The RRC may operate between 915.050 MHz (min. useable frequency) and 927.800 MHz (max. useable frequency) on a set of channels positioned at 50 kHz multiples (e.g. 915.050, 915.100, 915.150....927.750, 927.800).

This gives a raster of 256 possible channels positions where to place the channels actually scanned in any hopping sequence.

This doesn't imply that all 256 channels are used in every hopping sequence.

On the contrary, a smaller set of channels is usually chosen: while preserving maximum spread of channels over the available band, it is wise to avoid evenly spaced sets, so as to guarantee maximum mitigation of intermodulation effects between similar systems operating in the same area.

In any case, minimum number of channel in a set is 64, which is exceeding the specification in FCC 15.247.

For example consider the following 4 tables which are used for series production.

Table 4. Channel group 3 (85 channels, 100 kHz minimum channel spacing).

For testing a special programming is provided; anyway we deem it representative of any real world hopping sequence that can be programmed into the devices.

First, special programming allows fixed frequency measurements at min, med and max operating frequency; this is not available for series production units, but is required for testing.

Then two evenly spaced hopping sequences of 64 channels are provided, one including the min freq channel at 915.050 MHz, the other including the max freq channel at 927.800 MHz.

Although they are not available for series production units, both these hopping sequences are suitable for valid measurements of FH timing parameters. In fact, FH Timing parameters measurements is not dependent on channel positioning.

927,80	Worst case	G18055224	103,23	70,126

Remarks: the above table shows the results of radiated measurements, in agreement with cl. 3.0 of KDB 558074 D01 DTS Meas Guidance v04.

Conducted measurements are not applicable because the antenna connector is not available. The following formula, provided in document ANSI C63.10 Annex G, has been used for the conversion between radiated to conducted values:

$$\text{Conducted value} = (E \times d)^2 / (30 \times G)$$

Where:

$E = (10^{(\text{dB}\mu\text{V}/\text{m})/20})/1000000$, the maximum measured fundamental field strength in V/m

$G = 10^{\text{dBi}/10}$, the numeric gain of the transmitting antenna: 1 (0 dBi)

d = the distance in meters from which the field strength was measured (10 m)

P = the power in watts

Acceptance limits for emissions in non-restricted frequency bands

In any 100 kHz bandwidth outside the frequency band in which the spread spectrum or digitally modulated intentional radiator is operating, the radio frequency power that is produced by the intentional radiator shall be at least 20 dB below that in the 100 kHz bandwidth within the band that contains the highest level of the desired power, based on either an RF conducted or a radiated measurement, provided the transmitter demonstrates compliance with the peak conducted power limits.

Remarks: EUT was tested in 3 orthogonal planes. The results in this table show the highest values. No spurious other than harmonics have been found. The results have been extrapolated to the specified distance using an extrapolation factor.
Harmonics marked with an * are in non-restricted frequency bands, for these frequency bands the limit is 20 dB below the highest power level. The highest measured power level is 104,10 dB μ V/m, so the final measurements on non-restricted frequency bands must be lower than 84,10 dB μ V/m.
