THE AMERICAN
ASSOCIATION
FOR LABORATORY
ACCREDITATION

ACCREDITED LABORATORY

A2LA has accredited

L.S. COMPLIANCE, INC.
Cedarburg, WI

for technical competence in the field of

Electrical (EMC) Testing

The accreditation covers the specific tests and types of tests listed on the agreed scope of accreditation. This laboratory meets the requirements of ISO/IEC Guide 25-1990 "General Requirements for the Competence of Calibration and Testing Laboratories" (equivalent to relevant requirements of the ISO 9000 series of standards) and any additional program requirements in the identified field of testing.

Presented this 30th day of December, 1998.

President
For the Accreditation Council
Certificate Number 1255.01
Valid to January 31, 2001

For tests or types of tests to which this accreditation applies, please refer to the laboratory's Electrical (EMC) Scope of Accreditation

2.3 SUMMARY OF TEST REPORT

MANUFACTURER:	Recognition Source
MODEL:	DCMI
SERIAL:	PD22 (preproduction)
DESCRIPTION:	Spread Spectrum data packet transceiver
FREQUENCY RANGE:	902-928 MHz

The DCMI was found to **meet** the radiated emission specification of Title 47 CFR FCC, Part 15, subpart C. for an intentional radiator

The DCMI was also found to **meet** the radiated emission specification of Title 47 CFR, FCC Part 15, subpart B for emissions with regards to the receiver and digital sections of the product.

This product is a composite device, with the digital sections subject to verification. Therefore this technical report will primary contain data that is pertinent to the certification of the transmitter section of the product.

2.4 INTRODUCTION

During May and June of 2001, a series of Radiated and Conducted Emissions tests were performed on a sample model of the DCMI, a spread spectrum transmitter module, designed for wireless data transfer, to be used in a door opener security system. These tests were performed using the test procedures outlined in ANSI C63.4-1992 for intentional radiators, and in accordance with the requirements set forth in FCC Part 15.247 for a spread spectrum transmitter. Tests were also performed as outlined in ANSI C63.4-1992 for non-intentional radiators, in order to verify compliance with the limits set forth in part 15.109 for and to allow verification of emissions for the digital section of the product. These tests were performed by Kenneth L. Boston, PE, of L. S. Compliance, Inc.

2.5 PURPOSE

The above mentioned tests were performed in order to determine the compliance of the DCMI spread spectrum transceiver with limits contained in various provisions of Title 47 CFR, FCC Part 15, including:

15.207	15.247b	15.247e
15.205	15.247c	15.109
15.247a2	15.247d	

Various of these tests, including the conducted RF out the antenna port and the jamming margin test are contained in an additional test report that is attached to this report. All radiated emissions tests were performed to measure the emissions in the frequency bands described by the above sections, and to determine whether said emissions are below the limits established by the above sections. These tests were performed in accordance with the procedure described in the American National Standard for methods of measurement of Radio-Noise Emissions from Low-Voltage Electrical and Electronic Equipment in the Range of 9 kHz to 40 GHz (ANSI C63.4-1992). Another document used as reference for the EMI receiver specification was the International Special Committee on Radio Interference (CISPR) number 16-1 (1993).

2.6 Conducted (AC LINE) Test Setup and measurements

The DCMI spread spectrum device is powered from a DC source, a 12 VDC buss connection from the Host Security panel, and does not derive its power directly from the public mains. There fore no conducted emissions of Disturbances to the Public mains need to be performed. Conducted emissions of RF signals at the antenna port are covered in appendix D of this report.

2.7 RADIATED EMISSIONS TEST SETUP

The test sample was operated within the 3 meter Semi-Anechoic, FCC listed chamber located at L.S. Compliance in Cedarburg, WI. The sample was positioned on a small wood pedestal, which was centered on the flush-mounted 2m diameter metal turntable. The test sample was operated on a small DC power supply, for this testing only. The test sample was configured to run in a continuous transmit mode during the 15.247 and 15.205 measurements. The sample was set to run in a continuous transmit loop. One test sample was set to operate on either channel 1 (low), channel 8 (medium) or channel 15 (high) while being tested as an intentional radiator, in order to determine compliance within a frequency range of 902-928 MHz, as dictated by FCC part 15.31m.

The system was also mounted on the 80 CM high wooden table, centered on the turntable for measurement of spurious signals emanating from the system while in the transmit mode, at frequencies below 1 GHz. 1 meter shielded multiple conductor cable was also attached to the i/o and comm ports of the DCMI to simulate the cabling that would be present in an actual field installation into a security system.

Please refer to Section 2.11 for pictures of the test setup.

2.8 RADIATED EMISSION TEST PROCEDURE

The fundamental and spurious (harmonic) emissions of the transmitter were tested for compliance to Title 47 CFR, FCC Part 15.247c limits for Direct Sequence Spread Spectrum systems, and the 15.205 general limits, within the restricted bands. For the calculations used to determine the 1 meter limits, see Appendix A. The test sample was tested from the lowest frequency generated by the transmitter to the 10th harmonic of the fundamental frequency generated by the device. The appropriate limits were also observed where any spurious signals were located within any of the restricted bands as described in Part 15.205a. These frequencies, and their associated limits, are referenced in Section 2.10. The sample was placed on the pedestal of table and placed in the 3 Meter chamber, then the antenna mast was placed such that the antenna was either 1 meter or 3 meters from the test object. A biconical antenna was used to measure emissions from 30 to 200 MHz, a log periodic was used to measure emissions from 200 to 1000 MHz, and a double ridged waveguide horn was used to measure emissions above 1 GHz. The test object was programmed to operate in continuous transmit, and the resultant signals were maximized by rotating the turntable 360 degrees, and by raising and lowering the antenna between 1 and 4 meters. The test object was also given several different orientations to determine the maximum signal levels, using both horizontal and vertical antenna polarities. Emissions above 1 GHz were also measured at a 1 meter separation, using the HP Microwave spectrum analyzer.

No significant emissions were found aside from the transmitter fundamental, harmonics, and some spurious signals. The unit was scanned for emissions in both transmit and receive modes, over the range 30 to 10000 MHz to establish compliance with Part 15.247c and 15.205 for the system. Also, the scans were performed to evaluate the digital controller section of the product, which is subject to verification as a Class B digital device. The same procedures as detailed for the transmitter tests described above were used to perform these measurements. The results of the system measurements are found in Appendix B, with graphs of the signature scans found in Appendix C.

2.9 TEST EQUIPMENT UTILIZED FOR RADIATED EMISSIONS TEST

A list of the test equipment and antennas used for the tests can be found in Section 2.13, which includes the calibration information as well as the equipment description. All equipment is calibrated and used according to the user manuals supplied by the manufacturer. All antenna calibrations were performed at a N.I.S.T traceable site, and the resultant correction factors were entered into the Hewlett Packard 8546A EMI receiver software database. The connecting cables used were also measured for loss using a calibrated signal generator and the HP 8546A EMI receiver. The resulting loss factors were entered into the HP 8546A database. This allowed for automatic changes in the antenna correction factor, as well as cable loss or other corrections, to be added to the EMI receiver display while taking measurements. Thus, the resulting data taken from the HP 8546A is an actual reading and can be entered into the database as a corrected meter reading. The HP 8546A EMI receiver was operated with a bandwidth of 120 kHz when receiving signals below 1 GHz, and with a bandwidth of 1 MHz when receiving signals above 1 GHz, in accordance with CISPR 16. Both the Peak and Quasi-peak detector functions were used.

For measurements in the upper microwave region, a HP E4407B 26.5 GHz spectrum analyzer was used. Antenna factors for the horn antenna, a short jumper cable and a high pass filter were entered into the analyzer as correction factors. This allowed for direct readings to be made of the field strength. During emissions testing, signals where significant levels were noted were measured using the 1 MHz IF bandwidth, and a 10 or 100 Hz video bandwidth, resulting in an average measurement mode of the analyzer. Peak readings were also obtained using a 1 MHz IF and 1 MHz video bandwidth.

2.10- Restricted Bands affecting this product

3 Meter limits

Frequency (MHz)	Limit (μ V)	Limit (dB/ μ V/m)
37.5-38.25	100	40.0
73.74.6	100	40.0
74.8-75.2	100	40.0

9000-9200	500	54.0
9300-9500	500	54.0

Plus others in the frequency range below 960 MHz, not listed were spurious signals were not present.

2.11 – Photos taken during testing

View of DCMI spread spectrum transceiver during the Radiated Emissions tests.

2.12 SUMMARY OF RESULTS AND CONCLUSIONS

Based on the procedures outlined in this report, and the test results included in appendices B and C, it can be determined that the DCMI does **meet** the emission requirements of Title 47 CFR, FCC Part 15 Subpart C for an intentional radiator.

The enclosed test results pertain to the samples of the test item listed, and only for the tests performed on the data sheets. Any subsequent modification or changes to the test items could invalidate the data contained herein, and could therefore invalidate the findings of this report.

APPENDIX A:

SAMPLE CALCULATIONS

FCC ID : PM7-DCMI2001

Calculation of Radiated Emissions limits for FCC Part 15.205 (above 1 GHz)

The following table depicts the Class B limits for an unintentional radiator: Limits are established at a measurement distance of 3 meters and limits corrected for a 1 meter measurement distance which are extrapolated from the 3 meter limit.

Frequency (MHz)	3m limit (dB mV/m)	1m limit (dB mV/m)
960 MHz up	54	63.54

- The 1 meter limits were calculated by adding a factor of 9.54 dB, derived from:

$$20\log_{10}(3/1) = 9.54 \text{ dB } \mu\text{V/m}$$

$$1\text{m limit} = 3\text{m limit} + \text{factor}$$

$$= 54 \text{ dB } \mu\text{V/m} + 9.54 \text{ dB } \mu\text{V/m} = 63.54 \text{ dB } \mu\text{V/m}$$

$$\text{rounded off} = 63.5 \text{ dB } \mu\text{V/m}$$

15.205/15,209 Limits

Frequency (MHz)	Harmonic limit (mV/m)	Harmonic limit (dB mV/m)
30-88	100	40.0
88-216	150	43.5
216-960	200	46.0
960-10000	500	54.0

Duty Cycle Correction Factor Calculation

For a graphical presentation of the pulses being transmitted from the DCMI spread spectrum transceiver, refer to Appendix C. The DCMI sends a pulse of about 10 milliseconds length in response to a pulse sent out by the IRL unit, whenever a magnetic striped card is swiped through the card slot on the IRL. Cycle timing and human response time lag prevents the transmission of a set of pulses in any period less than 4 seconds. The spread spectrum pulse, including card data is sent only once by the IRL unit, and echoed back only once by the DCMI unit. It does not repeat until the card is swiped again. For derivation of an average value over a 100 millisecond window, the on-time of the DCMI unit pulse is divided by the 15.31 time slot of 100 milliseconds. This is used to develop a relaxation factor to be used in the radiated emissions measurements. Described below is the data packet construction, and the data bit length.

Clock oscillator is 12 MHz, data rate is 62,500 bps

First preamble:	216 bits
First header:	80 bits
First trailer	32 bits
Second preamble	216 bits
Second header	80 bits
Second trailer	32 bits
656 bits X 0.016 ms per bit = 10.496 ms total length. (round to 10.5 ms)	

$$\begin{aligned}\text{Relaxation Factor} &= 20 \log (10.5/100) \\ &= 19.6 \text{ dB}\end{aligned}$$

APPENDIX B:
