

- 6) Why do test photos appear to show one mode tested in the E7900, the other out in the open? Generally an LMA would be tested internal to a host, or optionally both with and without host for the initial filing. It is noted that the report justifies worse case out in the open, however this is not necessarily always the case. Were both configurations at least checked?

Response: A statement was added to Section 2.2 of the test report explicitly confirming that both installed and standalone configurations were checked. Both configurations were evaluated during pre-test or spot-check measurements installed inside the E7900 host and operated standalone outside the host. The standalone configuration produced equal or higher emissions/field strength across the applicable limits and frequencies. Based on that comparison, the standalone configuration was selected as the worst-case configuration for formal testing and documentation.
