load that is placed on the

Test Report for the Westell, Incorporated, Booster Amplifier, Model DSP85-L7/PG

turntable (except for the fundamental reading which had an antenna). Since the transmitter has an integral antenna, the tests are to be run with the unit operating into the integral antenna. Measurements were made from the lowest radio frequency generated in the equipment to the tenth harmonic of the carrier. The transmitter was keyed during the tests.

For each spurious frequency, the test antenna was raised and lowered from 1 m to 4m to obtain a maximum reading on the spectrum analyzer with the test antenna at horizontal polarity. Then the turntable was rotated 360° to determine the maximum reading. This procedure was repeated to obtain the highest possible reading. This maximum reading was recorded.

Each measurement was repeated for each spurious frequency with the test antenna polarized vertically.

Figure 1. Drawing of Radiated Emissions Setup

Notes:

- Test Antenna height varied from 1 to 4 meters
- Distance from antenna to tested system is 3 meters
- Not to Scale

Frequency MHz	Test Antenna	Substitution Antenna	Receiver	Signal Generator
30 - 200	ANT-03	ANT-04	REC-21	SIG-28
200 - 1000	ANT-06	ANT-07	REC-21	SIG-28
1000-18,000	ANT-13	ANT-36	REC-21	SIG-28
18,000-23,000	ANT-48	N/A	REC-21	SIG-28

There were no detected signals above 18 GHz, so no substitution antenna was used above 18 GHz.

Test Report for the Westell, Incorporated, Booster Amplifier, Model DSP85-L7/PG

The transmitter was removed and replaced with a broadband substitution antenna. The substitution antenna is calibrated so that the gain relative to a dipole is known. The center of the substitution antenna was approximately at the same location as the center of the transmitter.

The substitution antenna was fed at the transmitter end with a signal generator connected to the antenna by means of a non-radiating cable. With the antennas at both ends horizontally polarized, and with the signal generator tuned to a particular spurious frequency, the test antenna was raised and lowered to obtain a maximum reading at the spectrum analyzer. The level of the signal generator output was adjusted until the previously recorded maximum reading for this set of conditions was obtained. The measurements were repeated with both antennas horizontally and vertically polarized for each spurious frequency.

The power in dBm into a reference ideal half-wave dipole antenna was calculated by reducing the readings obtained in steps k) and l) by the power loss in the cable between the generator and the antenna, and further corrected for the gain of the substitution antenna used relative to an ideal half-wave dipole antenna by the following formula:

$$Pd(\text{dBm}) = Pg(\text{dBm}) - \text{cable loss (dB)} + \text{antenna gain (dB)}$$

where:

P_d is the dipole equivalent power and

P_g is the generator output power into the substitution antenna.

The P_d levels record in step m) are the absolute levels of radiated spurious emissions in dBm.

Since by mathematical definition, $P(\text{dBm}) - (43 + 10 \times \text{LOG } P(\text{W})) = -13 \text{ dBm}$, the limit for spurious emissions was set to -13 dBm equivalent radiated power.

Notes on Columns:

1. Frequency of highest power.
2. Minimum distance between the user and the antenna as specified by user manual.
3. Power output from EUT; See section 14.3 of this test report.
4. Antenna gain supplied by the client for combination of cable loss and antenna gain.
5. Effective radiated Power; Used for calculating field strength
6. Field strength at MPE distance. (needed for power density calculation)
7. Power density is calculated from field strength measurement and antenna gain.
8. Reference CFR 1.1310, Table 1: Limits for Maximum Permissible Exposure (MPE), Section (B): Limits for General Population/Uncontrolled Exposure.

18.0 MEASUREMENT INSTRUMENTATION UNCERTAINTY

Measurement	Uncertainty
Radiated Emissions, E-field, 3 meters, 30 to 200 MHz	3.3 dB
Radiated Emissions, E-field, 3 meters, 200 to 1000 MHz	4.9 dB
Radiated Emissions, E-field, 3 meters, 1 to 18 GHz	4.8 dB
Bandwidth using marker delta method	1% of frequency span
Conducted power	0.8 dB
Amplitude measurement 1-8000 MHz;	1.5 dB

The uncertainties represent expanded uncertainties expressed at approximately the 95% confidence level using a coverage factor of k=2 in accordance with CISPR 16-4-2.
