APPLICANT

MODOTTEL Co.,Ltd.

Classification: Licensed Portable Transmitter Held to Ear (PCE)
FCC Rule Part(s): §24(E), §22(H), §22.901(d), §2
EUT Type: Tri-Mode Dual-Band Analog / PCS Phone (AMPS/CDMA)
Model(s): WTE-500
TX Frequency Range: 824.04 ~ 848.97 MHz (AMPS) / 824.70 ~ 848.31 MHz (CDMA)
1851.25 ~ 1908.75 MHz (PCS CDMA)
RX Frequency Range: 869.04 ~ 893.97 MHz (AMPS) / 869.70 ~ 893.31 MHz (CDMA)
1931.25 ~ 1988.75 MHz (PCS CDMA)
Max. RF Output Power: 0.388W ERP AMPS (25.89dBm) / 0.357W ERP CDMA (25.53dBm)
0.292W EIRP PCS CDMA (24.65dBm)
Max. SAR Measurement: 1.45W/kg AMPS Head SAR ; 1.40W/kg AMPS Body SAR
1.31W/kg CDMA Head SAR ; 1.30W/kg CDMA Body SAR
1.44W/kg PCS Head SAR ; 1.38W/kg PCS Body SAR
Emission Designators: 40K0F8W / 40K0F1D(AMPS), 1M25F9W(CDMA)
Test Device Serial No.: Identical prototype

This equipment has been shown to be capable of compliance with the applicable technical standards as indicated in the measurement report and was tested in accordance with the Measurement procedures specified in §2,947.

I attest to the accuracy of data. All measurements reported herein were performed by me or were made under my supervision and are correct to the best of my knowledge and belief. I assume full responsibility for the completeness of these measurements and vouch for the qualifications of all persons taking them.

4.1 DESCRIPTION OF TESTS

4.2 Transmitter Audio Frequency Response

The frequency response of the audio modulating circuit over the frequency range 100-5000Hz is measured. The audio signal generator is connected to the audio input circuit/microphone of the EUT. The audio signal input is adjusted to obtain 50% modulation at 1kHz and this point is taken as the 0dB reference. With the input held constant and below the limit at all frequency, the audio signal generator is varied from 100 to 50kHz.

4.3 Audio Low Pass Filter Frequency Response

The response in dB relative to 1kHz is measured using the HP8901 a Modulation Analyzer. For the frequency response of the audio low-pass filter, the audio input is connected at the input to the modulation limiter and the modulated stage. The audio output is connected at the output of the modulated stage. The corresponding plots are shown herein.

4.4 Modulation Limiting

The audio signal generator is connected to the audio put circuit/microphone of the EUT. The modulation response is measured for each of the three modulating frequencies(300Hz, 1000Hz and 3000Hz), and the input voltage is varied form 30% modulation ($\pm 3.6\text{kHz}$ deviation) to at least 20dB higher than the saturation point. Measurements of modulation and the plots are attached herein . Measurements were performed for ST, SAT and wide-band data modulations. The corresponding results are shown herein.

Note: ST, SAT and wide-band data were internally generated by the EUT.

4.1 DESCRIPTION OF TESTS (CONTINUOUS)

4.5 Occupied Bandwidth Emission Limits

- (a) On any frequency outside a licensee's frequency block, the power of any emission shall be attenuated below the transmitter power (P) by at least $43+10\log(P)$ dB.
- (b) Compliance with these provisions is based on the use of measurement instrumentation employing a resolution bandwidth of 1MHz or greater. However, in the 1MHz bands immediately outside and adjacent to the frequency block a resolution bandwidth of at least one percent of the emission bandwidth of the fundamental emission of the transmitter may be employed. The emission bandwidth is defined as the width of the signal between two points, one below the carrier center frequency and one above the carrier center frequency, outside of which all emission are attenuated at least 26dB below the transmitter power.
- (c) When measuring the emission limits, the nominal carrier frequency shall be adjusted as close to the licensee's frequency block edges, both upper and lower, as the design permits.
- (d) The measurement of emission power can be expressed in peak or average values, provided they are expressed in the same parameters as the transmitter power.

4.1 DESCRIPTION OF TESTS (CONTINUOUS)

4.6 Occupied Bandwidth

The audio signal generator is adjusted to 1kHz. The output level is set to ± 6 kHz deviation. With the level constant, the frequency is set to 2500Hz. Then the audio signal level is increased by 16dB. The occupied bandwidth data is obtained for the SAT(Supervisory Audio Tone), ST(Signaling Tone), WBD(Wideband data), and DTMF(Dual Tone Multi Frequencies). The results are shown on the attached graphs.

Specified Limits:

- a. On any frequency removed from the assigned carrier frequency by more 20kHz, up to and including 45kHz, the sideband is at least 26dB below the carrier.
- b. On any frequency removed from the assigned carrier frequency by more 45kHz, up to and including 90kHz, the sideband is at least 45dB below the carrier.
- c. On any frequency removed from the assigned carrier frequency by more 90kHz, up to and multiple of the carrier frequency, the sideband is at least 60dB below the carrier or $40 + \log_{10}(\text{mean power output in Watts})\text{dB}$, whichever is the smaller attenuation.

4.7 Spurious and Harmonic Emissions at Antenna Terminal

The level of carrier and the various conducted spurious and harmonics frequencies is measured by means of a calibrated spectrum analyzer. The spectrum is scanned from the lowest frequency generated in the equipment up to 10GHz. The transmitter is modulated with a 2500Hz tone at a level of 16dB greater than that required to provided 50% modulation.

At the input terminals of the spectrum analyzer, an isolator (RF circulator with on port terminated with 50ohms)and an 870MHz to 890MHz bandpass filter is connected between the test transceiver (for conducted tests) or the receive antenna (for radiated tests) and the analyzer. The rejection of the bandpass filter to signals in the 825-845MHz range is adequate to limit the transmit energy from the test transceiver which appears to a level which will allow the analyzer to measure signals less than -90dBm. Calibration of the test receiver is performed in the 870-890MHz range to insure accuracy to allow variation in the bandpass filter insertion loss to be calobrated.

4.8 Frequencies

At the input terminals of the spectrum analyzer, an isolator (RF pad) and a high-pass filter are connected between the test transceiver (for conducted tests) or the receive antenna (for radiated tests) and the analyzer. The high-pass filter(signals below 1.6GHz)is to limit the fundamental frequency from interfering with the measurement of low-level spurious and harmonic emissions and to ensure that the preamplifier is not saturated.

4.1 DESCRIPTION OF TESTS (CONTINUOUS)

4.9 Radiation Spurious and Harmonic Emissions

Radiation and harmonic emission are measured outdoors at our 3-meter test range. The equipment under test is placed on a wooden turntable 3-meters from the receive antenna. The receive antenna height and turntable rotation were adjusted for the highest reading on the receive spectrum analyzer. A half-wave dipole was substituted in place of the EUT. This dipole antenna was driven by a signal generator with the level of the signal generator being adjusted to obtain the same receive spectrum analyzer reading. This level is recorded. For readings above 1GHz, the above procedure is repeated using horn antennas and the difference between the gain of the horn and an isotropic or dipole antenna are taken into consideration.

4.10 Frequency Stability / Temperature Variation.

The frequency stability of the transmitter is measured by:

- a) Temperature: The temperature is varied from -30°C to +60°C using an environmental chamber.
- b) Primary Supply Voltage: The primary supply voltage is varied from 85% to 1150% of the voltage normally at the input to the device or at the power supply terminals if cables are not normally supplied.

Specification- The frequency stability shall be sufficient to ensure that the fundamental emission stays within the authorized frequency block. The frequency stability of the transmitter shall be maintained within $\pm 0.00025(\pm 2.5\text{ppm})$ of the center frequency.

Time Period and Procedure:

1. The carrier frequency of the transmitter and the individual oscillators is measured at room temperature (25°C to 27°C to provide a reference).
2. The equipment is subjected to an overnight "soak" at -30°C without power applied.
3. After the overnight "soak" at 30°C (usually 14-16 hours), the equipment is turned on in a "standby" condition for one minute before applying power to the transmitter. Measurement of the carrier frequency of the transmitter and the individual oscillators is made within a three minute interval after applying power to the transmitter.
4. Frequency measurements are made at 10°C interval up to room temperature. At least a period of one and one half-hour is provided to allow stabilization of the equipment at each temperature level.
5. Again the transmitter carrier frequency and the individual oscillators is measured at room temperature to begin measurement of the upper temperature levels.
6. Frequency measurements are at 10 intervals starting at -30°C up to +50°C allowing at least two hours at each temperature for stabilization. In all measurements the frequency is measured within three minutes after re-applying power to the transmitter.
7. The artificial load is mounted external to the temperature chamber.

NOTE: The EUT is tested down to the battery endpoint.

NOTE

Radiated Spurious Emission Measurements by Substitution Method
according to ANSI/TIA/EIA-603-A-2001, Aug. 15, 2001:

The EUT was placed on a wooden turn table 3-meters from the receive antenna. The receive antenna height and turntable rotation was adjusted for the highest reading on the receive spectrum analyzer. A half-wave dipole was substituted in place of the EUT. This dipole antenna was driven by a signal generator and the level of the signal generator was adjusted to obtain the same receive spectrum analyzer reading. This spurious level is recorded. For readings above 1GHz, the above procedure is repeated using horn antennas and the difference between the gain of the horn and an isotropic or dipole antenna are taken into consideration.

13.1 SAMPLE CALCULATIONS

A. Emission Designator

Emission Designator = 1M25F9W

CDMA BW = 1.25 MHz

F = Frequency Modulation

9 = Composite Digital Info

W = Combination (Audio/Data)

(Measured at the 99.75% power bandwidth)

Emission Designator=40K0F8W

Calculation: Voice+SAT

Modulation: Voice is 2.5kHz and SAT is 6kHz-Maximum modulation is M=6kHz

Deviation: Voice is 12kHz and SAT is 2kHz- Maximum deviation is D=12+2=14kHz

Bn= 2xM+2xDK with K=1

Bn= 40kHz

Calculation: Signaling Tone (ST)+SAT

Modulation: ST is 10kHz and SAT is 6kHz-Maximum modulation is M=10kHz

Deviation: ST is 8kHz and SAT is 2kHz- Maximum deviation is D=8+2=10kHz

Bn= 2xM+2xDK with K=1

Bn= 40kHz

Emission Designator=40K0F1D

Calculation: Voice + SAT

Modulation: Wideband Data is 10kHz and SAT is 6kHz- Maximum modulation is M=10kHz

Deviation: Wideband Data is 8kHz and SAT is 2kHz- Maximum deviation is D=8+2=10kHz

Bn= 2xM+2xDK with K=1

Bn= 40kHz

B. Spurious Radiated Emission - PCS Band

Example: Channel 25 PCS Mode 2nd Harmonic(3702.50MHz)

The receive analyzer reading at 3 meters with the EUT on the turntable was -81.0dBm. The gain of the substituted antenna is 8.1 dBi. The signal generator connected to the substituted antenna terminals is adjusted to produce a reading of -81.0dBm on the receive analyzer. The loss of the cable between the signal generator and the terminals of the substituted antenna is 2.0dB at 3702.50MHz. So 6.1dB is added to the signal generator reading of -30.9dBm yielding -24.80dBm. The fundamental EIRP was 25.501 dBm so this harmonic was 25.501dBm-(-24.80)=50.3dBc.

14.1 CONCLUSION

The data collected shows that the **Modottel Tri-Mode Dual-Band Analog/PCS Phone (AMPS/CDMA) FCC ID: POQWTE-500** complies with all the requirements of Parts 2,22 and 24 of the FCC rules.
