3.8 Conducted Unwanted Receiver Emissions

For a license-exempt radio apparatus RSS-GEN, 7.4 requires the spurious emissions from the receiver at any discrete frequency, measured at the antenna port by the antenna-conducted method, shall not exceed 2 nW in the frequency range 30-1000 MHz and 5 nW above 1 GHz.

3.8.1 Measurement Method

This test was performed in accordance with Clause 11.11.3 of ANSI C63.10-2020.

3.8.2 Test Data

The EUT test data is provided below.

The transmitter was disabled via test software.

The EUT was configured in a receive only mode.

The receiver was set to sweep the 2.4GHz ISM band, in an active receiver mode.

Figure 86: Conducted Unwanted Receiver Emissions, Plot 4

3.9 General Field Strength Requirements – Radiated Emissions

3.9.1 Requirements

Compliance Standard: FCC Part 15.205 and 15.209

FCC Compliance Limits		
Frequency Range	3m Limit	
30 – 88 MHz	100 μ V/m (QP)	
88 – 216 MHz	150 μ V/m (QP)	
216 – 960 MHz	200 μ V/m (QP)	
> 960 MHz	500 μ V/m (AVG)	5000 μ V/m (Peak)

3.9.2 Test Procedure Summary

The requirements of FCC Part 15, RSS-Gen, and ICES-003 call for the EUT to be placed on a 1m X 1.5m non-conductive motorized turntable at a height of 80cm for radiated testing of frequencies up to 1000 MHz, and a height of 1.5m for testing of frequencies above 1000 MHz. Please note that the radiated emissions measured during this testing, were performed at a distance of 3-meters.

An initial pre-scan of the EUT was performed to identify any emissions that exceed, or come within 6dB of, the applicable limit. This pre-scan was performed with the employment of a spectrum analyzer peak detector function. The highest amplitude (worst-case) emissions noted during the pre-scan were selected for final compliance measurements.

The emissions from the EUT were measured continuously at every azimuth by rotating the turntable. Broadband log periodic and double-ridged horn antennas were mounted on an antenna mast to determine the height of maximum emissions. The height of the antenna was varied between 1 and 4 meters. The output of the antenna was connected to the input of the spectrum analyzer and the emissions in the frequency range of 30 MHz to 26.5 GHz were evaluated. The EUT peripherals were placed on the table in accordance with ANSI C63.4. Cables were varied in position to produce maximum emissions. Both the horizontal and vertical field components were measured.

The detector function was set to quasi-peak for measurements below 1 GHz. The measurement bandwidth of the spectrum analyzer system was set to at least 120 kHz, with all post-detector filtering no less than 10 times the measurement bandwidth. For measurements above 1 GHz, both the peak and the average levels are recorded, using a measurement bandwidth of 1 MHz. For average measurements, a video bandwidth setting of 10 Hz was used, in the case of video averaging; otherwise, an EMI AVG detector shall be employed.

To ensure that the support laptop did not interfere with radiated measurements of frequencies above 1GHz, the applicant has completely disabled the WiFi capabilities within the computer's bios. For measurements of frequencies below 1000 MHz, the laptop and the AC/DC power supply were shielded from the test site via the use of EMF/EMI Faraday Blankets. Due to the shielding effectiveness of these protective materials, the support laptop did not adversely impact the 3m radiated emissions testing.

3.9.3 Radiated Data Reduction and Reporting

To convert the raw spectrum analyzer radiated data into a form that can be compared with the FCC limits, it is necessary to account for various calibration factors that are supplied with the antenna(s) and other measurement equipment. These factors include the antenna factor ((AF)(in dB/m)), cable loss factors ((CF)(in dB)), and the pre-amplifier gain [if applicable] ((G)(in dB)). These correction values are algebraically added to the raw Spectrum Analyzer Voltage (in dBμV) to obtain the corrected radiated electric field, which shall be the final corrected logarithm amplitude ((Corr. Meas.)(in dBμV/m)). This logarithm amplitude is then compared to the FCC limit, which has been converted to a unit of log in dBμV/m.

Example:

Spectrum Analyzer Voltage:	VdBμV (SA)
Antenna Correction Factor:	AFdB/m
Cable Correction Factor:	CFdB
Pre-Amplifier Gain (if applicable):	GdB
Electric Field:	$E_{dB\mu V/m} = V_{dB\mu V (SA)} + AF_{dB/m} + CF_{dB} - G_{dB}$
To convert from linear units of measure:	$dBuV/m = 20\text{LOG}(uV/m)$
To convert FCC limits, based on D_{Measure} :	$3m \text{ Limit} = 10m \text{ Limit} + 20\text{LOG}(10/3)$

Environmental Conditions During Radiated Emissions Testing

Ambient Temperature:	20 °C
Relative Humidity:	55 %

3.9.4 Measurement Method and Results

Prior to testing, the EUT was investigated for the worst-case setup configuration. The EUT's primary power source was varied between the AC mains cord and the DeWalt battery pack. In this case, the EUT emissions are worse-case when the EUT is coupled to the public mains network. As such, the EUT was powered by 120VAC, 60Hz during this test. When powered by the battery, the EUT does not create any emissions that are worse than the emission reported below.

Additionally, the EUT auxiliary port(s) and USB port(s) [on the side of the chassis] were investigated for unwanted emissions. A near field investigation demonstrated that populating these ports had no impact on the EUT emissions. That is, the results of this test are unchanged whether the AUX ports are used/populated. These ports do not cause the EUT to radiate any emission that is worse than the emissions reported below.

The EUT was tested while positioned in the worst-case orientation, based on a three-axes (orthogonal plane) evaluation of the fundamental field strength at 3-meters. The EUT position that produced the highest TX field strength, was maintained.

For testing of frequencies from 30MHz to 1GHz, the EUT production sample was used. The wireless BT link was exercised by pairing the speaker to a smartphone and streaming music. The smartphone companion was kept behind the receive antenna in the corner of the chamber, and it was confirmed (through a quick investigation) that the support peripheral did not adversely impact the result of the test.

For testing of frequencies above 1GHz, the EUT was configured in a fully-modulated mode, with the hopping stopped, to dwell on the appropriate test channel.

The frequency range of 30 MHz to 26.5 GHz was investigated.

There were no emissions detected in the frequency range of 7 GHz to 26.5 GHz.

The EUT complies with the requirements this section.

Table 12: Radiated Emissions Test Data, 30 MHz to 1000 MHz

Frequency (MHz)	Detector	Corr. Meas (dBuV/m)	Limit (dBuV/m)	Delta (dB)	Turn Table (deg)	Antenna (cm)

3.10 AC Powerline Conducted Emissions

3.10.1 Requirements

Compliance Standard: FCC Part 15.207

FCC Compliance Limits		
Frequency Range	Class B Digital Device	
	Quasi-peak	Average
0.15 – 0.5 MHz	66 to 56 dB μ V	56 to 46 dB μ V
0.5 – 5 MHz	56 dB μ V	46 dB μ V
0.5 – 30 MHz	60 dB μ V	50 dB μ V

3.10.2 Test Procedure

The requirements of FCC Part 15 and ICES-003 call for the EUT to be placed on an 80cm-high 1 X 1.5-meter non-conductive table above a ground plane. Power to the EUT was provided through a Solar Corporation 50 Ω /50 μ H Line Impedance Stabilization Network bonded to a 3 X 2-meter ground plane. The LISN has its AC input supplied from a filtered AC power source. Power was supplied to the peripherals through a second LISN. The peripherals were placed on the table in accordance with ANSI C63.4. Power and data cables were moved about to obtain maximum emissions.

The 50 Ω output of the LISN was connected to the input of the spectrum analyzer and the emissions in the frequency range of 150 kHz to 30 MHz were measured. The detector function was set to quasi-peak, peak, or average as appropriate, and the resolution bandwidth during testing was at least 9 kHz, with all post-detector filtering no less than 10 times the resolution bandwidth. For average measurements, the post-detector filter was set to 10 Hz.

These emissions must meet the limits specified in §15.207 for quasi-peak and average measurements.

Environmental Conditions During Conducted Emissions Testing

Ambient Temperature:	16 °C
Relative Humidity:	44 %

3.10.3 Conducted Data Reduction and Reporting

The comparison between the Conducted emissions level and the FCC limit is calculated as shown in the following example:

Spectrum Analyzer Voltage: $V_{dB\mu V}(raw)$

LISN Correction Factor: LISN dB

Cable Correction Factor: CF dB

Voltage: $V_{dB\mu V} = V_{dB\mu V}(raw) + LISN\ dB + CF\ dB$

3.10.4 Test Data

The EUT complies with the Class B Conducted Emissions requirements.

The EUT was evaluated in both a TX On mode and in an TX Off mode. Disabling the transmitter had no impact on the emissions.

The EUT can operate by DeWalt battery power. However, the EUT cannot charge the battery.

Also, the EUT cannot be coupled to a public AC mains network and have the battery installed simultaneously. (AC power or battery power, but not both). (and the EUT is not a battery charger).

The worst-case emission test data is provided below.

This data shall also serve to satisfy the digital unwanted emissions requirements for both FCC 15B and ISED Canada.

4.2 Measurement Uncertainty

All results reported herein relate only to the equipment tested. The basis for uncertainty calculation uses ANSI/NCSL Z540-2-1997 (R2002) with a type B evaluation of the standard uncertainty. Elements contributing to the standard uncertainty are combined using the method described in Equation 1 to arrive at the total standard uncertainty. The standard uncertainty is multiplied by the coverage factor to determine the expanded uncertainty which is generally accepted for use in commercial, industrial, and regulatory applications and when health and safety are concerned (see Equation 2). A coverage factor was selected to yield a 95% confidence in the uncertainty estimation.

Equation 1: Standard Uncertainty

$$u_c = \pm \sqrt{\frac{a^2}{div_a^2} + \frac{b^2}{div_b^2} + \frac{c^2}{div_c^2} + \dots}$$

Where:

uc	= standard uncertainty
a, b, c,..	= individual uncertainty elements
Diva, b, c	= the individual uncertainty element divisor based on the probability distribution
Divisor	= 1.732 for rectangular distribution
Divisor	= 2 for normal distribution
Divisor	= 1.414 for trapezoid distribution

Equation 2: Expanded Uncertainty

$$U = ku_c$$

Where:

U = expanded uncertainty

k = coverage factor

k ≤ 2 for 95% coverage (ANSI/NCSL Z540-2 Annex G)

uc = standard uncertainty

The measurement uncertainty complies with the maximum allowed uncertainty from CISPR 16-4-2. Measurement uncertainty is not used to adjust the measurements to determine compliance. The expanded uncertainty values for the various scopes in the WLL accreditation are provided in Table 22 below.

Table 22: Expanded Uncertainty List

Scope	Standard(s)	Expanded Uncertainty
Conducted Emissions	CISPR11, CISPR32, CISPR14, FCC Part 15	± 2.63 dB
Radiated Emissions	CISPR11, CISPR32, CISPR14, FCC Part 15	± 4.55 dB
