Gain Measurement Method Explained:

- a) **Calibration:** Use Two Antennas (one has to have a known gain [In this case Ref]) to measure and record the S parameter S_{21} which is the input/output relationship between the ports on the Network analyzer

- a. Normalize the calibration to produce 0 DB reference on the network Analyzer.
- b. All cable loss factors are accounted for in the system.

Notes: A1 represents Arch antennas in system

The software instructs the VNA to produce a sweep signal over the frequency range specified.

The it will generate the signal is a swept CW between the start and end frequency and pausing at predetermined points long enough to collect measurement.

Calibration diagram

- b) **DUT Measurements:** Replace reference Antenna with DUT Antenna (maintaining the same conditions) distance etc.

DUT Measurement diagram

- c) Remeasure S_{21} response which now represents the gain relative to reference antenna. Collect $G(\text{Rel})$.
- d) Calculate $G(\text{Dut}) = G(\text{ref}) + G(\text{rel})$

Note: The chamber measurement system is automated. The measurement is taken at multiple locations points by rotating the DUT and the Arch.
