2.4 Power control principle

Downlink:

MU will test the input power level at location mark1 and send the value to MCU, software will compare the value with the standard value (10dBm), if the received value is higher than standard value, MCU will set ATT at mark 2. (ATT= input power value-standard value) Detection circuit detect the RU downlink output power at location mark3 and send to differential comparator to compare with the standard output power (41dBm), and the output of differential comparator will send control level to attenuator at location mark4 to make sure the output power at mark 3 is not higher than 41dBm, so that RU downlink output power is not higher than 39dBm (the gain between mark 3 and Ant port is -2dB).

Uplink:

Mark5 and Mark6 in MRU are the ALC(auto level control) circuit. Detection circuit detect the RU uplink output power at location mark6 and send to differential comparator to compare with the standard RU uplink output power (+1dBm), and the output of differential comparator will send control level to attenuator at location mark5 to make sure the RU uplink output power is not higher than +1dBm, so that MU uplink output power is not higher than -18dBm.

5 Test results

5.1 EUT operation

Test Date (yy-mm-dd): Sep 05, 2014 to Sep 17, 2014
Test Method: FCC part 2
Test Requirement: FCC part 22, part 24, part 27, part 90
Power supply: AC 120V 60Hz

Test Requirement:

Fiber-optic distribution systems are a type of in-building radiation system that receives RF signals from an antenna, distributes the signal over fiber-optic cable, and then retransmits at another location for example within a building or tunnel. Most fiber-optic systems are signal booster; however, some may be repeaters. These systems generally have two enclosures typically called host (or local or donor unit) and remote. Some systems may also have an optional expander box for fan-out to multiple remotes. The system transmits downlink signals from the remote unit to handsets, portables, or clients, and transmits uplink signals via from the host unit. Usually but not always the uplink goes through an intermediate amplifier to a “donor” antenna. Therefore both uplink and downlink must be tested, unless filing effectively documents how connection of uplink to donor antenna with or without an intermediate amplifier will be prevented, such as for always only a cabled connection to a base station. Fiber-optic systems are not amplifiers (AMP equipment class) – they are equipment class TNB or PCB. The same approval procedures also apply for multiple-enclosure systems connected by coax cable.

1) host unit

- a) transmits uplink to base station via antenna thru coax, passive interface unit, or active interface unit(amplifier).
- b) sends base-station downlink via fiber-optic or coax to remote.
- c) receives handset uplink via fiber-optic or coax from remote.
- d) separate FCC ID from remote, unless electrically identical.
- e) non-transmitting host unit
 - i) connects directly to a base station via coax cable but does not connect to antenna or amplifier.
 - ii) Part 15 digital device subject to Verification, no FCC ID.

2) remote unit

FCC ID: PX8MRU-6100

- a) receives base-station downlink via fiber-optic or coax from host, transmits via antenna to handsets.
- b) Returns handset uplink via fiber-optic or coax to **host**.
- c) Separate FCC ID from **remote**, unless electrically identical.

3) *passive interface unit*

- a) contains attenuators, splitters,combiners.
- b) coax cable connection between **host** and base-station.
- c) Pass device, no FCC ID.

4) *active interface unit*

- a) amplifies uplink signal from host unit for transmit by donor antenna.
- b) attenuates downlink from donor antenna.
- c) coax cable connection between **host** and **active interface unit**.
- d) Usually has separate FCC ID; in some cases could be combined/included with **host** as one enclosure.

Remark:

GENERAL DEFINITIONS FOR CERTIFICATION PURPOSES:

The following three general definitions are applicable in this annex for equipment authorization purpose. The general term “extender” is the same as booster, but booster should be used rather than extender. The general term “translator” is the same as repeater, but repeater should be used rather than translator.

External radio frequency power amplifier(ERFPA) –any device which, (1) when used in conjunction with a radio transmitter signal source, is capable of amplification of that signal, and (2) is not an integral part of a radio transmitter as manufactured. The EAS equipment class AMP is used only for an ERFPA device inserted between a transmitter (TNB/PCB) and an antenna (has only one antenna port).

Booster is a device that automatically reradiates signals from base transmitters without channel translation, for the purpose of improving the reliability of existing service by increasing the signal strength in dead spots. An “in-building radiation system” is a signal booster. These devices are not intended to extend the size of coverage from the originating base station. A booster can be either single or multiple channels.

Repeater is a device that retransmits the signals of other stations. Repeaters are different from boosters in that they can include frequency translation and can extend coverage beyond the design of the original base station. A repeater is typically single channel but can also be multiple channels.

For Consumer Signal Boosters, uniform test procedures consistent with the new requirements in the Order are continuing under review and presently under development, and as soon as

available will be released as a separate attachment under this KDB 935210 publication number. In addition, per the Order for §§90.219 (d) and 90.219 (e) contain specific provisions for which information and test data must be included in application; uniform test procedures for the §90.219 requirements will be amended to KDB 935210 as soon available.

For devices other than consumer signal boosters, tests should be done with each typical signal. e.g., for F3E emissions use 2500 Hz with 2.5kHz or 5 kHz deviation. Use of CW signal for some tests is acceptable in lieu of actual emission, in cases when CW signal gives worst case.

The EUT include host unit and remote unit.

Host separates FCC ID from ***remote***.

Test conditions: Normal conditions

Test configuration:

Figure 1: Downlink RF Output Power Configuration

Test Procedure: RF output power test procedure:

- Connect the equipment as illustrated, when the output power is over the maximum value of the Spectrum Analyzer, add the attenuator to avoid destroying the facility.
- Set the center frequency of the Spectrum Analyzer to assigned transmitter frequency, key the transmitter, and set the level of the carrier to the full scale reference line.
- Do not apply any tone to modulate the EUT
- Adjust the Spectrum Analyzer for the following setting:
 Resolution Bandwidth >> the carrier bandwidth;
 Video Bandwidth refer to standard requirement;
 Use Spectrum Analyzer channel power measurement;
 Record the frequencies and levels of carrier power;
 Calculate the signal link way loss and final power value;

Remark: Output power:

Power on Form 731 should be clearly understood as either composite of multi-channels or per carrier, If power is composite

include in comments field: "Power output listed is composite for multi-channel operation."

Check that the input drive level is at the maximum input rating and maximum gain setting for all tests. Check both uplink and downlink input level. See manual or brochures/technical description for maximum rating. May need to check FCC identifier of transmitter used for tests.

Confirm device cannot operate in saturation. There are means to control maximum power and to assure linear operation.

EUT Operation: The output power of EUT be set to maximum value, the gain of EUT be set to maximum value by software through the manufacture

Test conditions: Normal conditions

Test configuration:

Figure 2: Downlink Conducted Spurious Emission Configuration

Test Procedure:

Conducted Emission test procedure:

- Connect the equipment as illustrated, with the notch filter by-passed, when the output power is over the max. value of the Spectrum Analyzer, add the attenuator to avoid destroying the facility.
- Set the center frequency of the Spectrum Analyzer to assigned transmitter frequency, key the transmitter, and set the level of the carrier to the full scale reference line.
- Do not apply any tone to modulate the EUT
- Adjust the Spectrum Analyzer for the following setting:
 - Resolution Bandwidth (base the standard, apply the different set), her is 100kHz for frequency band less than 1 GHz, 1 MHz for frequency over 1 GHz
 - Video Bandwidth refer to standard requirement

- e) Adjust the center frequency of the spectrum analyzer for incremental coverage of the range from:
 - 1) the lowest radio frequency generated in the equipment, it can be 9 kHz base the test method, here select 30 MHz as lowest frequency start point;
 - 2) the highest radio frequency shall higher than 10 times of carrier frequency;
- f) Record the frequencies and levels of spurious emissions;

Remark:

The notch filter is used for avoid the EUT fundamental carrier output power making the spectrum overload and the harmonic spurious brought by it.

When the EUT fundamental carrier is not enough to make the status, the notch filter could be not used.
