Release Notes

Contains link to the 4.0 Symantec Identity Security Platform release and patches.

This topic includes the links to all the major and minor releases of IDSP:

- Release Notes - 4.0.2
- Release Notes - 4.0.1
- Release Notes - 4.0

Release Notes 4.0.2

View information about the Symantec Identity Security Platform 4.0.2 release.

New Features and Improvements

- The Kubernetes community has announced the retirement of the ingress-nginx project. Starting March 2026, the community stops providing bug fixes and security updates for ingress-nginx. In response, the Identity Security Platform (IDSP) is transitioning from the legacy Nginx Ingress controller to the Kubernetes Gateway API standard.
  The Gateway API is the standard alternative replacing the Nginx Ingress controller across all platform clusters. It provides a unified, extensible framework for managing ingress traffic, enabling advanced routing, improved security integrations through declarative custom resources such as BackendTLSPolicy, and better native support across multi-cloud environments.
  Symantec Identity Security Platform supports Envoy Gateway (recommended for cross-cloud portability), GKE L7 Gateway, Azure Application Gateway for Containers, AWS Load Balancer Controller, and Avi AKO for VMware environments.
  For more information on the Gateway API, see Configuring Gateway API for Ingress. (F162847)
- A new automated scheduler has been introduced to manage inactive device cleanup, helping maintain optimal database performance by preventing device tables from growing indefinitely. See Inactive Device Purging Scheduler. (F162848)
- Added the ability to customize scheduler configurations during installation or upgrade operations. Users can now configure custom execution times and batch sizes for various system schedulers using command-line parameters. For detailed information on scheduler configuration parameters, refer to the "**Customizing Scheduler Settings" section within each Scheduler Job** topic under the Scheduler Jobs documentation. (DE661080)
- The Device Name ("deviceDetails" in Known Devices and "name" attribute in the Trusted Devices API) framework has been enhanced to include additional information in the Known and Trusted Devices API response.

See Trusted Devices API response, and Known Devices API response examples. (DE649741) (DE661898)

- A new application metadata property, **Delay IDP Rule**, has been introduced to support device-specific identity provider configurations. For more information, see App Metadata. (F164347)

App Metadata	Description
• urn:iam:app:delayProtocolLevelIdpDiscoveryUntilSignin (API terminology) • Delayed IDP Discovery (UI terminology)	Identity Provider discovery can now be deferred until the ".../auth/v1/authenticate" API request, allowing discovery to run with full user and client context instead of during the initial protocol redirect. Client context from authenticate requests is now processed earlier in the authentication flow, ensuring availability during IDP discovery and subsequent steps.

- This release enhances the customizable **New Device Sign-in** email template to include machine details. The out-of-the-box template includes the placeholders, $$DEVICE_DETAILS$$, $$OS_DETAILS$$, and $$BROWSER_DETAILS$$.

  You can customize the email template contents using the Message Template API. See Managing Message Templates. (F162563)
- Added the ability for end users to initiate a password change using the Forgot Password link on the login screen, or in a self-initiated Reset Password flow in your client app for SiteMinder implementations. See Changing Password Using Forgot Password or Self-initialized Reset Password Policy-based Flows. (F141954)
- Previously, the Reset Password Policy supported only the sign-in client app. With this release, you can now change the application that is assigned to this policy. See Reset Password Policy for more details about this policy. (F141954)
- This release introduces a new application metadata attribute (`urn:iam:app:samlStrictCompliance`). When this metadata attribute is set to `true`, the following attributes are not sent as part of the SAML assertion issued by Symantec Identity Security Platform. The default value is `false`. (F162393)
  - app_id
  - session_state
  - user_guid
  - idp_guid
  - user_loginid
  - user_riskscore
  - sid
- Identity and Access Tokens include granular Authentication Methods References (AMRs), such as `["SMS", "OTP", "PWD"]` or `["EMAIL", "OTP", "PWD"]`, by default for all valid Refresh Tokens, regardless of the `useGranularAMRForOTP` tenant setting. Previously, granular AMRs were only included when the `useGranularAMRForOTP` setting was enabled, and even then, only Refresh Tokens issued after enabling the setting produced Identity Tokens with granular AMRs. Pre-existing Refresh Tokens continued to produce non-granular values (for example, `["OTP", "PWD"]`), requiring users to re-authenticate. With this enhancement, granular AMRs are applied universally to all valid Refresh Tokens — both new and pre-existing — without requiring the tenant setting to be enabled or forcing user re-authentication.

  For more information on Granular OTP, see Enhanced OTP Authentication Method References (AMR). (DE651244)
- Symantec Identity Security Platform can now be placed into a Read-Only state during database maintenance, enabling administrators to perform maintenance operations without requiring a complete service shutdown. For more information, see Upgrade Procedure with No Active Database Transactions (DE657507).
- The `.../factor/v1/FIDORegChallengeVerifier` API has been enhanced to provide additional metadata about authenticator. The **`"authenticatorAaguid"`** attribute value is now returned only when the

enableFIDOMetadataAttestation tenant setting is enabled during Identity Security Platform (IDSP) deployment. See ".../factor/v1/FIDORegChallengeVerifier" API response. (F165058)

- A new application metadata setting, "**skipAuthenticationForTrustedDevice**", has been added. When enabled, this feature allows users on trusted devices to safely and seamlessly bypass the complete authentication flow. This enhancement improves the user experience by treating the recognized device as a valid authentication factor, removing the need for repeated interactive logins on known, secure devices. To accurately reflect this authentication method, the system includes the `POP` (Proof of Possession) value in the AMR claim when it produces the Identity Token Hint (ITH).This application metadata is covered in the Application Metadata topic. (F166010)
- The IDSP Admin service now includes a "**strikeCount**" field (integer) in the "get user" GET ".../admin/v1/Users/{{REPLACE-BY-USERID-OR-USERLOGINID}}" endpoint response. This field displays the user's current strike count from authentication failures, enabling administrators to monitor user strike status directly without additional API calls. (DE661957)

Fixed Issues

- The ivr_phone_number attribute disappears from the admin console when configured as multi-value for auto enrollment, preventing voice OTP delivery to multiple phone numbers.
  As part of this fix, added the following:
  - New app metadata, "urn:iam:app:**allowIvrCredsOfTag",** see Application Metadata properties
  - Support for ivr_phone_number in the "mvAttributeMapping" LDAP attribute, see Managing LDAP Directory Configuration

  (DE661784)
- The credential exclusion (urn:iam:app:**excludeCredsNotUsedForXDays**) app metadata setting that filters out credentials not used within a specified number of days does not properly exclude credentials that have never been used (those with blank/null lastUsed values). (DE659218)
- In an integration flow, the Credential Usage metrics in the Grafana dashboard show SMS and Email OTP as "Primary" authentication methods, when these factors are configured as second factors. (DE658403)
- A duplicate entry was created for an existing trusted device for a user. This issue occurred when a single device was shared between two users. If one user removed the shared device and then re-accessed it, the **IA Risk** device tag rotation triggered the creation of a duplicate entry for an existing trusted device. (DE661315)
- An issue was found where users were unable to log in immediately after creating a custom tenant. A race condition in the db transaction during tenant creation and incorrect caching entry was leading to this issue. (DE663688)
- An issue was observed in JIT provisioning where case-variant Multi-Value Attributes (emails, phones, addresses) were not correctly deduplicated, leading to redundant record creation during federated authentication. (DE664062)
- Introduced a new app metadata configuration:

App Metadata	Description
• urn:iam:app:includeAdditionalContextInLaunchApp (API terminology) • Enhanced Launch Context (UI terminology)	Applications can receive additional context parameters (logout URL, session state) when users are redirected to the launch URL after successful authentication.

  For more information on these Application Metadata, see Application Metadata Properties.(DE663788)
- AMR Not Handled Correctly for Attribute-Based Authentication Factor in Policy Rules. When a Policy Rule includes an Attribute-Based Authentication Factor, the Authentication Methods Reference (AMR) is not functioning as expected in two ways:

  - The AMR value associated with the Attribute-Based Authentication Factor is not included in the generated ID Token after authentication.
  - When the ".../authentication" endpoint is called with an existingIDToken payload that already contains the AMR for the Attribute-Based Authentication Factor, the system does not recognize it — causing the factor to be re-prompted instead of being skipped. (DE666159)
- In the mandatory authentication flow, if the obligation sequence is interrupted in the setting,`inlineEnrollmentFactorsRequired` value, all subsequent inline enrollment factors with a priority equal to or higher than the break point are skipped. For example, when the policy enforces PASSWORD (priority 1) and FIDO (priority 2, unregistered), and `inlineEnrollmentFactorsRequired` is set to "EMAILOTP:1, SMSOTP:1, MOBILEOTP:3, PUSH:3" — only factors with priority lower than the break point (EMAILOTP, SMSOTP) are presented. MOBILEOTP and PUSH (priority 3) are silently skipped, resulting in an incomplete authentication challenge. (DE660411)
- The Symantec Identity Security Platform Swagger documentation took an excessively long time to respond (often over 30 seconds). This delay frequently resulted in 503 errors for clients due to proxy timeouts. (DE662755)
- The Swagger API specifications for the Authentication Factor APIs (`/admin/v1/AuthenticationFactor`) and the Authenticator API (`/factor/v1/Authenticator`) were missing from the technical documentation. (DE666398)
- Improved the performance of app tile rendering in the Self Service Console. (DE662603), (DE662604)
- When the user being authorized is assigned a high number of applications, the Self Service Console dashboard experienced issues loading. (DE662598)
- The text "enrollment required" would sometimes erroneously appear on the sign-in screen for users. (DE664413)
- The provided username is ignored when application metadata to delay idpProtocol discovery is set to `true` . (DE664775)
- Password validation rules now enforce that passwords cannot contain the user displayName (Full Name Value) composed by the displayName Rule on the internalIdStore. If the displayName contains delimiters (such as commas, periods, underscores, or dashes), Symantec Identity Security Platform splits the displayName and confirms that each section is not included in the password. This validation ignores any displayName (and its sections) smaller than three characters. (DE664231)
- On the Symantec Identity Security Platform external tenant, the internal *cred sync initiate* audit event obscures the password. (DE666718)
- Symantec Identity Security Platform does not update the deleted email/phone/device credentials list and does not send notifications for deleted email/phone/device credentials when syncing credentials using the scim2/v1/Me APIs. (DE665556)
- An *internal.cred.sync.initiate* audit event is created even if the Service Account creation failed, due to duplicate account 409 errors. (DE665532)
- The `T_USER` table column that stores Apptile Group and Notification data (including banner and admin notifications) has been altered from its previous data type to `LONGTEXT` . This change accommodates larger payloads such as HTML-formatted banner content and Apptile Group JSON data that previously exceeded the column size limit. (DE662925)
- Updated Nginx-Ingress version from 4.14.0 to.4.14.3 (DE662438)
- Third-party libraries identified as vulnerable in the previous release of Symantec Identity Security Platform have been upgraded to mitigate security risks in external components. (DE662732), (DE662936), (DE663510), (DE664246), (DE666336).

Known Issues

- When an Identity Provider (IDP) is force-deleted, the background scheduler fails to remove its stale references from the authorization policies. As a result, the deleted IDP incorrectly persists in the UI under the Administrators and Roles screens. (DE669313)
- Trusted Device Identification (TDI) flow does not enforce password reset when `passwordMustChange` is enabled
  - **Password reset screen is not displayed during Trusted Device Identification (TDI) flow when `passwordMustChange` is enabled**

When a user with the `passwordMustChange` attribute set to `true` authenticates through the TDI flow, the password reset screen is not presented after completing PASSWORD authentication (primary obligation). Instead, the user is logged in to the AdminConsole without being prompted to change their password. This bypasses the intended password reset enforcement.

– **Authentication is skipped entirely in TDI flow when both `passwordMustChange` and `skipAuthenticationForTrustedDevice` are configured**
When the `passwordMustChange` attribute is enabled for a user and the application metadata `urn:iam:app:skipAuthenticationForTrustedDevice` is also set, the PASSWORD challenge is skipped entirely during the TDI flow. This allows the user to log in without any authentication challenge, bypassing both the trusted device authentication and the password reset requirement.

Upgrade Considerations

IMPORTANT

- **IDSP Supports Incremental Upgrades**:
  IDSP facilitates incremental upgrade paths. If you plan to upgrade to the latest release, IDSP v4.0.2, and you are currently using an earlier version, it is advisable to first upgrade to the latest patch of the subsequent minor release before moving on to IDSP 4.0.2.
  IDSP uses the following format for naming release versions: MAJOR.MINOR.PATCH. For example, in the release version 4.0.x, "4" is the MAJOR version, "0" is the MINOR version, and "x" is the PATCH version.
  Upgrade Use Cases:
  - ***Upgrade Scenario 1***: Upgrade from IDSP v3.3 to IDSP v4.0
    Recommended Upgrade Path: You should follow this upgrade path- **3.3.x > 3.4.x > 4.0.2**
    Example: 3.3.6 > 3.4.8 > 4.0.2
  - ***Upgrade Scenario 2***: Upgrade from IDSP v3.4.x to IDSP v4.0.x
    Recommended Upgrade Path: You can directly proceed with the upgrade to v4.0.2 without any intermediate steps.
    Example: 3.4.8 > 4.0.2
- The dataseed job may take longer than usual during the upgrade due to the `ALTER TABLE` statement on the `T_USER` table. The duration depends on the number of records in the table. Plan the maintenance window accordingly.
- **Oracle SQL file Updates**: This release includes Oracle database schema changes that may require manual SQL file updates for environments with separate database administration. For detailed upgrade procedures and SQL file application order, see the Oracle SQL File Updates.

See Upgrading IDSP.

Rollback Considerations

Hazelcast 5.7.0 Upgrade — Impact on Zero Downtime

The Hazelcast upgrade from 5.3.5 to 5.7.0 introduces the following considerations for Zero Downtime (ZDT) deployments.

Upgrade

The Helm upgrade command remains unchanged and performs a rolling update, recreating Hazelcast pods sequentially. However, deployments with a single Hazelcast pod will experience a brief service disruption, as the existing pod is terminated before the replacement pod becomes ready.

Rollback

Rolling back from Hazelcast 5.7.0 to 5.3.5 requires manual intervention. During rollback, newly created pods running 5.3.5 cannot establish a connection with existing pods still running 5.7.0, causing the new pods to enter a crash loop. To resolve this, all existing Hazelcast pods must be forcefully deleted so that every pod restarts cleanly on the rolled-back version.

Rollback Command

Run the following command to perform the rollback. The command executes three steps sequentially, each step proceeds only if the previous step succeeds.

```
helm rollback ${RELEASENAME} <revision> -n ${NAMESPACE} && \
kubectl delete pods -l app.kubernetes.io/name=hazelcast-entp -n ${NAMESPACE} && \
kubectl rollout status statefulset/ssp-hazelcast-entp -n ${NAMESPACE} --timeout=5m
```

Step	Description
Step 1: Helm Rollback `helm rollback ${RELEASENAME} <revision> -n ${NAMESPACE}`	Rolls back the Hazelcast Helm release to the specified revision number, reverting all chart configurations, image versions, and Helm values to their state at that revision.
Step 2: Delete Pods `kubectl delete pods -l app.kubernetes.io/name=hazelcast-entp -n ${NAMESPACE}`	Force-deletes all running Hazelcast pods matching the label `app.kubernetes.io/name=hazelcast-entp`. Because these pods are managed by a StatefulSet, Kubernetes automatically recreates them using the rolled-back configuration, ensuring a clean restart on the correct version.
Step 3: Verify Rollout `kubectl rollout status statefulset/ssp-hazelcast-entp -n ${NAMESPACE} --timeout=5m`	Monitors the StatefulSet rollout and waits up to five minutes for all pods to reach a ready state. If the pods do not become healthy within this period, the command exits with an error.

Symantec Identity Security Platform Kit Location and Build Details

See Release 4.0.2 Build Details.

IDSP Knowledge Articles

All IDSP knowledge articles can be found here, Symantec Identity Security Platform Knowledge Articles.

Release Date

The IDSP v4.0.2 release was distributed on May 19, 2026.

Release Notes 4.0.1

View information about the Symantec Identity Security Platform 4.0.1 release.

This topic includes the following sections:

- New Features and Improvement
- Fixed Issues
- Upgrade Considerations
- Symantec Identity Security Platform Kit Location and Build Details
- Symantec Identity Security Platform Knowledge Articles
- Release Date

New Features and Improvements

- Enhanced password expiration warning dialog in the Sign-in UI with a new "Change Now" button that provides users with immediate access to password reset functionality. (F163525)
- The enhanced factor selection screen in the Sign-in UI clearly distinguishes between authentication factors that are already enrolled and those that require initial setup. Selecting an unenrolled factor now seamlessly initiates an inline enrollment workflow. For more information, see Support for Factor Enrollment Status Indicator with Tenant Configuration and CSS Customization. (F163537)
- Starting from Symantec Identity Security Platform v4.0.1, the `requireAccessControl` application setting is now mandatory for all new application creations replacing the previous optional configuration. This setting supports three values, true, false, and tenant. The default value is `tenant` . Applications created previously with null value are handled through backward compatibility mechanisms. (DE660807),(DE660782)
- The Service Account option in the Self-Service Console is now dynamic. It appears only for users with an existing service account and remains hidden for those without one. (F163549)
- The new Diagnostics feature introduces a comprehensive logging and troubleshooting capability within the Admin Console, enabling administrators to capture, view, and analyze detailed logs for specific user sessions in real-time. See Diagnostics. (DE660155)
- **For upgrades to 4.0.1:** If you previously configured the **End User Password Reset Vanity URL** parameter of the internal identity store (`endUserPasswordResetVanityUrls`), you must complete the following procedure to correct it after upgrading to 4.0.1:
  a. Using the The Internal Identity Store Configuration API, clear the parameter value by setting the `endUserPasswordResetVanityUrls` attribute to double quotes ("").
  b. Reconfigure your vanity URLs using the Admin Console UI or the API.

  If you do not make this change, you will see validation errors in the Admin Console and be unable to save the identity store.

Fixed Issues

- Vanity URL configuration in IDStore breaks Self-Service Console access due to missing "/common/" path. (DE660788)
- iOS browsers experienced navigation failures in the Self-Service Console when administrative banners containing HTML anchor tags (<a href="">) were enabled. (DE660792)
- Users experienced display issues with the Self-Service Console's Personal Information page. The email type, phone type, and address type dropdown lists were not rendering correctly, preventing users from selecting appropriate contact information types when updating their profiles. (DE660477)
- Multiple MCP (Model Context Protocol) clients experienced integration failures when attempting to connect to the IDSP MCP Server. (DE660569)
- The authentication flow incorrectly triggered external identity token revocation validation checks. (DE660045)
- App Launcher failed to save flow state information to the database when configured for DB Persistence mode. (DE660791)
- Random failures in SCIM APIs may occur due to thread safety violations. (DE660786)
- SCIM requests with invalid JSON bodies may throw a 500 internal server error, rather than a 400 bad request error. (DE660793)
- Changed the control element for the **Service Configuration** > **End User Notification** option in the Admin Console to a selection box. (DE660195)
- The configured request timeout variable (GEOLOCATION_REQUEST_TIMEOUT) was not honored by any of the Symantec Identity Security Platform services, potentially increasing the overall time of the transactions. (DE661053)
- In Active/Active (A/A) deployments with browser geo-steering, access tokens issued in one region may be redeemed in a different region, causing session validation failures. (DE660790)
- The geolocation service exhibits high latency, resulting in long response time of other services that are dependent on the geolocation service. (DE660784)
- The geolocation service returns HTTP 404 status for invalid or unknown IP addresses instead of the expected HTTP 200 with appropriate response body. (DE660785)
- Access policy creation and update operations fail to process principal conditions containing "appRoles" with wildcard format "/*", causing these conditions to be omitted from the final policy configuration. (DE661232)
- In Bring Your Own Identity (BYOI) flow, "RememberMe" functionality was not working. (DE660787)
- Following the upgrade to IDSP v4.0, users experienced authentication failures when calling SPI (Service Provider Interface) tokens from SCIM (System for Cross-domain Identity Management) operations. (DE660781)
- The BYOI flow was not enforcing maximum session limits per user, allowing users to exceed configured session thresholds. (DE661313)
- User disambiguation process failed when groups mapping was configured in Claims but the Identity Provider (IDP) returned no group information. (DE661166)
- Third-party libraries identified as vulnerable in the previous release of Symantec Identity Security Platform have been upgraded to mitigate security risks in external components. (DE660653), (DE661226), (DE661032)

Upgrade Considerations

IMPORTANT

- **IDSP Supports Incremental Upgrades**:
  IDSP facilitates incremental upgrade paths. If you plan to upgrade to the latest release, IDSP v4.0.1, and you are currently using an earlier version, it is advisable to first upgrade to the latest patch of the subsequent minor release before moving on to IDSP 4.0.1.
  IDSP uses the following format for naming release versions: MAJOR.MINOR.PATCH. For example, in the release version 4.0.x, "4" is the MAJOR version, "0" is the MINOR version, and "x" is the PATCH version.
  Upgrade Use Cases:
  - ***Upgrade Scenario 1***: Upgrade from IDSP v3.3 to IDSP v4.0
    Recommended Upgrade Path: You should follow this upgrade path- **3.3.x > 3.4.x > 4.0.1**

Example: 3.3.6 > 3.4.8 > 4.0.1

- ***Upgrade Scenario 2***: Upgrade from IDSP v3.4.x to IDSP v4.0.x
  Recommended Upgrade Path: You can directly proceed with the upgrade to v4.0.1 without any intermediate steps.
  Example: 3.4.8 > 4.0.1

- **Oracle SQL file Updates**: This release does not include any Oracle database schema changes. However, if you plan to upgrade from Authentication Hub v3.4.8 to Symantec Identity Security Platform v4.0.1, you need to apply all the SQL files mentioned in v4.0. See Oracle SQL File Updates.

See Upgrading IDSP.

Product Rebranding: Introducing Symantec Identity Security Platform

VIP Authentication Hub is now ***Symantec Identity Security Platform (IDSP)***.

This rebrand reflects the solution's significant evolution over the past five years from a focused authentication product into a comprehensive, modern identity and access management platform. What began as VIP Authentication Hub —delivering strong authentication and FIDO2/passkey capabilities—has expanded to include local identity services, advanced federation (SAML, OIDC) flows, granular administration, access policies, OAuth resource scope configuration, customizable self-service console, personal access tokens, and application dashboards. The new name, Symantec Identity Security Platform, accurately represents these broader capabilities and positions the solution within the Symantec product family.

What this means for you: All functionality remains intact. Existing deployments, integrations, and APIs continue to work without modification. Documentation for version 4.0 and later will reference "Symantec Identity Security Platform" or "IDSP," while previous version documentation will retain the "VIP Authentication Hub" name.

VIP Authentication Hub v3.4 and prior releases continue to reside at their original location: VIP Authentication Hub Homepage.

New Features and Improvements

- IDSP 4.0 introduces a new Identity Credential Verifier role that grants permission to update the verified status of an email or phone number in the User Profile. This role can be granted to a User/Client.

  IMPORTANT
  You must add the Identity Credential Verifier role to allow administrators to set a user's email and phone verified state using SCIM. See Administrators and Roles.
- Resource Server: This new feature enables seamless creation and configuration of Resource Server applications, offering robust control over protected resources through the IDSP Admin Console and can also be executed using REST API. Users can now define essential attributes, and a set of resource server-specific scopes. It also facilitates the configuration of consent policies with dedicated URLs for privacy policies. This capability is particularly useful for securing protected resources by enabling granular access control and ensuring only authorized client applications can access sensitive data and functionalities.
  - Complete Application Lifecycle - Streamlined provisioning of Resource Server applications with unique scope identifiers, primary audience configuration, and custom resource server-specific scopes with detailed descriptions and consent requirements
  - Advanced Authorization Management - This release introduces Application Roles, that enables fine-grained access control for Resource Server applications. Application Roles provide administrators with the ability to delegate resource-specific privileges by updating the authorization policies that act as application roles with precise privilege assignment, and built-in role delegation capabilities.
  - Enhanced Security & Compliance - Comprehensive consent management framework with configurable requirements per scope, tenant-level controls for consent persistence.
  - Full OIDC Flow Support - Complete implementation of authorization code flow with resource server integration, and seamless token exchange processes.
  - The Signin UI Consent feature introduces a consent management system that enhances user privacy and application security by requiring explicit user approval for resource server application access. Administrators can configure these consent experiences through the Admin Console's OAuth Resource Server tab, where they define scopes with custom consent labels and descriptions that appear to users at runtime. When applications request specific privileges (scopes), users are presented with a dynamic consent screen that displays the application name, detailed descriptions of requested permissions, and optional usage policy links. See Signin UI Consent for Resource Server Applications, Creating Resource Server using Admin Console.

  See Creating Resource Server using Admin Console, Creating a Resource Server Application using REST API, for complete resource server flow using REST API, see Resource Server Application Flow.
- Self-Service Console (UI) include the following updates:

- Application Dashboard: Presents a collection of application tiles, organized into sections of your choice. It provides the users with a personalized dashboard of applications they can access. This help users quickly find, organize, and launch their various work-related applications. See My Applications.
- Notifications System: Provides two types of notification, one provides system-wide alerts and other provides personal notifications for application assignments. Provides real-time updates and alerts. See My Applications.
- My Known Devices: Provides a security feature allowing users to review and revoke access from devices they previously marked as known, enhancing control over their account security. See My Known Devices.
- My Refresh Tokens: Allows to view and manage refresh tokens associated with your account. It provide control over your active sessions by enabling them to revoke individual or multiple refresh tokens. See My Refresh Tokens.
- My Sessions: Provides a comprehensive overview of all devices and applications currently signed into your account. Real-time session monitoring displaying all active user sessions with detailed information including IP addresses and browsers. See My Sessions.
- Change Password: This feature behavior has been changed to support two types of password change flows, authentication policy driven flow or Verified credential flow based on whichever the admin configures for the user. See Change Password.
- Third-Party Apps: Complete management of external application connections with detailed permission visibility and access history. Enables easy revocation of third-party access. See Third-Party Applications.
- My Access: Displays a list of applications that the user has access to. See My Access.
- Generation of Personal Access Token (PAT): Allows PAT generation and lifecycle management with privilege-based token creation. Provides secure API authentication, granular permission control, and administrative token capabilities. See Generation of Personal Access Token.
- Verified Credentials in Personal Information: Multi-factor credential verification system supporting email and phone verification with real-time status tracking. Offers self-service verification processes. See Personal Information.
- For Self-Service Console Admins - A number of tenant settings have been introduced to control the Self-Service Console Homepage. See Self-Service Console Tenant Settings.
- Symantec Identity Security Platform Localization - The Self-Service Console now supports multiple languages, enabling users worldwide to manage their accounts in their native language. This feature includes support for out-of-the-box languages, with the ability to add custom locales. Administrators can configure different languages for different tenants and users will automatically see the console in their preferred language based on browser settings or tenant configuration. See Localizing the Symantec Identity Security Platform UI Consoles and Additional Information on Localizing the Self-Service Console.

See Self-Service Console for more information on these UI enhancements.

- Self-Service Console (API) include the following updates:
  By default, all the applications that are authorized or granted to an end user appear (as application tiles) on the Self Service Console dashboard for an end user. The following Self Service Console REST APIs are added to allow administrators and end users to manage the groups, apps, and notification settings of the dashboard:
  - AppTiles: As an end user, use this API to manage how apps are grouped on your Self Service Console dashboard. You can manage (add, remove, or rename) your groups or move apps into and out of your groups.
  - UserAppTiles: As an administrator, use this API to manage how apps are grouped for all of your end users on the Self Service Console dashboard. You can manage (add, remove, or rename) groups or move apps into and out of the groups.
  - Preferences: As an end user, use this API to set how apps are displayed on your dashboard, such as the app order, size of the app tiles, and more.
  - UserPreferences: As an administrator, use this API to set how apps are displayed for all of your end users, such as the app order, size of the app tiles, and more.
  - MyNotifications: Use this API to view all Self Service Console notifications sent to you as an end user.
  - Notifications: By default, the Self Service Console provides notifications when apps are removed or added to a user, app-specific notifications, and general notifications. The Self Service Console generates the app addition and removal emails. However, as an administrator, use the Notifications API to manage (view, create, or delete) app-

specific and general notifications. When creating notifications, you can choose the audience, the dates that they are sent and expire, their priority, and more.

See Self-Service Console APIs for more information on these APIs.

- The following features are related to Risk Service:
  - Risk Policy Management is a comprehensive security feature that empowers administrators with granular control over authentication risk assessment and access management. This advanced capability allows organizations to create, configure, and deploy sophisticated risk evaluation policies that operate seamlessly in the background without impacting user experience. The feature supports complex rule structures including action-based conditions (such as "authenticate" operations), application-specific targeting through precise ID matching, and channel-specific configurations for web, mobile, and other platforms. Risk policies integrate with different risk rules. Each policy supports configurable risk scores across multiple risk rules for comprehensive assessment. You can now configure Risk policies from the Admin Console. See Risk Policy in Admin Console.The system includes complete REST API management with CREATE, READ, UPDATE, and DELETE operations protected by the urn:iam:t.configs API scope. See Risk Policies using REST API.
  - Enhanced Admin Console with Risk Service configuration, providing administrators with granular control over risk assessment and rule management. This feature allows you to fine-tune how risk is calculated and applied to authentication events, improving your security posture. See Risk Service.
  - Two new configuration settings, "maxNumberOfDevicesPerUser", and "deviceLimitAction" have been added to the existing Device Recognition functionality to provide administrators with granular control over device management per user. These settings enable limiting the number of registered devices per user and defining the action to take when the device limit is exceeded. See Device Recognition.
  - A new configuration setting, "enableStaticScore" has been added to the Behavioral Engine risk rule that provides administrators with enhanced control over risk scoring for behavioral anomalies. See Behavioral Engine
  - Enterprise IP List Management capabilities - New APIs facilitate the upload of Allowed or Blocked IP lists. Administrators can monitor the real-time status of these uploads, download existing IP lists, and delete them entirely, ensuring flexible and efficient management of network access policies. See Allowed or Blocked IP List for REST API Usage (REST API), and Allowed and Risky IP Address section in the Admin Console documentation.
  - A new automated scheduler system has been introduced to manage the cleanup of old risk event records from the IDSP database. This feature helps maintain optimal database performance by removing outdated records and reducing storage overhead.
    - Risk Active User Event Data Clean-up: Runs every 30 minutes to remove risk events that are older than 720 days for active users. Enable using "isRiskCleanupEnabled" global setting. Disabled by default.
    - Risk Inactive User Event Data Clean-up: Runs on Sundays to remove risk events that are older than 720 days for inactive users. Enable using "isRiskInactiveUsersEventsCleanupEnabled" global setting. Disabled by default.

    See Scheduler Job.
- Service accounts are specialized accounts for service-level users such as trusted clients. Service accounts are not subject to the same limits that an interactive user would be for authentication session lifetime and credential lifetime. This release improves the visibility and management of service accounts through the Admin Console and through APIs.
  - In the Admin Console:
    - If a user is marked as a service account, the **Service Account** control is set to **Yes** on the **Users** page or the **Account** > **Users** page.
    - The **Service Account** tab is added to the **Accounts** page for a user in the Admin Console to provide information about service accounts. Managers can view, lock/unlock, and disable/enable service accounts for their users in the **Service Account** tab.

    See Accounts.
  - Through the Service Account APIs. Three new service account management APIs are added:
    - MeServiceAccounts API allows end users to view and validate their service accounts
    - MeServiceAccountsLocker API allows end users to lock or unlock their service accounts
    - ServiceAccounts API allows administrators to view and validate the service accounts for their users

See Managing Service Accounts.

You can manage a service account if you are the assigned manager (as defined in the `user.manager` property) or have the `urn:iam:t.serviceaccountsadmin` privilege.

- Introduced an enhancement to the signing key management that significantly improves the robustness and continuity of service during cryptographic key rollovers. The system now automatically retains previous signing keys for a configurable grace period (default: 3 days) after new keys are activated, allowing JWT token validation to gracefully fall back to previous keys when primary verification fails.
  This enhancement includes two new configuration settings:
  – "successiveSigningKeyUpdateIntervalMins" (global setting, default: 30 minutes) to prevent rapid successive key update calls
  – "gracePeriodToRetainPreviousSigningKeyDays" (tenant setting, default: 3 days) to control the retention period for previous keys.
  The feature supports enhanced API operations through POST and PATCH endpoints for signing key management and dynamically manages JWK entries to support current, previous, and next key pairs simultaneously. This improvement eliminates service interruptions during key rollovers, provides dependent applications ample time to transition to new keys, See Managing Signing Key using REST API.
- Previously, self-service and recovery actions were initiated using Verified Credentials (a token is sent to the end user email or phone that the end user redeems to complete the self-service or recovery action). With this release, three pre-configured policies are added to control user authentication when they perform the following self-service recovery and activation actions (policy-based approach):
  – Activating an account (ActivateAccountPolicy)
  – Unlocking an account (UnlockAccountPolicy)
  – Resetting a password (ResetPasswordPolicy)
  These policies apply only to your sign-in client app. You cannot change the application that is assigned to this policy. Also, you cannot add any custom actions to this policy. See Authentication and Access Policies for more details about these new policies.
  Use one of the following methods to set whether to use the Verified Credential approach or the policy-based approach:
  – In the Admin Console, select **Settings** > **Identity Store Configuration** > **Internal Identity Store** and select **Verified Credential** or **Policy** for **Password Recovery Flow Type**, **Account Unlock Flow Type**, and **Account Activation Flow Type**. See Internal Identity Store Configuration
  – In the InternalIdStoreConfig API, set `identity` (Verified Credential) or `policy` (policy-based) for `passwordRecoveryFlowType` , `accountUnlockFlowType` , or `accountUnlockFlowType` . See Internal Identity Store Configuration.
- A new configuration setting, "persistAdditionalContextInRiskEvent" has been introduced to control the persistence of additional context information for risk events in the VIP Authentication Hub database. This setting controls whether additional context information related to risk events should be stored in the VIP Authentication Hub database. Enabling this setting will result in consumption of additional DB storage. DB should be sized appropriately before enabling this setting. By default, this setting is false. See Managing Settings.
- The existing "trackLastLogin" tenant setting has been enhanced to also allow tracking of user credential usage by recording the timestamp of every authentication attempt. When this setting is enabled, the system updates the "lastUsedDatetime" attribute for all those user credentials that are used during the authentication flow, capturing only successful logins attempts to provide visibility into credential activity. See Managing Settings.
- A new enhancement has been implemented to support IP address persistence throughout the complete trusted client authentication flow. This feature enables access to the user's IP address during token operations that occur after the authentication flow completion, providing enhanced security context and audit capabilities.
- A new security enhancement has been implemented to restrict Multi-Factor Authentication (MFA) factor enrollment using a new authentication policy attribute called, "inlineEnrollmentAllowed". This optional property enables you to explicitly permit or prevent enrollment based on the security context (for example allowing it on-network but disabling it off-network to prevent unauthorized additions). See Authentication Policy - inlineEnrollmentAllowed attribute.
- The following features are related to Passkey:

  - Enhanced Security with FIDO Metadata Attestation and Device Identification: This release introduces FIDO Metadata Attestation capabilities that not only verify the authenticity and security of FIDO Alliance certified security keys and passkey authenticators during registration, but also provide detailed device identification and tagging functionality. The system now captures and displays specific authenticator information including device origin, model details (such as "YubiKey 5C NFC"), platform type (Mac, Windows), browser information, and other pertinent device characteristics through the Authenticator Attestation Globally Unique Identifier (AAGUID).

    A new "enableFIDOMetadataAttestation" tenant setting enables FIDO attestation, while the ".../system/admin/v1/FIDOMetadataUploader" API facilitates secure upload of FIDO metadata. This enhancement boosts trust, strengthens security, and helps ensure only genuine devices are enrolled. See FIDO Attestation and Uploading FIDO Attestation Metadata.
  - Starting with IDSP release 4.0, the system implements automatic passkey overwrite logic to prevent multiple passkeys (which are stale passkeys on client password manager due to deletion of passkeys from server side) for the same domain. When a user creates a new passkey for a domain where they already have an existing passkey stored, the client-side passkey storage will automatically overwrite the previous passkey with the newly created one for the same user, same domain at the time of passkey re-registration.

    This enhancement eliminates potential confusion from having multiple stale passkeys in the passkey manager on the given platform. The overwrite occurs seamlessly on the client side during the passkey creation process, with the new passkey being the active credential for that domain while the previous passkey is automatically removed from local storage.
- App Groups - Application Group Management enables administrators to better organize and control application access. A comprehensive set of new and updated REST APIs now facilitates the full lifecycle of application groups, from creation and retrieval to detailed updates and deletion, including the ability to add or remove individual applications. These API improvements are also reflected within the Admin Console's intuitive user interface. See Application Group Rest APIs and Admin Console - Application Groups.
- "Enhanced Resource Deletion" feature, empowers administrators to forcefully delete in-use IDSP resources like Applications and IDPs. By adding a "force=true" query parameter to existing DELETE APIs, resources are immediately removed from primary storage and hidden from the core operations. The resourcesCleanupScheduler job then systematically cleans up all outdated references from dependent policies and configurations. Additionally, the /admin/v1/ReferencingObjectsHelper API now includes an "allowResourceToBeForcefullyDeletable" parameter, guiding administrators on permitted force deletions. This feature is also supported using Admin Console. See Resource Deletion in IDSP.
- This release introduces enhancements for managing and controlling the use of user credentials, particularly phone numbers and email addresses, by allowing them to be categorized with specific tags and enabling applications to enforce usage policies based on these tags.
  - Users and administrators can now apply tags (for example, "business", "personal", "work", "home") to phone and email credentials. This allows for a clear distinction between different types of contact information for a single user.
  - LDAP Integration: A new LDAP configuration attribute, mvAttributeMapping, enables the mapping of multi-valued LDAP attributes to these tags. This flexible JSON-based configuration ensures that credential tags are accurately sourced and synchronized from your LDAP directory.
  - Applications can now define specific metadata to control which tagged credentials are permissible for various authentication and communication flows:
    - urn:iam:app:allowSmsCredsOfTag
    - urn:iam:app:allowEmailCredsOfTag
    - urn:iam:app:excludeCredsNnotUsedForXDays

  For descriptions, see Application Metadata topic.
- In addition to the email notifications sent when an administrator performs an action, the Admin Console can now send email or SMS notifications to end users for the following system-generated actions:
  - Account activation (sign in on new device)
  - Account lock or unlock
  - Password reset

The Admin Console can now also send email or SMS notifications to end users for the following actions performed either by administrators or users:
  - Credential activity (credential added, updated, or removed)
  - End user email changed
  - End user account deleted

  End-user email and SMS messages are sent using default message templates. However, you must configure which messages are sent and customize the content of the messages:
  - Configure which end-user notifications are sent in the Admin Console (see End-user Notifications under Service Configuration) or in tenant settings (using the `notifyEventsConfig` property described in Managing Settings).
  - Customize the email and SMS message contents using the Message Template API (see Managing Message Templates or #unique_80).
- The following features are related to Admin Console (UI):
  - The Admin Console provides the option to set a custom password reset URL that is provided to end users when you reset a password from the the Admin Console. With this release, you are also able to configure multiple vanity URLs on the **Internal Identity Store** configuration page. When end users request that a password be reset, the administrator can select which of these URLs to send to the end user in the password reset email.

    If end user password reset vanity URLs are configured on the **Internal Identity Store** configuration page, the **Account Activation Link** field on the **Add New User** page also uses these URLs.

    Note that any custom URLs that you set for the **Password Reset Changer URL** supersedes the vanity URLs. If you do not set any vanity URLs, or have configured a custom URL for the **Pasword Reset Changer URL**, vanity URLs are not displayed to the administrator when resetting an end user password nor in the **Account Activation Link** during user creation.
  - The **"Override max search results limit"** enhancement introduces a new checkbox in most of the resource filters (such as - application, certificates, policies, secrets, certs, IDP etc) that allows tenant administrators to bypass the standard search result limitations in the Admin console. When enabled, this feature overrides the default maximum of 500 Admin Resources displayed, which is normally enforced through the "maxAdminResourcesReturnedByGetAll" tenant setting. See Adding an Application .
  - The "Accounts" user interface has been enhanced with advanced search and filtering capabilities, providing administrators to quickly locate specific accounts using multiple search criteria and filter combinations. This enhancement significantly improves the user experience for managing large account databases. See Accounts.
- The new password expiration warning feature is governed by coordinated settings across two configuration sections in the Admin Console, ensuring consistent enforcement and user awareness.
  - Password validity is controlled through the **Internal Identity Store** under **Password Policies**, where the **“Password Expires After”** attribute defines the password lifespan. This configuration includes the **“Evaluate Password Expiration Rules On Authentication”** option, which enforces real-time validation by checking password expiration during every user authentication attempt. See Setting a Password Policy.
  - User-facing notifications are managed through the **Service Configuration** setting **“Days before password expiry to show a sign-in warning (0 disables warning)”**, which determines how far in advance users are alerted about an upcoming password expiration during sign-in. See Service Configuration.
- If you manually configure an Identity Provider, this release lets you configure Symantec Identity Security Platform to sign SAML authentication requests sent to the Identity Provider. You can choose whether to sign the request using the key pair provided by the Identity Provider or your tenant key. See Identity Providers (Admin Console configuration) or Creating Identity Provider using "/IdentityProviders" API (API configuration) for details.
- MTLS - This release introduces OAuth Mutual Transport Layer Security (mTLS), bolstering security for client interactions with critical OAuth endpoints (Token, Revoke, Introspect) by authenticating clients via their certificates. See Configuring OAuth mTLS between Symantec Identity Security Platform Clients and Cluster .
- Improved LDAP Configuration Updates with bindPasswordSecretAlias: Previously, when modifying an LDAP configuration using the PUT method, the bindPassword field was often pre-filled with "" if bindPasswordSecretAlias was in use. This caused updates to fail unless the bindPassword field was manually cleared before each PUT operation, as "" is not a valid password.

With this enhancement, if the bindPasswordSecretAlias value is supplied in the LDAP configuration during a POST/PUT/GET operation, the bindPassword field is not shown in the response. The response only includes the bindPasswordSecretAlias. See Managing LDAP Configuration.

- This release introduces comprehensive input validation for all REST API endpoints (includes POST, PUT, and PATCH operations), providing robust protection against malicious input and improving overall system security. See Using REST APIs.
- Custom user attributes of type `string` , `int` , and `date` support multiple, comma-separated values. See User Schema Extensions for the Identity Service.
- Automatic creation of the user display name is streamlined. The user display name (`displayName`) is generated from the Display Name Template defined in your identity store. See Internal Identity Store Configuration.

  By default, the Display Name Template is set to `givenName` and `familyName` . You can customize this template to specify user attributes of your choice. If some or all of the values specified in the DisplayName Template are present, the display name is set using the values that are present. If none of the values specified in the Display Name Template are present, the display name defaults to the user `Login` value.

  For details about display name generation, see the following topics:
  - User and Group Schemas
  - Identity Provider Discovery - Just-In-Time (JIT) User Provisioning
  - Configuring the Zero Footprint Identity
- This release adds a Resource Counter Helper API that allows clients to retrieve a count of all resources in a tenant, by resource type. This API also allows clients to retrieve a count of tenants in the system. See Resource Counter Helper API.
- You can now set whether groups are read-only using the GroupOperator API. You can also use the GroupOperator API to view the read-only status of a group. See Group Operator API.
- When using the Group API or Bulk API to perform a PUT, POST, or PATCH operation to add multiple members to a group, you can set the **allowPartialSuccess** flag to continue processing if the API cannot complete the group membership add operation on all users. Without this flag, the APIs returns an error and make no changes if it cannot correctly process all group membership add operations. Setting the **allowPartialSuccess** flag allows the API to capture invalid operations while still processing valid operations. See Group API and Bulk API.
- The User object is updated to include the `groupMembershipLastModified` attribute. This attribute identifies the date and time that the user was added to or removed from a group.
- If a user that is assigned as a manager to other accounts (users, service accounts, and so on) is deleted using the User API, the accounts are not automatically assigned a new manager. The new `replacementManager` parameter assigns the manager that is included in the parameter as the new manager for all accounts that were previously assigned to the deleted manager. See User API.
- The behavior of ABAC and GBAC is updated to reflect the concept of unconditional access, unconditional deny, and conditional access. For example, if a qualifier (C, R, U, or D) is missing from a resource type, the operation is treated as unconditionally denied. If resource types have multiple scopes, the priority order is: unconditional access, unconditional deny, and conditional access. See Scoping Constraints Overview.
- Added the field `denyOps` to scoping constraints. If any scoping constraint for a resource type has `denyOps` defined, the operation is denied for that resource type. For example, if a resource type has `denyOps=U` , the principal cannot update any resources of this type. See Scoping Constraints Overview.
- Previously, if the value of `allowStartIndexSearchParam` in the internal Identity Store is set to `false` , and you included a `startIndex` value in your search parameters, the search threw an error. Now, the search uses the `startIndex` provided in the search parameters if the principal has the `t.allowstartindexsearchparam` privilege. Otherwise, the search sets the start index to 1. See Scopes and APIs Table.
- Added two optional search parameters to the User API and the Group API:
  - The `skiplimit` parameter allows principals with the correct privileges to retrieve all users and groups that match the filter without bounding to the value of the `scimSearchLimit` setting that is defined in the Identity Store configuration.
  - The parameter `countonly` allows a SCIM search to return the number of users or groups present in the tenant.

See User API and Group API.

- Added Identity Service SCIM error code 89410860 to identify when user and group searches time out. See Identity Service SCIM Error Codes. This topic has also been updated to include previously undocumented error codes.
- Added two search response headers:
  - X-MAX-RESOURCES-LIMIT-REACHED: This response header is returned in the following circumstances:
    - For SCIM users and groups, the response header is shown when the number of matching users or groups is equal to or greater than the value of:
      - The `scimSearchLimit` value defined in Internal Identity Store configuration; or,
      - The value of `count` in the API request.
    - For other resources, the header is shown when the number of matching resources equals or is greater then the `maxAdminResourcesReturnedByGetAll` value defined in Tenant Settings.
  - X-TOTAL-COUNT: This response header is returned for user and group SCIM searches. Adding this header brings the user and group searches into parity with all other resource searches.
- The Admin and Scheduler pods max memory limit has been increased to 3Gi (Gibibyte).
- A new OIDC Grant type called, "Resource Owner" has been added to the list of grant types that can be used. However, this grant type is explicitly noted as a legacy grant type that should only be used when a legacy component specifically requires it. See Resource Owner grant type.
- Additional validation for Identity Provider (IDP) configuration using Zero Footprint Identity (ZFP). When modifying existing IDP used as an authentication factor to enable Zero Footprint Identity and Identity Verification, the system now requires the "allowZfpIdpVerifyIdentity" metadata field to be specified on the IDP as "true". Such identity verification is used only in IDP-as-a-Factor flows and not in Bring-Your-Own-Identity flows, hence to minimize confusion regarding identity verification with ZFP IDPs, use of IDP metadata is required. See IDP Metadata properties.
- SAML Application now supports the ${saml_idp_init} placeholder for the launcherUrl field, which automatically populates the URL with the "app.samlEffectiveIdpInitiatedUrlPreferred" value during launcherUrl invocation, eliminating the need for manual URL entry.
- The following four tenant settings are being deprecated and will no longer be exposed through the ".../auth/v1/BrandingSettings" API response:
  - loginLabel
  - loginHint
  - passwordLabel
  - passwordHint
- ***New key-value pairs added in the OOTB locales in SignIn UI***

  To know how to update these key-value pairs in your custom locale, see Updating the custom locale content manually when additions are made in the OOTB Locales.
  - The following new key pairs have been added in this release for Signin UI:

Index	Value
passwordExpiry.passwordExpiresInHeader	Password Expires In
passwordExpiry.daysLabel	{{count}} Days
passwordExpiry.message	For security reasons, you'll be required to set
passwordExpiry.btnOK	OK
identity.passwordreset.screen_pwreset.submsg_success_activate	Your account has been successfully acti
actionResult.title_unlockAccount	Unlock Account
actionResult.unlockSuccess	Your account has been successfully unl
actionResult.title_resetPassword	Reset Password
actionResult.resetpwSuccess	Your password has been reset success

actionResult.title_activateAccount	Activate Account
actionResult.activationSuccess	Your account has been successfully act
identity.verifyPage.screen_title_email	Verify Your Email
identity.verifyPage.screen_title_phone	Verify Your Phone
identity.verifyPage.emailVerified	Your email has been successfully verifie
identity.verifyPage.phoneVerified	Your phone has been successfully verifi
userConsent.header	{{appName}} wants the following access
userConsent.processDataNote	Review the <span class=\"consentUsagePolic understand how this data will be used.
userConsent.btnCancel	Cancel
userConsent.btnAllow	Allow
userConsent.btnClose	Close

Fixed Issues

- An error was discovered in the IDSP risk service's device recognition component. This flaw bypassed intended device recognition security measures, potentially leading to inaccurate risk assessments. (DE641058)
- Continued use of Bitnami images in IDSP after Bitnami has announced a significant change to their container image licensing model, transitioning from free open-source images to a paid subscription model. (DE643277)
- iOS SDK was returning incorrect codes and messages for Passkeys Login. (DE648159)
- Biometric error flows return identical error codes for both Enrollment and Authentication scenarios when duplicate passkeys are detected and the biometric popup is closed, resulting in incorrect error messages being displayed to users. (DE648771)
- Custom Providers created prior to the 3.4.2 release do not contain the "skipUserStrikeCountIncrement" field in their configuration. When these legacy providers are used in version 3.4.2, the system throws a 400 Bad Request exception, preventing authentication operations from completing successfully. (DE651841)
- Identified issues with the passkey enrollment process in mobile applications, including creation of multiple passkeys from the same device and missing AAGUID (Authenticator Attestation Globally Unique Identifier) in the FIDORegChallengeVerifier service, resulting in passkeys without platform identification. (DE644244)
- If an administrator initiated a workflow (such as password reset) from an internal vanity URL that generated end user-facing emails, the links in the emails did not include the end-user vanity URL. (DE645499)
- OOTB Sign-in application did not automatically detect device type (desktop, mobile, tablet) and include this information in the clientContext of the .../auth/v1/authenticate endpoint. This prevented Authentication Policies from utilizing Context conditions to implement device-specific authentication factor requirements and policy configurations. (DE644726)

Known Issues

- After upgrading from a previous version of IDSP to IDSP v4.0, all existing user sessions are automatically terminated and users are required to re-authenticate. (DE659394)

Upgrade Considerations

IMPORTANT

- **IDSP Supports Incremental Upgrades**:
  IDSP facilitates incremental upgrade paths. If you plan to upgrade to the latest release, IDSP v4.0, and you are currently using an earlier version, it is advisable to first upgrade to the latest patch of the subsequent minor release before moving on to IDSP 4.0.

IDSP uses the following format for naming release versions: MAJOR.MINOR.PATCH. For example, in the release version 4.0.x, "4" is the MAJOR version, "0" is the MINOR version, and "x" is the PATCH version.

Upgrade Use Cases:

- ***Upgrade Scenario 1***: Upgrade from IDSP v3.3 to IDSP v4.0
  Recommended Upgrade Path: You should follow this upgrade path- **3.3.x > 3.4.x > 4.0**
  Example: 3.3.6 > 3.4.8 > 4.0
- ***Upgrade Scenario 2***: Upgrade from IDSP v3.4.x to IDSP v4.0
  Recommended Upgrade Path: You can directly proceed with the upgrade to v4.0 without any intermediate steps.
  Example: 3.4.8 > 4.0

- **Oracle SQL file Updates**: This release includes Oracle database schema changes that may require manual SQL file updates for environments with separate database administration. For detailed upgrade procedures and SQL file application order, see the Oracle SQL File Updates topic.

See Upgrading IDSP.

Rollback Consideration

- When rolling back from IDSP v4.0.0 to any previous version, special attention must be paid to Authorization Policy PUT operations to ensure compatibility.
  - The "effect" field introduced in version 4.0.0 is not supported in earlier releases of IDSP.
  - Before performing Authorization Policy PUT operations after a rollback, ensure that the "effect" field is removed from all request payloads, otherwise requests containing the "effect" field will be rejected.
- The "class" path for the message providers have changed in IDSP v4.0. Therefore, before rolling back from IDSP v4.0 to any previous version, you must revert the old class path values in the message provider configuration as they are not backward compatible.
  The following table shows the Message Provider Class Path migration introduced in v4.0:

Old Path	New Path
com.broadcom.layer7authentication.mds.service.providers.sms.TwilioSmsService	com.broadcom.layer7authentication.core.service.mds.pr
com.broadcom.layer7authentication.mds.service.providers.email.TwilioSendGridEmailService	com.broadcom.layer7authentication.core.service.mds.pr EmailService
com.broadcom.layer7authentication.mds.service.providers.push.PushFCMService	com.broadcom.layer7authentication.core.service.mds.pr e
com.broadcom.layer7authentication.mds.providers.email.EmailIEService	com.broadcom.layer7authentication.core.service.mds.pr
com.broadcom.layer7authentication.mds.service.providers.email.TwilioSendGridEmailService	com.broadcom.layer7authentication.core.service.mds.se ndGridEmailService
com.broadcom.layer7authentication.mds.service.providers.sms.ClickATellSMSService	com.broadcom.layer7authentication.core.service.mds.se llSMSService
com.broadcom.layer7authentication.mds.service.providers.email.SMTPEmailService	com.broadcom.layer7authentication.core.service.mds.se mailService

For more information, see Managing Message Providers Configurations.

Symantec Identity Security Platform Kit Location and Build Details

See Release 4.0 Build Details.

IDSP Knowledge Articles

All IDSP knowledge articles can be found here, Symantec Identity Security Platform Knowledge Articles.

Release Date

The IDSP v4.0 release was distributed on January 12, 2026.

Oracle SQL File Updates

Manual Oracle SQL file updates required for environments with separate database administration.

This release introduces Oracle database schema changes that may require manual SQL updates in environments where database administration is handled separately. While the schema is normally upgraded automatically as part of the dataseed job, certain Oracle database instances may need to be updated manually outside the standard process when database administration is decoupled from the Symantec Identity Security Platform deployment.

Fresh Install of Symantec Identity Security Platform

For fresh installations of IDSP, the database schema setup is streamlined and simplified.

If manual updates of the schema are required for a fresh install, follow these steps:

1. **Download and run** the consolidated Oracle SQL file from the Symantec Identity Security Platform Support Portal > My Downloads (Formarly known as VIP Authentication Hub in the portal and select the appropriate version number). For fresh installations, use the single consolidated Oracle SQL file (**IDSP_4.0_Oracle_SQL_Fresh_Install.sql**) that contains all necessary schema updates, rather than applying multiple individual files.
2. Once the **consolidated DB file** has run successfully, proceed with the installation.
3. **Enable the property**, `"ssp.featureFlags.dataseed.skipSchemaInit"="true"` before completing the installation of IDSP.

Note: Fresh installations benefit from using a single, comprehensive SQL file that includes all schema changes, eliminating the need to apply multiple incremental updates sequentially.

Upgrade to IDSP from Previous Releases

For upgrades from previous versions of IDSP, incremental SQL files must be applied in the correct sequence to ensure proper schema migration.

If manual updates of the schema are required for upgrades, instead of performing an automatic upgrade (step 12), follow these steps:

1. **Download and run** the individual Oracle SQL files from the Symantec Identity Security Platform Support Portal > My Downloads (Formarly known as VIP Authentication Hub in the portal and select the appropriate version number). This manual update is required due to changes in the Oracle SQL database in this release.
2. Apply the SQL files in the correct sequential order as shown in the table below.
3. Once all required **DB files** have run successfully, proceed with the upgrade.
4. **Enable the property**, `"ssp.featureFlags.dataseed.skipSchemaInit"="true"` before upgrading to the latest version of IDSP.

Example Upgrade Scenario:
To upgrade from IDSP v3.4 to IDSP v4.0, you must apply 3.4.x, and 4.0 SQL files depending on which patch you are moving from. If you are on a specific patch version of IDSP and you intend to upgrade to another patch version, download and apply only the Oracle SQL files relevant to the patches you are moving to.

This is the order to apply the SQL files for upgrades:

Seq. No.	File version
A	VIP_Authentication_Hub_3.4_Oracle_SQL_file.sql
B	VIP_Authentication_Hub_3.4.1_Oracle_SQL_file.sql
C	VIP_Authentication_Hub_3.4.2_Oracle_SQL_file.sql
D	VIP_Authentication_Hub_3.4.3_Oracle_SQL_file.sql
E	VIP_Authentication_Hub_3.4.4_Oracle_SQL_file.sql
F	VIP_Authentication_Hub_3.4.5_Oracle_SQL_file.sql
G	VIP_Authentication_Hub_3.4.6_Oracle_SQL_file.sql
H	VIP_Authentication_Hub_3.4.7_Oracle_SQL_file.sql
I	IDSP_4.0_Oracle_SQL_upgrade_file.sql
J	IDSP_4.0.2_Oracle_SQL_upgrade_file.sql

To know how these container images can be pulled from the Broadcom registry, see Pulling images from the Broadcom registry.

Oracle SQL DB file

- The IDSP v 4.0.2 does not include any Oracle database schema changes.

Postman Collection

- The IDSP **v4.0.2** Postman Collection is available for download from the Support Portal > My Downloads
- Best Practice for using the IDSP Postman collection, see Using IDSP postman collection

Identity Security Platform Release 4.0.1 Build Details

Symantec Identity Security Platform Release 4.0.1 Build Details

The latest SDK and Sample Source Code kit can be downloaded from the Support Portal > My Downloads.

This topic includes the following sections:

- Build Details for this release
- Broadcom Container Image ID's
- Oracle SQL DB file
- Postman Collection

Build Details for this Release

Chart Name	Chart Version	Chart Description
ssp_helm_charts/ssp-infra	4.0.1+1015	Helm chart to deploy Fluent Bit, Prometheus Metrics Adapter, Arango DB operator, Database (internal mode)
ssp_helm_charts/ssp	4.0.1+1015	Helm chart to deploy Security Services Platform
ssp_helm_charts/ssp-sample-app	4.0.1+1015	Helm chart to deploy a sample application for the Secure Services Platform

ssp_helm_charts/ssp-data "ssp-data" chart gets updated on a weekly basis. It is recommended to perform a "**helm repo update**" to get the latest chart.	2026.04	Helm chart to deploy Security Services Platform Data Loader
ssp_helm_charts/ssp-symantec-dir	4.0.1+1015	Helm chart to deploy a Demo ID Store (CA Directory)

Oracle SQL DB file

- The IDSP **4.0** Oracle SQL DB file can be downloaded from the Support Portal > My Downloads (Search for Identity Security Platform in the portal and select the appropriate version number). For more information, see Oracle SQL File Updates topic.

Postman Collection

- The IDSP **v4.0** Postman Collection is available for download from the Support Portal > My Downloads
- Best Practice for using the IDSP Postman collection, see Using IDSP postman collection

Overview

Learn about the Symantec Identity Security Platform (IDSP).

About Symantec Identity Security Platform (IDSP)

The Symantec Identity Security Platform (IDSP) is a comprehensive, modern identity and access management solution built on cloud-native, container-based architecture. Designed with an API-first approach, IDSP delivers enterprise-grade authentication, authorization, and identity services through a flexible, policy-driven framework that adapts to your evolving security requirements.

Whether you are implementing passwordless authentication, securing APIs with OAuth, managing user identities, or building zero trust architectures, IDSP provides the complete toolkit administrators and developers need to deliver trusted access across modern applications and legacy systems alike.

This topic includes the following sections:

- Core Capabilities
- Architecture Highlights
- Use Cases
- Getting Started

Core Capabilities

Policy-Driven Security Framework

At the heart of IDSP is a unique policy orchestration engine that eliminates hard-coded security logic. Define and modify authentication journeys, identity federation workflows, and risk evaluation rules through flexible policies rather than configuration files or code changes. This architecture allows security teams to adapt quickly to new threats and business requirements without vendor dependencies or extensive customization efforts.

- **Value for Administrators**: Adjust security postures in response to emerging threats or compliance requirements without architectural changes or system downtime.
- **Value for Developers**: Build applications that leverage centralized authentication policies without embedding security logic in application code.

Passwordless Authentication and Strong Security

IDSP supports industry-leading authentication methods based on FIDO2 standards, including biometric authentication, hardware security keys, and passkeys (supporting cross-device scenarios). Users can authenticate using fingerprint, facial recognition, or physical security keys—eliminating password vulnerabilities while delivering frictionless user experiences across desktop, mobile, and web applications. Traditional authentication factors such as SMS and Email-delivered security codes and software authenticator applications are also supported.

- **Value for Administrators**: Reduce help desk burden from password resets and account lockouts with “self-service capabilities”, while strengthening the security posture by eliminating credential theft vectors.
- **Value for Developers**: Implement modern authentication in your applications without managing the complexity of FIDO2 protocols, device attestation, or certificate management.

Comprehensive Identity Services

The platform includes an integrated local identity store that is exposed through SCIM (System for Cross-domain Identity Management) standards and persisted in a database-backed service. Support for advanced federation protocols (SAML

2.0, OpenID Connect) enables bring-your-own-identity scenarios with just-in-time provisioning, allowing seamless integration with external identity providers while maintaining local control.

- **Value for Administrators**: Maintain a single authoritative identity source while federating with external providers, reducing identity sprawl and simplifying user lifecycle management.
- **Value for Developers**: Access identity data through standard REST APIs and SCIM endpoints, enabling rapid integration without proprietary protocols or vendor lock-in.

OAuth Resource Server and API Security

IDSP functions as the OAuth authorization server to support third party resource servers, enabling you to define custom scopes, application roles, and user consent workflows tailored to your applications' specific authorization requirements. You can generate access tokens with fine-grained permissions, implement user consent for sensitive operations, and control API access at the scope level.

- **Value for Administrators**: Centrally manage API authorization policies and monitor token usage across all applications from a single console.
- **Value for Developers**: Protect your APIs with industry-standard OAuth flows, define custom permission scopes for your services, and leverage built-in token validation without building an authorization infrastructure.

Personal Access Tokens and Zero Trust

To enforce zero trust and least-privilege access, users and developers can create Personal Access Tokens (PATs) with only the necessary privileges.

These tokens support secure, automated workflows and developer tool integration without the need to share privileged credentials. Access tokens have configurable lifecycles, up to one hour, and can be optionally paired with refresh tokens that last up to one week and are linked to specific clients.

- **Value for Administrators**: Eliminate the proliferation of service accounts and shared credentials while maintaining audit trails of who generated which tokens with what permissions.
- **Value for Developers**: Securely authenticate development tools, scripts, and CI/CD pipelines with scoped tokens instead of embedding passwords or long-lived credentials in code.

Adaptive Risk Management

The integrated risk service evaluates authentication attempts in real-time based on contextual factors including device posture, geolocation, user behavior patterns, and threat intelligence. It is possible to configure risk policies per application to apply appropriate security controls—for stricter evaluation for sensitive financial systems, streamlined access for low-risk internal tools. Support for Continuous Authentication Event Protocol (CAEP) enables coordinated responses across your security ecosystem when risk conditions change.

- **Value for Administrators**: Balance security and user experience by applying risk-based policies that challenge suspicious access while streamlining trusted scenarios.
- **Value for Developers**: Integrate risk signals into your applications through CAEP events, allowing applications to respond dynamically to security state changes without building risk engines.

Self-Service Console and End-User Experience

IDSP includes a fully customizable self-service console where end users manage their own credentials, enroll authentication factors, reset passwords through policy-driven recovery flows, view and launch authorized applications, and manage active sessions. The application dashboard provides a centralized launchpad for all authorized applications with single sign-on support.

- **Value for Administrators**: Dramatically reduces help desk ticket volume while improving security through user-managed strong authentication enrollment and white-label branding that matches corporate identity.
- **Value for Developers**: Provide end users with pre-built UI components for credential management and app discovery, or leverage the APIs to build custom self-service experiences integrated into your applications.

Granular Administration and Compliance

Role-based administration combined with resource authorization constraints enables separation of duties and least-privilege administration. Help desk staff can manage only their assigned user populations, application owners can configure only their integrations, and compliance requirements for segregated responsibilities are met through enforced permission boundaries and comprehensive audit logging.

- **Value for Administrators**: Meet regulatory compliance requirements with provable separation of duties, delegated administration, and complete audit trails of all administrative actions.
- **Value for Developers**: Programmatically manage administrative delegation through APIs, enabling self-service application onboarding and automated provisioning workflows.

Enterprise Scalability and High Availability

Built on container-based, cloud-native architecture, IDSP supports enterprise-scale deployments with multi-region configurations, active-active high availability, and simplified disaster recovery. Deploy across geographic regions to ensure that authentication services remain operational despite regional outages, network issues, or disaster scenarios. Built-in support for multi-tenancy provides separation for business units or external partners needing isolated, customizable identity environments.

- **Value for Administrators**: Meet SLA requirements for mission-critical authentication infrastructure with proven resilience patterns and operational simplicity.
- **Value for Developers**: Build applications with confidence that the authentication layer scales to support growth and remains available during infrastructure disruptions.

API-First Architecture and Developer Tools

Every capability in IDSP is exposed through comprehensive REST APIs, enabling full programmatic control of authentication, authorization, identity management, and administration. Dynamic client registration allows applications to self-register, SDK support accelerates integration, and extensive API documentation provides the guidance developers need.

- **Value for Administrators**: Automate operational tasks, integrate with IT service management tools, and enable self-service scenarios without manual intervention.
- **Value for Developers**: Integrate IDSP into applications, DevOps pipelines, and automation workflows with well-documented APIs, reducing time-to-production from months to days.

Legacy Integration and Modernization Bridge

IDSP provides native integration with Symantec SiteMinder and other Broadcom solutions, protecting existing technology investments while enabling gradual migration to modern patterns. Support for SAML, OIDC, and bring-your-own-identity scenarios means you can modernize incrementally without rip-and-replace disruption.

- **Value for Administrators**: Protect infrastructure investments while creating a clear path toward modern identity architectures aligned with business priorities.
- **Value for Developers**: Build new applications using modern protocols while maintaining compatibility with legacy systems during transition periods.

Architecture Highlights

Container-Based Deployment:

- Kubernetes-native architecture for cloud, on-premises, or hybrid environments
- Horizontal scaling to meet demand
- Rolling updates with zero-downtime maintenance

Standard-Based Integration:

- FIDO2/WebAuthn for passwordless authentication
- OAuth 2.0 and OpenID Connect for authorization and federation
- SAML 2.0 for legacy federation scenarios
- SCIM 2.0 for identity provisioning
- CAEP for continuous authentication events

Database-Backend Persistence:

- No LDAP dependencies—modern database architecture
- Support for enterprise database platforms - MySQL, Oracle, PostgreSQL

Use Cases

For Administrators:

- Replace aging authentication infrastructure with a modern, cloud-native platform
- Implement zero trust architectures with identity as the control plane
- Enable passwordless authentication across enterprise applications
- Reduce operational costs through self-service and automation
- Meet compliance requirements with granular access controls and audit trails

For Developers:

- Secure APIs with OAuth 2.0 authorization and custom scopes
- Integrate authentication into applications through REST APIs
- Build modern web and mobile applications with passkey support
- Automate development workflows with personal access tokens
- Create custom user experiences leveraging IDSP's identity services

Getting Started

This documentation provides comprehensive guidance for planning, deploying, configuring, and operating the Symantec Identity Security Platform:

- **Planning & Architecture**: Understand deployment models, capacity planning, and integration patterns
- **Installation & Configuration**: Step-by-step guides for deploying IDSP in your environment
- **Administrator Guide**: Complete reference for configuring policies, managing identities, and delegating administration
- **Developer Guide**: API documentation, SDK references, and integration tutorials
- **Operations & Maintenance**: Monitoring, backup, disaster recovery, and troubleshooting procedures
- **Release Notes**: Latest features, enhancements, and known issues

Administering

Contains information on Symantec Identity Security Platform Administration.

The administration function in IDSP is overseen by a group of administrators, comprising Infrastructure Administrators, System Administrators, and Tenant Administrators, among others. In the Administrative model, each administrator is assigned distinct responsibilities primarily centered around access management and restrictions. Tasks are executed via APIs and the Admin Console. Detailed roles and responsibilities are outlined in the Administrative Model documentation.

In the Resource Authorization model, you define policies, called scoping constraints, that can declare resource attribute permissions and resource instance rules. When combined with your Administrative model, Resource Authorization provides finer-grained administrator access across the granted Resource privileges.

This section includes the following topics:

- Administrative Model
- Resource Authorization
- Managing Authorization

Administrative Model

Covers the Roles and Responsibilities, and Operations performed by the Infra Administrators, System Administrators, and Business Administrators.

Overview

The Symantec Identity Security Platform business capability supports an administrative model that includes the following roles, each with specific responsibilities and access levels:

Client	Tasks	Notes
Infrastructure Administrator (Infra Admin)	• Bootstrap initial System Administrators	This is the "Super User" role. The single credential that is created for this role should be secured and made available only when needed.
System Administrator (System Admin)	• Configure operational parameters such as expiry settings, LDAP ID Stores, etc. • Assist Tenant Admins in case of issues such as lost account, accidental removal of privileges, etc.	System Admin can perform certain configuration operations on behalf of the Tenant Admin. Operations that are performed in the context of business tenants are subject to constraints imposed by system-level settings.
***Tenant Administrator** (Tenant Admin)	• Manage Security Policies • Manage tenant-level settings, such as CORS, etc. • Integrate with applications	Currently, this role also covers tasks that a ***Developer*** would perform to integrate IDSP into an application.

*** A Default Tenant Admin user is created with similar privileges.**

The OAuth2-based API security model aligns with these administrative roles through security privileges granted to application clients. Out-of-the-box authorization policies regulate access based on assigned roles.

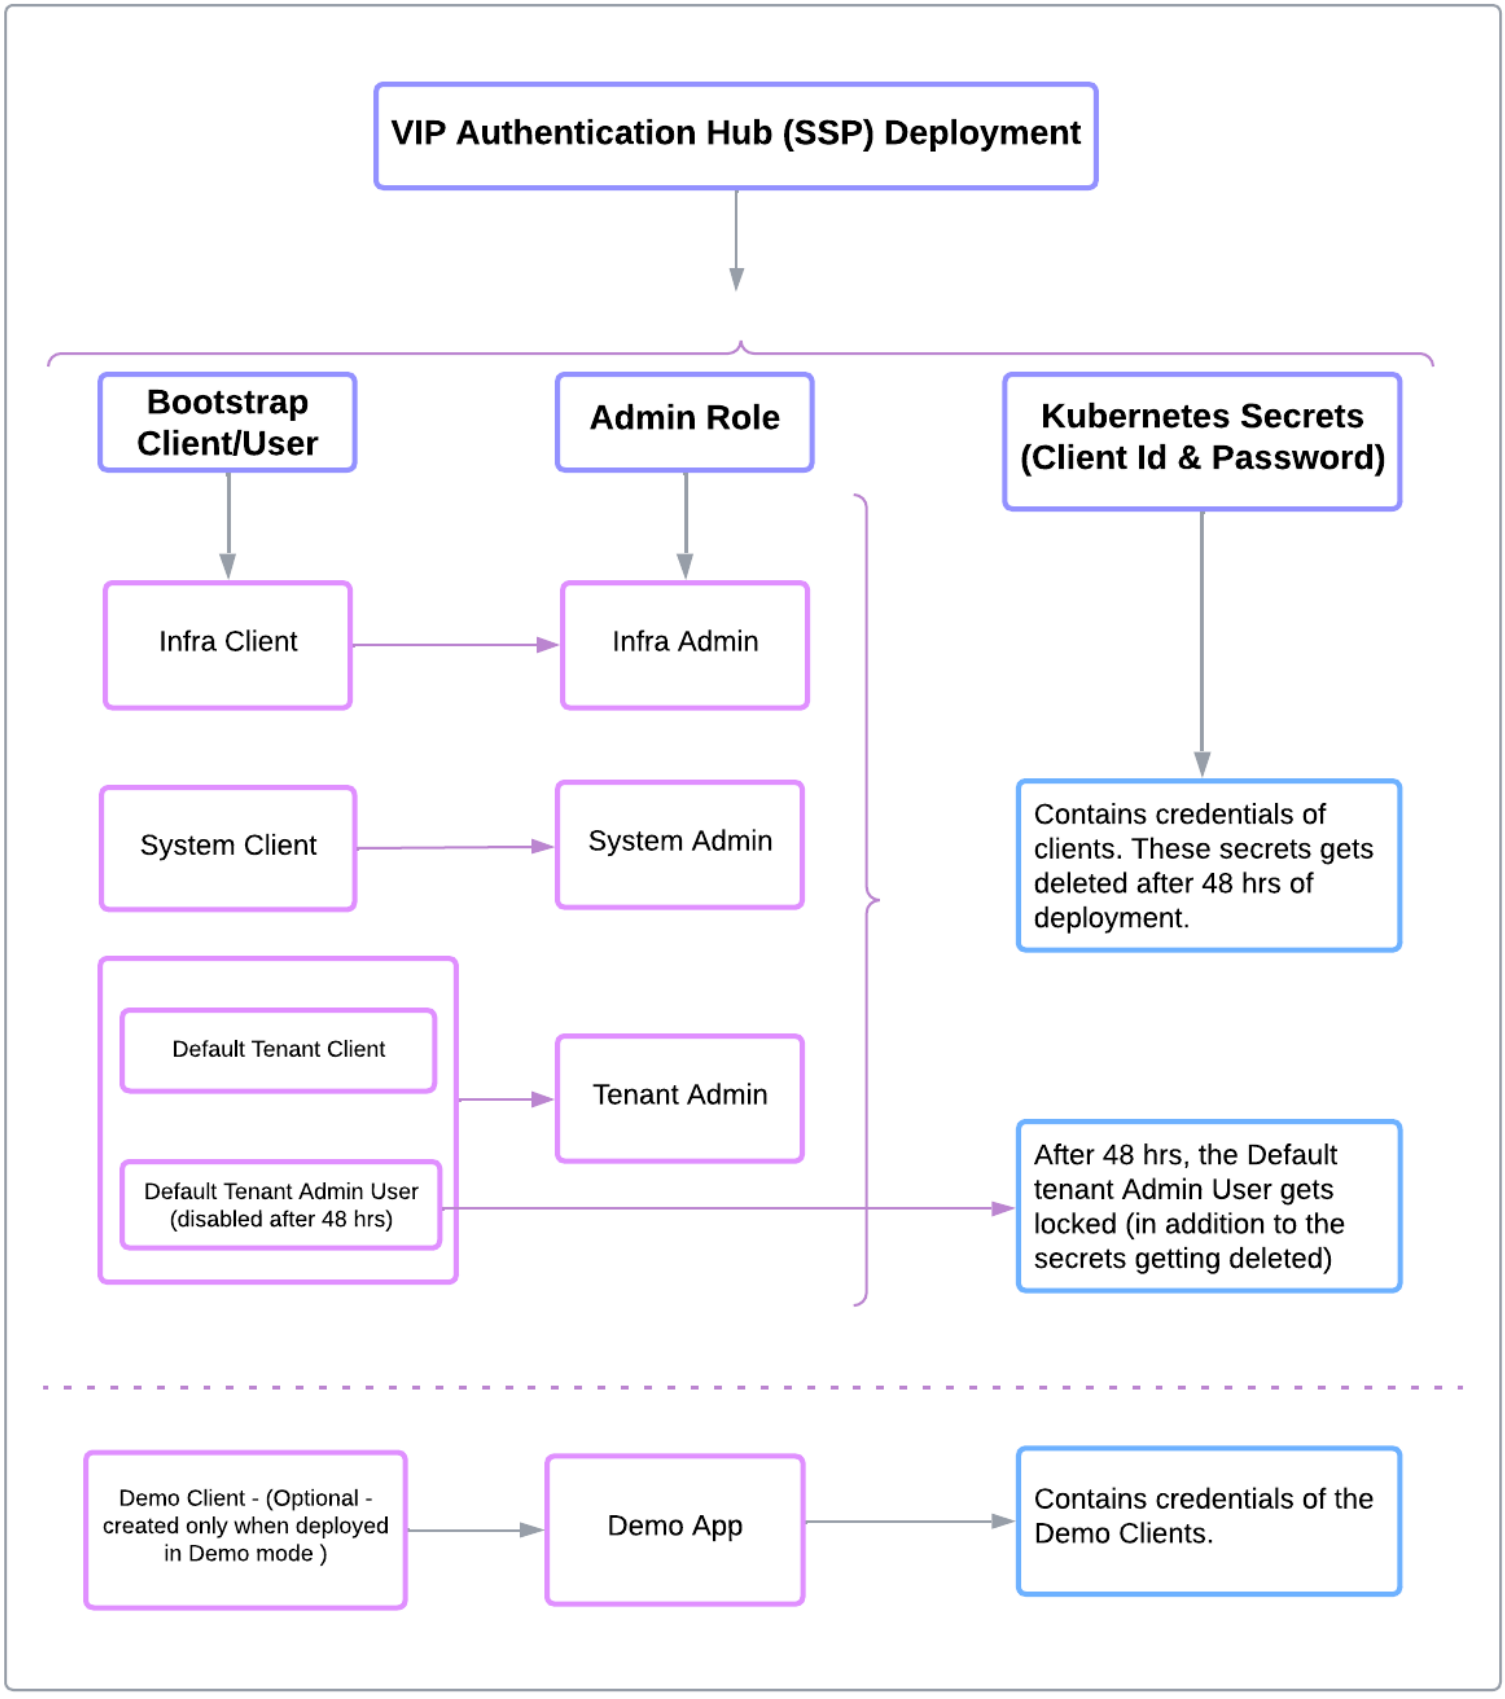
The bootstrap clients' credentials for the Infra, System and the Default Tenant clients are created by IDSP during the initial deployment and are made available to you through the Kubernetes secrets.

The admin client (defaultTenantClient) and admin user (defaultTenantAdminUser) are client and user credentials, respectively, for the "default" tenant bootstrapped by the initial deployment.

Apart from these bootstrap admin clients, IDSP provides various out-of-the-box admin roles, each with distinct permissions and restrictions. These roles are governed by Authorization Policies, with each role corresponding to a specific policy. Each admin role is assigned particular privileges (scopes) that enable the various administrator types to perform their regular tasks. See Admin Roles.

Initial Deployment of Clients and Roles

The following diagram illustrates the **IDSP Deployment clients and roles,** and highlights how various clients credentials are handled within the deployment.



VIP Authentication Hub (SSP) Deployment
Bootstrap Client/User
Admin Role
Kubernetes Secrets (Client Id & Password)
Infra Client
Infra Admin
System Client
System Admin
Contains credentials of clients. These secrets gets deleted after 48 hrs of deployment.
Default Tenant Client
Tenant Admin
Default Tenant Admin User (disabled after 48 hrs)
After 48 hrs, the Default tenant Admin User gets locked (in addition to the secrets getting deleted)
Demo Client - (Optional - created only when deployed in Demo mode)
Demo App
Contains credentials of the Demo Clients.

The breakdown of the components is explained here:

- **IDSP** - This is the IDSP solution, when deployed includes the Infra, System and Default Clients.
- **Clients/Users** - Three client types are deployed automatically with the IDSP solution.
  - **Infra Client**- Represents infra-level client. The credentials for this client is stored in Kubernetes secrets.
  - **System Client**- Represents system-level client. The credentials for this client is stored in Kubernetes secrets.
  - **Default Tenant Client**- Represents tenant-level client. The credentials for this client is stored in Kubernetes secrets. Default client created for tenant-level operations during IDSP deployment includes-
    - **Default Tenant Client** - Tenant client created for handling tenant-specific operations.
    - **Default Tenant Admin User** - An admin user for the default tenant, created during deployment.

      NOTE
      This user is automatically disabled after 48 hours for security reasons. Credentials for this user are stored in Kubernetes secrets, which will be deleted after 48 hours.
  - **(Optional) Demo Client** - Created for testing purposes only when the demo mode is enabled during the IDSP deployment. The credentials for this client is stored in Kubernetes secrets.
- **Admin Roles**- This has already been explained in the Overview section.
- **Kubernetes Secrets** - These credentials are stored as Kubernetes secrets and are available for 48 hours after deployment. After this period, due to security concerns with exposing sensitive credentials for a prolonged time, these credentials are automatically removed. To prevent loss of access, administrators must securely store these credentials immediately upon retrieval.

To know how to retrieve the bootstrap client credentials, see Retrieving Initial Credentials for the Bootstrap clients .

To see few examples of how these roles work in IDSP, see Roles and Responsibilities of Bootstrap clients .

Roles and Responsibilites of Bootstrap Clients

The following content shows few examples of the responsibilities shared by the Bootstrap clients (Infra, System and Tenant Administrators).

This topic includes the following sections:

- Infrastructure Administrator
- System Administrator
  - Obtaining Access Token for System Admin Tasks
  - Example 1: Managing System Settings
  - Example 2: Assist Tenant Admin to fix a tenant specific problem
- Tenant Administrator

Infrastructure Administrator

As an Infra Admin, you will be provided with a single "Infra Client" credential immediately after the initial deployment, to assist you with configuring the first User System Administrator by defining the LDAP Directory and granting appropriate users or groups to the System Admin role. Also, you may choose to create a client having the System Admin role instead of, or in addition to, designating users to be System Admins.

For this release, we automatically seed the System Client having the System Admin role, so that you do not have to perform any specific steps. However, you may be required to use the InfraClient in case of issues with the SystemClient, such as:

- when the secret for the system client has been lost and must be reset
- authorization policy has been mistakenly updated to lock out administrators, and must be reset

In general, this credential is the "super user" credential and you should store it in a secure location.

System Administrator

As a System Admin, you may need to perform certain system admin tasks post installation to configure the environment and meet administration and/or security/governance needs. For example, you may want to configure maximum expiration interval for tokens, or delegate the right to perform system administration to some admin users, etc. These tasks are performed by Users or Applications having the System Admin role. For convenience, you can use the"SystemClient" credential seeded out of the box to perform such tasks.

Obtaining Access Token for System Admin Tasks

Obtaining the access token is the first step towards performing the tasks that are related to your role. The following example shows how to get the access token.

1. Use the following cURL command to get the access token(default tenant) using system admin credentials provided out of the box.
   Request:

```
curl -L -X POST 'https://iam.acme.com/system/oauth2/v1/token' \
-H 'Content-Type: application/x-www-form-urlencoded' \
-u '<systemClientID>:<systemClientSecret>'
--data-urlencode 'grant_type=client_credentials' \
--data-urlencode 'scope=urn:iam:myscopes'
```

   NOTE
   In the example, replace ***<iam.acme.com>*** with your deployment's ingress host. You can retrieve it by using this command:
   `kubectl get ingress -n <namespace>`

   Response: The following is the response that gives you the access token. Use this access token value in the next examples to perform System Admin tasks.

```
{
"access_token": "<access token value>",
"token_type": "Bearer",
"expires_in": 360
}
```

Example 1: Managing System Settings

As a System Admin, you may want to update a setting in the System Configuration. For example, you may want to update the maximum lifetime for the issued access token. As a security consideration, the lifetime of an access token should be kept short, and your organization may have specific policies in place regarding this.

Follow these steps:

1. To get all system settings, execute the following request from POSTMAN (or CURL):
   NOTE
   In the example, replace <iam.acme.com> with your deployment's ingress host and enter the access token that you have obtained in the previous step.
   Request:

```
curl -L -X GET 'https://iam.acme.com/system/admin/v1/Settings' \
-H 'Content-Type: application/json' \
```

```
-H 'Authorization: Bearer <token>' \
--data-raw '
```

Response:

```
[
  {
      "name": "persistEnrolledFactorsinIDP",
      "value": "false",
      "origin": "global"
  },
  {
      "name": "azCodeExpirySecs",
      "value": "120",
      "origin": "global"
  },
  {
      "name": "accessTokenExpiryMaxMins",
      "value": "60",
      "origin": "global"
  },
  {
      "name": "isInlineOTPEnrollmentToBePersisted",
      "value": "true",
      "origin": "global"

      "value": "7",
      "origin": "global"
  },
  {
      "name": "isInlineEnrollmentAllowed",
      "value": "true",
      "origin": "global"
  },
  {
      "name": "idTokenExpirySecs",
      "value": "21600",
      "origin": "global"
  },
  {
      "name": "pushAuthTimeoutSecs",
      "value": "300",
      "origin": "global"
  },
  {
      "name": "accessTokenExpirySecs",
      "value": "3600",
      "origin": "global"
  },
  {
      "name": "idTokenExpiryMaxMins",
      "value": "720",
      "origin": "global"
```

```
  },
  {
      "name": "useOriginalIdentityTokenExpiry",
      "value": "false",
      "origin": "global"
  },
  {
      "name": "inlineEnrollmentFactorsRequired",
      "value": "PASSWORD",
      "origin": "global"
  },
  {
      "name": "riskProviderToBeUsed",
      "value": "SSP",
      "origin": "global"
  },
  {
      "name": "logLevel",
      "value": "INFO",
      "origin": "global"
  },
  {
      "name": "pushRegTimeoutSecs",
      "value": "300",
      "origin": "global"
  },
  {
      "name": "signAlgo",
      "value": "RS256",
      "origin": "global"
  },
  {
      "name": "logRequestPayloads",
      "value": "true",
      "origin": "global"
  },
  {
      "name": "cacheRefreshIntervalMins",
      "value": "1",
      "origin": "global"
  }
]
```

2. To update the access token expiry system setting, execute the following PATCH request from POSTMAN (or CURL):

   NOTE
   In the example, replace <iam.acme.com> with your deployment's ingress host and enter the access token that you have obtained in the previous step.

Request:

```
curl -L -X PATCH 'https://iam.acme.com/system/admin/v1/Settings' \
-H 'Content-Type: application/json' \
-H 'Authorization: Bearer <token>' \
--data-raw '[
  {
```

```
        "name": "accessTokenExpirySecs",
        "value": "360"
    }
]
```

Response:

```
[
    {
        "name": "persistEnrolledFactorsinIDP",
        "value": "false",
        "origin": "global"
    },
    {
        "name": "azCodeExpirySecs",
        "value": "120",
        "origin": "global"
    },
    {
        "name": "accessTokenExpiryMaxMins",
        "value": "60",
        "origin": "global"
    },
    {
        "name": "isInlineOTPEnrollmentToBePersisted",
        "value": "true",
        "origin": "global"
    },
    {
        "name": "refreshTokenExpiryDays",
        "value": "7",
        "origin": "global"
    },
    {
        "name": "isInlineEnrollmentAllowed",
        "value": "true",
        "origin": "global"
    },
    {
        "name": "idTokenExpirySecs",
        "value": "21600",
        "origin": "global"
    },
    {
        "name": "pushAuthTimeoutSecs",
        "value": "300",
        "origin": "global"
    },
    {
        "name": "accessTokenExpirySecs",
        "value": "360",
        "origin": "global"
    },
    {
        "name": "idTokenExpiryMaxMins",
```

```
        "value": "720",
        "origin": "global"
    },
    {
        "name": "useOriginalIdentityTokenExpiry",
        "value": "false",
        "origin": "global"
    },
    {
        "name": "inlineEnrollmentFactorsRequired",
        "value": "PASSWORD",
        "origin": "global"
    },
    {
        "name": "riskProviderToBeUsed",
        "value": "SSP",
        "origin": "global"
    },
    {
        "name": "logLevel",
        "value": "INFO",
        "origin": "global"
    },
    {
        "name": "pushRegTimeoutSecs",
        "value": "300",
        "origin": "global"
    },
    {
        "name": "signAlgo",
        "value": "RS256",
        "origin": "global"
    },
    {
        "name": "logRequestPayloads",
        "value": "true",
        "origin": "global"
    },
    {
        "name": "cacheRefreshIntervalMins",
        "value": "1",
        "origin": "global"
    }
        ]
```

Example 2: Assist Tenant Admin to fix a tenant specific problem

There may be a situation where tenant admins accidentally lock themselves out, for example, by mistakenly updating the Admin Role policy to exclude their own identity, or by mistakenly updating the LDAP Config, hence disabling connectivity to that LDAP Directory. To fix such issues, you as a System Admin have the right to execute cross-tenant operations (APIs) to fix the problem.

Executing cross-tenant operations requires the request for Access Token to be performed in the context of the business tenant while specifying the System Client's tenancy as the request header.

You must perform a GET operation on the tenant's LDAP Config:

Get a cross-tenant access token (for the "default" tenant) using system admin credentials of the client in the "system" tenant:

> **NOTE**
> In the example, replace <iam.acme.com> with your deployment's ingress host.

Request:

```
curl -L -X POST 'https://iam.acme.com/default/oauth2/v1/token' \
-H 'Content-Type: application/x-www-form-urlencoded' \
-H 'X-CLIENT-TENANT-NAME: system' \
-u '<systemClientID>:<systemClientSecret>'
--data-urlencode 'grant_type=client_credentials' \
--data-urlencode 'scope=urn:iam:myscopes'
```

Response:

```
{
"access_token": "<access token value>",
"token_type": "Bearer",
"expires_in": 360
}
```

Get Tenant LDAP config using cross-tenant access token:

> **NOTE**
> In the example, replace <iam.acme.com> with your deployment's ingress host and enter the access token that you have obtained in the previous step.

Request:

```
curl -L -X GET 'https://iam.acme.com/default/admin/v1/LDAPconfigs' \
-H 'Authorization: Bearer <token>'
```

Response:

```
[
  {
      "configName": "TestConfig",
      "configDescription": "CA DIR k8s with default data",
      "sslEnabled": "NO",
      "certificate": null,
      "certificateAlias": null,

    }
]
```

Tenant Administrator

As a Tenant administrator, your tasks cover what is necessary to integrate applications with security services provided by Symantec Identity Security Platform. For example:

- Creating an "application" entity representing protected applications
- Creating and managing Authentication Policies defining the level of authentication required by the application
- Managing configuration settings such as certificates, message templates, available authentication factors, etc.
- Creating and Managing a "Identity Stores" entity representing the identity store with users to be authenticated by IDSP
- Delegating Tenant Admin role to users and groups. Also to applications that wish to invoke IDSP APIs

Resource Authorization

Describes how Resource Authorization provides fine-grained administrator access by using scoping constraints.

The default Administrative model provides course-grained administrator access by using granted Administrative roles and their associated privileges. In this default model, Administrators can see all resource instances and all of the resource instance attributes. The Resource Authorization model lets you define policies, called scoping constraints, that can declare resource attribute permissions and resource instance rules. When combined with your Administrative model, Resource Authorization provides finer-grained administrator access across the granted Resource privileges.

Resource authorization allows you to control the level of access an entity (a user, group, app, or instance), has to a particular resource in the system. That is, resource authorization allows you to set the following for any entity:

- What can the entity see and manage?
- What can the entity grant or revoke?
- What does the entity have granted to it?

When you create your policies, you naturally create separate resources, such as when you create policies for SAML apps and policies for OIDC apps. However, defining all of the possible separate resources manually through policies is prohibitive. Instead, you can use resource authorization to segregate privileges more granularly, and with more reusabilities.

The Resource Allocation APIs support three access control levels:

- **Resource Privilege Scope (RPS):** RPS controls privilege-level access to the resource, which is secured by an OAuth2 scope, and delegated by virtue of assigning an Admin Role. RPS constitutes the default course-grained access model.

  For example: urn:iam:t.apps, urn:iam:t.session, urn:iam:t.users

  See Managing Authorization for details about defining administrator roles.

NOTE
You can use wildcards in the resource attribute.

- **Resource Data Scope (RDS):** RDS is a control that defines data level access for User attributes such as the user ID, given name, or email address. Resource Data Scopes are defined as data elements with specific permissions in a ScopingConstraint policy.
  You can extend Resource data by adding additional tags, which can be used for Resource Authorization criteria in addition to other tagging purposes. For example, if you tag a resource with a scope, you can include that scope in a constraint statement for any policy that affects that resource. See Scoping Constraints Overview and Managing Scoping Constraints for more detail on adding a scoping constraint.
- **Resource Instance Scope (RIS):** RIS is a control that defines instance-level access to a resource such as a User, Group, App, Identity Provider, Secret, Certificate, and so on. The RIS is enforced by policy enforcement points that control access to a resource (typically a resource controller). An RIS is defined as instance elements containing admin scope rules (controls) in a ScopingConstraint policy.
  You add criteria (attribute tags) directly into your API schema to define the scope attribute for each resource. Once a resource is tagged with a criteria, you can include that criteria in a constraint statement for any policy that affects that resource. See Scoping Constraints Overview and Managing Scoping Constraints for more detail on adding a scoping constraint.

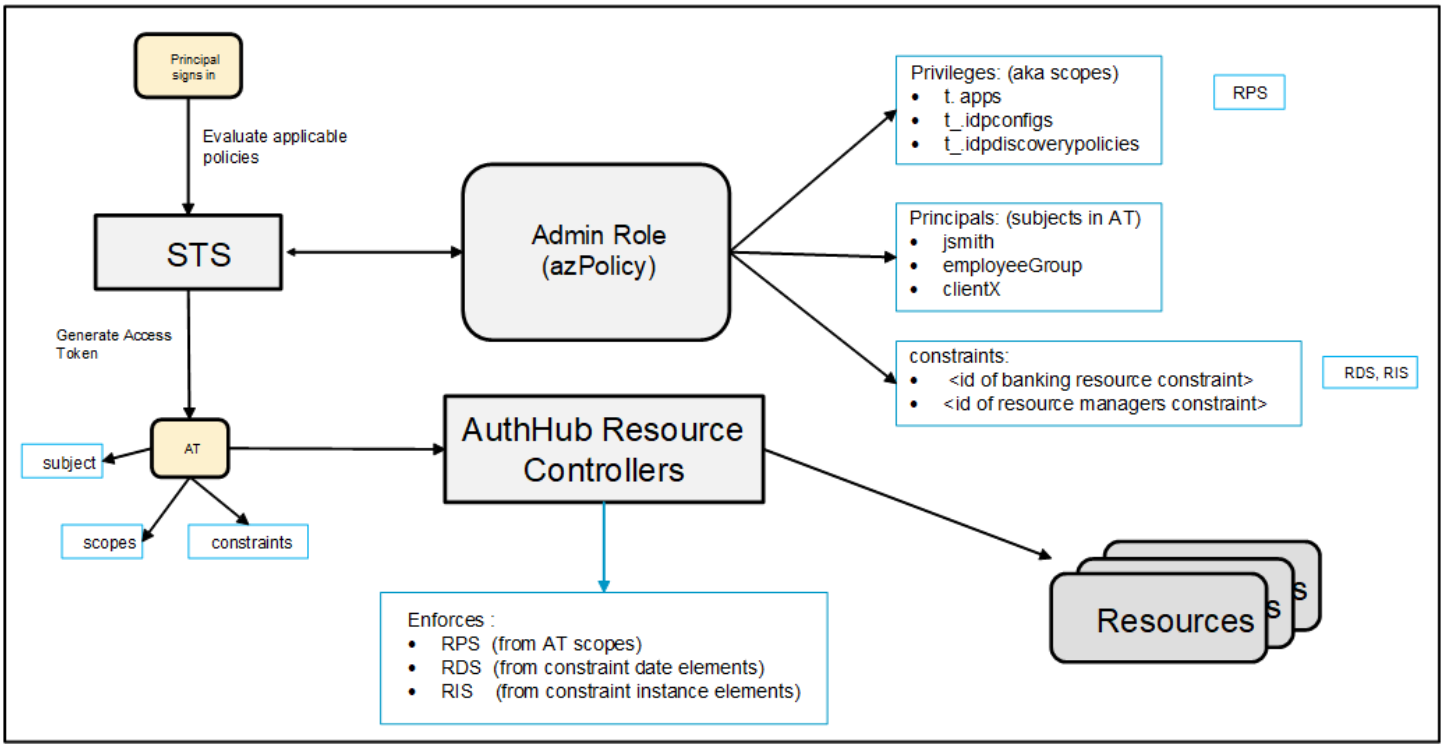
When an entity attempts to perform an operation against a resource, the requesting API checks the policy for the following:

- Conditions (when the policy applies)
- Principals (to whom the policy applies)
- RPS or scopes (what privileges the administrator is assigned)
- Constraints based on RDS and RIS (to which attributes does the administrator can access)

The combinations of these are included in the Access Token that defines what the administrator has access to and can manage.

The following image illustrates the resource access flow with Resource Authorization constraints in place.

Figure 1: Resource Access Flow



Next:

Defining a Resource Authorization Model

Defining a Resource Authorization Model

Describes how to define your Resource Authorization model.

The Resource Authorization model for a deployment can vary depending upon the several factors, such as:

- The balance between functional administration and business need (for example, whether it should be centralized, decentralized, or a combination of both)
- The state of the resource data and data consistency (for example, whether the deployment has common schemas and consistent data values)

Resource Authorization provides flexible capabilities to handle various authorization models. The two main approaches are typically devised based on either a centralized or a decentralized model.

Centralized Administration

A centralized administration model is defined by top-down alignment of resources based on some business-driven partitioning, such as by organization, business or product line, department, and so on. Administrators and resources are typically provisioned along these lines. This partitioning allows you to construct policies based on data attribute values that are directly aligned to your business needs.

Administrative privileges are typically centralized within the business partition. For example, a banking admin can administer banking resources. Resource management tends to maintain the centralized model. In this model, Administrators can only create and manage resource within their partition. However, these rigid centralized tendencies can sometimes be relaxed, such as allowing an Administrative scope to cross partitions.

The following figures illustrate the centralized administration model for two different organizations.

Figure 2: Centralized Banking Organization Administration Model

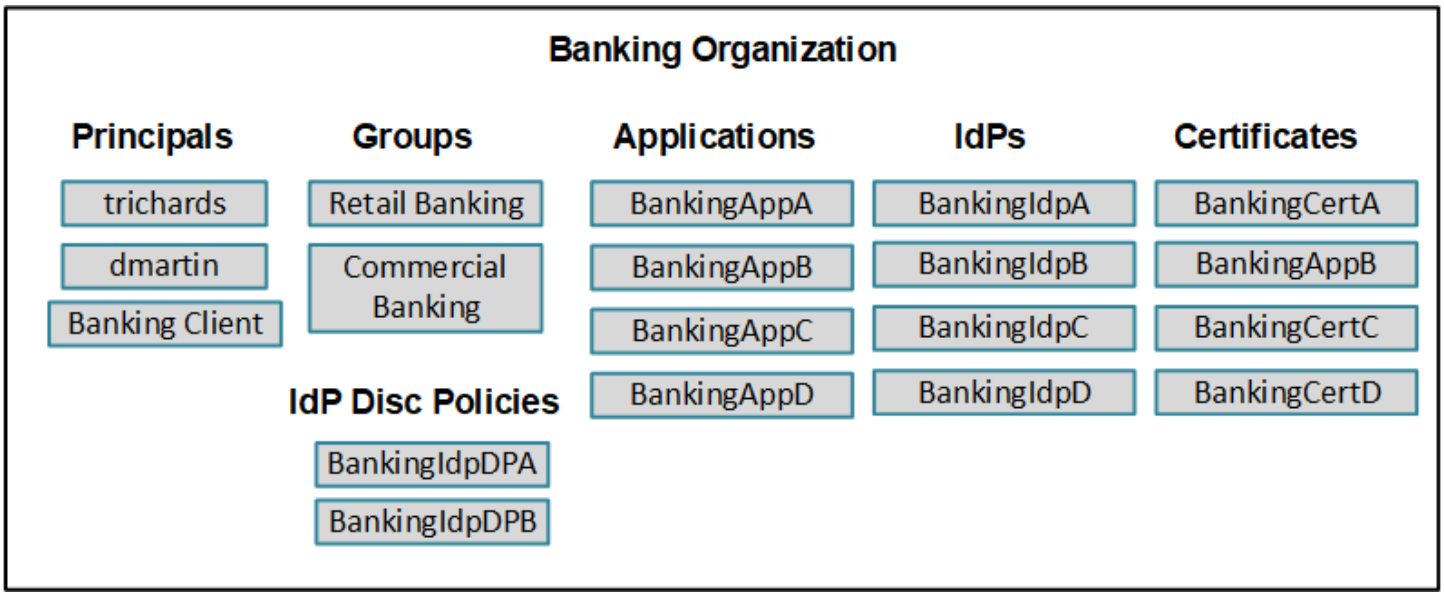


Figure 3: Centralized Investments Organization Administration Model

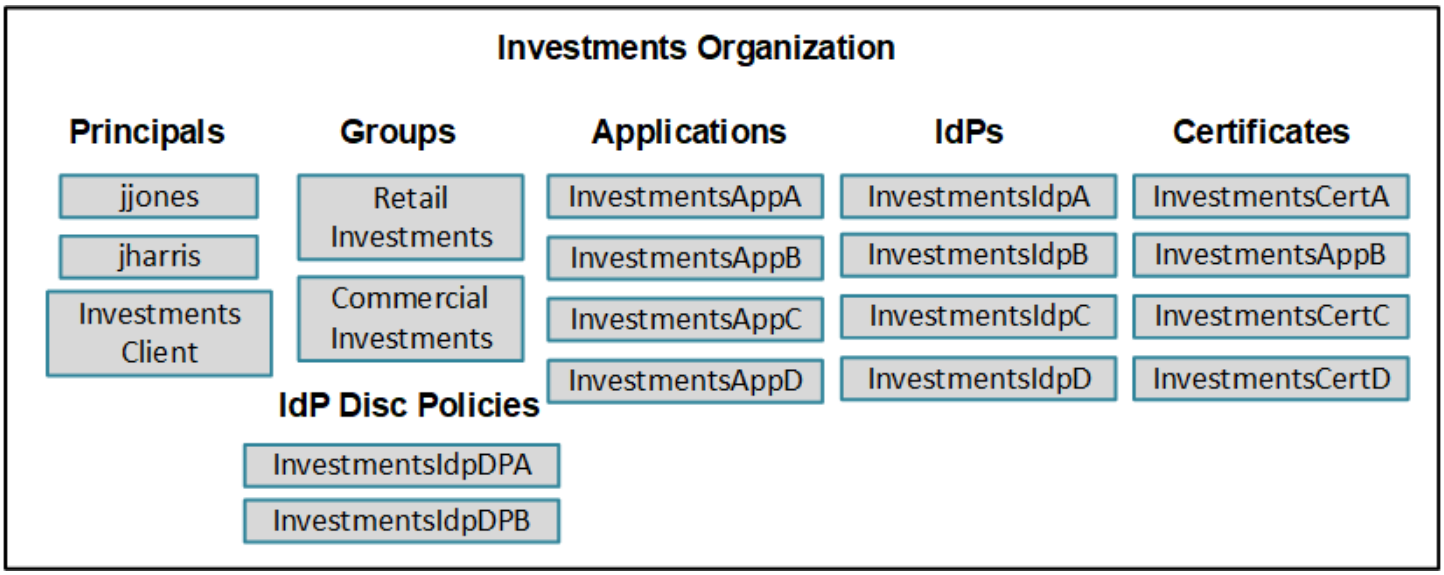


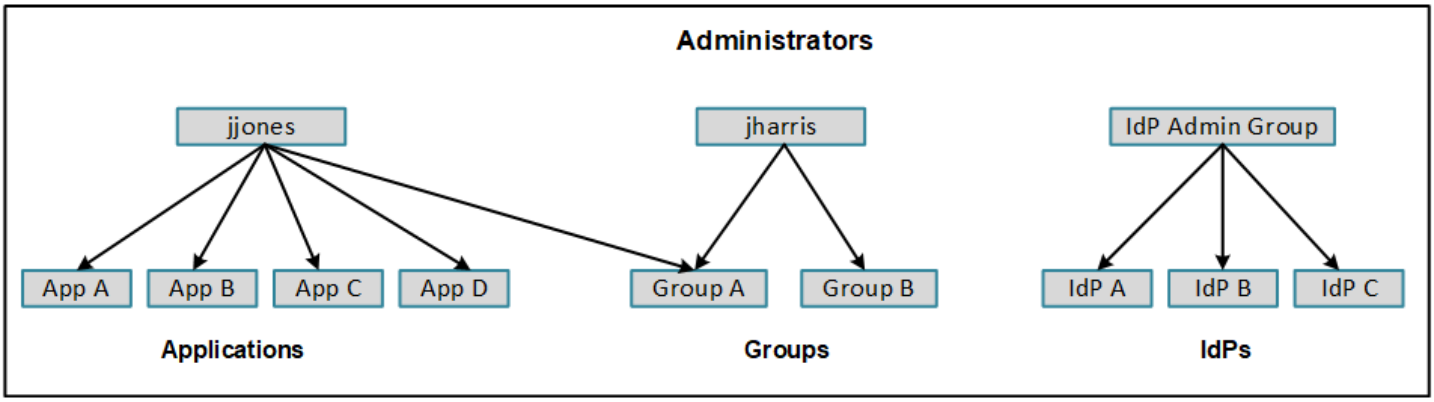
Decentralized Administration

A decentralized administration model has no unifying, top-level, business-defined structure. Administration is spread out based on other functional administrative needs. The decentralized model allows different areas of the business to define administrative needs differently. Decentralization relies on a named manager model where access is granted to specific resource instances for a user, group, or client.

The decentralized administration model requires a higher level of manual administration. However, using groups as the basis of access can alleviate this administrative burden.

The following figure illustrates the decentralized administration model.

Figure 4: Decentralized Administration Model



Resource Authorization Scoping Constraints

Describes the access control mechanisms available in the Resource Authorization model.

The following table describes the access control mechanisms that are supported by the Resource Authorization model:

Table 1: Resource Authorization access control mechanisms

Access	Resources	Usage	Notes
User attributes (ABAC)	User	User - any User Schema attribute	It is highly recommended to use **User.organization** or User custom attributes since these attributes are indexed in the Internal Id Store.
adminscope.criteria (ABAC)	ABAC for Group, Application, IDP, IDP Discovery, AuthN/ AuthZ Policy, Secrets, Certificates	**adminscope.criteria** is a schema extension that is added for tagging non-user Resources.	**adminscope.criteria** is an attribute that can be used as an ABAC constraint in a Scoping Constraint policy or as a general resource tagging mechanism. The attribute takes the form of: `name=value` Multiple name=value pairs can be defined.
adminscope.managedby	All	Named manager of a resource. Supports several bindings: • Non-user Resources: **adminscope.managedby** • User resources: **User.managerIdUser.Groups**	**adminscope.managedby** relies on delegation of access to resources for a subject (user, client, group) using the Subdelegation APIs. • **User.managerId** is the SCIM supported manager/ user relationship • **User.groups** allows an Admin who belongs to a group to manage user members in that same group.

Access	Resources	Usage	Notes
Owner	All	The default constraint when none of the previous access control mechanisms apply.	

Building A Resource Model

Describes how to build a Resource Authorization model using Scoping constraints.

Resource Authorization is based on enforcement of applicable constraints (or *Admin Scopes*) as defined in the Scoping Constraints associated with an Administrative Role. While Administrative Roles define resource privilege scope (RPS), any associated Scoping Constraints can restrict those privileges by defined resource instance scope (RIS) rules, or by resource data scope (RDS) rules.

If no Scoping Constraints are added to Administrative Roles, or a Scoping Constraint has been added but is marked inactive, then no restrictions are applied to the privileges of those Administrative Roles.

> **NOTE**
> RDS applies only to User resources.

You manage (create, read, update, and delete) Scoping Constraints using the Scoping Constraints API. Once a Scoping Constraint is defined, it can be added/removed from an Administrative Role using the Scoping Constraints API or the **Administrative Role > Constraints** page of the Admin Console.

- For information on using the Scoping Constraints API to manage Scoping Constraints, see Scoping Constraints API.
- For information on using the Admin Console to add or remove constraints, see Administrators and Roles

For detailed procedures on building and managing a Resource Authorization Model, see the following topics:

- Supported Resource Instance Scope (RIS)
- Adding or Removing a Constraint
- Enabling Resource Admin Scope Enforcement for Resource Authorization
- Understanding and Using the Default Constraints
- Determining Applicable RDS and RIS for a Given Principal Using Helper APIs

Resource Authorization results for Symantec Identity Security Platform Resource APIs (such as User, Group, applications, and so on) can often return complex outcomes. For information on using the `explain` parameter to understand Resource Authorization results, see Understanding Resource Authorization Results using Explain.

Scoping Constraints Overview

Overview

A Scoping Constraint is a policy that defines access controls for resources. A Scoping Constraint, which are associated with specific resource types, defines resource data access and resource instance access. These access controls are collectively referred to as scope or admin scope.

Resource Authorization is based on the enforcement of applicable admin scope as defined by the Scoping Constraints associated with an Administrative Role. While Administrative Roles define resource privilege scope (RPS), any associated Scoping Constraints can restrict those privileges by defined resource instance scope (RIS) rules, or by resource data scope (RDS) rules.

NOTE
Note RDS is restricted to User resources only.

Scoping Constraints are created, read, updated, and deleted via the Scoping Constraints API. Once a Scoping Constraint is defined, it can be added/removed from an Administrative Role using the Scoping Constraints API or the Admin Console's Administrative Role's Constraints page.

- For information on the using the Scoping Constraints API to manage Scoping Constraints, see Scoping Constraints API.
- For information on using the Admin Console to add or remove constraints, see Administrators and Roles

Scoping Constraints Definition

The following table lists the components of a Scoping Constraint.

Table 2: Scoping Definition

Scoping Constraint fields	Description	Values
name	A unique name for the constraint.	Varies
description (optional)	A description of the constraint.	Varies
resource	The associated resource type	Must be one of the following: • urn:iam:res:app • urn:iam:res:authnpolicy • urn:iam:res:authzpolicy • urn:iam:res:cert • urn:iam:res:group • urn:iam:res:idp • urn:iam:res:idppolicy • urn:iam:res:secret • urn:iam:res:user • urn:iam:res:* - all resources
status	The state of the constraint (active or inactive). Inactive constraints are ignored during enforcement.	• active • inactive

Scoping Constraint fields	Description	Values
abacOps (optional)	A control that defines the operations that are enforced when an ABAC constraint applies. You can add one of the following qualifiers to this control: • **+** This prefix allows the operation without enforcing the ABAC constraint. • **-** This prefix denies the control for the ABAC constraint. Providing no prefix enforces the ABAC constraint for the operation. If any scoping constraint includes the **+** prefix, it takes precedence over other constraints. If + is not provided in all scoping constraints for the resource type and one scoping constraint includes the - prefix in abacOps, the - prefix takes precedence over other constraints. If a qualifier is not explicitly added, it is treated as unconditionally denied. If the resource type has multiple scopes, the priority order is: unconditional access, unconditional deny, and conditional access.	• C - enforce constraints on create operations • R - enforce constraints on read operations • U - enforce constraints on update operations • D - enforce constraints on delete operations
gbacOps (optional)	A control that defines the operations that are enforced when a GBAC constraint applies. gbacOps is associated with the managedBy constraint conditions. Since managedBy is not applicable during resource create operations, 'C' is not enforced. You can add one of the following prefixes to this scoping constraint: • **+** This prefix allows the operation without enforcing the GBAC constraint. • **-** This prefix denies the control for the GBAC constraint. Providing no prefix enforces the GBAC constraint for the operation. If any scoping constraint includes the **+** prefix, it takes precedence over other constraints. If + is not provided in all scoping constraints for the resource type and one scoping constraint includes the - prefix in gbacOps, the - prefix takes precedence over other constraints. If a qualifier is not explicitly added, it is treated as unconditionally denied. If the resource type has multiple scopes, the priority order is: unconditional access, unconditional deny, and conditional access.	• C - enforce constraints on create operations • R - enforce constraints on read operations • U - enforce constraints on update operations • D - enforce constraints on delete operations

Scoping Constraint fields	Description	Values
denyOps (optional)	A control used to explicitly deny an operation (matching is case-insensitive). The default value is null. If any scoping constraint for a resource type has this control, the operation is denied for that resource type. For example, if a resource type has denyOps=U, the principal cannot update any resources of this type.	• C - enforce constraints on create operations • R - enforce constraints on read operations • U - enforce constraints on update operations • D - enforce constraints on delete operations
adminScopeApi (optional)	A control override that, when set to **true**, enforces RPS and constraint RDS rules, but ignores constraint RIS rules	• true • false
data	For RDS only: A list of attributes and their associated permissions.	See specific details in Supported Resource Data Scope (Attribute Permissions). If the data list is empty, then no attribute permissions are defined and all attributes are considered RW.
instance	For RIS only: a list of access rules.	See specific details in Supported Resource Instance Scope (RIS). If the instance list is empty, no instance rules are applied for this policy.
disableOwner	If disableOwner = true, whether the current principal is the owner of a resource is not considered when enforcing the scoping constraint.	• true • false (default)

Supported Resource Data Scope (Attribute Permissions)

Describes how to use Resource Data Scope (RDS), or *attribute permissions*.

The data element of a Scoping Constraint defines the permissions that are allowed on User attributes. Note that data is allowed on User resources only. The following example illustrates the format of the data section attribute permissions:

```
"data":  [
         {
            "attr": "attribute_name | * " ,
            "priv": "<permission>"
            },
]
```

If the data list is empty or not present in the constraint, then the attribute access is *unconstrained*.

The following table describes the resource attribute permissions:

Table 3: Resource Attribute Permissions

Permission	Description
r	Administrator can read/view the attribute. This setting is the default unless explicitly declared otherwise.
w	Administrator can write/update the attribute.
rw	Administrator can read/view and write/update the attribute.
-	The administrator has no permission (cannot read/view or write/update the attribute).

The POST and PUT APIs take a JSON payload as in the following example:

```
{
        "name": "<the unique constraint name>",
        "description": "<some description>",
        "status":  "active",
        "resource": "urn:iam:res:user",
            "data": [
                    "attr": "given_name",
                    "priv": "r"
                },
                {
                    "attr": "is_locked",
                    "priv": "w"
                },
                {
                    "attr": "family_name",
                    "priv": "r"
                },
                {
                    "attr": "email",
                    "priv": "rw"
                }

                    ]
```

The `attr` element must contain an attribute name conforming to the logical attribute set. These attributes can be returned from the `UserSchemaHelper` API. The name attribute is the value of the attribute name that is defined in a Scoping Constraint. The following example shows the birthdate attribute output from the schema helper:

```
"birthdate": {
        "account": false,
        "searchable": false,
        "visible": true,
        "operational": false,
        "mva": false,
        "name": "birthDate",
        "type": "DATE",
        "visibleToDisambiguationQuery": false,
        "scimUri": "urn:ietf:params:scim:schemas:extension:iam:ssp:1.0:User:birthDate",
        "scimAttributeName": "birthDate",
        "scimWritable": true,
        "values": null,
        "custom": false
```

Attribute Permissions

By default, the attribute permissions of a resource are assumed to be unconstrained. An Administrator applying a Scoping Constraint can use the following semantics:

1. If a set of attribute permissions are explicitly defined in a Scoping Constraint, then those defined permissions are enforced.
2. If an attribute permission is not explicitly declared in a Scoping Constraint, then the default permission is ‘r’.

3. Within a given Scoping Constraint, you can use wildcards for the attribute name to define the default permission, with other declared permissions overriding the wildcard default.

In the following Scoping Constraint definition example, an HR Administrator needs ‘rw’ permissions on HR-based attributes, and all other attributes default to ‘r':

```
{
        "name": "HR Support",
        "description": "HR Support needs RW on specific HR attrs",
        "status":  "active",
        "resource": "urn:iam:res:user",
                "data": [
                        {
                        "attr": "given_name",
                        "priv": "rw"
                        },
                        {
                        "attr": "family_name",
                        "priv": "rw"
                        },
                        {
                        "attr": "email",
                        "priv": "rw"
                        },
                        {
                        "attr": "phone_number",
                        "priv": "rw"
                        },
                        {
                        "attr": "address",
                        "priv": "rw"
                        },
                        {
                        "attr": "title",
                        "priv": "rw"
                        },
                        {
                        "attr": "organization",
                        "priv": "rw"
                        }
                        // all other attributes not listed explicitly, have ‘r’ permission
                ]
        }
```

As another example, an Application Owner needs ‘rw’ permissions on a small set of application-based attributes, and ‘r’ permission on others to help identify the User. The rest of the attributes should not be visible. The following Scoping Constraint definition example supports this use case:

```
{
        "name": "App Support",
        "description": "Applications support ", "resource": "urn:iam:res:user",
                "data": [
                        {
                        "attr": "*",    //Declare No permission by default
```

```
                    "priv": "-"
                    },
                    {
                    "attr": "AcmeAppLoginId",    //Declare RW on App attrs
                    "priv": "rw"
                    },
                    {
                    "attr": "AcmeAppSegment",
                    "priv": "rw"
                    },
                    {
                    "attr": "WidgetAppProjects",
                    "priv": "rw"
                    },
                    {
                    "attr": "WidgetAppDefaultProject",
                    "priv": "rw"
                    },
                    {
                    "attr": "user_loginId",    //Declare R on user identifying attrs
                    "priv": "r"
                    },
                   "attr": "given_name",
                    "priv": "r"
                    },
                    {
                    "attr": "family_name",
                    "priv": "r"
                    },
                    {
                    "attr": "email",
                    "priv": "r"
                    },
                    {
                    "attr": "title",
                    "priv": "r"
                    },
                    {
                    "attr": "organization",
                    "priv": "r"
                    }
            ]
    }
```

Supported Resource Instance Scope (RIS)

Describes how to use Resource Instance Scope (RIS).

The instance section defines scope rules that are based on resource attributes, and takes the following form:

```
 attr": "<some attribute name>",
 "scope": [
           {
```

```
            "op": "eq | sw",
            "value": "<some attribute value>"
        }
    ]
```

Attributes that are defined in the instance element are subject to frequent query operations. For user resources, this attribute can be any attribute that is defined in the User schema. However, it is highly recommended to choose attributes that are marked as `searchable=true` . Searchable attributes have high-performance indexing enabled. See the UserSchemaHelper API or the Internal Identity Store Configuration configuration for the Admin Console for a list of searchable User attributes.

The adminscope.criteria attribute that is defined for non-user resources is searchable and indexed.

Comparison Operators

The following table shows the comparison operators that are supported by instance attribute scope rules.

Table 4: Supported comparison operators, for instance, attribute scope rules

Operator	Comparison	Supported Data Types	Examples
eq	equals	string, integer, boolean date	• attr: organization • op: eq • value: retail
sw	starts with	string	• attr: organization • op: sw • value: retail • matches: retail • banking, retailInvestments Special match semantics, comparison matches value portion: • attr. adminscope.criteria • op: sw • value: organization=retail Matches: • organization=retailBanking • organization=retailInvestments

Common Resource Access Controls

You can use the following common attributes:

- **adminscope.criteria**

Table 5: adminscope.criteria attribute

Attribute	Description	User Binding

adminscope.criteria	Sets of {name=value} pairs. For example:
	
	`"attr": "adminscope.criteria",`
	`"scope": [`
	`{`
	`"op": "eq",`
	`"value": "enrollment=platinum"`
	`}`
	`]`
		An optional mapping that resolves to a User-based attribute. For example:
		`"attr": "adminscope.criteria",`
		`"scope": [`
		`{`
		`"op": "eq",`
		`"value": "enrollment=platinum"`
		`"userAttr": "enrolledIn"`
		`}`
		`]`
		In this example, users with an **enrolledIn** attribute value that is equal to *platinum* match the constraint condition.

- **adminscope.managedby**

Table 6: adminscope.managedby attribute

Attribute	Description	User Binding

adminscope.managedby	A definition of a manager with specialized values, used to resolve various resource manager models. For example:
	
	`"attr": "adminscope.managedby",`
	`"scope": [`
	`{`
	`"op": "eq",`
	`"value":`
	`"urn:iam:adminscope:me",`
	`"userAttr": "managerId"`
	`},`
	`{`
	`"op": "eq",`
	`"value":`
	`"urn:iam:adminscope:megroups",`
	`"userAttr": "groups"`
	`}`
	`]`
		• value: "urn:iam:adminscope:me”
		A declaration that resolves to manager records (of type **user/client**) that match the ID of the current principal.
		• value: "urn:iam:adminscope:megroups”
		A declaration that resolves to manager records (of type **group**) that match one of the current principal groups where that principal is a member.
		• userAttr: managerId
		Resolves to users whose **managerid** value matches the Id of the current principal
		• userAttr: groups
		Resolves to groups that match one of the **User.groups** values of the current principal.

Evaluating Multiple Scopes in RIS

In constraint definitions, if the same attribute is defined with different values, these values are ORed during evaluation. For example, given the following constraint, the evaluation matches resources who contain either **silver** or **platinum** values for the enrollment criteria.

```
"attr": "adminscope.criteria",
 "scope": [
   {
```

```
     "op": "eq",
     "value": "enrollment=platinum"
    },
 {
     "op": "eq",
     "value": "enrollment=silver"
    },
   ]
```

If two different attributes are defined in a constraint, then the two attribute and their values are evaluated using an AND operation. For example, given the following constraint, the evaluation matches resources who contain **enrollment=platinum** and **organization=banking**.

```
 "instance": [
          {
              "attr": "enrollment",
              "scope": [
                 {
                    "op" : "eq",
                    "value" : "platinum"
                 }
              ]
          },
          {
              "attr": "organization",
              "scope": [
                 {
                    "op" : "eq",
                    "value" : "banking"
                 }
              ]
          }
         ]
```

Understanding and Using the Default Constraints

When deploying a new tenant or upgrading an existing tenant to version 3.3 or later, the system deploys default constraints. These constraints are deployed in an inactive state and are added to out-of-the-box Administrative Roles that contain privileges for resources that can be constrained using Resource Authorization. To enable the use of the constraint, the status must be changed from **inactive** to **active** using the Scoping Constraints API.

The default constraints cover the full set of supported constraint styles. The deployment of the default constraints and the roles they have been added to are shown in the following table.

Table 7: Default constraints and their roles

Constraint Name	Resource	Administrative Roles	See
Default Constraint	urn:iam:res.*	• IdentityClientPolicy • IntegrationAdminPolicy • IntegrationAuditorPolicy • ConfigurationAdminPolicy • ConfigurationAuditorPolicy • IdentityAdminPolicy	Default Constraint
Default Me Constraint	urn:iam:res.me	Self Administration	Default ME Constraint
Unrestricted Constraint	urn:iam:res.*	Deployment specific. Only used during 3.3 upgrades, and deployed when out-of-the-box Administrative Roles have been granted to principals.	Unrestricted Constraint

Default Constraint

Describes the Default Constraint added to Administrative Roles with new tenants or when upgrading.

The default constraint supports the full spectrum of Authorization styles for centralized and decentralized models. This topic describes the specifics of each constraint style.

The adminscope.criteria Constraint

The following adminscope.criteria definition assumes that partitioning of resources for ABAC is done by organization. This constraint assumes that there is some organization value that is provisioned for resources which matches the organization of principals requesting access to those resources. This concept is a core concept of the centralized administration model that is achieved by attribution.

The adminscope.criteria constraint uses the following format:

```
{
  "attr": "adminscope.criteria",
  "scope": [
     {
         "op": "eq",
         "value": "organization=${requestprincipal.organization}",
         "userAttr": "organization"
     }
   ]
}
```

The following table lists the provisioned resources with matching organization values.

Table 8: Provisioned resources with matching org vales

Resource Type	adminscope.criteria
group, applications, IDPs, and so on.	`"adminscope.criteria": [ "organization=banking ]`
User Principal	`"urn:ietf:params:scim:schemas:extension:enterprise:2.0:User": { "organization": "banking },`
Client Principal (such as Application)	`"metadata": [ { ”name": "organization", "value": "banking" }, ... ]`

The `userAttr` specifier is used to look up the matching organization value to resolve the matching organization for requested Users and for the requesting User principal.

Using the `requestprincipal` Substitution Variable

When resolving an attribute value for the requesting principal, you can use a substitution variable at runtime to determine the value for that principal. For example:

```
Format:  ${requestPrincipal.atttibuteName}
```

In the default constraint, the given organization is the provisioned attribute, and the **organization** is the `attributeName` .

The adminscope.managedby Constraint

The adminscope.managedby constraint covers the various manager models that can be deployed for resource management.

- Individual named managers matching the requested principal are evaluated using `urn:iam:adminscope:me` value processing.
- Groups acting as resource managers evaluate the set of groups that the principal has against the group-based managers during `urn:iam:adminscope:megroups` value processing.

The adminscope.managedby constraint uses the following format:

```
{
  "attr": "adminscope.managedby",
  "scope": [
     {
        "op": "eq",
        "value": "urn:iam:adminscope:me",
        "userAttr": "managerId"
      },
      {
         "op": "eq",
         "value": "urn:iam:adminscope:megroups",
         "userAttr": "groups"
```

```
        }
    ]
}
```

Default ME Constraint

Describes the Default ME Constraint added to Administrative Roles with new tenants or when upgrading.

The Default ME Constraint is used by, and enforced by, User self-modification operations that are invoked using `${SSP_FQDN}/{{apiPathTenant}}/scim2/v1/Me` .

NOTE

- To know the value of ${SSP_FQDN} environment variable, see Configuring IDSP Environment Variables.
- The default value for `<tenantName>` is "default".
- Replace the text {{text}} including {{}} characters with appropriate values, in all the endpoints shown in the above table.
  For example:
  `https://{{host}}/{{tenantName}}/scim2/v1/Me`
  should look similar to:
  `https://example.com/default/scim2/v1/Me`
- To know more about the scopes that are required to secure these APIs, refer to the Rest APIs and Associated Privileges section.

This constraint contains RDS constraints only. The attributes that are defined in the data section of this constraint define what attributes a User can modify on their own profile.

Unrestricted Constraint

Describes the default Unrestricted Constraint added to Administrative Roles with new tenants or when upgrading.

The Unrestricted Constraint is a special purpose constraint that is used to preserve the unconstrained behavior of principals that are assigned to Administrative Roles before v3.3. This constraint is only deployed during upgrades to v3.3. The constraint only applies to principals that have been assigned to any of the out-of-the-box Administrative Roles whose privileges include resources that can be constrained. The unconstrained semantics of this constraint is achieved using the following attribute:

```
"adminScopeApi" : true,
```

This setting defers enforcement to the API scopes presented in the Access Token and ignores any RIS-defined constraint.

Adding or Removing a Constraint

Describes how to add a scoping constraint to, or remove a scoping constraint from, an Administrative Role.

After you define a Scoping Constraint, you can bind it to an Administrative Role:

- You can add or remove a scoping constraint using the AdminScopeConstrainer API. For information about adding or removing a scope constraint using the APIs, see Managing Scoping Constraints.
- The Admin Roles Detail page of the Admin Console provides a Constraints page that allows you to view or manage (add/remove) existing constraints that are defined by the Scoping Constraints API to a role. For information on using the Admin Console to add or remove constraints, see Administrators and Roles

Enabling Resource Admin Scope Enforcement for Resource Authorization

Describes Admin Scope enforcement for the Resource Authorization Model.

By default, the setting for Admin Scope enforcement is set to **false**. Enforcement is controlled by a global setting with an optional tenant-specific override. The following table describes the setting and the enforcement behavior when the setting (`isAdminScopeEnforced`) is set to **false** (the default). Using this setting allows deployments to build their authorization model over time and roll out the enforcement when fully tested.

Modify the `isAdminScopeEnforced` setting on the Managing Settings page.

Table 9: Default behavior for Admin Scope enforcement

Operation	Effect
Resource Access	No defined constraints are enforced
Constraint Definition (API only) Admin Role to constraint bindings	Allowed
Admin Role and Resource Delegations	Not allowed (APIs return 403 error)
Delegations Discovery	Allowed
Admin Console Resource page attribute value restrictions	No value restrictions are enforced

Determining Applicable RDS and RIS for a Given Principal Using Helper APIs

Describes how to use the Helper APIs to determine the applicable RDS and RIS for a given principal.

When the Resource Authorization model is ready to be evaluated, you can use Resource Schema Helpers to determine if the evaluations of the deployed constraints alongside deployed resource data are working properly. The following schema helpers return the evaluation of RDS and RIS values when passed an Access Token of the current principal to be evaluated:

Table 10: RDS and RIS evaluation schema helpers

Helper	Token	Output showing attribute constraint allowed values (RIS) and allowed permissions (RDS)	Interpreting the Results
admin/v1/UserSchemaHelper	Access Token for principal under test	"organization": { "account": false, "searchable": true, "visible": true, "operational": false, "mva": false, "name": "organization", "type": "STRING", **"permissions": "rw",** "custom": false … **"values"**: ["banking"], **"valueSchema"**: ["{\"op\":\"eq\",\"name\":null, \"value\":\"banking\"}"], "displayName": "Organization", }	The highlighted and underlined output shows evaluated RDS and RIS User constraints of the organization attribute for this principal as follows: • RDS permissions: rw • RIS – values: allowed values: banking – valueSchema: evaluated RIS “value eq banking”
		"groups": { "account": **false**, "searchable": **false**, "visible": **true**, "operational": **false**, "mva": **true**, **"values"**: ["CommercialBanking", "RetailBanking"], **"valueSchema"**: ["{\"op\":\"eq\",\"name\":null, \"value\":\"CommercialBanking \"}",	The highlighted and underlined output shows evaluated RDS and RIS User constraints of the groups attribute for this principal as follows: • RDS permissions: r • RIS – values: allowed values: • CommercialBanking • RetailBanking • valueSchema: evaluated RIS – “value eq CommercialBanking” – “value eq RetailBanking”

Running the Postman API Resource Authorization Demo

Describes how to run the step-by-step Resource Authorization demo using the Postman API.

The Resource Authorization demo provides a comprehensive demonstration of the following scenarios:

- A centralized model based on provisioning of resources and principals for two organizations (banking and investments)
- A decentralized model using delegation of managers to individual resources
- Admin Role and Resource Delegation

The demo provides setup and teardown of all data including:

- Organization-based clients
- Organization-based functional admins
- End Users, Groups Applications, IDPs. IDP Discovery Policies, Certificates
- Roles and Constraints

The demo creates a clone of the ‘Default Constraint’, and relies on these out-of-the-box constraints for most the use cases.

Running the Demo Setup

The Resource Authorization demo is part of the `AuthHub.postman_collection.json`. Run the Setup folder as a runnable collection using `Run Folder` as a run-once option. You should check **Persist Responses for a session** to check for any specific API failure responses.

Running the Resource Authorization Requests

The folders in this section execute specific authorization use cases. Each folder has a set of requests that are intended to be executed in the sequence defined. To ensure expected results, follow the sequence; Grant, Execute Operations, Revoke.

Verifying Expected Results

The Resource Authorization Folder has a subfolder that is named `Helper Authorization Verifications`. These helpers can be used to verify and troubleshoot results. The Helper requests use the same token that is used by the invoking principals in Resource Authorization requests. The attribute permissions and attribute values returned reflect the evaluated constraints for that principal.

Resource Authorization results for Symantec Identity Security Platform Resource APIs (such as User, Group, applications, and so on) can often return complex outcomes. Any IDSP Resource API that is subject to Resource Authorization supports the `explain` parameter. Use the `explain` parameter to provide detailed analysis and explanations of these outcomes.

See Understanding Resource Authorization Results using Explain.

Managing Authorization

Learn about Symantec Identity Security Platform Authorization Policies, administrator roles, and scopes that define the access permissions to be granted to an identity to access protected resources.

Within the IDSP, the process of authorization is managed through authorization policies. A collection of preloaded authorization policies controls access to administrative capabilities represented by individual permissions. These permissions serve as the basis for granting administrative capabilities to users, groups, or client applications. The following is the overview of the authorization methodology in IDSP:

- ***Permissions***: Determines the extent of access or the specific operations that the users, groups, or client applications can perform in IDSP. These permissions are modeled as OAUTH scopes used to secure IDSP APIs protected by an OAUTH security model. See Table of Scopes and its corresponding APIs.
- ***Policies***: Authorization Policies, (also referred to as AuthZ policies), defines the permissions that are granted to users, groups, or client apps within IDSP. These policies are governed by rules that specify the conditions for access permissions. IDSP comes preloaded with various tenant admin policies. However, only admins with the "urn:iam:t.adminroles" privilege, granted through a set of defined Admin Role APIs, can modify the "principal" condition within these policies. To know more about the Admin Roles API endpoints, see Authorization APIs.
- ***Roles***: Allows specific tasks or access rights to be delegated to users, groups, and client apps within IDSP. The solution offers various tenant admin roles, which are implemented through authorization policies. Each admin role is

equipped with distinct scopes, granting administrators the authority to execute their assigned tasks effectively. Details about the various tenant admin roles are covered in the next section. See Admin Roles.
Within the IDSP ecosystem, these administrators have the capability to perform their tasks using IDSP APIs.
The Admin Console UI has also been adjusted to support the Tenant Administrator (full access), Tenant Auditor (everything read-only), Credential administrator, and Identity administrator. All other admin roles are only supported by using APIs.
This comprehensive role-based access enables them to execute a range of administrative duties, including user lifecycle management, application provisioning, and configuration customization.

Important notes about Admin Roles:

- The admin policies that are preloaded into the solution are not removable by any of the administrators.
- The System Admin Policy Role has been entrusted with the authority to perform GET/POST/DELETE/PUT/PATCH operations using the AuthZ policies that are not embedded (seeded) in the solution. Additionally, they have the capability to modify ***ONLY*** the "***principal***" condition for any seeded policies (for example, Account Administrator Role). However, it is important to note that the System Administrator does not have the authority to delete any embedded IDSP policies.
- The Tenant Admin Policy Role is granted permission to modify **ONLY** the "***principal***" within an embedded policy (for example, Account Administrator Role). To know more about Policy condition, see Principle Condition.
- The ***PUT https://${SSP_FQDN}/<tenantName>/admin/v1/AuthZPolicies/{{authZPolicyID}}*** operation that a tenant admin could perform to update the "***principal***" condition for any embedded policy has been deprecated. Instead the POST operation using the https://${SSP_FQDN}/<tenantName>/admin/v1/AdminRolesDelegator API can be used.

Administrative Roles

The various predefined admin roles which are implemented by their respective policies have been explained in the following sections:

- Infrastructure Administrator
- System Administrator
- Signin Client
- Account Administrator
- Authentication Client
- Configuration Administrator
- Configuration Auditor
- Credential Administrator
- Identity Administrator
- Idstore Administrator
- Identity Client
- Integration Administrator
- Integration Auditor
- Risk Client
- Tenant Administrator
- Tenant Auditor
- Diagnostics Administrator
- User Password Administrator
- Registration Client Administrator

Infrastructure Administrator

Table 11: Infrastructure Administrator and Associated Privileges (scopes)

Policy Name	Purpose	Privileges given to this role
InfraPolicy	The Infrastructure Administrator role is associated with the client called, **InfraClient** which performs infra-level operations such as tenant management and also seeds the first System Administrator identity and grants appropriate users or groups to the System Admin role. This role is empowered to oversee various tasks related to Applications, ID Stores, Identity Providers, Authentication and Authorization Policies, Authentication Factors, Risk Providers, and more. The "***Break Glass***" privilege is assigned to the Infra Admin Policy (InfraPolicy) role with the purpose of handling critical situations in which admins holding the System Admin Policy role encounter difficulties in performing their tasks. For example, • when the secret for the system client has been lost and must be reset • authorization policy has been mistakenly updated to lock out administrators, and must be reset In general, this credential is the "***super user***" credential and you should store it in a secure location.	• "urn:iam:t.apps" • "urn:iam:t.ldapconfigs" • "urn:iam:t.idstoreconfigs" • "urn:iam:t.idpconfigs" • "urn:iam:t.authpolicies" • "urn:iam:t.authzpolicies" • "urn:iam:g.settings" • "urn:iam:t.configs" • "urn:iam:t.signingkey" The privileges that are associated with the ***Infrastructure Administrator*** role are restricted to "***Client Only***," with no extension of these privileges to regular "User" and "Group" entities.

System Administrator

Table 12: System Administrator Role and Associated Privileges (scopes)

Policy Name	Purpose	Privileges given to this role
SystemAdminPolicy	The System Administrator role is granted permission to perform all activities that are related to system configurations. Using this role, the admin can invoke any system APIs defined in the solution to assess certain system admin tasks post to configure the environment and meet administration and/or security/ governance needs. For example, you may want to configure maximum expiration interval for tokens, or delegate the right to perform system administration to some admin users, etc. These tasks are performed by Users or Applications having the System Admin role. For convenience, you can use the"SystemClient" credential that is seeded out of the box to perform such tasks. This role is empowered to oversee various tasks that are related to Applications, ID Stores, Identity Providers, Authentication and Authorization Policies, Authentication Factors, Tenant Configurations, Global Settings, Admin Roles, and many more. The "***crosstenant***" ("urn:iam:g.crosstenant") scope granted to the System Administrator allows the admin to carry out operations across tenants by obtaining a cross-tenant Access Token (AT). For example, the System Admin can perform GET, POST, DELETE, PUT, or PATCH operations on policies that are not embedded (seeded) in the solution. Additionally, they have the capability to modify ***ONLY*** the "***principal***" condition for any embedded policies. However, it is important to note that the System Administrator does not have the authority to delete any embedded IDSP policies	• "urn:iam:g.tenant" • "urn:iam:g.crosstenant" • "urn:iam:t.authenticate" • "urn:iam:t.apps" • "urn:iam:t.certs" • "urn:iam:t.secrets" • "urn:iam:t.secretsgetter" • "urn:iam:t.ldapconfigs" • "urn:iam:t.idstoreconfigs" • "urn:iam:t.idpconfigs" • "urn:iam:t.authpolicies" • "urn:iam:t.authzpolicies" • "urn:iam:g.settings" • "urn:iam:t.configs" • "urn:iam:t.signingkey" • "urn:iam:t.adminroles" • "urn:iam:g.authzpolicywriter" The privileges that are associated with the ***System Administrator*** role extends to "***Client***", "***User***" and "***Group***" entities

Tenant Administrator

Table 13: Tenant Administrator Role and Associated Privileges (scopes)

Policy Name	Purpose	Privileges given to this role
TenantAdminPolicy	The Tenant Administrator role is granted permission to perform all activities that are related to a tenant. The tenant policy that represents this role is associated with the client called, **DefaultTenantClient** and the scope notation, `urn:iam:t.*` represents tenant-level privileges. A user named, "***DefaultTenantAdminUser"*** with full administrative rights is also provisioned. The Tenant Administrator role is empowered to oversee various tasks that are related to Applications, ID Stores, Identity Providers, Authentication and Authorization Policies, Authentication Factors, Tenant Configurations, Global Settings, Admin Roles, Secrets, Signing Keys, and many more. Some of the tasks that a tenant admin performs are listed here: • Creating an "application" entity representing protected applications • Creating and managing Authentication Policies defining the level of authentication that is required by the application • Managing configuration settings such as certificates, message templates, available authentication factors, etc. • Creating and Managing a "LDAPConfig" entity representing the identity store with users to be authenticated by IDSP • Delegating Tenant Admin role to users and groups. Also to applications that wish to invoke IDSP APIs.	• "urn:iam:t.all" The privileges of ***Tenant Administrator*** role extends to "***Client***", "***User***" and "***Group***" entities

Signin Client

Table 14: Signin Client Role and Associated Privileges (scopes)

Policy Name	Purpose	Privileges given to this role
SigninClient	The Signin Client role is granted permission to view and manage the out-of-the-box SignIn application that is provided by IDSP. The Signin Client policy that represents this role is associated with the client called, **SigninClient**. The Signin Client Role is empowered to oversee various tasks that are related to Factor Authentication, Branding, Password Reset, UI Locale, and more. The crosstenant ("urn:iam:g.crosstenant") scopes granted to the Signin Client allows the admin to carry out operations across tenants by obtaining a cross-tenant Access Token (AT).	• "urn:iam:t.authenticate" • "urn:iam:g.crosstenant" The privileges that are associated with the ***Signin Client*** role are restricted to "***Client Only***," with no extension of these privileges to regular "User" and "Group" entities.

Account Administrator

Table 15: Account Administrator Role and Associated Privileges (scopes)

Policy Name	Purpose	Privileges given to this role
AccountAdminPolicy	The Account Administrator role is granted permission to manage user accounts in IDSP. For example, the Account Administrator can check the user's "Status", and also update the user's account status as "Locked" or "Unlocked" in the ID Store.	"urn:iam:t.accountadmin" The privileges that are associated with the ***Account Administrator*** role extends to "***Client***", "***User***" and "***Group***" entities.

Authentication Client

Table 16: The Authentication Client Role and Associated Privileges (scopes)

Policy Name	Purpose	Privileges given to this role
AuthClientPolicy	The Authentication Client role is granted permission to perform operations that are related to authentication to implement a custom Signin app. The Authentication Client policy that represents this role is associated with the client called, **SigninClient** which performs authenticate operations for the SignIn app. The Authentication Client role grants clients the capability to initiate and execute an authentication flow in IDSP. It does not grant any additional privileges, and the desired purpose is to obtain an access token for the user with their designated scopes. The user may be a tenant administrator or a user with a self-service API. .	"urn:iam:t.authenticate" The privileges that are associated with the ***Authentication Client*** role are restricted to "***Client Only***," with no extension of these privileges to regular "User" and "Group" entities.

Configuration Administrator

Table 17: Configuration Administrator Role and Associated Privileges (scopes)

Policy Name	Purpose	Privileges given to this role
ConfigurationAdminPolicy	The Configuration Administrator role is empowered to oversee various tasks that are related to Security Settings, Authentication policies, ID Stores, Tenant Configurations, Certificates, Secrets, Signing Keys, and more.	• "urn:iam:t.configs" • "urn:iam:t.authpolicies" • "urn:iam:t.idstoreconfigs" • "urn:iam:t.certs" • "urn:iam:t.secrets" • "urn:iam:t.signingkey" • "urn:iam:t.idstorebrowser" • "urn:iam:t.adminroles" The privileges that are associated with the **Configuration Administrator** role extends to "***Client***", "***User***" and "***Group***" entities.

Configuration Auditor

Table 18: Configuration Auditor Role and Associated Privileges (scopes)

Policy Name	Purpose	Privileges given to this role
ConfigurationAuditorPolicy	The Configuration Auditor role is granted permission to audit tasks that are related to Security Settings, Authentication policies, ID Stores (Users and Groups), Tenant Configurations, Certificates, Secrets, Signing Keys, Admin Roles, and more.	• "urn:iam:t.configs" • "urn:iam:t.authpolicies" • "urn:iam:t.idstoreconfigs" • "urn:iam:t.certs" • "urn:iam:t.secrets" • "urn:iam:t.signingkey" • "urn:iam:t.auditonly" • "urn:iam:t.adminroles" • "urn:iam:t.idstorebrowser" The privileges that are associated with the ***Configuration Auditor*** role extends to "***Client***", "***User***" and "***Group***" entities.

Credential Administrator

Table 19: Credential Administrator Role and Associated Privileges (scopes)

Policy Name	Purpose	Privileges given to this role
CredentialAdminPolicy	The Credential Administrator role is granted permission to oversee various aspects in an organization, including managing user account lock status, credentials, trusted and recognized devices, and overseeing user sessions.	• "urn:iam:t.userdata" • "urn:iam:t.session" The privileges that are associated with the ***Credential Administrator*** role extends to "***Client***", "***User***" and "***Group***" entities.

Identity Administrator

Table 20: Identity Administrator Role and Associated Privileges (scopes)

Policy Name	Purpose	Privileges given to this role
IdentityAdminPolicy	The Identity Administrator role is granted the authority to oversee the management of "users" and "groups" within the internal Identity Store. Additionally, users who are entrusted with this role have the permission to manage various other aspects such as user account lock status, credentials, trusted devices, known devices, and sessions.	• "urn:iam:t.users" • "urn:iam:t.groups" • "urn:iam:t.session" The privileges that are associated with the ***Identity Administrator*** role extends to "***Client***", "***User***" and "***Group***" entities.

Idstore Administrator

Table 21: Idstore Administrator Role and Associated Privileges (scopes)

Policy Name	Purpose	Privileges given to this role
IdstoreAdminPolicy	The Idstore Administrator role is granted the permission to oversee the management of both "users" and "groups" within the configured identity stores.	• "urn:iam:t.idstoreadmin" The privileges that are associated with the ***Idstore Administrator*** role extends to "***Client***", "***User***" and "***Group***" entities.

Identity Client

Table 22: Identity Client Role and Associated Privileges (scopes)

Policy Name	Purpose	Privileges given to this role
IdentityClientPolicy	The Identity Client role is granted the permission to oversee the identity-related operations.	• "urn:iam:t.identityclient" The privileges that are associated with the ***Identity Client*** role are restricted to "***Client Only***," with no extension of these privileges to regular "User" and "Group."

Integration Administrator

Table 23: Integration Administrator Role and Associated Privileges given to this role (scopes)

Policy Name	Purpose	Privileges
IntegrationAdminPolicy	The Integration Administrator role is granted the authority to manage Applications, IDPs (Identity Providers), and IDP Discovery policies. Additionally, they manage Identity Stores, Certificates, and Secrets.	• "urn:iam:t.apps" • "urn:iam:t.idpconfigs" • "urn:iam:t.idstoreconfigs" • "urn:iam:t.certs" • "urn:iam:t.secrets" • "urn:iam:t.idstorebrowser" • "urn:iam:t.idpdiscoverypolicies" • "urn:iam:t.dcr" The privileges that are associated with the ***Integration Administrator*** role extends to "***Client***", "***User***" and "***Group***" entities.

Integration Auditor

Table 24: Integration Auditor Role and Associated Privileges (scopes)

Policy Name	Purpose	Privileges given to this role
IntegrationAuditorPolicy	The Integration Auditor role is granted the authority to audit Applications, IDPs, IDP Discovery policies. Additionally, admins entrusted with this role can audit Identity Stores, Certificates, and Secrets. This role is equipped with the read-only access, and while cannot execute any operations, they are able to view all App, IDPs, and IDP Discovery policies.	• "urn:iam:t.apps" • "urn:iam:t.idpconfigs" • "urn:iam:t.idstoreconfigs" • "urn:iam:t.certs" • "urn:iam:t.secrets" • "urn:iam:t.auditonly" • "urn:iam:t.idpdiscoverypolicies" The privileges of ***Integration Auditor*** role extends to "***Client***", "***User***" and "***Group***" entities.

Risk Client

Table 25: Risk Client Role and Associated Privileges (scopes)

Policy Name	Purpose	Privileges given to this role
RiskClientPolicy	The Risk Client role is granted the authority to perform risk-related operations.	• "urn:iam:t.risk" The privileges of the ***Risk Client*** role are restricted to "***Client Only***," with no extension of these privileges to regular "User" and "Group."

Tenant Auditor

Table 26: Tenant Auditor Role and Associated Privileges (scopes)

Policy Name	Purpose	Privileges given to this role
TenantAuditorPolicy	The Tenant Auditor role is given the authorization to conduct audits on all operations within a tenant. They are equipped with the read-only access, and while they cannot execute any operations, they are able to view all tenant-related activities.	• "urn:iam:t.all" • "urn:iam:t.auditonly" • "urn:iam:t.adminroles" The privileges of ***Tenant Auditor*** role extends to "***Client***", "***User***" and "***Group***" entities.

Diagnostics Administrator

Table 27: Diagnostics Administrator Role and Associated Privileges (scopes)

Policy Name	Purpose	Privileges given to this role
DiagnosticsAdminPolicy	This is for internal use only.	• "urn:iam:t.diagnosticsadmin"

User Password Administrator

Table 28: User Password Administrator Role and Associated Privileges (scopes)

Policy Name	Purpose	Privileges given to this role
UserPasswordAdministratorPolicy	The User Password Administrator is granted permission to manage user passwords.	• "urn:iam:t.userpasswordadmin" The privileges of ***User Password*** role extends to "***Client***", and "***User***" entities.

Registration Client Administrator

Table 29: Registration Client Administrator Role and Associated Privileges (scopes)

Policy Name	Purpose	Privileges given to this role
RegistrationClientPolicy	The Registration Client Administrator is granted the authority to call the dynamic client registration API with the initial access token.	• "urn:iam:t.dcr" The privileges that are associated with the ***Registration Client*** role are restricted to "***Client Only***," with no extension of these privileges to regular "User" and "Group" entities.

See the following topics:

Authorization API

Learn about the Symantec Identity Security Platform Authorization Policy Stricture, Authorization APIs, its operations, and examples.

This topic includes the following sections:

- Authorization Policy Structure
- Authorization APIs
- Authorization API Examples
  - Performing GET operation on Tenant Authorization Policy
  - Performing GET operation on Admin Roles
  - Performing POST operation on Admin Roles
  - Performing DELETE operation on Admin Roles
- Examples of Managing System Admin Operations
- Steps to grant "$AUTHCLIENT_PRIVILEGES" privileges to a client app
- Performing GET operation on My Admin Roles

Authorization Policy Structure

Authorization Policies, also referred to as AuthZ policies, determine the permissions that should be assigned to a user, group, or client application for accessing and performing actions on a protected resource. An administrator can create an authorization policy for an application, and can perform CRUD operations on it. Each policy comprises of rules, and each rule comprises of "**conditions**" and "**result**", which helps in determining how the admins should be granted permissions

and access to the solution. Eventually, the authorization policy lays out an authorization guideline for the admins which is governed by the "***principal***" condition that is specified within the rules of the policy. The "***principal***" condition supports three values, "clientApp", "user" and "group".

NOTE

- Symantec Identity Security Platform provides a default OOTB authorization policy for OOTB application (called SSP_APP). This policy cannot be updated or edited. However, with Symantec Identity Security Platform v4.0 onwards, you can now create authorization policy for custom applications, such as a Resource Server app.
- Application group is not supported in Authorization policy.

The following sample is an example of a request payload for an Authorization Policy:

```
{
"policyName": "SampleAdminAuthzPolicy",
"description": "Sample admin authorization policy",
"status": "active",
"isGrantableClientOnly": false,
"isSubdelegatable": false,

"displayName": "Sample admin authorization policy",
"apps": [
{
"name": "SSP",
"id": "$SSP_APP"
}
],
"rules": [
{
"conditions": {
  "principal": {
      "clientApp": {
          "operator": "in",
          "value": [
              "<CHANGE-ME>"
          ]
      },
      "user": {
          "operator": "in",
          "value": [
              "<CHANGE-ME>"
          ]
      },
      "group": {
          "operator": "in",
          "value": [
              "<CHANGE-ME>"
          ]
      }
  }
},
"result": {
  "msg": "This is a sample admin authorization policy",
  "privileges": [
```

```
        "urn:iam:t.idpconfigs",
        "urn:iam:t.ldapconfigs",
        "urn:iam:t.idstoreconfigs"
    ]
  }
  }
  ]
  }
```

Authorization Policy Attributes

The details of the policy attributes are described here:

- **policy name** – The name displays the title of the policy
- **description** – The description details a brief about the policy
- **status** – The status displays whether a policy is **active** or **inactive**
- **isGrantableClientOnly** - This attribute is a boolean value that restricts the values that can be passed when set to "true" or "false."
  - When "isGrantableClientOnly" is set to "***true***," it only permits "***clientApp***" in the principal condition.
  - When "isGrantableClientOnly" is set to "***false***," it allows "***User***," and "***Group***" in the principal condition.
- **isSubdelegatable** - This attribute is a boolean value that restricts whether a principal who has been granted a role can then delegate that role to another principal.
  - When "isSubdelegatable " is set to "***true***," the principal can delegate the role to another principal. The Delegate option for that role appears in the Administrative Console, and the role can be delegated using the `AdminRolesSubdelegator` API.
  - When "isSubdelegatable " is set to "***false***," the principal cannot delegate the role to another principal. The Delegate option for that role does not appear in the Administrative Console, and any attempts to delegate the role using the `AdminRolesSubdelegator` API fail.
- **displayName** - This attribute is used to provide a descriptive title or identifier for the policy, making it easier for administrators and users to understand the function of the policy.
- **apps** – This attribute denotes the name and id of the "clientApp" to which this authorization policy is applied. An OOTB authorization policy with client app (called $SSP_APP) is provided by Symantec Identity Security Platform. This authorization policy cannot be updated or edited.
  - With Symantec Identity Security Platform v4.0 onwards, you can create separate authorization policy for a custom application such as OAuth resource server application.

  For more information on apps in general, see Application API.
- **rules** - Rules include **conditions** and **result**. If the specified conditions in the rule are met, then the corresponding result is applied.
  - **conditions**: This attribute allows you to specify a "***principal***" condition to a rule. The "***principal***" condition supports these values: "***clientapp"***, "***group"*** and "***user***". To know more about users and groups, see Principle Condition.
  - **result** - This property displays the following two sub-properties:
    - **msg**- This property allows for a brief, informative description of the authorization policy. This property can include details about the objectives of the policy, usage guidelines, or any other relevant information to help admins understand its role and functionality."
    - **privileges**- This attribute outlines the set of permissions that are granted by the authorization policy. This attribute specifies the actions, operations, or capabilities that users, groups, or clients are authorized to perform on the protected resource.

Authorization APIs

As a System Administrator, you can use the following Security APIs to retrieve and update privileges of the client apps or users in the system.

Operation Description	Admin Roles	Operation Type	Endp
Retrieves all AuthZ Policies	System/Tenant Admin	GET	https https
Retrieves the AuthZ policy of the given policy Id.	System/Tenant Admin	GET	https https
Creates a new AuthZ Policy	System Admin	POST	https
Updates existing AuthZ Policy of the given policy Id.	System Admin	PUT	https ICY_
Deletes an AuthZ Policy by specifying of the given policy Id. ***Note that System admins cannot delete the embedded policies.***	System Admin	DELETE	https POL To fo Reso
Admin Role APIs			
Retrieves all the admin roles that are configured in the solution	System/Tenant Admin	GET	https https
Grants access to an admin role. With this API, the admin can overwrite only the "***principal"*** condition in the policy configuration. (The "***principal"*** condition can include Group, User, and Client App).	System/Tenant Admin	POST (Grants admin access)	https https
Revokes admin access from an administrator role. With this API, the admin can overwrite only the "***principal"*** condition in the policy configuration. (The "***principal"*** condition can include Group, User, and Client App).	System/Tenant Admin	DELETE (Revokes admin access)	https https
Returns the list of admin capabilities that are associated with the given user.	User Access Token	GET	https

Important notes about Admin Roles:

- The admin policies that are preloaded into the solution are not removable by any of the administrators.
- The System Admin Policy Role has been entrusted with the authority to perform GET/POST/DELETE/PUT/PATCH operations using the AuthZ policies that are not embedded (seeded) in the solution. Additionally, they have the capability to modify ***ONLY*** the "***principal***" condition for any seeded policies (for example, Account Administrator Role). However, it is important to note that the System Administrator does not have the authority to delete any embedded IDSP policies.
- The Tenant Admin Policy Role is granted permission to modify **ONLY** the "***principal***" within an embedded policy (for example, Account Administrator Role). To know more about Policy condition, see Principle Condition.
- The ***PUT https://${SSP_FQDN}/<tenantName>/admin/v1/AuthZPolicies/{{authZPolicyID}}*** operation that a tenant admin could perform to update the "***principal***" condition for any embedded policy has been deprecated. Instead the POST operation using the https://${SSP_FQDN}/<tenantName>/admin/v1/AdminRolesDelegator API can be used.

See Managing Authorization in IDSP using the Admin Roles.

NOTE

- To know the value of ${SSP_FQDN} environment variable, see Configuring IDSP Environment Variables.
- The default value for `<tenantName>` is "default". "system" is the default value for <systemTenantName>.
- Replace the text {text}/<text> including {}/<> characters with appropriate values in all the endpoints.

For example: `https://${SSP_FQDN}/<tenantName>/admin/v1/AuthenticationFactor` should look similar to: `https://example.com/default/admin/v1/AuthZPolicies`

- To know about the scopes that are supported by these endpoints, see Rest APIs and Associated Privileges section.

Example of Authorization API Operations

Performing GET operation on Tenant Authorization Policy

The following example shows the request and response of ***Tenant Authorization Policy API***.

Perform a GET request using the following Authorization API:

```
https://${SSP_FQDN}/<tenantName>/admin/v1/AuthZPolicies
```

The response fetches the authorization policies.

```

For sample request and response payloads of all the mentioned URLs, refer to Security API Swagger documentation.

Performing GET operation on Admin Roles

The following example shows the GET request and response of the ***Admin Roles Delegator API***.

Perform a GET request using the following Authorization API:

```
https://${SSP_FQDN}/<tenantName>/admin/v1/AdminRolesDelegator
```

The response fetches all the embedded policies of the Admin roles in IDSP. Response:

```
[

{

"policyName": "SystemAdminPolicy",

"description": "Role for the System Administrator",

"displayName": "System Administrator",
```

```
"status": "active",
"isGrantableClientOnly": false,
"apps": [
{
  "name": "ssp",
  "id": "$SSP_APP"
}
],
"rules": [
{
  "conditions": {
      "principal": {
          "clientApp": {
              "operator": "in",
              "value": [
                  "$SYSTEM_CLIENT_APP_ID"
              ]
          }
      }
  },
  "result": {
      "msg": "This is System admin authorization policy",
      "privileges": [
          "urn:iam:g.tenant",
          "urn:iam:g.crosstenant",
          "urn:iam:g.settings",
          "urn:iam:t.configs",
```

```
            "urn:iam:t.idpconfigs",
            "urn:iam:t.ldapconfigs",
            "urn:iam:t.idstoreconfigs",

Performing POST operation on Admin Roles

The following example shows the POST request and response of the ***Admin Roles Delegator API***.

Perform a POST request using the following Authorization API:

```
https://${SSP_FQDN}/<tenantName>/admin/v1/AdminRolesDelegator
```

Request: The following example shows the payload where the admin is requesting to add a user who is known as "droth".

```
{
"id": "d9122c83-7ec5-4450-a31c-7b99c88a5e51",
"principal": {
"user": {
"operator": "in",
"value": [
  "droth"
]
}
}
}
```

Response: The response returns the name of the role which has been updated with a new user (droth).

```
{
"id": "d9122c83-7ec5-4450-a31c-7b99c88a5e51",
"name": "ConfigurationAdminPolicy",
"displayName": "Configuration Administrator",
"description": "Manage security Settings, Signing Keys, Authentication Policies. Also manage Identity Stores,
 Certificates, Secrets.",
"principal": {
"user": {
"operator": "in",
"value": [
  "droth",
"nbruce"
]
}
```

```
},
"isGrantableClientOnly": false
}
```

Performing DELETE operation on Admin Roles

The following example shows the DELETE request and response of ***Admin Roles Delegator API***.

Perform a DELETE request using the following Authorization API:

```
https://${SSP_FQDN}/<tenantName>/admin/v1/AdminRolesDelegator
```

API Request: In the following example, the admin is revoking the access from the user, "droth":

```
{
"id": "d9122c83-7ec5-4450-a31c-7b99c88a5e51",
"principal": {
"user": {
"operator": "in",
"value": [
  "droth"
]
}
}
}
```

API Response: The response displays the role from which the user (droth) has been revoked.

```
{
"id": "d9122c83-7ec5-4450-a31c-7b99c88a5e51",
"name": "ConfigurationAdminPolicy",
"displayName": "Configuration Administrator",
"description": "Manage security Settings, Signing Keys, Authentication Policies. Also manage Identity Stores,
 Certificates, Secrets.",
"principal": {
"user": {
"operator": "in",
"value": [
"nbruce"
]
}
},
"isGrantableClientOnly": false
}
```

Examples of Managing System Admin Operations

Follow these steps:

You must configure the LDAP Directory containing your system administrators and must grant the System Admin Role to the user or group.

1. Run the following API to create an LDAP Configuration to connect with the LDAP Id store and authenticate users:
   Request:

   ```
   curl -L -X POST 'https://iam.example.com/system/admin/v1/LDAPconfigs' \
   -H 'Content-Type: application/json' \
   -H 'Authorization: Bearer <token>' \
   --data-raw '{
   ```

```
"configName": "SytemAdminStore",
"configDescription": "SystemAdministrator Store",
"sslEnabled": "NO",
"ldapQueryStart": "(&(cn=",
"ldapQueryEnd": ")(objectClass=*))",
"attributes": "uid,displayName,telephoneNumber,mail,memberof",
"objectClasses": "string",

2. Grant a System Admin Role to a user or a group in the LDAP Directory.
   Get the system app id to authzclient system policy:
   Request:

```
curl -L -X GET 'https://iam.example.com/system/admin/v1/Apps' \
-H 'Authorization: Bearer <token>'
```

   Response:

```
[
```

```
{
"status": "active",

3. Update the Authorization (AuthZ) policy with the system admin group:
   Request:

```
curl -L -X PATCH 'https://iam.example.com/system/admin/v1/AuthZPolicies/27d6ac59-387c-4311-81eb-
c6632c2abe47' \
-H 'Content-Type: application/json' \
-H 'Authorization: Bearer <token>' \
--data-raw '{
"rules": [
{
"conditions": {
  "principal": {
      "clientApp": {
          "value": [

              "256fe4b4-1d37-4c30-91fa-f8d8d1262e47"
          ]
      }

  ,
      "group": {
          "value": [
              "Admin"
          ]
      }
}
}
}
```

```
]
}'
```

Response:

```
{
"policyId": "27d6ac59-387c-4311-81eb-c6632c2abe47",
"policyName": "SystemAdminPolicy",
"description": "Policy for System Admin",
"status": "active",
"matchAnyApp": false,
"apps": [
{
"name": "ssp",
"id": "3690ac36-c805-43ef-8318-627023b16d64"
}
],
"rules": [
{
"conditions": {
  "principal": {
      "group": {
          "operator": "in",
          "value": [
              "Admin"
          ]
      },
      "clientApp": {
          "operator": "in",
          "value": [
              "256fe4b4-1d37-4c30-91fa-f8d8d1262e47"
          ]
      }
  }
},
"result": {
  "msg": "This is System admin authorization policy",
  "privileges": [
      "urn:iam:g.crosstenant",
      "urn:iam:g.settings",
      "urn:iam:t.ldapconfigs",
      "urn:iam:t.authzpolicies",
      "urn:iam:t.authenticate",
      "urn:iam:t.apps",
      "urn:iam:t.certs",
      "urn:iam:t.signingkey"
  ]
}
}
],
"createdDate": "2020-06-10 05:36:21",
"updatedDate": "2020-06-10 05:36:21"
}
```

Once the Admin role has been updated, it is now possible to invoke APIs in the context of a specific user.

Steps to grant "$AUTHCLIENT_PRIVILEGES" privileges to a client app, click here.

1. Perform a GET https://${SSP_FQDN}/<tenantName>/admin/v1/AuthZPolicies to retrieve all the authorization policies configured in the solution.
2. Look for the "AuthClientPolicy" and copy the policy Id and the rule Id of the conditions>principal>clientApp. A sample of "AuthClientPolicy" is shown in the following example:

```
{
"policyId": "fac76b22-7555-4cf2-86f0-6a6028acba00",
"policyName": "AuthClientPolicy",
"description": "Policy for Authentication Client",
"status": "active",
"matchAnyApp": false,
"apps": [
{
  "name": "SSP",
  "id": "$SSP_APP"
}
],
"rules": [
{
  "id": "2d7978fb-5bed-4a26-90b3-cc3788c27d26",
  "conditions": {
      "principal": {
          "clientApp": {
              "operator": "in",
              "value": [
                  "42753c4a-08be-4db6-a589-09fd883c1efe"
              ]
          }
      }
  },
  "result": {
      "msg": "This policy allows clients to call authentication APIs",
      "privileges": [
          "$AUTHCLIENT_PRIVILEGES"
      ]
  }
}
],
"createdDate": "2021-04-28 05:15:49",
"preventedOperations": "Delete"
}
```

3. Go to the PATCH https://${SSP_FQDN}/<tenantName>/admin/v1/AuthZPolicies/<REPLACE-BY-POLICY-ID>
   a. Replace the policy id in the header. Use the policy Id of the AuthClientPolicy.
   b. In the following payload, replace the value of {{RuleId}} from the preceding authClient Policy.
   c. Replace the value of the app Id that you have got after creating the app.

```
{
"op": "add",
"path": "/rules/[id eq \"{{RuleId}}\"]/conditions/principal/clientApp",
"value": "<REPLACE-BY-CLIENT-APPID>"
},
```

4. The response grants "$AUTHCLIENT_PRIVILEGES" to the application.

```
{
"policyId": "fac76b22-7555-4cf2-86f0-6a6028acba00",
"policyName": "AuthClientPolicy",
"description": "Policy for Authentication Client",
"status": "active",
"matchAnyApp": false,
"apps": [
{
"name": "SSP",
"id": "$SSP_APP"
}
],
"rules": [
{
"id": "2d7978fb-5bed-4a26-90b3-cc3788c27d26",
"conditions": {
  "principal": {
      "clientApp": {
          "operator": "in",
          "value": [
              "9a53235f-e64f-4cb3-b0a9-bffa4e8367e7",
              "42753c4a-08be-4db6-a589-09fd883c1efe"
          ]
      }
  }
},
"result": {
  "msg": "This policy allows clients to call authentication APIs",
  "privileges": [
      "$AUTHCLIENT_PRIVILEGES"
  ]
}
}
],
"createdDate": "2021-04-28 05:15:49",
"updatedBy": {
"principalType": "CLIENT",
"principalId": "b57baefb-cea4-4459-86ee-c19fcefc8c45",

},
"updatedDate": "2021-05-14 09:57:07",
"preventedOperations": "Delete"
}
```

Performing GET operation on My Admin Roles

- Perform a GET request using the following Authorization Admin API:

  NOTE
  Before performing this step, ensure that you have retrieved the **User Access Token**.

  ```
  GET https://${SSP_FQDN}/<tenantName>/admin/v1/MyAdminRoles
  ```

  The response fetches the list of admin capabilities that are associated with the given user.

  ```
  [
  ```

```
{
"id": "0b3d26ac-6b32-42c6-b3ef-7c8cae61883f",
"name": "TenantAdminPolicy",
"displayName": "Tenant Administrator",
"description": "Manage everything in a tenant",
"privileges": [
"urn:iam:t.all"
]
},
{
"id": "1b38a3ef-3dd8-49be-9c86-c3acc92ecb68",
"name": "CredentialAdminPolicy",
"displayName": "Credential Administrator",
"description": "Manage user account credentials, trusted devices, known devices. Also manage user
 sessions.",
"privileges": [
"urn:iam:t.userdata",
"urn:iam:t.session"
]
}
]
```

Application Roles and Privileges

This topic explains how applications can retrieve user roles and privileges through multiple integration protocols.

Applications serve multiple types of consumers, including human users and non-human entities. Each consumer requires specific authorization and personalization to ensure the application behaves appropriately for their assigned access level.

The system determines the appropriate access level using access control concepts including:

- App Roles
- App Privileges
- Enterprise Groups
- User Attributes
- Business Rules
- Other access control mechanisms

Applications can discover app-specific access control concepts (such as App Roles and App Privileges) through multiple integration patterns. The application's architecture determines which integration pattern to choose from the available options.

Application Roles and Privileges

App Integration Approach	App Integration Protocol	App Cardinality	App Roles	App Privileges

User attributes returned by SCIM contains SCIM-standard roles & entitlement attributes	SCIM /Users	All apps	<pre>"roles": [

Functional Administration

Describes how tenant administrators (or select administrators with higher privileges) define Administrative Roles, Policies, User Schemas, Scoping Constraints, and assignment of privileges to Functional Administrators.

Functional Administration is the process during which the overall structure and security model is defined that will allow Business Administration to then perform its functions within this structure. Defining a deployment's Resource Authorization model and how the model will be deployed becomes a pre-requisite for functional administration. For Symantec Identity Security Platform, functional administration is the process in which tenant administrators (or select administrators with higher privileges) define administrative roles, policies, user schemas, scoping constraints, and assignment of privileges to functional administrators. This process may include certain resources that need tighter administrative control such as Groups, Applications, Certificates, and Secrets.

Transitioning to Business Administration

One critical aspect of functional administration is the ability to transition rights and responsibilities to business administrators. The transition typically involves granting initial access to administrators responsible for certain operations of the business such as managing particular user populations, or managing sets of applications and Identity Providers needed for their business responsibilities.

The transition from functional administration to business administration then allows business administrators to scale their administration capacity by delegating their rights and responsibilities. Under the delegation model, higher privileges typically required during functional administration are not required. Delegation allows you to delegate the privileges that you have without requiring special privileges. This allows business administration to scale up or down as needed.

- Role and Resource Access
- Delegation

Role and Resource Access

Describes how to use the criteria and scoping constraints of Resource Authorization to assign roles and grant access to resources.

Role and resource access is managed by the administrative grant role capability or by Resource Authorization delegation.

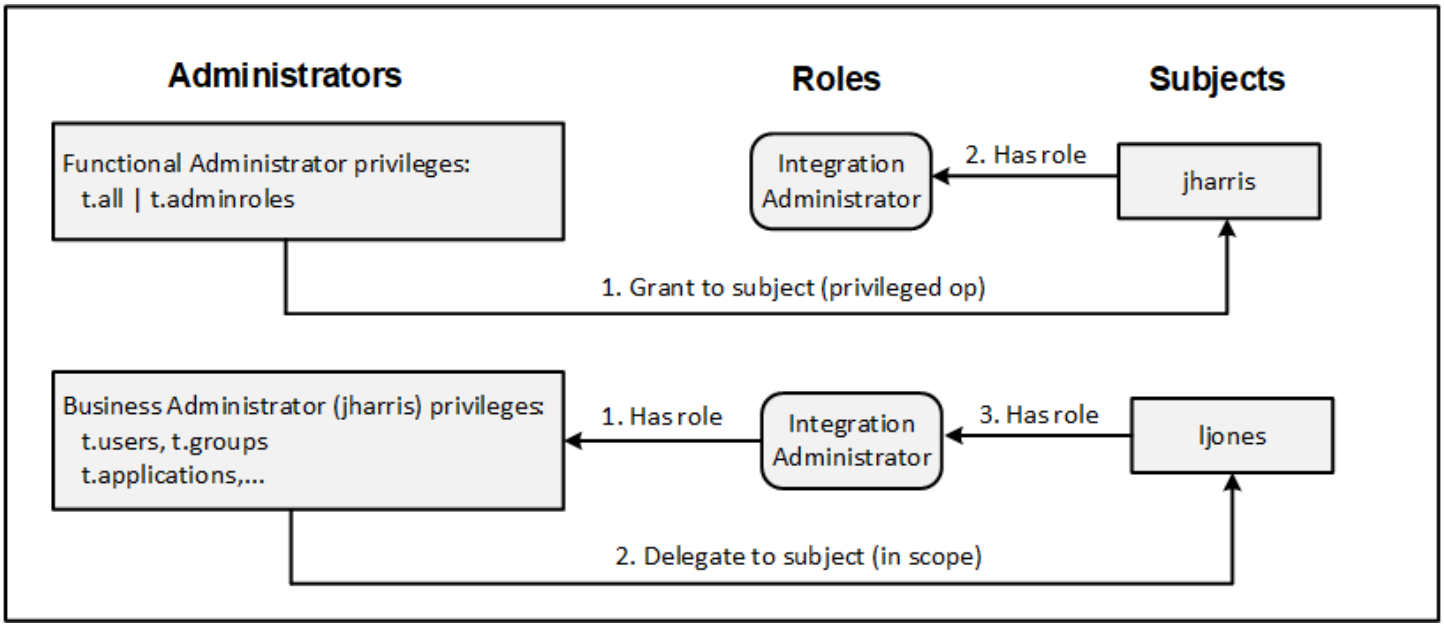
Granting Role Access

The grant role capability is restricted to privileged administrators. Resource Authorization introduces a delegation capability which allows administrators to delegate the roles that they have without requiring any higher privilege.

Administrator role delegation does impose enforcement over to whom an administrator can delegate privileges. The subject of the delegation must be within the admin scope of the administrator. However, administrators with higher privileges and that invoke delegation operations are not subject to these admin scope restrictions.

The role access options are shown in the following diagram:

Figure 5: Role Access Options



Granting Resource Access

The Resource Authorization capabilities include the ability for administrators to grant access to resources. This ability applies to the following resource types:

- Groups
- Applications
- Identity Providers
- Identity Provider Discovery Policies
- Certificates
- Secrets
- Authorization Policies

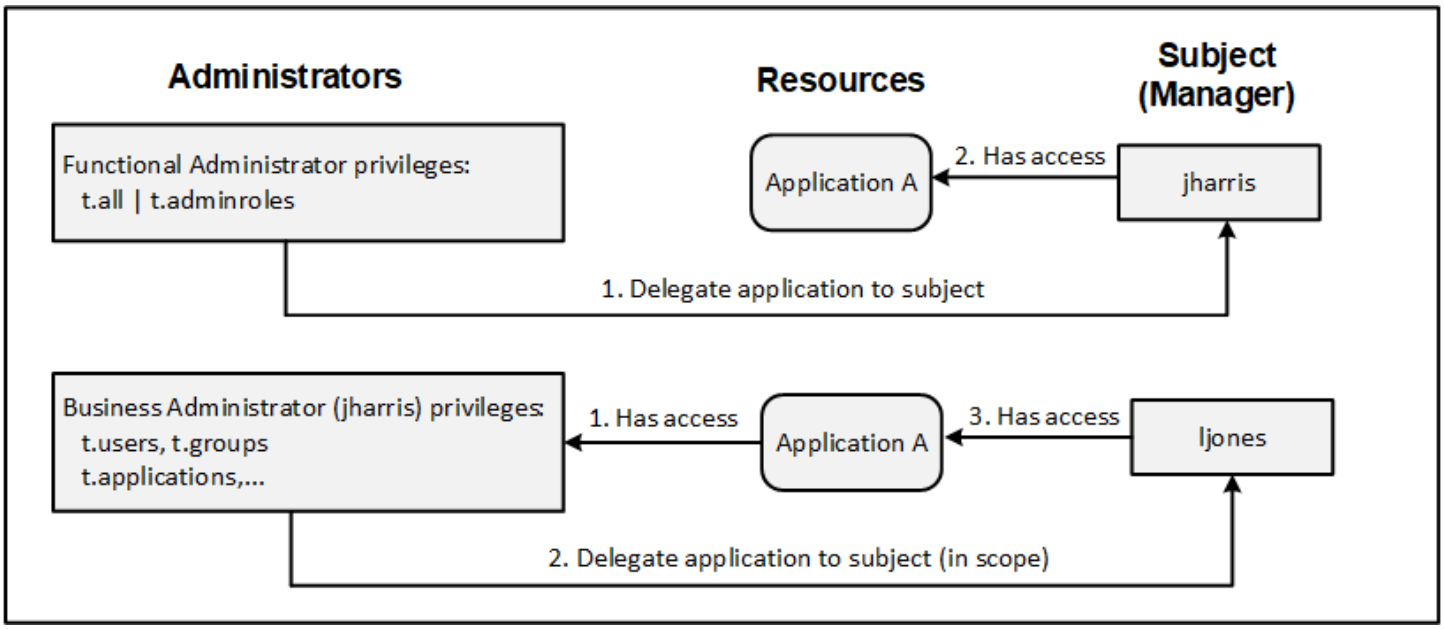
The granting of resources supports the `managedby` access control. When granting access to a resource, the subject is then added to the list of managers for the resource. When resource access is restricted by `managedby` access controls, only managers that are added through delegation are allowed access.

Resource delegation does impose enforcement over to whom an administrator can delegate privileges. The subject of the delegation must be within the admin scope of the administrator. However, administrators with higher privileges that invoke delegation operations are not subject to these admin scope restrictions. The higher privileges that are required for the grant role capability must include one of the following scopes:

- urn:iam:t.all
- urn:iam:t.adminroles

The resource access options are shown in the following diagram:

Figure 6: Resource Access Options



Delegation

Describes how delegation allows you to assign the roles or privileges of one entity to another entity.

Delegation is the ability to grant your roles or resources to others. This ability allows business administrators to scale administrative capability up or down as the business needs change.

There are two types of delegations: Admin Role Delegation and Resource Delegation. Adding or removing a delegation is subject to administrative scope checks. When attempting to delegate a role or a resource to a subject, the administrator must have administrative scope over the subject or else the delegation is denied. However, if the administrator initiated

the delegation attempts to remove a delegation, no administrative scope check is required; you can remove what you delegated.

However, if an administrator has the following privileges, no administrative scope checks are enforced:

- urn:iam:t.all
- urn:iam:t.adminroles

You can manage role and resource delegations (view, add, or remove) directly through the Delegation APIs. See Delegations APIs.

> **NOTE**
> You can also view or remove the roles and resources that are assigned by you or to you from the *Profiles* page of the Admin Console. See Profiles.

Delegations Definitions

The following list provides Symantec Identity Security Platform delegation-related terms and their definitions.

Principal (grantor) — The user (administrator) or client doing the delegation

Subject (grantee) — The user (administrator) or client/group to which access is being delegated

Resource Type — The type of the IDSP resource. The Resource Type must be one of the following options:

- Admin Role
- Group
- Application
- Identity Providers
- Identity Provider Discovery Policies
- Certificates
- Secrets
- Authorization Policies

Resource — The ID of the role or resource

Installing

Includes links to deployment overview, deployment sizing, cluster environment preparation, database considerations, deployment procedures, configuring admin access, upgrade instructions, and uninstallation guidelines for the Symantec Identity Security Platform solution.

IDSP enables the deployment of its instances in Kubernetes to manage containerized applications in a clustered environment. The solution enables container replication, scaling, high availability and simplifies the process of deployment, configuration, versioning, and updates.

To know more about the deployment of IDSP on Kubernetes, see the following topics:

- Overview of IDSP Deployment
- Sizing the Deployment
- Preparing the Infrastructure Before Deploying the Solution
- Database Considerations
- Deploying the Services
- Configuring Administrative Access
- Upgrading IDSP
- Uninstalling the Solution and Enclave Services

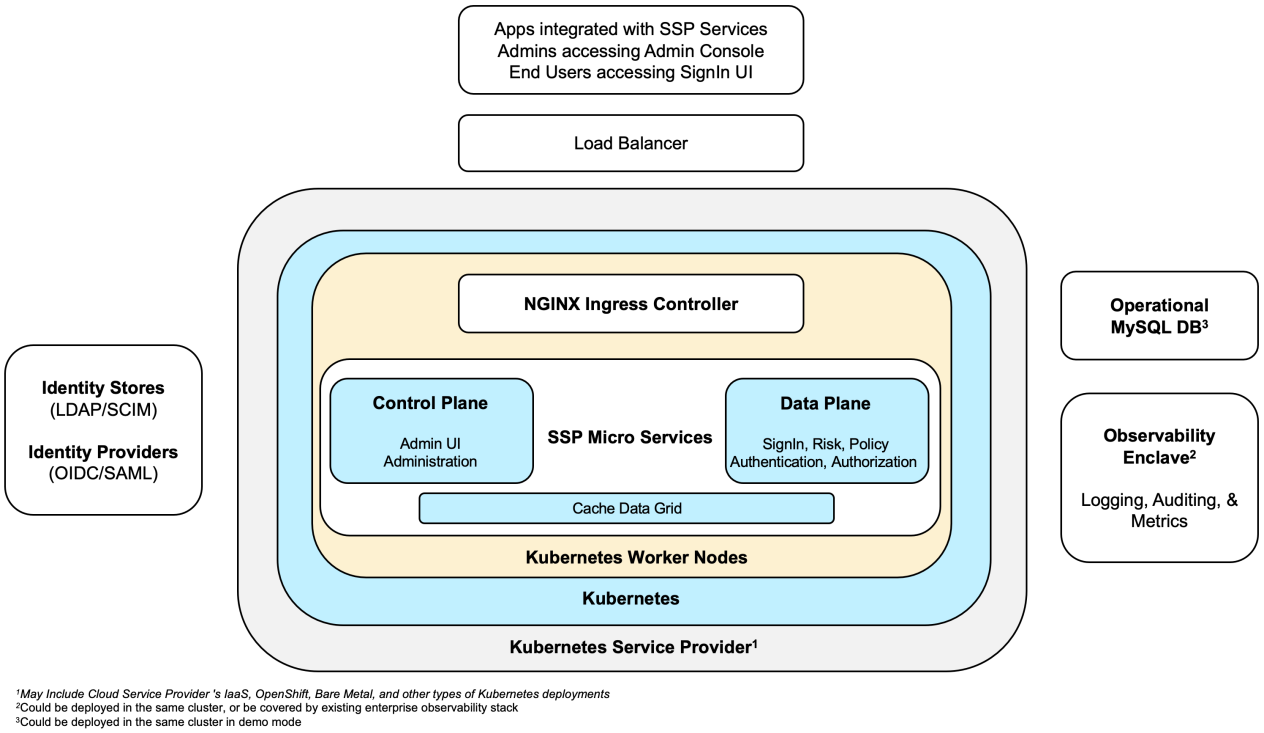
Overview of Symantec Identity Security Platform Deployment

Details the Kubernetes deployment of Symantec Identity Security Platform, covering its architectural components, namespace organization, and the roles and dependencies of its microservices.

This topic includes the following sections:

- Overview of IDSP Deployment in a Kubernetes Cluster
- IDSP Cluster Information
- IDSP Micro-Services Descriptions

The following image provides an overview of how IDSP is deployed in a Kubernetes Cluster environment.



[1]*May Include Cloud Service Provider 's IaaS, OpenShift, Bare Metal, and other types of Kubernetes deployments*
[2]Could be deployed in the same cluster, or be covered by existing enterprise observability stack
[3]Could be deployed in the same cluster in demo mode

IDSP Cluster Information

IDSP solution is composed of multiple microservices, each deployed as a container within a Kubernetes Pod. Readiness probes are configured for each microservice to manage the container lifecycle and ensure the Pod's availability to serve requests.

The following table outlines the IDSP namespaces and the Pods deployed within each.

Suggested namespaces	Services running under each namespace	Description
Ingress	NGINX Ingress	The external traffic to the IDSP is handled t configuration which is read by the Ingress C Chart provides the ingress configuration to the URI path.
logging	• Elasticsearch • Kibana	IDSP writes the logging to standard out stre default. All the logs that are generated by th stack (ElasticSearch, Fluent-bit, and Kibana
monitoring	• Prometheus and Grafana	The solution uses Prometheus for metric ins metrics data and alerts.

ssp	• hazelcast • opa • geolocation • admin • iarisk • azserver • auth-mgr • factor • identity • scheduler • SignIn UI • Admin Console • Self-Service Console • Infrastructure (Fluent-bit, Database) • Custom Metrics Prometheus Adapter	• IDSP microservices comprise Factor se • Security Services Platform comprises a • Infrastructure Services: — IDSP services write log messages in stream all messages to Elasticsearch — Custom Metrics Prometheus Adapte scaler.

IDSP Microservices Descriptions

The following table provides detailed descriptions and dependencies for each IDSP microservice.

Micro-Service Name	Description
hazelcast	**Cache service for IDSP** Provides high-performance distributed caching for the IDSP platform. Manages session state, configur tokens, and shared data across the microservices cluster. Ensures data consistency, supports cache in tolerance for cached data across multiple nodes in the Kubernetes deployment.
opa	**Open Policy Agent (Policy Engine)** Serves as the centralized policy decision point implementing fine-grained authorization policies. Evalua authorization policies, risk policies, and identity provider discovery policies. Processes policy queries fr as-code approach and returns policy decisions based on configured rules, contextual information, and
geolocation	**Geolocation Service** Provides IP-based geolocation services for risk assessment and location-based security analysis. Dete authentication requests, identifies country changes, detects VPN/proxy usage, and supports the risk en factors. Essential for compliance with geographic access restrictions and fraud detection.
admin	**Administration Operations Service** Comprehensive administrative service handling all tenant and system management operations. Provid applications, users, groups, policies, certificates, signing keys, identity stores, and system settings. Ma configurations, resource lifecycle, and administrative workflows through both REST APIs and the Admi
iarisk	**Intelligent Adaptive Risk Engine** IDSP risk assessment engine that evaluates user, client, and machine risk scores using behavioral ana location analysis, and historical patterns. Implements adaptive risk policies, manages risk thresholds, p authentication decisions.
azserver	**OAuth Authorization Server & SAML Identity Provider** Implements OAuth 2.0/OpenID Connect authorization server and SAML 2.0 identity provider functional (access tokens, ID tokens), authorization code flows, client authentication, SAML assertions, federation authentication. Manages signing keys for token and assertion and JWKS/SAML metadata publishing.
auth-mgr	**Authentication Orchestrator Service** Central authentication orchestration service that coordinates the complete multi-factor authentication fl policy evaluation, factor selection, risk-based authentication decisions, and integration with external ide communication between risk engine, policy engine, factor services, and identity stores to provide seam

factor	**Multi-Factor Authentication Service** Comprehensive authentication factor service supporting various authentication methods including pass push notifications, FIDO/WebAuthn, TOTP, custom authenticators, and biometric factors. Manages fac lifecycle management, and integrates with external authentication systems and IDSPcredential service
identity	**Identity Operations Service** Manages identity lifecycle operations for both internal identity store and external identity sources. Hand management, group operations, identity data persistence, and service account management. Provides synchronization, LDAP integration, and supports both disambiguation and authentication identity stores
scheduler	**Task Scheduling Service** Provides comprehensive job scheduling and background task execution capabilities for the IDSP platfo maintenance tasks, certificate renewals, cleanup operations, policy synchronization, audit log processi operations across the distributed system.
adminconsole	**Administrative Management Console** A web-based administrative interface for system and tenant administrators. Offers administrative workf comprehensive management of users, applications, policies, configurations, certificates, identity stores
signIn	**Authentication User Interface** Modern, responsive web-based user interface for authentication flows supporting multi-language locali accessibility features, and mobile-responsive design. Handles user interactions during authentication, f and self-service operations. Integrates with the authentication orchestrator for seamless user experien
selfserviceconsole	**End-User Self-Service Portal** A web-based self-service portal enabling end users to manage their authentication settings, view and r manage authentication factors, update profile information, perform password operations, and view auth intuitive interface for personal account management and credential lifecycle.

Kubernetes Support

This page mentions the supported Kubernetes and Helm versions in Symantec Identity Security Platform.

IDSP supports running the solution on Kubernetes. More specifically, we support all active Kubernetes releases, including equivalent OpenShift versions.

Kubernetes Distributions

IDSP specifically tests and supports the following Kubernetes distributions when running supported Kubernetes versions as indicated earlier:

- Azure Kubernetes Service (AKS)
- Amazon Elastic Kubernetes Service (EKS)
- Google Kubernetes Engine (GKE)
- OpenShift Container Platform (OCP)
- VKS (VCF with VMware vSphere Kubernetes Services)

The tested versions of Kubernetes and OpenShift are noted in the next section.

Recommended Kubernetes and Helm Version Requirements

The recommended Kubernetes requirements to deploy IDSP are mentioned in the following table:

Software	Description	Providers	Tested Versions
Kubernetes	Kubernetes (K8s) is an open-source system to manage containerized applications in a clustered environment.	Google Kubernetes Engine (GKE)	1.32, 1.33, and 1.34
		Amazon Kubernetes Service (EKS)	1.32, 1.33, and 1.34
		Azure Kubernetes Service (AKS)	1.32, 1.33, and 1.34
		OpenShift Container Platform (OCP)	OpenShift 4.18

Software	Description	Providers	Tested Versions
		VKS (VCF with VMware vSphere Kubernetes Services)	v1.31.4+vmware.1-fips
HELM	Helm is an application package manager running on top of Kubernetes which is used to deploy Helm charts.	_	3.10 and above

Prerequisites

Familiarize with the recommended software and hardware requirements before deploying a Symantec Identity Security Platform solution.

Before setting up the Kubernetes environment for IDSP, ensure that the following recommended prerequisites are met.

- Kubernetes and Helm Requirements
- Cloud Cluster Environment Requirements
- Sizing Your Deployment
- Supported Databases
- Supported User Repository
- LDAP Reasonable Commercial Effort Statement
- Security Consideration

Kubernetes and Helm Requirements

For supported Kubernetes and Helm requirements to deploy IDSP, see Kubernetes Support.

Cloud Cluster Environment Requirements

To deploy IDSP in a **production environment**, there are a number of considerations to be made to ready a cloud cluster. These are described in Preparing the Cloud Cluster Environment page.

Sizing Your Deployment

To effectively size a **production deployment**, see the "Sizing the Deployment" page for crucial information about your system's requirements. This page includes an attached, interactive sizing sheet. By entering details about your system into the sheet, the sizing sheet automatically computes and generates the necessary information for sizing your system's CPU and memory, database, and storage needs.

To deploy IDSP in a **demo mode**, see the table with minimum cluster infrastructure requirements here.

Supported Databases

To know about the supported databases in IDSP, see Database Considerations.

Supported User Repository

User Repository	Versions
Internal Identity Store	Embedded
Symantec Directory	14.1
Microsoft Active Directory	2016
SCIM	2.0

LDAP Reasonable Commercial Effort Statement

This Support Statement applies to IDSP product that offers documented support for one or more LDAP v3 compliant user stores. Broadcom strives to meet our clients' diverse and ever changing needs. Broadcom products support and manage many of today's leading platforms, operating systems and various user stores across the IT enterprise. Many of our clients use variants of the LDAP server implementations as user store, for example, Symantec Directory, Microsoft Active Directory, Oracle Directory services. Broadcom does not test every LDAP v3 compliant directory server and cannot certify specific client configurations. To facilitate a quick resolution and isolate the root cause of any potential product issue encountered running on LDAP v3 compliant user store, Broadcom is establishing the following support protocol for IDSP operated in these environments:

- The client is responsible for properly configuring their LDAP user store that must be compatible with LDAP v3 standard.
- The client is responsible for having an active maintenance agreement for both their IDSP product and for the LDAP v3 directory server.
- While Broadcom does not require that clients recreate each issue before contacting support, we can request that the client diagnose and troubleshoot specific issues on a supported LDAP v3 directory server. Broadcom will only do this when we have reason to believe that the issue is directly related to LDAP server variant that is in use.
- Compatible LDAP v3 variants are diverse; Broadcom may require extra time to understand, collect data, troubleshoot, and possibly reproduce reported issues.
- If Broadcom Support cannot directly identify the root cause as a Broadcom or an LDAP v3 compatible directory server issue, client can open a support issue with their LDAP vendor and any other necessary third-party vendors to expedite the resolution of the issue. Broadcom, the vendor(s), and the client will work together toward a quick resolution where there is business relationship mechanism to do so. Note if the customer does not have a Vendor support agreement for their LDAP directory server variant, there is no third-party Broadcom may work with.
- Any known issues with running IDSP on specific LDAP v3 compatible variants will be noted in the respective product documentation.

Security Considerations

See the Security Considerations section for guidelines to be applied on day one of the deployments.

Helm Charts

The Symantec Identity Security Platform uses Kubernetes container-orchestration system to deploy its application package. The package includes a set of helm charts that comprises a collection of Kubernetes manifest files. The helm charts help you to define, install, and upgrade services within the cluster.

Helm is a native tool of the Kubernetes that functions as a package manager and streamlines the deployed services within a cluster. To know more about HELM, refer to the HELM website.

A HELM chart includes the following files:

File Name	Description
Templates folder containing Kubernetes manifest files	The templates folder contains YAML file templates defining Kubernetes resources, for example, Deployments, Services, Ingress. When Helm evaluates a chart, it sends all the files in the templates folder through the template rendering engine along with a set of deployment configuration values. It then collects the results of those templates and sends them to Kubernetes.
values.yaml	This file contains the default values for a chart, including container image, service type, port, and so on. These values may be overridden by users during helm installation or helm upgrade.

Helm Charts

The IDSP package includes the following Helm Charts:

Helm Chart Name	Description
ssp	This chart deploys IDSP services.
ssp-sample-app	This chart deploys a sample application in IDSP.
ssp-infra	This is the IDSP Infrastructure chart that supplies optional Fluent-Bit log collector and demo database.
ssp-data	This is the IDSP ssp-data chart that uploads the fraud IP data into the IDSP (solution) database which is required for risk evaluation. ***Note***: You can deploy the "ssp-data" chart only after deploying the IDSP chart.

Reference Links:

- To know more about deploying the ssp, ssp-infra, and ssp-data chart, see Deploying the Symantec Identity Security Platform.
- To know about ssp-sample-app, see Deploying the Sample Application.

Sizing the Deployment

Learn about deployment sizing.

It is critical to ensure that Symantec Identity Security Platform is properly implemented within the time frame that is determined by your requirements. The more thoroughly you plan your deployment, the more solid your configuration is, and you meet timelines and milestones while staying within your budget.

This topic includes the following sections:

- Deployment Sizing Considerations
- Sizing Systems (includes an interactive deployment sizing sheet)
- Recommended Cluster Infrastructure Requirements for Demo Mode

Deployment Sizing Considerations

When sizing a deployment in production, consider reading and gathering information about the following important aspects regarding your system:

- ***Number of users supported***

Determine the number of users that are supported in your deployment based on system usage. Once you have determined the number of users, you can project future growth.

- ***Number of users that can authenticate concurrently***

  Determine the average number of users that can concurrently authenticate using IDSP. Equally important is to determine the maximum number of users that can concurrently (Peak Load) authenticate using IDSP so that the system can be configured to scale accordingly.
- ***Percentage of authentications that require MFA***

  Depending on the type of application and its associated policies, authentication can require a single factor or multiple factors (MFA). Determine what % of authentications require MFA as it impacts the overall requests throughput (req/sec), hence impacting the authentication throughput (auth/sec) that the system can support.
- ***High Availability Requirements***

  High Availability (HA) refers to the ability of your system to operate continuously for a specified length of time. Design your system to prevent single points of failure and support continuous availability. Before deciding IDSP deployment in HA mode, decide how critical the IDSP service is to warrant the deployment in HA mode and across multiple sites.

  If HA is required, based on the size of your deployment, you can create a deployment architecture using a single zone configuration. For larger deployments, consider implementing a multi zone configuration. If the service experiences a complete failure at one zone, you can redirect client traffic to another zone and you can continue with your operation.
- ***Protected Applications***

  Determine the type of applications that IDSP must protect. Applications can be web applications or programmatic clients (example, Mobile apps). Web applications are integrated using OIDC protocol and programmatic applications use the API-based integration with IDSP (OAuth2).

  The client type determines the components that are required for deployment and sizing. For example, if the customer integrates with IDSP only using APIs then the SignIn component sizing can be ignored as it is not involved in the API-based authentication flows. Similarly, if the customer decides not to use Risk in authentication flows, then the Risk component installation and sizing can be ignored.
- ***Security Requisites***

  Firewalls provide an additional layer of security for your deployment. If you are planning to deploy IDSP behind a firewall, deploy a reverse proxy, such as Gateway. For another level of security, consider using multiple DNS infrastructures using zones; one zone for internal clients, another zone for external clients. To provide additional performance, you can deploy the DNS zones behind a load balancer.
- ***Ingress Deployment***

  One of the pre-requisites for IDSP is to have an ingress controller deployed in the Kubernetes cluster environment. Each enterprise has its own solution around ingress. In some environments, ingress is already configured in the cluster and must be shared by all applications. In some of the enterprises, ingress deployment and configuration are the responsibility of the product team.
- ***Observability and Monitoring Requisites***

  Observability (Elastic/Kibana) and monitoring (Prometheus/Grafana) tools are referred to as enclave services in IDSP. Enclave services can be deployed as part of IDSP deployment or IDSP can be linked to an existing enclave service in your environment. Enclave services must have its own CPU/Memory/Storage requirements. If enclave services are deployed as part of IDSP deployment, then it must share the Kubernetes cluster with the IDSP service.
- ***Disaster Recovery Requisites***

  Determine disaster recovery procedures to recover from events such as server hardware failures, network connections down-time, site failures.
  - Determine if the Disaster Recovery must be active always and the active load must be distributed between primary and Disaster Recovery nodes in the Active-Active mode, or if the Disaster Recovery must be in the passive mode.
  - Govern the impact of losing the transaction data (For example, flow state of in-progress authentications).

Sizing Systems

Once you have gathered the required information regarding your system, enter those details into the deployment sizing sheet.

Click the deployment sizing sheet.

The sizing sheet computes and generates the following information:

- **System CPU and Memory:** A sizing sheet computes the total CPU and memory that is required to handle the load. The sizing sheet also provides the following details:
  - Services or components of IDSP that are required to be deployed.
  - Minimum/maximum number of pods required for each service.
  - Minimum/Maximum memory and CPU for each pod of all the deployed services.
  - Total number of IP addresses required across all pods and services.
  - Total CPU and memory that is required to deploy various services of IDSP including enclave services.
- **Sizing Database:** IDSP requires MySQL database for storing the operational and transactional data that is required for authenticating users. The sizing sheet generates the following sizing details that are required for the database.
  - CPU required
  - Memory required
  - Disk size for the first year (GB)
  - Data growth per year after first year (GB)
  - Maximum number of database connections required
- **Storage**
  Enclave services provide the observability (Elastic/Kibana) and monitoring (Prometheus/Grafana) capabilities for IDSP. These components require persistent volumes to store data generated by various IDSP services. Based on the load supported by IDSP, the data storage for these components varies. Sizing sheet computes the size that is required per day for the Elasticsearch and Prometheus PVCs. As per the customer retention policy, the PVCs should be created with the appropriate size. Policies should be defined in the enclave services as per the customer's retention policy.
  Example: If the storage requirement for Elasticsearch is 1GB per day and the customer retention policy requires the log data to be available for 90 days, then the PVC of Elasticsearch should be 90 * 1 GB/Day = 90 GB.

Recommended Cluster Infrastructure Requirements for Demo Mode

To deploy IDSP in a demo mode, see the following table for minimum cluster requirements:

Parameter	Minimum Cluster Requirements
CPU	14 cores available in the cluster (7 cores in case enclave services are not deployed).
RAM	44 GB available in the cluster. (28 GB in case enclave services are not deployed).

NOTE

- The number of worker nodes that are required will be determined by the number of cores and RAM used per machine.
  For example, when using 4-core machines with 16GB RAM and, a 100-GB hard drive, as your worker nodes, you need three worker nodes cluster that can scale to four nodes (to accommodate for rolling upgrade).
- In the Cloud environment, the control planes, also known as Master Node(s), could be handled by their respective Cloud platforms. If your cloud provider does not transparently handle the control plane, or you deploy the solution in Baremetal, you need additional machines to be used as Master nodes.

Preparing the Infrastructure Before Deploying the Solution

Includes links to sections on how to prepare the Cloud Infrastructure to deploy Symantec Identity Security Platform.

Before deploying IDSP in your environment, ensure you set up these environments with the necessary steps and also check the database considerations. This topic includes the following information:

- Preparing the Cloud Environment
- Preparing the OpenShift Environment

Preparing the Kubernetes Cluster Environment

This topic outlines the essential steps to prepare your Kubernetes environment for deploying Symantec Identity Security Platform.

The solution is designed to operate on Kubernetes Services from various providers, including:

- Google Kubernetes Engine (GKE)
- Amazon Elastic Kubernetes Service (EKS)
- Azure Kubernetes Service (AKS)
- VKS (VCF with VMware Kubernetes Services)

NOTE

- Before proceeding with the deployment, ensure you consult the general Prerequisites for deploying IDSP in your Kubernetes environment.
- While this document focuses on setting up IDSP, specific Kubernetes cluster provisioning details should be referred to on the Kubernetes site or your chosen external cluster provisioning site. Our instructions only include how to set up the IDSP on the cluster that you have provisioned.
- **Administrative Acess**: During deployment, a bootstrap deployer user account is created as a Kubernetes Secret, expiring in 48 hours. See Retrieving Initial Credentials for the clients section for more details. It is critical to use the Admin Console tool to create your own administrative account promptly. To ensure you have sufficient time to establish ingress and access the Admin Console, consider extending the bootstrap credential's expiry period by deploying the chart with the parameter: `--set ssp.global.seedData.disclosureExpiryHours=96`
- **Security Best Practice**: Once your administrative account is established, it is recommended to remove the generic deployer account. In the event of an administrative lockout, this deployer account can be re-created by re-running the Helm chart.
- **Firewall Configuration**: Your organization's firewall policy must permit outbound SMTP traffic on TCP ports 25, 587, or 465, depending on your message provider configuration. See Managing Message Provider Configuration for more info. Additionally, outbound HTTPS traffic on port 443 must be allowed to connect to the Twilio REST API at https://api.twilio.com/. For more details, see Requirements-for-Connecting-to-the-Twilio-REST-API.
- For the rest of the options in the cluster, take the defaults.

The basic guidelines to create a cluster to deploy IDSP in demo mode in any of these environments have been covered in this topic.

NOTE
For details about resource requirements to deploy IDSP to support production loads, see Sizing the Deployment.

- Minimum Cluster Requirement for Google Kubernetes Engine (GKE)
- Minimum Cluster Requirement for Amazon Elastic Kubernetes Service (EKS)
- Minimum Cluster Requirement for Azure Kubernetes Service (AKS)
- Minimum Cluster Requirement for VCF with VMware Kubernetes Services (VKS)
- Validating the Cluster

Minimum Kubernetes Cluster Requirement for Google Kubernetes Engine (GKE)

When you create a GKE cluster to deploy IDSP, follow these **minimum** requirements:

Cluster Fields	Description
Location Type	Zonal (recommended)
Kubernetes Version	1.32.x (This is the minimum supported version. For other supported Kubernetes Versions, see here.)
Node Pool Size	This refers to the configuration of worker nodes in a node pool when deploying a cluster. Enable auto-scale and set min as 5 and max as 6.
Operating System (OS)	Container-Optimized OS with containerd (cos_containerd)
Instance Type	n2d-standard-4 (Resource Capacity- 4 vCPU / 16 GB RAM on each node)

NOTE

- To grant cluster-admin permission to your gcp user account, see Granting "Cluster-Admin" Permission.

Minimum Kubernetes Cluster Requirement for Amazon Elastic Kubernetes Service (EKS)

When you create an EKS cluster to deploy IDSP, follow these **minimum** requirements:

Cluster Fields	Description
Location Type	Region

Kubernetes Version	1.32.x (This is the minimum supported version. For other supported Kubernetes Versions, see here.) If you are using Kubernetes version 1.30 or later, ensure your EKS cluster includes the following annotation in the default storage class:
	`apiVersion: storage.k8s.io/v1`
	`kind: StorageClass`
	`metadata:`
	`annotations:`
	`storageclass.kubernetes.io/is-default-class: "true"`
	Note: This annotation is necessary to avoid issues with Persistent Volume Claim creation, especially when using services like Kibana.

Node Pool Size	This refers to the configuration of worker nodes in a node pool when deploying a cluster. Enable auto-scale and set min as 5 and max as 6.
Operating System (OS)	Linux (amd64)
Instance Type	t3.xlarge (Resource Capacity- 4 vCPU / 16-GB RAM on each node)

NOTE

- From AWS EKS version 1.23 onwards, the in-tree Amazon EBS storage provisioner has been deprecated. A storage class driver ("AWS EBS CSI driver") has to be installed on the cluster to allow the provisioning of persistent storage. For more info see, AWS EKS Storage Classes and Amazon EBS CSI driver.
- IDSP supports both IMDSv1 and IMDSv2 instances in an AWS cluster. However, it is recommended to use IMDSv2 for its enhanced security. See Security Considerations for more info.

Minimum Kubernetes Cluster Requirement for Azure Kubernetes Service (AKS)

When you create an AKS cluster to deploy IDSP, follow these **minimum** requirements:

Cluster Fields	Description
Location Type	region
Kubernetes Version	1.32.x (This is the minimum supported version. For other supported Kubernetes Versions, see here.)
Node Pool Size	This refers to the configuration of worker nodes in a node pool when deploying a cluster. Enable auto-scale and set min as 5 and max as 6.
Operating System (OS)	Azure Linux / Ubuntu Linux
Instance Type	Standard_D4s_v3 (Resource Capacity- 4 vCPU / 16-GB RAM on each node)

Minimum Kubernetes Cluster Requirement for VCF with VMware Kubernetes Services (VKS)

When you create an VKS cluster to deploy IDSP, follow these **minimum** requirements:

Cluster Fields	Description
Location Type	region
Kubernetes Version	1.32.x (This is the minimum supported version. For other supported Kubernetes Versions, see here.)
Node Pool Size	This refers to the configuration of worker nodes in a node pool when deploying a cluster. Enable auto-scale and set min as 5 and max as 6.
Operating System (OS)	Ubuntu
Instance Type	Standard_D4s_v3 (Resource Capacity- 4 vCPU / 16-GB RAM on each node)

Validating the Cluster

To validate that the cluster is operational, run the following command:

```
kubectl get nodes
```

This command retrieves all the nodes. For a cluster to be successfully operational, check that the nodes in the cluster are in the "Ready" state.

Similarly, run the following command to check that all the default system pods in the cluster are in *running state and ready:*

```
kubectl get pods --all-namespaces
```

Next Step

Deploying the Services

Preparing the OpenShift Cluster Environment

Learn the prerequisite steps to perform before deploying Symantec Identity Security Platform in your OpenShift cluster environment.

This topic includes the following sections:

- Minimum Cluster Requirement for OpenShift
- Required Security Context Constraints (SCC) for IDSP Infra Helm Chart
- Validating the Cluster

NOTE

- Refer to the Prerequisites before deploying IDSP in your OpenShift environment.
- To set up your OpenShift cluster, visit the OpenShift site. Our instructions only include how to set up the IDSP on the cluster that you have provisioned.
- For details about resource requirements to deploy IDSP to support production loads, see Sizing the Deployment.

Minimum Cluster Requirement for OpenShift

When you create an OpenShift cluster to deploy IDSP, follow these **minimum** requirements:

Cluster Fields	Description
Location Type	region/zonal
OpenShift Version	OpenShift 4.18 (This is the minimum supported version. For other supported Kubernetes Versions, see here.)
Node Pool Size	5-6 worker nodes
Instance Size	4 CPUs 16-GB RAM on each worker node

NOTE

- Based on the TCP port that your organization uses for outgoing SMTP communication, your firewall policy should allow the outbound traffic on one of the following ports: TCP 25, 587, or 465. See Managing Message Provider Configuration for more info.
- Twilio uses HTTPS on standard port 443. Therefore, firewalls and proxies must allow outbound HTTPS traffic on port 443 to connect to the REST API hosted in https://api.twilio.com/. For more details, see Requirements-for-Connecting-to-the-Twilio-REST-API.
- For the rest of the options in the cluster, take the defaults.

Required Security Context Constraints (SCC) for IDSP Infra Helm Chart

IDSP runs under the most secure out-of-the-box OpenShift security profile, Security Context Constraints (SCC), "restricted-v2" SCC. Therefore, deploying IDSP on OpenShift does not call for any additional SCC. However, some of the prerequisite IDSP infrastructure components, like the NGINX Ingress controller or the Infra chart which deploys fluent bit for log streaming, requires a custom SCC.

You may have to deploy SCCs for the following reasons:

- ***Ingress NGINX***- If you intend to deploy NGINX Ingress in an OpenShift cluster. See Deploying Ingress in OpenShift.
- ***Fluent-bit*** - IDSP Infra helm chart deploys fluent bit for log streaming that requires the following SCC. The SCC is deployed automatically by the ssp-infra chart but can also be manually applied. In case you must deploy it manually, use the following command:

```
cat <<EOF | kubectl apply -f -
apiVersion: security.openshift.io/v1
kind: SecurityContextConstraints
metadata:
  name: fluent-bit-scc
```

```
allowPrivilegedContainer: true
allowPrivilegeEscalation: true
allowHostDirVolumePlugin: true
defaultAllowPrivilegeEscalation: false
# forbid host namespaces
allowHostNetwork: false
allowHostIPC: false
allowHostPorts: false
allowHostPID: false
allowedCapabilities: []
forbiddenSysctls:
- "*"
readOnlyRootFilesystem: false
requiredDropCapabilities:
- MKNOD
runAsUser:
  type: RunAsAny
seLinuxContext:
  type: MustRunAs
supplementalGroups:
  type: RunAsAny
volumes:
  - configMap
  - emptyDir
  - hostPath
  - persistentVolumeClaim
  - secret
EOF
```

Once you create the SCC manually, add the following parameter to the IDSP Infra Helm chart deployment:

```
--set fluent-bit.openShift.securityContextConstraints.create=false
```

Validating the Cluster

To validate that the cluster is operational, run the following command:

```
kubectl get nodes
```

This command retrieves all the nodes. For a cluster to be successfully operational, check that the nodes in the cluster are in the "Ready" state.

Similarly, run the following command to check that all the default system pods in the cluster are in the *running state and ready:*

```
kubectl get pods --all-namespaces
```

Next Step

Deploying the Services

Database Considerations

This topic provides an overview of the database options and configuration considerations for deploying Symantec Identity Security Platform.

Deployment Modes

IDSP database subsystem supports the following deployment modes, giving you flexibility based on your needs:

These modes have been covered in detail in the following links:

- Out-of-the-Box Demo Database Mode - This is a simplified, default setup, typically used for initial evaluation or non-production environments. It comes pre-configured to work seamlessly with MySQL.
- Customer Database Mode - This mode is for production environments where you connect to your own, externally managed database.

Supported Database Types

IDSP is designed to work with several popular database platforms. The following table summarises the supported databases and their compatible platforms and versions.

Platform	Database Type	Supported DB Version	Infra chart configuration	SSP chart configuration
• Google Cloud • Microsoft Azure • Amazon Web Services • OpenShift	MySQL (default) See Demo Database mode, and Customer Database mode for more info.	8.0, 8.4	• "db.enabled=true" (in Demo mode) • "db.enabled=false" (in Customer Database Mode)	--set ssp.db.type=mysql
• Google Cloud • Microsoft Azure • Amazon Web Services	PostgreSQL See Customer Database mode for more info.	14.19, 15.14, 17.7	"db.enabled=false" (In Customer Database Mode).	--set ssp.db.type=postgresql
• Google Cloud • Microsoft Azure • Amazon Web Services	Oracle See Customer Database mode for more info.	19c	"db.enabled=false" (in Customer Database Mode)	--set ssp.db.type=oracle
• Amazon Web Services	Aurora MySQL	8.0	"db.enabled=false" (in Customer Database Mode)	--set ssp.db.type=mysql

By following these guidelines, you can ensure your IDSP deployment is correctly configured for your chosen database environment.

Database in SSL Mode

IDSP supports SSL mode in databases. To know more about it, see Using Database in SSL Mode - In this mode, the solution deploys an SSL connection by default (sslMode=REQUIRED), however does not validate the server's issuer or server's identity in the server certificate.

Out-of-the-Box Demo Database Mode

The OOTB Demo database is a database created for demonstration purposes. Learn how to create it in Symantec Identity Security Platform by following the steps provided here.

In this mode, the IDSP infra chart creates a single MySQL database instance. This is the default mode of operation that is used only for demo purposes and not in production. By default, the infra chart's database configuration value *"db.enabled=true"* results in the creation of a single database instance.

NOTE
The IDSP infra chart does not use the memory requests and limits for the database deployment. However, if you want to deploy the database with any memory limit, use a minimum of 4G as a "***requests***" and "***limits***" value. The 4G limit is due to the requirement of the IDSP data chart deployment. The data chart requires a minimum of 4G limit for its job to complete successfully.

The following is an example from the values.yaml showing the values that can be used in "***requests***" and "***limits***":

```
pxc:
   crVersion: 1.10.0
   resources:
     requests:
       memory: 1G
       cpu: 600m
       # ephemeral-storage: 1Gi
     limits:
       memory: 4G
       cpu: "2000m"
       # ephemeral-storage: 1Gi
```

The following table displays the key database-related artifacts that are created by the infra chart deployed in the demo mode.

NOTE
The examples mentioned in the following section use *"ah-dev"* as the release name and *"dev"* as the namespace.

- The "ah-dev-ssp-db-pxc-0" pod is where the database service is running.
- The "infra-ah-dev-create-db-job-r5vns" pod is where the job to create the database schema is running.
- The "datadir-ah-dev-ssp-db-pxc-0" (PVC) Persistent Volume Claim represents the database persistence volume claim point to the persistence volume
- The "ah-dev-ssp-db-pxc" secret is where the database passwords are stored.

```
$ kubectl get pods -n dev
NAME                                                    READY   STATUS      RESTARTS   AGE
...

```

Deployment of Infra Helm Chart

Deploy the Infra chart normally without passing database-specific parameters. The database is deployed automatically with the default values as shown in the following table, with passwords randomized.

Optional parameters to pass into the Infra chart are as follows:

Parameter	Default Value	Purpose
db.schema.name	iamauth	Name of the database schema
db.schema.user	iamauth	Name of the database schema user
db.schema.password	N/A	Password of the database schema user. You can provide this through a password or secret. If you do not provide the password, it is randomized.
db.existingSecret	N/A	Secret containing database passwords to use (in base64)
db.enabled	true	Enable or disable embedded database.
db.sslMode	REQUIRED	Enable SSL. See Database in SSL mode for more info.
db.existingSslSecret	N/A	Secret containing SSL certs to use for SSL.

Once the infra chart is deployed, the Percona MySQL operator creates a single Database Service that is named, *ah-dev-ssp-db-pxc-0*.

- The infra chart deploys the Percona MySql Operator from the DockerHub registry. The actual location can be updated via infra chart's values.yaml, for example, using your own images from a "secure" registry.

Once the database becomes available, the *infra-ah-dev-create-db-job* is executed to create the database schema based on the values that are provided and/or defaulted to.

- The database passwords are placed inside **ah-dev-ssp-db-pxc** secret, containing various Percona passwords and "mysql-password" value that is used by IDSP to connect to its database schema.

Once you deploy the Infra chart and the db-creation-job is complete, you can execute the IDSP chart normally.

- For full automation, you should align the deployment of the IDSP chart with the completion of the database creation job.
- Use the following Kubernetes command:"`kubectl wait --for=condition=complete --timeout=5m job/<release-name>-create-db-job> -n <namespace>`"

Database Lifecycle Management

When you uninstall the IDSP chart, it does not perform any action on the database. Upgrading or uninstalling the infra chart does **not** touch the database file (DB PVC) and any upgrade or reinstall of the infra and IDSP charts continue to reuse the same PVC. If you must delete the database file at some point, then delete the PVC.

NOTE

- Uninstalling the infra chart keeps the database secret. Reinstalling the infra chart detects the database secret on installation and refuses to proceed until both the secret and related PVCs are removed. Otherwise, redeploy the infra chart by setting the parameter, *"--set db.existingSecret=**ah-dev-ssp-db-pxc**"* to reuse the existing database persistence.
- If you have deployed the infra chart in the external 'Customer Database Mode' and want to switch to the 'Internal Demo Mode' at a later stage, or you must uninstall and reinstall, make sure to run this command- *"kubectl delete secret ah-dev-ssp-db-pxc -n dev"* and *"kubectl delete secret internal-ah-dev-ssp-db -n dev"*.

Next Step

Deploy IDSP

Customer Database Mode

Learn how to connect a pre-created Custom Database to Symantec Identity Security Platform by configuring the necessary database connection parameters.

This topic includes the following sections:

- Creating a MySQL Database instance
- Creating a PostgreSQL Database instance
- Integrating an Oracle Database instance with IDSP
- Deployment Instructions
- Database connection related issues covered in troubleshooting section

Supported Database Types and Versions

The supported database types and versions are mentioned in the Database Considerations page.

Preparing the Database Instance

To prepare a database, perform the steps mentioned in this section based on your specific database type. These commands create a database, a user, and grant the necessary permissions.

IDSP requires a pre-created database instance. In the customer provided database mode, point the IDSP chart to your own database.

NOTE

- When running in a cloud environment, consider using a ***MySQL***, ***PostgreSQL***, or ***Oracle*** compatible cloud provider database service.
- When using Azure Database for MySQL server, set the "Server timezone" to UTC, by typing “+00:00”.

Creating a MySQL Database Instance

Follow these steps to create an instance of the MySQL database.

1. Connect to the MySQL service by running a MySQL client container on your Kubernetes cluster where you plan to deploy IDSP.
2. Running the following SQL commands creates a database, a user within the MySQL database server and grant permissions to the user.

   NOTE
   IDSP supports connecting to a MySQL database using a "**mysql_native_password**" user.

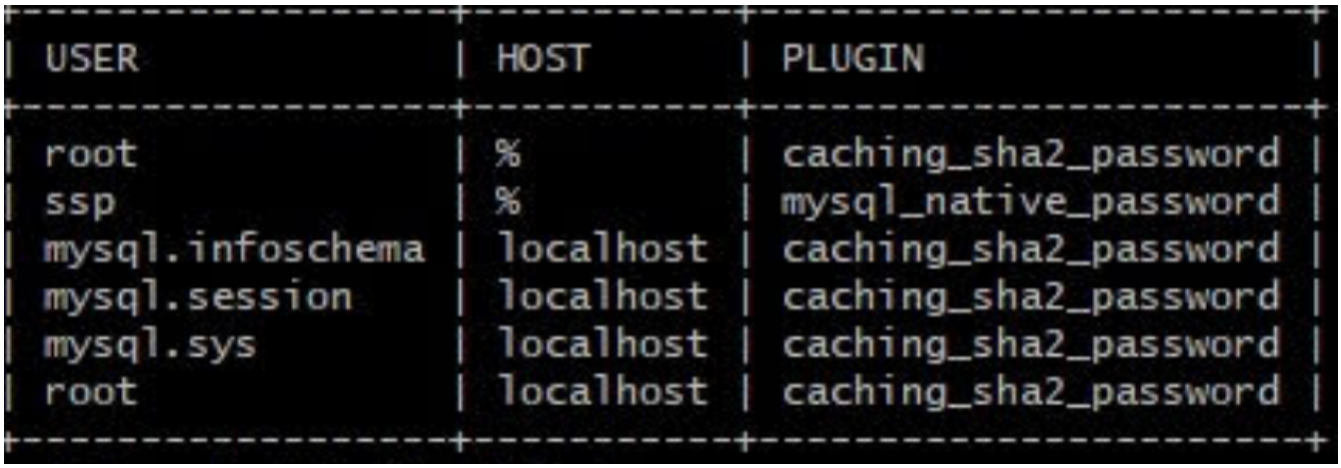
```
export SCHEMA_NAME=<db_name>
export SCHEMA_USER=<db_user>
export SCHEMA_PWD=<db_user_password>;

kubectl run -it --rm --image=mysql:8.0.26 --restart=Never mysql-client -- mysql -h<db_host_fqdn> -
u<db_admin_user> -p<db_admin_password> -e "DROP DATABASE IF EXISTS ${SCHEMA_NAME}; CREATE DATABASE IF NOT
 EXISTS ${SCHEMA_NAME}; CREATE USER IF NOT EXISTS ${SCHEMA_USER} IDENTIFIED WITH mysql_native_password
 BY '${SCHEMA_PWD}'; ALTER USER ${SCHEMA_USER} IDENTIFIED WITH mysql_native_password BY '${SCHEMA_PWD}';
 GRANT ALL ON ${SCHEMA_NAME}.* TO ${SCHEMA_USER};"
```

3. (**Optional Step**) Before proceeding with the next steps, confirm that the user password is stored with the "**mysql_native_password**" mechanism.
   Run the following SQL command to display the password plugin mechanism for the created ${SCHEMA_USER}:

```
kubectl run -it --rm --image=mysql:8.0.26 --restart=Never mysql-client -- mysql -h <db_host_fqdn> -
u<db_admin_user> -p<db_admin_password> -e"SELECT USER, HOST, PLUGIN from mysql.user;"
```

   The following sample screenshot shows that the MySQL password plugin for the newly created "ssp" user is set to "mysql_native_password" (instead of "caching_sha2_password").



USER	HOST	PLUGIN
root	%	caching_sha2_password
ssp	%	mysql_native_password
mysql.infoschema	localhost	caching_sha2_password
mysql.session	localhost	caching_sha2_password
mysql.sys	localhost	caching_sha2_password
root	localhost	caching_sha2_password

   NOTE
   The Database user account should have no limits for "max_questions" and "max_queries" server status variables. See https://dev.mysql.com for more details. To see current parameters, sign in to the database as the DB user and execute the following queries:

   - SHOW SESSION STATUS LIKE 'questions';
   - SHOW SESSION STATUS LIKE 'queries';

Creating a PostgreSQL Database Instance

Follow these steps to create an instance of the PostgreSQL database in your Kubernetes cluster.

1. Connect to your Kubernetes cluster.
2. Connect to the PostgreSQL service by running a PostgreSQL client container on your Kubernetes cluster where you plan to deploy IDSP.

Running the following SQL commands creates a database, a user within the PostgreSQL database server, and grants permissions to the user to perform the required db tasks:

```
export SCHEMA_NAME=<db_name>
export SCHEMA_USER=<db_user>
export SCHEMA_PWD=<db_user_password>;
kubectl run -i --rm --tty percona-client --image=perconalab/percona-distribution-postgresql:15
 --restart=Never -- psql postgres://<db_admin_user>:<db_admin_password>@<db_host_fqdn> -
c \"DROP  DATABASE IF EXISTS ${SCHEMA_NAME};\"; kubectl run -i --rm --tty percona-client
 --image=perconalab/percona-distribution-postgresql:15 --restart=Never -- psql postgres://
<db_admin_user>:<db_admin_password>@<db_host_fqdn> -c \"CREATE DATABASE ${SCHEMA_NAME}
 ENCODING='UTF8';\"; kubectl run -i --rm --tty percona-client --image=perconalab/percona-distribution-
postgresql:15 --restart=Never -- psql postgres://<db_admin_user>:<db_admin_password>@<db_host_fqdn>
 -c \"DROP USER IF EXISTS ${SCHEMA_USER};\"; kubectl run -i --rm --tty percona-client --
image=perconalab/percona-distribution-postgresql:15 --restart=Never -- psql postgres://
<db_admin_user>:<db_admin_password>@<db_host_fqdn> -c \"CREATE USER ${SCHEMA_USER} WITH ENCRYPTED PASSWORD
 '${SCHEMA_PWD}';\"; kubectl run -i --rm --tty percona-client --image=perconalab/percona-distribution-
postgresql:15 --restart=Never -- psql postgres://<db_admin_user>:<db_admin_password>@<db_host_fqdn> -c
 \"GRANT ALL PRIVILEGES ON DATABASE ${SCHEMA_NAME} TO ${SCHEMA_USER};\
```

Where,

- db_admin_user - Name of the database schema user.
- db_admin_password - Password of the database schema user.
- db_host_fqdn - Hostname of the server that has the PostgreSQL deployed.

Integrating Oracle Database Instance with IDSP

To integrate Oracle databse with IDSP, ensure that the user has required privileges such as DDL (Data Definition Language) including creating procedures, DML (Data Manipulation Language), and the ability to establish connections.

For any database connection related issues, see the troubleshooting link at the end of this page.

Deployment Instructions

Infra Chart Configuration

Set the parameter, `db.enabled=false` in the `infra chart` to prevent the system from creating an internal database.

> **NOTE**
> If you configure "db.enabled=false", ensure external database details are prepared for input during the IDSP deployment.

IDSP Chart Configuration

To deploy the IDSP chart, configure the database connection using the parameters outlined in the provided table, ensuring it references your designated database for this deployment.

Parameter	Default Value	
ssp.db.serviceHost		FQDN host of the database
ssp.db.servicePort	• MySQL- 3306	Port of the database service Port values in other DBs are • postgresql - 5432 • oracle - 1521 (SSL port

Parameter	Default Value	
ssp.db.schema	iamauth	Name of the database sche ssp.db.schema parameters
ssp.db.name	iamauth	• Name of the database s (in MySQL db) • Name of the database (in PostgreSQL db) • Name of the database s (in Oracle db) **Note:** If you plan to use **Note:** see these section • Using Oracle JDBC • Using Oracle JDBC
ssp.db.user	iamauth	Name of the database sche
ssp.db.password	N/A	Password of the database s This parameter should not b The DB password should ei both values are specified, th
ssp.db.existingSecret	N/A	The name of the secret cont The name of the key in the s use this option, the secret is deployed. IDSP mounts this secret into This means that whenever t the password in the mounte password to be used to con The secret is expected to ha • 'db-password' (for read/ • 'read-db-password' (for r • when not found, the file To know more about Databa
ssp.db.existingVaultFolder	""	When using a vault injected the file named, 'mysql-passv the file is expected to contai IDSP does not use the ssp. Passwords are reloaded fro

- Oracle JDBC Setup (with LDAP examples)
- Database Lifecycle Management

Database Connection Pool

Explore the configurable parameters for the Database Connection Pool in Symantec Identity Security Platform.

IDSP supports the use of Database Connection Pool configured at the time of deploying the IDSP chart for its operational database.

The operating parameters of the DB pool are global and must be configured at the time of deploying the IDSP chart. The default Database Connection Pool parameters are maintained in IDSP helm chart's values.yaml.

The DB pool parameters that you can pass while deploying IDSP helm chart using ***--set <name>="<value>"*** helm parameters, are as follows:

Database Pool Config Value	Default	Description
ssp.global.db.maxPoolSizeRead	200	Max number of database connections for reads
ssp.global.db.maxPoolSizeWrite	200	Max number of database connections for writes
ssp.global.db.minIdleSize	5	Minimum number of idle database connections
ssp.global.db.connectionTimeoutMillis	30000	Maximum amount of time to wait for a database connection, in milliseconds
ssp.global.db.idleTimeoutMillis	12000	Maximum lifetime of an idle database connection before its closed, in milliseconds
ssp.global.db.maxLifetimeMillis	1800000	Maximum lifetime of a database connection, in milliseconds. Usually this number should be less than the firewall's TCP keepalive timeout if one is present.

Oracle JDBC Setup for Symantec Identity Security Platform

Learn about Oracle JDBC DB configurations when integrating with Symantec Identity Security Platform.

This topic includes the following sections:

- Using Oracle JDBC
- Using Oracle JDBC with LDAP

Using Oracle JDBC

When using Oracle JDBC (Java Database Connectivity), configure the following parameters:

1. Set the parameter "***ssp.db.connection.type***" to "***oracle***".
2. Set the parameter "***ssp.db.jdbcUrl***" to specify your ***JDBC url.***
   The following example demonstrates a sample JDBC url:

```
"jdbc:oracle:thin:@(DESCRIPTION=(LOAD_BALANCE=OFF)(FAILOVER=ON)(ADDRESS_LIST=(ADDRESS=(PROTOCOL=TCP)
(HOST=<your-host1>)(PORT=50001))(ADDRESS=(PROTOCOL=TCP)(HOST=<your-host2>)(PORT=50001)))
(CONNECT_DATA=(SERVER=DEDICATED)(SERVICE_NAME=<your-service-name>)))"
```

Using Oracle JDBC with LDAP

In scenarios where the Oracle database host is managed within LDAP, the JDBC driver interacts with LDAP to fetch the required connection information.

When using Oracle JDBC (Java Database Connectivity) with LDAP, configure the following parameters:

1. Set the parameter "***ssp.db.connection.type***" to "***oracleldap***".
2. Set the parameter "***ssp.db.jdbcUrl***" to specify the ***complete JDBC url***

NOTE

- If the JDBC URL is passed as a "--set" parameter in the Helm command and contains a comma (,), it should be escaped with a backslash (\) and the value should be encapsulated with single quotes (').
- The following example demonstrates how to use (\) and (') in the Helm command:
  `--set ssp.db.jdbcUrl='jdbc:oracle:thin:@ldap://oidhost1.test.com:46301/cn=OracleContext\,dc=oracle\,dc=com/devd b'`

Database Lifecycle Management

This section covers how to manage your database and its connection details after the initial deployment.

- **Upgrades and Uninstalls**: Upgrading or uninstalling the Symantec Identity Security Platform chart does **not** impact your external database. The data and settings in your database will remain intact.
- **Password Changes**: To change the database password after the initial installation, use the IDSP Helm chart upgrade command.
  adding, *"--set reuse-values=true"* parameter and specify the new password using the following option:
  – `--set ssp.db.password=<schema-password>` (passed in a clear text)
- If you prefer to pass the password in the IDSP chart using a secret, create the secret and pass it in the following command-line parameter: `--set sp.db.existingSecret-<existing-k8s-secret-with-schema-user-password-in-base64>`

NOTE
If you previously used the existingSecret option to specify the secret name, you should change the password directly in the specified secret object and not use the "ssp.db.password" option.

Handling Database Passwords

For better security, it is highly recommended to use a Kubernetes secret to manage database passwords. This allows for seamless password rotation without impacting the IDSP chart.

Using Database in SSL Mode

Symantec Identity Security Platform (solution) supports SSL mode in database.

The solution deploys an SSL connection by default (sslMode=REQUIRED), however does not validate the server's issuer or server's identity in the server certificate.

NOTE

- The solution does not support mutual SSL where the MySQL server validates the client's certificate.
- ***The information in this topic applies to PostgreSQL and Oracle databases as well. While the examples focus on MySQL, they are also relevant to PostgreSQL and Oracle DB types.***

In the solution, the SSL database mode is controlled by the configuration parameter, "`ssp.db.sslMode=<SSL Mode>`" which is specified in the values.yaml file.

The different values that are supported by SSL mode are:

- DISABLED - IDSP connects without SSL assuming MySQL Server allows it.
- PREFERRED - IDSP expects SSL assuming MySQL Server allows it. However, it connects without SSL, if MySQL server does not have ssl enabled.

  NOTE
  This mode is not supported in Oracle DB.
- REQUIRED - IDSP requires SSL assuming MySQL Server allows it (***default mode***).
- VERIFY_CA - IDSP requires validation of the MySQL server's SSL certificate to be signed by a trusted CA.
- VERIFY_IDENTITY - In addition to VERIFY_CA, IDSP requires validation of the MySQL server's SSL certificate to contain the MySQL Server's hostname used during the connection.

  NOTE
  In general, it is sufficient to provide one certificate representing the trusted CA that was used to sign MySQL Server's certificate during SSL negotiation.

Creating secret with DB SSL Certificate

SSL Modes, ***Verify_CA*** and ***Verify_Identity*** require CA certificates to verify the DB server certificate. When using customer DB ("external db mode"), one or more SSL certificates of the DB service has to be imported into the secret for the solution to establish the SSL connection to MySQL server. The solution requires each certificate to be provided in a separate file inside the secret. Each file within the secret should have the ".crt" extension, other file extensions are ignored. Once the SSL secret is created, pass the ssl certificates secret name by adding this attribute, --set **ssp.db.existingSslSecret**="*<secret name>*".

A database provider must provide the required certificate for the database service. This certificate is provided to IDSP through a Secret that is created in the same namespace where the solution is to be deployed. When initializing the MySQL connection, the solution loads all the certificates with the ".crt" extension into its trust store. If multiple certificates are required by the db provider, then create the secret using multiple .crt files.

Example: Using Azure's MySQL ("Customer Database" mode) with VERIFY_CA or VERIFY_IDENTITY ssl mode

1. Download and create a secret with DB SSL certs for the right region, using this command:

   NOTE

   - IDSP mounts the SSL secret and loads all files with "**.crt**" extension. Any file with an extension other than "**.crt**" is ignored.
   - To download the right certificate bundle to be used by IDSP, see the Azure documentation.

   ```
   kubectl create secret generic aazure-mysql-ssl-cert -n ${NAMESPACE} --from-file=us-east-1-bundle.crt=us-east-1-bundle.pem
   ```

2. The following parameters are added to the IDSP deployment to use an SSL connection to connect to the Azure MySQL DB. The parameters specify the name of the secret that contains the certificate (created above) and the SSL mode to be used.

   ```
   --set ssp.db.existingSslSecret="azure-mysql-ssl-cert" \
   --set ssp.db.sslMode="VERIFY_CA"
   ```

   In the following example, the CA cert is obtained from Azure's MySQL service as the "BaltimoreCyberTrustRoot.crt.pem" certificate file.

   ```
    -----BEGIN CERTIFICATE----
   MIIDdzCCAl+gAwIBAgIEAgAAuTANBgkqhkiG9w0BAQUFADBaMQswCQYDVQQGEwJJ
   RTESMBAGA1UEChMJQmFsdGltb3JlMRMwEQYDVQQLEwpDeWJlclRydXN0MSIwIAYD

R9I4LtD+gdwyah617jzV/OeBHRnDJELqYzmp
-----END CERTIFICATE-----
```

Example: Using AWS's MySQL ("Customer Database" mode) with VERIFY_CA or VERIFY_IDENTITY in SSL mode

1. Download and create a secret with DB SSL certs for the right region, using this command:

   NOTE

   - IDSP mounts the SSL secret and loads all files with "**.crt**" extension. Any file with an extension other than "**.crt**" is ignored.
   - To download the right certificate bundle to be used by IDSP, see the Amazon documentation.

   ```
   kubectl create secret generic aurora-mysql-ssl-cert -n ${NAMESPACE} --from-file=us-east-1-bundle.crt=us-east-1-bundle.pem
   ```

2. The following parameters are added to the IDSP deployment to use an SSL connection to connect to the AWS MySQL DB. The parameters specify the name of the secret that contains the certificate (created above) and the SSL mode to be used.

   ```
   --set ssp.db.existingSslSecret="aurora-mysql-ssl-cert" \
   --set ssp.db.sslMode="VERIFY_CA"
   ```

Example: Sample showing the creation of a secret with multiple certs

In the following example, a secret type generic, called "azure-mysql-ssl-cert" is created with two certificates, "BaltimoreCyberTrustRoot.crt" and "DigiCertGlobalRootG2.crt". This method of including two certificates is useful when you must specify a certificate chain or when your database is transitioning from one certificate to another.

The command loads the certificate files into the secret while renaming their extensions from ".crt.pem" to ".crt".

```
$ kubectl create secret generic azure-mysql-ssl-cert -n dev \
   --from-file=BaltimoreCyberTrustRoot.crt=BaltimoreCyberTrustRoot.crt.pem \
   --from-file=DigiCertGlobalRootG2.crt=DigiCertGlobalRootG2.crt.pem
```

Run the following command to verify the content of the newly created secret:

```
kubectl get secret mysql-ssl-cert -n <namespace> -o yaml
```

The following is a sample secret containing the certificates:

```
apiVersion: v1
  kind: Secret
  metadata:
    name: azure-mysql-ssl-cert
    namespace: dev
  type: Opaquedata:
    BaltimoreCyberTrustRoot.crt: LS0tLS1CRU ... 0tLS0tCgo=
    DigiCertGlobalRootG2.crt: LS0tLS1CRUdJTiBDRVJ ... RS0tLS0tCg==
```

See the Configuring the Environment Variables section for more information.

To troubleshoot issues related to db ssl connection, see here.

Information Stored in the Symantec Identity Security Platform Database

Learn about the user-account related information that Symantec Identity Security Platform may store in its database. These details are required by the solution to run its operations.

User information is stored in the database

The following user account-related details are stored by the solution in the database:

- User information such as the login identifier, first name, and last name may be stored if so configured administratively for the purpose of sending messages
- Status of the user (active or inactive)
- Email Addresses and Phone numbers in encrypted form may be stored if configured administratively for the purpose of using as authentication credentials
- Credential details include public certificates for PKI-based credentials (like FIDO2 devices), Push, TOTP in encrypted form
- User's Trusted Device details: As part of this, the IDSP saves a unique identifier known as TDI, that is unique to the end user's device. Subsequently, the identifier is also stored in the user's device (either as a cookie or secure storage in mobile devices). Basic information about the user's browser or mobile OS is also stored.
- When the risk is enabled, the following details are stored in the database:
  - signature of the devices used by the users: The device signature is a collection of device-specific attributes like OS details, browser details, screen details, time zone, language details. Similarly, for mobile devices, the device signature consists of mobile OS details, device name, model, wifi mac address, screen size, etc. These are collected using js or mobile SDK that is invoked from client applications and passed to the IDSP server in encoded form.
  - IP address from where the users accessed the system if and as may have been provided by the network infrastructure
- The data extracted by the "ssp-data" Helm chart, which is used to load the network watchlist and fraud IP data into the IDSP database for evaluating risk, is stored in the IDSP database.

  NOTE
  When using the Internal Identity Store, the entire user profile, including custom defined attributes, is stored in the database.

Risk evaluation data stored in the database

The data extracted by the "ssp-data" Helm chart, which is used to load the network watchlist and fraud IP data into the IDSP database for evaluating risk, is stored in the IDSP database.

Configuring Connectivity to Amazon Web Service (AWS) MySQL DB Without Using a DB Password

Learn the process of setting up connectivity to an AWS MySQL DB without the need for a database password.

This topic includes the following sections:

- Amazon EKS Pod Identity Prerequisite
- Verifying Access to the MySQL DB Using Access Token (AT)
- Deploying Symantec Identity Security Platform using AWS Pod Identity for database identification

Amazon EKS Pod Identity Prerequisite

In the following section, we have provided a few step highlights that would help you while you perform those steps before deploying Symantec Identity Security Platform:

> **NOTE**
> The following instructions use ***eksctl***- A command-line tool for working with EKS clusters that automates many individual tasks. The instructions require that you use version 0.62.0 or later. Refer to this link to install The eksctl command line utility.

1. **Connect to your AWS MySQL database** and create a ***DB user*** (that uses **AWSAuthenticationPlugin** for authentication).

   > **NOTE**
   > Before running the following command,
   >
   > - Replace <DB_HOST_FQDN> with the MySQL DB host FQDN.
   > - Replace <DB_PORT> with the MySQL DB port.
   > - Replace <DB_ADMIN_USER> by the database admin user name.
   > - Replace <DB_ADMIN_PASSWORD> by the database admin password

   a. Connect to your AWS MySQL DB instance using the database's *admin* user. You can either use the GUI approach or a command-line approach as specified below:

   ```
   kubectl run -it --rm --image=mysql:8.0.26 --restart=Never mysql-client -- mysql --enable-cleartext-
   plugin --host=<DB_HOST_FQDN>  --port=<DB_PORT> --user=<DB_ADMIN_USER>  --password=<DB_ADMIN_PASSWORD>
   ```

   b. Run the following MySQL command to create the DB schema (if not already created), the DB USER, and grant access permissions to the user (the following example uses a db name of "**iamauth**" and db user named, "**iamauth**"):

   ```
   CREATE DATABASE IF NOT EXISTS iamauth;

   CREATE USER IF NOT EXISTS iamauth IDENTIFIED WITH AWSAuthenticationPlugin AS 'RDS';

   GRANT ALL ON iamauth.* TO iamauth;

   SELECT user FROM mysql.user;

   exit;
   ```

2. **Create a DB connect IAM Policy that allows connection to DB with IAM Authentication**.

   > **NOTE**
   > Before running the following command,
   >
   > - Replace <AWS_REGION> with the AWS region of the MySQL DB.
   > - Replace <AWS_ACCOUNT_ID> with the AWS Account ID.
   >   To get the AWS Account info, use this command:
   >   ```
   >   aws sts get-caller-identity
   >   ```
   > - Replace <AWS_DB_CLUSTER_RESOURCE_ID> with the DB cluster resource ID.
   >   To get DB Clusters Name and ID, use this command:
   >   ```
   >   aws rds describe-db-clusters --query "DBClusters[*].
   >   [DBClusterIdentifier,DbClusterResourceId]"
   >   ```

   a. **Create a policy.json file** with the following content:

   ```
   {
      "Version": "2012-10-17",
      "Statement":
      [
          {
   ```

```
            "Effect": "Allow",
            "Action": [ "rds-db:connect" ],
            "Resource": [ "arn:aws:rds-
db:<AWS_REGION>:<AWS_ACCOUNT_ID>:dbuser:<AWS_DB_CLUSTER_RESOURCE_ID>/iamauth"]
        }
    ]
}
```

NOTE
If you want to configure AWS KMS for password encryption, then add the following action, along with the AWS MySQL DB action in the above policy.json file.

```
"Action": [
        "kms:ListKeys",
        "kms:Encrypt",
        "kms:Decrypt"
          ],
```

See Configuring Connectivity to AWS KMS for Password Encryption

b. **Create the IAM Policy** using this command:

```
aws iam create-policy --policy-name ssp-aws-policy --policy-document file://policy.json
```

3. **Create an OIDC provider for your Kubernetes EKS cluster**.
   a. Get the OIDC provider issuer name for your EKS cluster:

```
aws eks describe-cluster --name <cluster-name> --query "cluster.identity.oidc.issuer" --output text
```

   b. View your existing OIDC providers to see if there is one with the ID matching the ID for the above OIDC provider issuer name:

```
aws iam list-open-id-connect-providers
```

   c. If the OIDC provider does not exist, create one (see AWS documentation for more information):

```
eksctl utils associate-iam-oidc-provider --cluster <cluster-name> --approve
```

   d. Validate that your OIDC provider got created by listing the providers again:

```
aws iam list-open-id-connect-providers
```

4. **Create a Kubernetes Service Account and an AWS IAM role with the DB Connect Policy.**
This step associates the Kubernetes service account with the IAM Role. After performing this step, any pod that is running as this service account would be able to request an access token to connect to the database.
This step does the following:

- creates a Kubernetes Service account
- creates an IAM Role and assigns the DB Connect Policy to the role
- links the Kubernetes service account with the IAM role

NOTE
Before running the commands in this step,

- Make sure to define the NAMESPACE environment variable containing the name of the Kubernetes namespace where your IDSP is going to be deployed. See Configuring the Environment Variables section.
- Replace <cluster-name> with the name of your EKS cluster.

```
eksctl create iamserviceaccount \
  --name ssp-eks-iam-sa \
  --namespace ${NAMESPACE} \
  --cluster <cluster-name> \
  --attach-policy-arn arn:aws:iam::688201620683:policy/ssp-aws-policy \
```

```
--approve \
--role-name cluster-<cluster-name>-ssp-eks-iam-sa
```

Verifying Access to the MySQL DB Using Access Token (AT)

Validate that the AWS Pod Identity is properly deployed and configured before deploying the IDSP helm chart using the following command:

NOTE
Before running the commands in this step,

- Make sure to define the NAMESPACE environment variable containing the name of the Kubernetes namespace where your IDSP is going to be deployed. See Configuring the Environment Variables section.
- Replace <DB_HOST_FQDN> with the MySQL DB host FQDN.
- Replace <DB_PORT> with the MySQL DB port.
- Replace <AWS_REGION> with the AWS region of the MySQL DB.
- The following example uses the db user as "iamauth".

1. Start a MySql pod running as the Kubernetes service account created in step 4 above (in this example, the service account used is "**ssp-eks-iam-sa**"):

```
kubectl run -n ${NAMESPACE} -it --rm --image=mysql:8.0.XX --restart=Never --overrides='{ "spec":
 { "serviceAccount": "ssp-eks-iam-sa" }  }'  mysql-client -- bash -c "apt update -y; apt install curl
 zip -y; curl "https://awscli.amazonaws.com/awscli-exe-linux-x86_64.zip" -o "awscliv2.zip" ; unzip
 awscliv2.zip ; ./aws/install; bash"
```

2. While inside the container shell, use the command "**env**" to ensure that the AWS_ROLE_ARN, and AWS_WEB_IDENTITY_TOKEN_FILE environment variables are defined in the container's shell environment.

```
env
```

3. Acquire an access token for the MySQL DB using the following command:

```
export AT="'aws rds generate-db-auth-token \
            --hostname <DB_HOST_FQDN> \
            --port <DB_PORT> \
            --region <AWS_REGION> \
            --username iamauth'"

echo ${AT}
```

4. Use the access token retrieved in the previous step to authenticate to your MySQL database:

```
mysql --enable-cleartext-plugin --host=<DB_HOST_FQDN> --port=<DB_PORT>  --user=iamauth  --
password="${AT}"
```

Deploying IDSP using AWS Pod Identity for database identification

1. Create a *Kubernetes Secret* containing the **IDSP bootstrap metadata** to instruct IDSP how to acquire the Access Token required to connect to the Operational DB (resource type OP_DB).

NOTE

- If the metadata for this resource type cannot be located, IDSP falls back to using a regular DB password, if provided.
- Before running the commands in this step, make sure to define the NAMESPACE environment variable containing the name of the Kubernetes namespace where your IDSP is going to be deployed. See Setting Up SSP Services section.

- Replace <DB_HOST_FQDN> with the MySQL DB host FQDN.
- Replace <DB_PORT> with the MySQL DB port.
- Replace <DB_REGION> with the DB region, for example, - "us-east-1"
- The following example uses the db user as "iamauth".

a. Create a file (for example, aws_rds_iam_auth_pod_identity_md.json) with the following content:

```
[
  {
    "version": "1",
    "comment": "Native AWS Aurora MySQL Identity",
    "resourceType": "OP_DB",
    "responseType": "AWS_RDS_SDK",
    "url": "",
    "method": "",
    "headers": [],
    "params": [
      "region=<DB_REGION>",
      "host=<DB_HOST_FQDN>",
      "port=<DB_PORT>",
      "user=iamauth"
    ],
    "azType": "NONE",
    "azBasicAuthUsername": "",
    "azBasicAuthPassword": "",
    "azBearer": ""
  }
]
```

b. Create a Kubernetes Secret with the content of the preceding file, **make sure the name of the file in the Kubernetes Secret is *"bootstrapmetadata.json"***. The following command uses the example file name, "aws_rds_iam_auth_pod_identity_md.json" (created in the previous step):

NOTE

- Before running this command, ensure that the variables, ${RELEASENAME}, ${NAMESPACE} are set as mentioned in step 1 of Configuring the Environment Variables section.
- The following command uses ${RELEASENAME}-ssp-bootstrapmetadata for the name of the Kubernetes secret. You can use any name to the Kubernetes secret, however, ensure that the secret name is provided during the IDSP helm chart deployment (--set ssp.global.bootstrapmetadata.existingSecret).

```
kubectl create secret generic ${RELEASENAME}-ssp-bootstrapmetadata -n ${NAMESPACE} --from-file=bootstrapmetadata.json=aws_rds_iam_auth_pod_identity_md.json
```

2. Deploy the IDSP chart following the steps mentioned in the Configuring the Environment Variables section. When deploying the IDSP helm chart and the ssp-data chart , use the following additional parameters, making sure to set the DB host, port, and username appropriately for the database schema created in step 1(b) of the "AWS Pod Identity Prerequisite" section and instruct IDSP pods to run as the Kubernetes Service Account created in the preceding steps, and set the DB password to an empty string:

– Pass the DB username created in step (1) of the "AWS Pod Identity Prerequisite" section.

```
--set ssp.db.user="iamauth"
```

– Pass the secret name containing the bootstrap metadata JSON file (created in the previous step)

```
--set ssp.global.bootstrapmetadata.existingSecret=${RELEASENAME}-ssp-bootstrapmetadata
```

NOTE

When you configure IDSP to use bootstrap metadata, the access token retrieved by it will be used in place of a password to connect to your MySQL database. When passing the " --

set ssp.global.bootstrapmetadata.existingSecret", make sure to set the DB password to an empty string: --set ssp.db.password=""

– Ensure to specify existingServiceAccount to instruct IDSP pods to run as the Kubernetes Service Account created in the preceding steps:

```
--set ssp.global.existingServiceAccount="ssp-eks-iam-sa"
```

Example: The following parameters are required to set up an IDSP to connect to the AWS MySQL DB using AWS Pod Identity:

NOTE
Before running the commands in this step,

- Replace <BOOTSTRAP_METADATA_SECRET_NAME> with the file name created in "step 1(a)" of Deploying IDSP using AWS Pod Identity for database identification section.
- Replace <DB_HOST_FQDN> with the MySQL DB host FQDN.
- Replace <DB_PORT> with the MySQL DB port.
- The following example uses the db user and db name as "iamauth".

```
--set ssp.global.bootstrapmetadata.existingSecret="<bootstrap-metadata-secret-name>"
--set ssp.global.existingServiceAccount="ssp-eks-iam-sa" \
--set ssp.db.serviceHost="<DB-HOST>" \
--set ssp.db.servicePort="<DB-PORT>" \
--set ssp.db.name="iamauth" \
--set ssp.db.user="iamauth"
```

Deploying the Services

Learn the sequence of steps to be followed to deploy Symantec Identity Security Platform in your cluster environment.

It is recommended that you follow the sequence of steps that are outlined here to deploy IDSP in your cluster.

1. **Deploy Ingress Controller** - The first step is to deploy a new or reuse an existing ingress controller to route the incoming traffic to different microservices.
2. **Deploy Enclave services** (also known as Observability services) - The second step is to deploy the enclave services. These are a group of external services (Elastic Search, Kibana, Prometheus, Grafana) that are plugged into our solution to collect information that is related to searching, logging, and monitoring from microservices that are running within the IDSP cluster.
   Deploy IDSP solution, after you have successfully completed the deployment of the preceding services. You can deploy the solution in your Cloud environment, or OpenShift. Before deploying, ensure that you check the **Pre-installation checklist**.
3. **Configure Enclave Services** - Perform this step to configure the enclave services to display IDSPcontent.
4. **Post Installation Steps** - Consider the tasks in the checklist after deploying the IDSP helm chart.
5. ***Configure Administrative Access*** - Covers the initial security credentials for the admin clients (Infra client, System client, and Default Tenant client) and admin user (defaultTenantAdminUser) that are provided out-of-the-box by IDSP during the initial deployment

Before going into the specifics of the deployment steps and getting the solution up and running, refer to the following table to view the external components and their capabilities that are part of the deployment process.

Software	Description	Chart Name	
NGINX Ingress Controller	An ingress controller is responsible for reading the ingress resource information and routing the incoming traffic to different microservices.	ingress-nginx	https://kubern
Elastic Operator	Elastic Cloud on Kubernetes (ECK) is a Kubernetes operator to orchestrate Elastic applications (Elasticsearch, Kibana, and so on) on Kubernetes.	eck-operator	https://helm.e
Elasticsearch	Elasticsearch is an open-source full-text search and analytics engine. It allows to store, search, and analyze logs.	elasticsearch	https://helm.e
Kibana	Kibana is an open-source analytics and visualization platform that is designed to work with Elasticsearch. It helps in analyzing and monitoring the logging information.	Kibana	https://helm.e
Prometheus Operator	Prometheus is an open-source monitoring and alerting toolkit for containers and micro-services.	kube-prometheus	https://charts.
Grafana Operator	A Kubernetes Operator for creating and managing Grafana instances.	grafana-operator	https://charts.

NOTE
Ensure that you review the software and cluster infrastructure requirements under the Prerequisites section before going ahead with the deployment.

Next Step

Deploying Ingress Controller

Pre-Installation Checklist

Consider the tasks mentioned in this checklist before deploying the Symantec Identity Security Platform helm chart.

Before you begin installing IDSP helm charts, prepare, configure, and review the following information, and perform the pre-installation tasks as required.

#	Pre-installations Tasks
1.	Check the entropy in your cluster to ensure the cluster has sufficient performance. See Checking Entropy Level.
2.	Prepare the private image registry. If your organization requires the IDSP helm chart to use images from your local image registry. Push the required images to your local image registry, see Using Local Image Registry. 1. If your image registry requires authentication, create a secret of type, docker-registry. See the Additional parameters section.
3.	Ensure that you go through the IDSP deployment guidelines to help you understand your requirement and plan your deployment so, see Sizing the Deployment.

4.	Ensure that the Ingress is deployed. See Deploying Ingress section. If you want a separate ingress for management, see Using an Existing Ingress Controller.
5.	**(Optional)** To set up the enclave (external) services offered by IDSP to be deployed in it is Kubernetes cluster and gather data for searching, logging, and monitoring from tools such as Kibana, Prometheus, and Grafana, see Deploying Enclave Services. If you want to use your own observability services, see Managing Observability. Before deploying IDSP, we recommend you to deploy the enclave services. However, if you must deploy the enclave services following the deployment of IDSP, you can do so by re-running the IDSP helm chart that makes the necessary adjustments. Broadcom team can assist you, if needed.
6.	Identify the host fqdn to be assigned to the IDSP and register it in the DNS (using the name and Ingress IP). See Constructing the Service FQDN.
7.	Obtain signed trusted certificates from your CA for external access. See the point on trusted certificates in the Additional parameters table.
8.	Choosing a database (internal, external), getting the db certificate, and create a secret. See Database Consideration. For MySQL DB, make sure that the db user used for IDSP deployment is not limited in "max_questions" and "max_queries". See DB user account note.
9.	Advanced Configuration: • Using your own TLS certificate for the internal cluster communication. See Using Custom CA for Intra Cluster SSL Communication. • If using an existing IDSP operational DB, configure an existing MEK secret for connecting to the database. See Master Encryption Key. • If you intend to update parameters, such as additionalLabels, nodeSelector, affinity, tolerations, or AWS AWS_STS_REGIONAL_ENDPOINTS for IDSP deployment, see Meeting Topology Requirements section.
10.	Check which container runtime is used in your cluster to set the fluent-bit parser mode. See the Table with additional parameters section.
11.	Configure your firewall to allow access to the following services: • enable access from the Internet to the end-user ingress, and (when using a separate ingress controller for system management) from the internal network to the mgmt ingress. • if you intend to use an LDAP ID store or SCIM ID store, ensure you allow access from the cluster to your id store. • If you intend to use SMTP, Twilio, or VIP Access Push to deliver email, SMS, or push messages from IDSP, ensure that your cluster has access to these services. See Required Ports in IDSP.
12.	When using LDAP Identity Store, IDSP supports the use of LDAP Connection Pool, see LDAP Connection Pool Considerations section.
13.	Review the Security Considerations section to know about various security related information that will help you in taking better decisions during the deployment process. See Security Considerations.
14.	Once IDSP has been deployed, the ***ssp-data helm*** chart may be optionally deployed, however it is necessary in the following cases. • when IA Risk service is operational (operational by default) • when location information associated with the user/client IP address is required in the audit events See Installing the ssp-data helm chart.
15.	Ensure that your network components are configured to preserve the client IP address, for IP-based and Country-based policies to function correctly. See Verifying the deployment section.

Required Ports in Symantec Identity Security Platform

Know about the port numbers and their respective purposes used by the Symantec Identity Security Platform solution.

This page provides a list of port numbers and their corresponding network traffic used by the IDSP solution. Opening these ports is essential to facilitate communication through the firewall, enabling the applications to function properly. If the port numbers differ from the default values, adjust the firewall configuration accordingly to ensure compatibility.

Table 30: Network Traffic Ports

Port Description	Default Port Numbers	Purpose	Inbound/ Outbound
Ingress (controller)	443	Enables communication with IDSP APIs, Admin Console, Signin UI, Kibana, Grafana, etc.	Inbound
External Database	• Mysql - 3306 • Postgress db - 5432	Enables communication between IDSP and External Database.	Outbound
External Service Provider	SMS • *Clicktell • Twilio- 443 Email • SMTP - 25, 587, 465 • *Emailie • *Twilio SendGrid • Corporate mail server - 25 IVR • 443	Enables communication between IDSP and external SMS, Email provider, IVR - required for sending OTP messages, password recovery messages, etc.	Outbound
Default Push and TOTP Provider	Default Push Provider - 443 (https://userservices-auth.vip.symantec.com/)	Enables communication between IDSP and VIP Symantec (Default) Push provider.	Outbound
External Push Provider	Custom Push - 443	Enables communication between IDSP and external Push provider.	Outbound
External Risk Engine	443	Enables communication between IDSP and external Risk Engine	Outbound
External LDAP Identity Store	389	Enables communication between IDSP and external LDAP user store	Outbound
External SCIM Identity Store	443	Enables communication between IDSP and external SCIM user store.	Outbound
Elastic Search	9200, 5601	Enables communication between Fluentbit and Elastic Search, if using elastic search for log storage.	Outbound
Siteminder Access Gateway	443	Enables communication between IDSP and Siteminder Access Gateway (REST API), if using SiteMinder Password services.	Outbound

NOTE
*If you are using services such as external IDP, Webhooks, or STS, and these services use non-standard ports, ensure that you open those ports for outbound connections form the cluster.

Table 31: Inter Pod Communication Ports

Port Description	Default Port Numbers	Purpose	Inbound/Outbound
IDSP services (REST API)	443	Enables communication to IDSP services from the Ingress(controller) and other IDSP services.	Inbound / Outbound
Hazelcast	5701	Enables communication between IDSPservices and the Hazelcast cluster.	Inbound
Hazelcast nodes inter-communication	5702	Enables communication between Hazelcast cluster member to member.	Inbound / Outbound
Internal Database	Mysql (demo db) - 3306	Enables communication between IDSP and Internal DB.	Inbound
IDSP Custom Authenticator (SPI webhook)	443	Enables communication between IDSP and Custom Authenticator	IDSP service - Outbound SPI webhook - Inbound
Jaeger	6831	Enables communication between IDSP and Jaeger	Inbound
Fluentbit	2020	Enables communication to Fluent Bit's built-in HTTP Server used to query internal information and monitor metrics.	Inbound

Checking Entropy Level in the Kubernetes Cluster

Learn how to check the entropy level in your Kubernetes cluster to avoid slowness in the performance of the Symantec Identity Security Platform solution.

Running IDSP in your Kubernetes cluster requires entropy for crypto and random number generation. You should confirm that the entropy level of your Kubernetes cluster nodes is sufficient. Lack of entropy may lead to slowness in the solution's performance.

Before deploying IDSP, ensure that the nodes in the cluster are able to generate random numbers in adequate rate to avoid performance issues in IDSP microservices.

To check the rate at which random numbers can be generated in the cluster nodes, use the following command:

```
kubectl run busybox --image=busybox:1.28 --rm -ti --restart=Never --command -- dd if=/dev/random of=/dev/null
 bs=1 count=1M
```

Or for older versions of the dd command use:

```
kubectl run busybox --image=busybox:1.28 --rm -ti --restart=Never --command -- time dd if=/dev/random of=/dev/
null bs=1 count=1M
```

The expected time for generating 1 Megabyte of random data should be about 2 seconds.

For example, the following command uses one of the Prometheus pods to execute the dd command:

NOTE

- This command assumes that Prometheus is deployed in the monitoring namespace. If the Prometheus is not deployed in the monitoring namespace, then replace "monitoring" with the correct namespace.
- The Prometheus-node-exporter is a DaemonSet and runs on all the nodes in the Kubernetes cluster. Therefore, executing the following command would run the dd tool on every node in the Kubernetes cluster.
- Depending on your Prometheus deployment, the labels set on your pods may be different. The following command uses the parameter, `--selector='app=prometheus-node-exporter'` which uses the label 'app=prometheus-node-exporter'. However, your environment may use the label "app.kubernetes.io/name=node-exporter" or even a different label. To check the labels of a specific pod run: `kubectl get pod -n monitoring prometheus-operator-node-exporter-td9x8 --show-labels`

```
(NAMESPACE=monitoring; kubectl get pods \
--namespace="${NAMESPACE}" \
--selector='app=prometheus-node-exporter' \
--output=name | while read POD; do echo "${POD}"; kubectl exec --namespace="${NAMESPACE}" "${POD}" \
-- dd if=/dev/random of=/dev/null bs=1 count=1M; echo; done)
```

Increasing the Entropy in the Kubernetes Cluster

The following methods can be used to increase the entropy at each of the ***Kubernetes nodes*** in your Kubernetes Cluster:

- If you are using a hosted Kubernetes service, consult with your cloud provider to find out if the entropy could be generated or the cluster nodes kernal could be updated so that entropy would not be required for random number generation.
- On Linux Kernel 5.6, /dev/random and getrandom do not require running an entropy generator. Consider upgrading your Kubernetes nodes to a Linux OS that uses kernel 5.6 or higher. For example, upgrading to Ubuntu 20.04.2 (which uses a Linux kernel newer than 5.6) should solve the entropy issue.
- Run an **Entropy Gathering Daemon (EGD)** that helps provide entropy to the Linux kernel. EGDs support multiple entropy sources including hardware sources. Running an EGD (such as rngd and havened) on each Kubernetes node in your cluster helps increase your cluster's entropy.
- If you are unable to change your Kubernetes nodes, you can choose to run an entropy generator as a DaemonSet in your Kubernetes cluster. The following is an example of such a deployment:

  NOTE

  - The image used in the following example is a third-party image (hortonworks/docker-haveged) and the pod would run in privileged mode to allow it access to the Kubernetes node it is running on. Therefore, before using this example in your Kubernetes cluster make sure to exercise caution and perform due diligence.
  - The tolerations section in the following DaemonSet manifest allows the pods of the DaemonSet to run on all nodes including the ones with a NoSchedule taint (for example, master nodes on BareMetal clusters).

```
$ cat <<EOF > haveged-ds.yaml
apiVersion: apps/v1
kind: DaemonSet
metadata:
  namespace: kube-system
  labels:
    run: haveged
  name: haveged
spec:
  selector:
    matchLabels:
      run: haveged
  template:
    metadata:
```

```
      labels:
        run: haveged
    spec:
      containers:
      - image: hortonworks/haveged:1.1.0
        name: haveged
        securityContext:
          privileged: true
      tolerations:
      - effect: NoSchedule
        operator: Exists
EOF

kubectl apply -f haveged-ds.yaml
```

Using Private Image Registry

Steps to pull images from Broadcom registry, push them to your private registry, and deploy Symantec Identity Security Platform using the images stored in your private registry.

A private image registry is used for enhanced security, as it provides you with more control and security over your image repositories. With a private image registry, you can ensure that only authorized users can push images to the registry, scan the images for vulnerabilities regularly so that it meets your company's security standards.

Migrating the images from the Broadcom image registry to your private image registry includes the following steps:

- Pulling images from the Broadcom registry
- Pushing images to your Private registry
- Deploying IDSP using the images stored in your private registry

Pulling images from Broadcom registry

1. To pull the IDSP images, authenticate to the Broadcom image registry (securityservices.packages.broadcom.com) . The following command is an example that shows how to authenticate to the Broadcom image registry using docker.

   ```
   docker login \
       --username "<BROADCOM_REGISTRY_USERNAME>" \
       --password "<BROADCOM_REGISTRY_PASSWORD>" \
       'securityservices.packages.broadcom.com'
   ```

   Where,

   – Password is the registry access token obtained from the support portal.

   The following are the docker pull images retrieved from the Broadcom image registry:

- docker pull securityservices.packages.broadcom.com/admin-svc:4.0.2.1075
- docker pull securityservices.packages.broadcom.com/authmgr:4.0.2.1075
- docker pull securityservices.packages.broadcom.com/factors-svc:4.0.2.1075
- docker pull securityservices.packages.broadcom.com/oidc-svc:4.0.2.1075
- docker pull securityservices.packages.broadcom.com/opa:4.0.2.1075
- docker pull securityservices.packages.broadcom.com/authswagger:4.0.2.1075
- docker pull securityservices.packages.broadcom.com/ssp-db-initializer:4.0.2.1075
- docker pull securityservices.packages.broadcom.com/authhub-adminconsole:4.0.2.1075
- docker pull securityservices.packages.broadcom.com/authhub-signin:4.0.2.1075
- docker pull securityservices.packages.broadcom.com/authhub-signin-legacy:4.0.2.1075
- docker pull securityservices.packages.broadcom.com/iaservice:4.0.2.1075
- docker pull securityservices.packages.broadcom.com/ssp-vault-secrets-initializer:4.0.2.1075
- docker pull securityservices.packages.broadcom.com/identity-svc:4.0.2.1075
- docker pull securityservices.packages.broadcom.com/ssprisk-svc:4.0.2.1075
- docker pull securityservices.packages.broadcom.com/ui-helper-svc:4.0.2.1075
- docker pull securityservices.packages.broadcom.com/geolocation-svc:4.0.2.1075
- docker pull securityservices.packages.broadcom.com/authhub-selfserviceconsole:4.0.2.1075
- docker pull securityservices.packages.broadcom.com/machineid-svc:4.0.2.1075
- docker pull securityservices.packages.broadcom.com/proxysidecar:4.0.2.1075
- docker pull securityservices.packages.broadcom.com/ssprouter:4.0.2.1075
- docker pull securityservices.packages.broadcom.com/hazelcast-enterprise:5.7.0-p0

The network data image contains fraud details and is released every week. There may be a newer version than the following version:

- docker pull securityservices.packages.broadcom.com/network-data-loader:2026.20

The following are the optional images used for the sample applications:

- docker pull securityservices.packages.broadcom.com/sample-rp:4.0.2.1075
- docker pull securityservices.packages.broadcom.com/sample-app:4.0.2.1075
- docker pull securityservices.packages.broadcom.com/spi-demo:4.0.2.1075
- docker pull securityservices.packages.broadcom.com/cadir:4.0.2.1075

Pushing images to your private registry

> **NOTE**
> While migrating the images from the Broadcom registry to your private registry, it is recommended to keep the same base path for all the IDSP images, image names and keep the original image tags. Doing this allows you to use the IDSP Helm chart parameter, "***imageRepositoryBase***" to configure IDSP chart to use the images from your private registry.

To push images to your private registry, follow these steps:

1. Tag the images to include your private image registry name.
   The following command is an example that shows how to tag the images before pushing them to the private image registry using the docker command:
   ```
   docker tag "<IMAGE_FULL_NAME>" "<PRIVATE_REGISTRY>/<IMAGE_FULL_NAME>"
   ```
   Where, PRIVATE_REGISTRY - this is the full name of the private registry image where you are storing the IDSP images. It is recommended to keep the origin of the image as part of the image path. An example of an image full name in the private registry: "images.example.com/securityservices.packages.broadcom.com/admin-svc:1.0.3211".
2. Push the images to the private registry using the new tag name.
   The following command is an example that shows how to push the images to the private image registry using the docker command:

```
docker push "<PRIVATE_REGISTRY>/<IMAGE_FULL_NAME>"
```

Deploying IDSP using the images stored in your private registry

To deploy IDSP using the images stored in your private image repository, add the following commands to the Deploying IDSP Helm Chart command:

```
--set ssp.global.ssp.registry.imageRepositoryBase="<PRIVATE_REGISTRY>/securityservices.packages.broadcom.com/"
 \
--set hazelcast-enterprise.image.repository="<PRIVATE_REGISTRY>/securityservices.packages.broadcom.com/
hazelcast-enterprise"
```

NOTE

- This configuration parameter assumes that all images are stored in a common base path.
- The "`--set ssp.global.ssp.registry.imageRepositoryBase` " command should be used when deploying the IDSP Infra helm chart, IDSP (ssp) helm chart, ssp-data helm chart, and Sample Web Application helm chart.
- The "`--set hazelcast-enterprise.image.repository` " command is needed ONLY when deploying IDSP helm chart. It is not required for deploying the IDSP Infra, ssp-data, or Sample Web Application helm charts.

Using Image Digest in Symantec Identity Security Platform Charts

Symantec Identity Security Platform charts' values.yaml contains both the image tag and the image digest of each image. Learn to use Image Digest to have the correct version of a container image in your environment.

As image tags are mutable, and multiple images can share the same tag, this makes it difficult to track which version of the container image is running in the cluster. To ensure that a pod is using the correct version of a container image, you can specify the image digest. The image digest uniquely identifies a specific version of the image. Therefore, to improve security, image digest (hash value) is preferred over using image tag.

This topic includes the following sub-topics:

- Using Image Digest
- Enabling useImageDigest Setting
- Updating the values.yaml with the Image Digest

You can refer to an image in a Kubernetes pod by using the image tag or by using the image digest:

Example of Image tag:

```
image: securityservices.packages.broadcom.com/admin-svc:1.0.3160
```

Example of Image digest:

```
image: securityservices.packages.broadcom.com/admin-svc:1.0.3160@sha256:aa8d179c015b01ef...
 985acd76b3e019189c88cb9b9510d0f1
```

NOTE
The separator between the image repository and the image tag is (:), whereas the separator between the image repository and the digest is (@).

Using Image Digest

IDSP charts support the use of image digest. The chart's values.yaml indicates the image for every component and for every image the chart's values.yaml specifies the image repository, tag, and digest (hash).

For Example:

```
admin:
```

```
imageRepository: "securityservices.packages.broadcom.com/admin-svc"
imageTag: 1.0.3170
imageDigest: "sha256:7a5538f3a3bcaf24eb7fd37e889078879651a6a02bc8ba85d01d570fdf43d6e7"
```

By default, IDSP charts' values.yaml contains both the image tag and the image digest of each image.

Enabling useImageDigest Setting

To use the image digest in the IDSP helm charts, set the global setting, "ssp.global.useImageDigest" to true in IDSP as shown in the following example:

```
ssp:
global:
useImageDigest: true
registry:
  credentials:
    password: pwd
    username: user
...
```

The IDSP helm charts use the following logic to determine whether to use an image digest, image tag, or the chart's AppVersion:

- If the "useImageDigest" parameter is set to true and the image digest is available, IDSP helm charts use it.
- If there is no image digest, the charts look for the image tag. IDSP helm charts use the Image tag if it is available.
- IDSP helm charts use the chart's AppVersion as the image tag if no image tag is available.

> **NOTE**
> To use the image digests for Hazelcast, you should set the hazelcast-enterprise.image.tag to null or "" as it is part of the Hazelcast Enterprise sub chart as shown in the following example: hazelcast-enterprise:
>
> ```
> image:
>    repository: "securityservices.packages.broadcom.com/hazelcast-enterprise"
>    tag: "5.1.3-ssl-D9P5"
>    # HC uses imageDigest only if image tag is empty (pass tag as "")
>    digest: "sha256:e653a5b73a515d553616f635939d8014c576e77920e5bad05f36a6553236482a"
> ```

Updating the values.yaml with the Image Digest

You can use the following command to retrieve the image digest of a container image:

```
export imageDigest =$(docker inspect --format='{{index .RepoDigests 0}}' us.gcr.io/saasdev-sed-ssp-hp/spi-demo:1.0.uc604043-1|cut -d'@' -f 2)
```

The following command can be used to update the values.yaml: This particular example uses: yp from: here.

```
yq -i ".ssp.factor.imageDigest = "$imageDigest"" 'ssp/values.yaml'
```

Ingress Overview

Symantec Identity Security Platform provides an Ingress resource that can be read by NGNIX Ingress controller to route the incoming traffic to the different microservices. The Ingress resource contains the rules that govern the traffic to the microservices.

IDSP supports different sets of operational APIs that are represented by endpoints that are exposed through an Ingress:

- **System management operations**: This set includes all the API endpoints that manage the infrastructure of the system such as managing the signing keys, managing the system-wide settings, creating tenants, exposing the

Enclave services. These operations execute in the context of the "system" tenant. The system management operations are mostly restricted to an internal audience.

- **Tenant management operations**: This set includes all the API endpoints that administer the security artifacts of a tenant such as policies, applications. These operations are multi-tenant. The tenant management operations can be exposed to an internal and/or external audience.
- **End user operations**: This set includes all the API endpoints that authenticate tenant end users and support the self-service credential management by tenant end users. These operations are multi-tenant. The end-user operations are typically exposed to an external audience.

Ingress Partitioning

IDSP provides different out-of-the-box Ingress objects to expose the system management and tenant management operations on the same Ingress controller. Due to security reasons as described in Security Considerations, you can choose to expose these operations on different Ingress controllers too.

As the end-user operations do not have an out of the box Ingress object defined, you can create such an Ingress object to expose this set of operational APIs *after deploying* IDSP. These operations are tied to a tenant vanity URL.

In a production environment, you can choose to expose the operational APIs sets using the following Ingress partitioning options:

- Expose system management and tenant management operations on the same Ingress controller on an internal network, while exposing end-user operations on a different Ingress controller on an external network.
- Expose system management on an Ingress controller on an internal network, while exposing the tenant management operations and end-user operations on a different Ingress controller on an external network.

Reference Links:

- Deploying one or more Ingress controllers, see Deploy Ingress Controller.
- Deploying Nginx Ingress controller in IDSP Namespace, see here.
- Deploying Ingress Controller in OpenShift Cluster, see here.
- Managing Custom Vanity Ingress, see Managing Custom Vanity Ingress.
- How Ingress works in Kubernetes, see Kubernetes.

Deploying Ingress Controller

Learn how to deploy an Ingress Controller in your cluster environment.

The default ingress deployment of Symantec Identity Security Platform exposes the system management and tenant management operations on the same Ingress Controller. Due to security reasons as described in Security Considerations, you can choose to expose these operations on different Ingress Controllers too.

This topic includes the following:

- Using an Existing Ingress Controller
- Deploying a New Ingress Controller
- Retrieving Ingress IP
- Setting "topologySpreadConstraints" for Ingress deployment

Using an Existing Ingress Controller

IDSP requires that you have an ingress controller of type, NGINX. The Ingress Helm Chart should be of version 4.14.3 and the Ingress-Nginx app version should be v1.14.3.

If you have an existing ingress controller that meets the preceding requirement, you can skip the ingress controller deployment steps that are mentioned in the following section **(Using a New Ingress Controller)** and use the ingressClassName during the IDSP deployment.

Your existing ingress controller deployment is associated with an Ingress Class. The ingress class name of your ingress controller should be used when deploying the IDSP chart. By default, the IDSP uses the **ingressClassName**, "nginx". In case, your ingress controller uses a different class name, specify it during IDSP (SSP helm chart) deployment using the following parameter:

```
--set ssp.ingress.ingressClassName=<ingress-class-name>
```

Deploying a New Nginx Ingress Controller

The following procedure describes how to deploy the Nginx ingress controller. The procedure also includes information about the parameter that must be set to expose the tenant management operations on a different ingress controller.

Follow these steps:

1. Create an ingress namespace.

   ```
   kubectl create ns ingress
   ```

2. Create a secret if you want to use specific credentials to pull images from the container registry. The following example shows how to create a secret for the Docker Hub registry with a name - "***docker-hub-reg-pullsecret***":

   ```
   kubectl create secret docker-registry docker-hub-reg-pullsecret -n <namespace> \
   --docker-server="https://index.docker.io/v2/" \
   --docker-username="<dockerhub-username>" \
   --docker-password="<dockerhub-password>"
   ```

   NOTE

   Docker Hub applies rate limiting to anonymous and free authenticated accounts for pulling images. If your deployment is going to pull images from Docker Hub, we recommend that you provide the deployment with your docker hub credentials. This is done by creating a secret and specifying it in the helm install command. For example, in the ingress-nginx Helm chart deployment command, add the following parameter:

   ```
   --set imagePullSecrets[0].name=docker-hub-reg-pullsecret
   ```

   where, docker-hub-reg-pullsecret is the name of a Kubernetes secret of type, docker-registry.

   If you exceed the limit for pulling images, your pod may not initialize and the pod gets into a state of "ImagePullBackOff". The following error messages may show up when you perform a kubectl describe pod:

   ```
   ERROR: toomanyrequests: Too Many Requests.
   OR
   You have reached your pull rate limit. You may increase the limit by authenticating and
    upgrading.
   ```

3. Locate the Helm chart and get the latest Helm chart updates.

   ```
   helm repo add ingress-nginx https://kubernetes.github.io/ingress-nginx
   helm repo update
   ```

4. ***[Only for OpenShift]*** Create a Security Context Constraints (SCC) policy to allow Ingress to use the NET_BIND_SERVICE capability and runAsUser 101 (default controller user).

   ```
   cat <<EOF | kubectl apply -f -
   apiVersion: security.openshift.io/v1
   kind: SecurityContextConstraints
   metadata:
   name: nginx-ingress-scc

   priority: null
   users:
   - system:serviceaccount:ingress:ingress-nginx-admission
   - system:serviceaccount:ingress:ingress-nginx
   groups: []

   allowHostDirVolumePlugin: false
   ```

```
allowHostIPC: false
allowHostNetwork: false
allowHostPID: false
allowHostPorts: false
allowPrivilegeEscalation: true
allowPrivilegedContainer: false
allowedCapabilities: null
defaultAddCapabilities:
- NET_BIND_SERVICE
readOnlyRootFilesystem: false
requiredDropCapabilities:
- ALL
runAsUser:
type: MustRunAs
uid: 101
fsGroup:
type: MustRunAs
seLinuxContext:
type: MustRunAs
supplementalGroups:
type: MustRunAs
volumes:
- secret
EOF
```

In the next step, select the platform hosting the OpenShift environment by choosing either the Public or Virtual Private Cloud (VPC) steps.

5. Deploy Ingress Controller.

NOTE

- If deploying the ingress-nginx controller in an ***OpenShift*** cluster environment, add the following parameter to the ingress-nginx helm deployment command:

```
--set controller.admissionWebhooks.patch.securityContext.runAsUser=101 \
--set controller.admissionWebhooks.patch.securityContext.fsGroup=$(kubectl get ns ingress -o
 jsonpath='{.metadata.annotations.openshift\.io/sa\.scc\.uid-range}'|cut -d '/' -f1) \
--set controller.allowSnippetAnnotations=true
```

- To enable the ingress-nginx controller metrics in the ingress deployment for monitoring purpose, add the following parameters to the ingress-nginx helm deployment command:

```
--set controller.metrics.enabled=true \
--set controller.metrics.serviceMonitor.enabled=true \
--set-string controller.metrics.serviceMonitor.additionalLabels."release"="prometheus-
operator"
```

- If you are planning to deploy multiple ingress controllers in order to create network separation between system management operations, tenant admin operations, and end-user operations, ensure you assign each of these deployments a dedicated ingress-class-name by adding the following parameter to the ingress-nginx helm deployment command:

```
--set controller.ingressClassResource.name=<new-ingress-class-name> \
--set controller.ingressClassResource.controllerValue=<controller name (default "k8s.io/
ingress-nginx")>
```

- The deployment parameters used in the AWS (EKS) environment command require "AWS load balancer controller" to be deployed in the AWS EKS cluster. For more info see, Installing the AWS Load Balancer Controller add-on.

– ***Deploy Ingress Controller in a cloud environment.***

- Deploy an ingress controller that is **publicly accessible on the Internet** by using a Load Balancer with a public IP address.

  Command to run in Amazon (EKS) environment:

```
helm install ingress-nginx -n ingress ingress-nginx/ingress-nginx \
--set controller.service.annotations."service\.beta\.kubernetes\.io/aws-load-balancer-
scheme"="internet-facing" \
--set controller.service.annotations."service\.beta\.kubernetes\.io/aws-load-balancer-
type"="external" \
--set controller.service.annotations."service\.beta\.kubernetes\.io/aws-load-balancer-proxy-
protocol"="*" \
--set controller.service.annotations."service\.beta\.kubernetes\.io/aws-load-balancer-nlb-target-
type"="instance" \
--set controller.service.annotations."service\.beta\.kubernetes\.io/aws-load-balancer-target-group-
attributes"="preserve_client_ip.enabled=true" \
--set-string controller.config.use-proxy-protocol="true" \
--set-string controller.config.use-forwarded-headers="true" \
--set imagePullSecrets[0].name=docker-hub-reg-pullsecret \
--set-string controller.config.annotation-value-word-blocklist="load_module\,lua_package\,_by_lua
\,location\,root\,proxy_pass\,serviceaccount\,{\,}\,\'\,\\\\" \
--version=4.14.3 \
--set controller.allowSnippetAnnotations=true \
--set controller.service.externalTrafficPolicy="Local" \
--set controller.config.annotations-risk-level=Critical
```

  Command to run in Google Cloud - GKE environments:

```
helm install ingress-nginx -n ingress ingress-nginx/ingress-nginx \
--set-string controller.config.use-forwarded-headers="true" \
--set imagePullSecrets[0].name=docker-hub-reg-pullsecret \
--set-string controller.config.annotation-value-word-blocklist="load_module\,lua_package\,_by_lua
\,location\,root\,proxy_pass\,serviceaccount\,{\,}\,\'\,\\\\" \
--version=4.14.3 \
--set controller.allowSnippetAnnotations=true \
--set controller.service.externalTrafficPolicy="Local" \
--set controller.config.annotations-risk-level=Critical
```

  Command to run in Azure - AKS environments:

```
helm install ingress-nginx -n ingress ingress-nginx/ingress-nginx \
--set-string controller.config.use-forwarded-headers="true" \
--set imagePullSecrets[0].name=docker-hub-reg-pullsecret \
--set-string controller.config.annotation-value-word-blocklist="load_module\,lua_package\,_by_lua
\,location\,root\,proxy_pass\,serviceaccount\,{\,}\,\'\,\\\\" \
--version=4.14.3 \
--set controller.allowSnippetAnnotations=true /
--set controller.config.annotations-risk-level=Critical
```

  NOTE
  To define a specific IP address for the load balancer of the Ingress service, use the **--set controller.service.loadBalancerIP=<IP-address>** parameter in the helm install command. For information about using this parameter and reserving an IP address, see the documentation of your cloud environment.

  Example:

```
helm install ingress-nginx -n ingress ingress-nginx/ingress-nginx \
--set-string controller.config.use-forwarded-headers="true" \
--set imagePullSecrets[0].name=docker-hub-reg-pullsecret \
--set controller.service.loadBalancerIP=192.168.255.255 \
```

```
--set-string controller.config.annotation-value-word-blocklist="load_module\,lua_package
\,_by_lua\,location\,root\,proxy_pass\,serviceaccount\,{\,}\,\'\,\\\\" \
--version=4.14.3 \
--set controller.allowSnippetAnnotations=true \
--set controller.service.externalTrafficPolicy="Local" \
--set controller.config.annotations-risk-level=Critical
```

Command to run in VKS - (VCF with VMware Kubernetes Services) Environment:

```
helm install ingress-nginx -n ingress ingress-nginx/ingress-nginx
--set controller.allowSnippetAnnotations=true \
--set controller.service.externalTrafficPolicy="Local" \
--set-string controller.config.use-forwarded-headers="true" \
--set controller.service.type=LoadBalancer \
--set controller.service.loadBalancerIP=<IPADDR> \
--set controller.image.pullPolicy="IfNotPresent" \
--set-string controller.config.annotation-value-word-blocklist="load_module\,lua_package\,_by_lua
\,location\,root\,proxy_pass\,serviceaccount\,{\,}\,\'\,\\\\" \
--version=4.14.3 \
--set controller.config.annotations-risk-level=Critical \
--set controller.service.loadBalancerClass=ako.vmware.com/avi-lb
```

- **Deploy ingress controller that is only accessible by applications in the same VPC network and compute region.**

  Command to run in Google Cloud (GKE) environment:

```
helm install ingress-nginx -n ingress ingress-nginx/ingress-nginx \
--set controller.service.annotations."cloud\.google\.com/load-balancer-type"="Internal" \
--set controller.service.externalTrafficPolicy="Local" \
--set-string controller.config.use-forwarded-headers="true" \
--set imagePullSecrets[0].name=docker-hub-reg-pullsecret \
--set-string controller.config.annotation-value-word-blocklist="load_module\,lua_package\,_by_lua
\,location\,root\,proxy_pass\,serviceaccount\,{\,}\,\'\,\\\\" \
--version=4.14.3 \
--set controller.allowSnippetAnnotations=true \
--set controller.config.annotations-risk-level=Critical
```

  Command to run in Amazon (EKS) environment:

```
helm install ingress-nginx -n ingress ingress-nginx/ingress-nginx \
--set controller.service.annotations."service\.beta\.kubernetes\.io/aws-load-balancer-
internal"="true" \
--set controller.service.annotations."service\.beta\.kubernetes\.io/aws-load-balancer-
type"="external" \
--set controller.service.annotations."service\.beta\.kubernetes\.io/aws-load-balancer-proxy-
protocol"="*" \
--set controller.service.annotations."service\.beta\.kubernetes\.io/aws-load-balancer-nlb-target-
type"="instance" \
--set controller.service.annotations."service\.beta\.kubernetes\.io/aws-load-balancer-target-group-
attributes"="preserve_client_ip.enabled=true" \
--set-string controller.config.use-proxy-protocol="true" \
--set-string controller.config.use-forwarded-headers="true" \
--set imagePullSecrets[0].name=docker-hub-reg-pullsecret \
--set-string controller.config.annotation-value-word-blocklist="load_module\,lua_package\,_by_lua
\,location\,root\,proxy_pass\,serviceaccount\,{\,}\,\'\,\\\\" \
--version=4.14.3 \
--set controller.allowSnippetAnnotations=true \
```

```
--set controller.service.externalTrafficPolicy="Local" \
--set controller.config.annotations-risk-level=Critical
```

Command to run in Azure (AKS) environment:

```
helm install ingress-nginx -n ingress ingress-nginx/ingress-nginx \
--set controller.service.annotations."service\.beta\.kubernetes\.io/azure-load-balancer-
internal"="true" \
--set-string controller.config.use-forwarded-headers="true" \
--set imagePullSecrets[0].name=docker-hub-reg-pullsecret \
--set-string controller.config.annotation-value-word-blocklist="load_module\,lua_package\,_by_lua
\,location\,root\,proxy_pass\,serviceaccount\,{\,}\,\'\,\\\\" \
--version=4.14.3 \
--set controller.allowSnippetAnnotations=true \
--set controller.config.annotations-risk-level=Critical
```

6. ***[Only for OpenShift]*** If you do not see the ingress pod, ensure that you have created the SCC object correctly by running the following command to inspect the Kubernetes events:

```
$ kubectl get events -n ingress

ingress 0s Warning FailedCreate job/ingress-nginx-admission-create Error creating: pods "ingress-
nginx-admission-create-" is forbidden: unable to validate against any security context constraint:
 [provider "anyuid": Forbidden: not usable by user or serviceaccount, provider nginx-ingress-
scc: .spec.securityContext.fsGroup: Invalid value: []int64{2000}: 2000 is not an allowed group,
 spec.containers[0].securityContext.runAsUser: Invalid value: 2000: must be: 101, provider
 restricted: .spec.securityContext.fsGroup: Invalid value: []int64{2000}: 2000 is not an allowed group,
 spec.containers[0].securityContext.runAsUser: Invalid value: 2000: must be in the ranges: [1000650000,
 1000659999], provider "nonroot": Forbidden: not usable by user or serviceaccount, provider "hostmount-
anyuid": Forbidden: not usable by user or serviceaccount, provider "machine-api-termination-handler":

 serviceaccount, provider "hostaccess": Forbidden: not usable by user or serviceaccount, provider "node-
exporter": Forbidden: not usable by user or serviceaccount, provider "privileged": Forbidden: not usable
 by user or serviceaccount]
```

7. To validate the deployment of Ingress Controller, run this command for both cloud provider and on-premise:

```
kubectl get nodes
kubectl get pods -n ingress
```

Verify that all the pods are in Running State and *Ready (1/1)*. It may take a little while for the pods to get to the ready state.

Retrieving the Ingress IP Address

1. To get the Ingress IP address, run the following command:

```
kubectl get svc -n ingress ingress-nginx-controller
```

Where, ingress-*nginx-controller* is the name of the ingress controller Kubernetes service. The ingress IP address is listed under the "EXTERNAL_IP" column. When running this command on a cloud provider cluster, the "EXTERNAL_IP" may take a few minutes to be displayed since the service load balancer must be provisioned.

Setting "topologySpreadConstraints" for Ingress deployment

To improve ingress deployment reliability when the "controller.kind" is set to "Deployment" (default), include the following topology constraint. This ensures that the ingress pods are spread across different cluster nodes, and when deployed on a multi-zone cluster, the pods will also be spread across different zones. This parameter contains multiple lines and therefore is easier to specify in an override values yaml file. For example:

```
controller:
topologySpreadConstraints:
```

```
- maxSkew: 1
  topologyKey: topology.kubernetes.io/zone
  whenUnsatisfiable: ScheduleAnyway
  labelSelector:
    matchLabels:
      app.kubernetes.io/name: '{{ include "ingress-nginx.name" . }}'
      app.kubernetes.io/instance: '{{ .Release.Name }}'
      app.kubernetes.io/component: controller
- maxSkew: 1
  topologyKey: kubernetes.io/hostname
  whenUnsatisfiable: ScheduleAnyway
  labelSelector:
    matchLabels:
      app.kubernetes.io/name: '{{ include "ingress-nginx.name" . }}'
      app.kubernetes.io/instance: '{{ .Release.Name }}'
      app.kubernetes.io/component: controller
```

Next Step

Deploying Enclave Services

Deploying NGINX Ingress in Symantec Identity Security Platform Namespace

Learn how to deploy Ingress in Symantec Identity Security Platform (IDSP)Namespace.

The standard option to deploy IDSP uses NGINX Ingress Controller deployed as a shared service in a global Kubernetes namespace. In a cluster where the operator has limited permissions, it may be required to deploy NGINX Ingress Controller as a private service in the IDSP Kubernetes namespace. Whether you want to deploy NGINX Ingress globally or scoped to a namespace, deploying on OpenShift requires use of custom SCC that may not always be welcome by organization's security/governance policy.

> **NOTE**
> The minimum required Kubernetes cluster privilege to deploy Ingress in the IDSP namespace is **Cluster Admin in the namespace**. This can be done by creating a RoleBinding to the cluster-admin ClusterRole in the namespace.

Follow these steps to deploy Nginx Ingress in the IDSP namespace on ***OpenShift***:

1. Creating the SCC (Security Context Constraints)
2. Deploying NGINX Ingress in IDSP namespace
3. Create the OpenShift Routes for IDSP's Business and Management Ingress hosts
4. Update the DNS to point IDSP Business

Creating the Security Context Constraints (SCC)

Use the following command to create a Security Context Constraints (SCC). Ensure that you update the "NAMESPACE" environment variable with the name of the **IDSP Kubernetes Namespace** before running it:

```
export NAMESPACE="<ssp_namespace>"
```

```
cat <<EOF | kubectl apply -f -
apiVersion: security.openshift.io/v1
kind: SecurityContextConstraints
```

```
metadata:
  name: nginx-ingress-scc

priority: null
users:
- system:serviceaccount:${NAMESPACE}:ingress-nginx
groups: []

allowHostDirVolumePlugin: false
allowHostIPC: false
allowHostNetwork: false
allowHostPID: false
allowHostPorts: false
allowPrivilegeEscalation: false
allowPrivilegedContainer: false
allowedCapabilities:
- NET_BIND_SERVICE
defaultAddCapabilities: null
readOnlyRootFilesystem: false
requiredDropCapabilities:
- ALL
runAsUser:
  type: MustRunAs
  uid: 101
fsGroup:
  type: MustRunAs
seLinuxContext:
  type: MustRunAs
supplementalGroups:
  type: MustRunAs
seccompProfiles:
- '*'
volumes:
- secret
EOF
```

Deploying NGINX Ingress in IDSP namespace

NOTE

- Minimum admin privileges require cluster-admin role scoped to the namespace where IDSP is going to be deployed.
- Do not apply the Role and RoleBining yaml manually.

Use the following commands to deploy NGINX Ingress in IDSP Namespace. Before proceeding with the Ingress deployment, ensure that you update the following environment variables:

- SSP_FQDN - IDSP FQDN
- NAMESPACE - IDSP Kubernetes Namespace
- RELEASENAME - IDSP Helm Releasename
- INGRESS_SERVICE_TYPE - It is recommended to use a service-type as LoadBalancer. If you do not have the permission to expose the ingress service as a load balancer, use cluster IP (This option requires you to create an

OpenShift Route object that will route traffic to this service, see Create the OpenShift Routes for IDSP's Business and Management Ingress hosts.

```
export SSP_FQDN="<ssp-FQDN>"
export NAMESPACE="<ssp-namespace>"
export INGRESS_SERVICE_TYPE="<LoadBalancer or ClusterIP>"

helm repo add ingress-nginx https://kubernetes.github.io/ingress-nginx
helm repo update
helm install ingress-nginx -n ${NAMESPACE} ingress-nginx/ingress-nginx \
  --version=4.14.3 \
  --set imagePullSecrets[0].name=docker-hub-reg-pullsecret \
  --set-string controller.config.annotation-value-word-blocklist="load_module\,lua_package\,_by_lua\,location
\,root\,proxy_pass\,serviceaccount\,{\,}\,\'\,\\\\" \
  --set controller.service.type=${INGRESS_SERVICE_TYPE} \
  --set controller.scope.enabled=true \
  --set controller.image.runAsUser=101 \
  --set controller.image.allowPrivilegeEscalation=false \
  --set controller.admissionWebhooks.enabled=false \
  --set controller.ingressClassResource.enabled=false \
  --set controller.watchIngressWithoutClass=true \
  --set controller.allowSnippetAnnotations=true \
  --set controller.service.externalTrafficPolicy="Local"
```

Create the OpenShift Routes for IDSP's Business and Management Ingress Hosts

If you chose INGRESS_SERVICE_TYPE="LoadBalancer" in the previous Helm command, you can ***skip*** this step. However, if you chose INGRESS_SERVICE_TYPE="ClusterIP", the Nginx Ingress service would not be exposed as a load balancer.

Perform the following step to expose the ingress service through an OpenShift route.

NOTE

- The environment variables used in the following command are defined in the previous step.
- The following command creates two route objects, one for tenant operations and the other for the system management operations. You may want to expose the system management route only to the intern network.
- For more information on exposing apps with OpenShift routes, see here.

- Use the following commands to create the IDSP's business and management routes:

```
cat <<EOF | kubectl apply -f -
kind: Route
apiVersion: route.openshift.io/v1
metadata:
  name: ${RELEASENAME}-ssp-route
  namespace: ${NAMESPACE}
  labels:
    app.kubernetes.io/component: route
    app.kubernetes.io/instance: ${RELEASENAME}
spec:
  host: ${SSP_FQDN}
  to:
    kind: Service
    name: ingress-nginx-controller
    weight: 100
```

```
  port:
    targetPort: https
  tls:
    termination: passthrough
    insecureEdgeTerminationPolicy: None
  wildcardPolicy: None
EOF

cat <<EOF | kubectl apply -f -
kind: Route
apiVersion: route.openshift.io/v1
metadata:
  name: ${RELEASENAME}-ssp-route-mgmt
  namespace: ${NAMESPACE}
  labels:
    app.kubernetes.io/component: route
    app.kubernetes.io/instance: ${RELEASENAME}
spec:
  host: mgmt-${SSP_FQDN}
  to:
    kind: Service
    name: ingress-nginx-controller
    weight: 100
  port:
    targetPort: https
  tls:
    termination: passthrough
    insecureEdgeTerminationPolicy: None
  wildcardPolicy: None
EOF
```

After creating the routes, confirm the routes are associated with the newly deployed NGINX Ingress Controller service in the IDSP namespace.

```
bash-4.4 ~ $ k get routes -n ssp1
NAME                      HOST/PORT                                                PATH   SERVICES                   PORT    TERMINATION          WILDCARD
sspvipdbos-ssp-route      nightly-os-ssp.clusters.demo.sspdev.dev.broadcom.com            ingress-nginx-controller   https   passthrough/None     None
sspvipdbos-ssp-route-mgmt mgmt-nightly-os-ssp.clusters.demo.sspdev.dev.broadcom.com       ingress-nginx-controller   https   passthrough/None     None
bash-4.4 ~ $
```

Updating the DNS to point to IDSP Service Business

Perform this step to update the DNS to point to the IDSP Business and the Management Host to OS Ingress Controller's external IP Address. The IP Address belongs to the "router-default" service in the "openshift-ingress" namespace that can be viewed through the OS Console UI or Kubernetes CLI.

```
bash-4.4 ~ $ kubectl get svc -n openshift-ingress
NAME                      TYPE           CLUSTER-IP      EXTERNAL-IP     PORT(S)                      AGE
router-default            LoadBalancer                                   80:31395/TCP,443:32088/TCP   95d
router-internal-default   ClusterIP                      <none>          80/TCP,443/TCP,1936/TCP      95d
bash-4.4 ~ $
```

Ingress Controller on OpenShift

Learn about various options to deploy Ingress in the OpenShift environment.

This topic includes the following sections:

- Multi-Tenant URL Patterns and Operations
- Deployment Configuration
- Advanced Configuration
- Multi-Tenancy Management

Multi-Tenant URL Patterns and Operations

IDSP is a multi-tenant service, even if the deployment is planning to use a single tenant. When using OpenShift Routes, URLs for the business ingress follow different patterns covering construction of the host FQDN such as SSP_FQDN = "authentication.corporate.acme.com".

NOTE

- For the management ingress, the URL always starts with "https://system.<SSP_FQDN>/system/...". The SSL certificate must be issued for the exact host FQDN, or a wildcard certificate must be issued for the SSP_FQDN host.
- "<tenant-placeholder-in-url-path>" in the API path is just a placeholder defaulting to "common". It does not need to correspond to the actual tenant name associated with the vanity host FQDN. This placeholder can be any URL-friendly string passed into the chart deployment.

URL Pattern Options

Routing Strategy	When to use this strategy	Business Ingress URL	Notes	Postman Configurations
Subdomain under SSP-FQDN host	When using tenant "default".	https://<tenant-name>**.<SSP_FQDN>**/<tenant-placeholder-in-url-path>/...	This is the default, out-of-the-box ingress configuration generated by the standard helm chart when deployed in the OpenShift Routes mode. SSL certificates must be issued for the exact host FQDNs, or a wildcard certificate must be issued for the SSP_FQDN host. Additional tenants created via /Tenants API will not be routable as no ingress/route definitions can be created supporting this strategy.	• pm.environment.set("apiPathTen "common"); • pm.environment.set("sspHost", "default.authentication.corporate • pm.environment.set("sspMgmtH "system.authentication.corporate
End User Vanity host	When using a tenant exposed via custom vanity hosts. Any tenant can be exposed using this strategy.	https://**login.acme.com**/<tenant-placeholder-in-url-path>/...	End User Vanity host created as per documentation enables use of custom vanity host domains. The tenant identified by the vanity host FQDN must exist. SSL certificate must be issued for the vanity host FQDN. Additional tenants to be exposed as vanity hosts are created by /Tenants system management API.	• pm.environment.set("apiPathTen "iam"); • pm.environment.set("sspHost", "login.acme.com"); • pm.environment.set("sspMgmtH "system.authentication.corporate

Routing Strategy	When to use this strategy	Business Ingress URL	Notes	Postman Configurations
X-TENANT-NAME header asserted on the API request exposed on SSP-FQDN host	When multi-tenancy is required. Any tenant can be exposed using this strategy.	https://**<SSP_FQDN>**/<tenant-placeholder-in-url-path>/... header: X-TENANT-NAME = <tenant-name>	APIs exposed by domain <SSP-FQDN> indicate resource tenancy using X-TENANT-NAME header. If the header is not provided, API request will fail with 400 BAD REQUEST status. The tenant identified by X-TENANT-NAME must exist. SSL certificate must be issued for the SSP_FQDN host. Additional tenants are created by /Tenants system management API. Clients using those tenants are responsible for sending X-TENANT-NAME header.	• pm.environment.set("apiPathTen "common"); • pm.environment.set("sspHost", "authentication.corporate.acme. • pm.environment.set("sspMgmtH "system.authentication.corporate

Deployment Configuration

Specifying "Ingress Type" and "Ingress ClassName"

- If you intend to use **OpenShift Routes** when deploying IDSP, pass these additional parameters in the IDSP helm deployment command.
- **Note that OpenShift Route requires OpenShift version 4.18 and above.**

Basic Deployment Parameters

For a basic OpenShift Routes deployment, you need these parameters:

```
--set ssp.ingress.type="openshiftroute" \
--set ssp.ingress.ingressClassName="openshift-default" \
--set ssp.ingress.host="${SSP_FQDN}" \
--set ssp.ingress.mgmt.host="${SSP_MGMT_FQDN}"
```

Optional Deployment Parameters

To deploy IDSP chart in "OpenShift Routes" mode, the following optional helm parameters can be provided during helm install/upgrade:

```
--set ssp.ingress.mgmt.ingressClassName="openshift-default"  # (optional, if not provided defaults to
 ssp.ingress.ingressClassName)
--set ssp.ingress.tls.host="${SSP_FQDN}"  # (optional, if not provided defaults to ssp.ingress.host)
--set ssp.ingress.mgmt.tls.host="${SSP_MGMT_FQDN}"  # (optional, if not provided defaults to
 ssp.ingress.mgmt.host)
--set ssp.ingress.tls.secretName="default-tls-secret-name"  # (optional, if not provided defaults to ssp-
general-tls)
--set ssp.ingress.mgmt.tls.secretName="system-tls-secret-name"  # (optional in case wildcard certificate is
 used for the SSP_FQDN host, if not provided defaults to ssp.ingress.tls.secretName)
--set ssp.ingress.openShiftRoute.defaultTenant="<default-tenant>"  # (optional, defaults to "default")
```

```
--set ssp.ingress.openShiftRoute.defaultTenantPlaceholderInPath="<tenant-placeholder-in-url-path>"  #
 (optional, defaults to "common")
```

Advanced Configuration

Supporting IDSP Tenant Name in the URL Path

From IDSP v3.2.1 onwards, to provision OpenShift Routes to use the IDSP FQDN host with a default tenant name included in the API path, the IDSP deployment process requires specifying the parameter:

`--set ssp.ingress.openShiftRoute.isDefaultTenantInPath=true`

This configuration lets OpenShift Routes to be provisioned as:

`https://<SSP-FQDN>/<tenant-name>/`

The specified default tenant can be routed to using a tenant in **host or in the URL path**. All other tenants are accessible using the vanity URLs only.

Configuration Options

- If "`ssp.ingress.openShiftRoute.isDefaultTenantInPath=false` " - routing for the default tenant uses the format: `https://<defaultTenant>.${SSP_FQDN}/common`
  Example: "`https://default.${SSP_FQDN}/common/... `"
- If "`ssp.ingress.openShiftRoute.isDefaultTenantInPath=true` " - routing for the default tenant uses the format: "`https://${SSP_FQDN}/<defaultTenant>`"
  Example: "`https://${SSP_FQDN}/default/...`"

To know the value of the ${SSP_FQDN} environment variable, see the Configuring IDSP Environment Variables documentation.

Multi-Tenancy Management

The "/Tenants" system management API creates a new tenant or updates an existing tenant. After creating a tenant, follow steps covered in Expose End User Operations on a Vanity Ingress section to create ingress definitions for the custom vanity host.

Configuring Gateway API for Ingress

Overview of transitioning to and configuring the Kubernetes Gateway API for ingress in IDSP.

The Symantec Identity Security Platform (IDSP) is transitioning from the legacy NGINX Ingress controller to the Kubernetes Gateway API standard. The Gateway API provides a unified, extensible framework for managing ingress traffic, enabling advanced routing, improved security integrations like BackendTLSPolicy, and better native support across multi-cloud environments.

Before deploying IDSP, you must configure a Gateway API controller for your cluster. Choose the deployment based on the platform that corresponds to your cloud provider or on-premises environment to prepare your infrastructure, configure your GatewayClass, establish secure traffic policies, and ensure seamless connectivity to the platform.

For more information about the Gateway API configuration in IDSP, see the following topics:

- Ingress vs Gateway API: Traffic Flow Comparison
- Gateway API Controller Capabilities
- Gateway API Controller Selection and Prerequisites
- Gateway API Setup and Ingress Configuration Reference
- Already Have a Gateway? Use It!
- Supported Gateways in IDSP

Ingress vs Gateway API: Traffic Flow Comparison

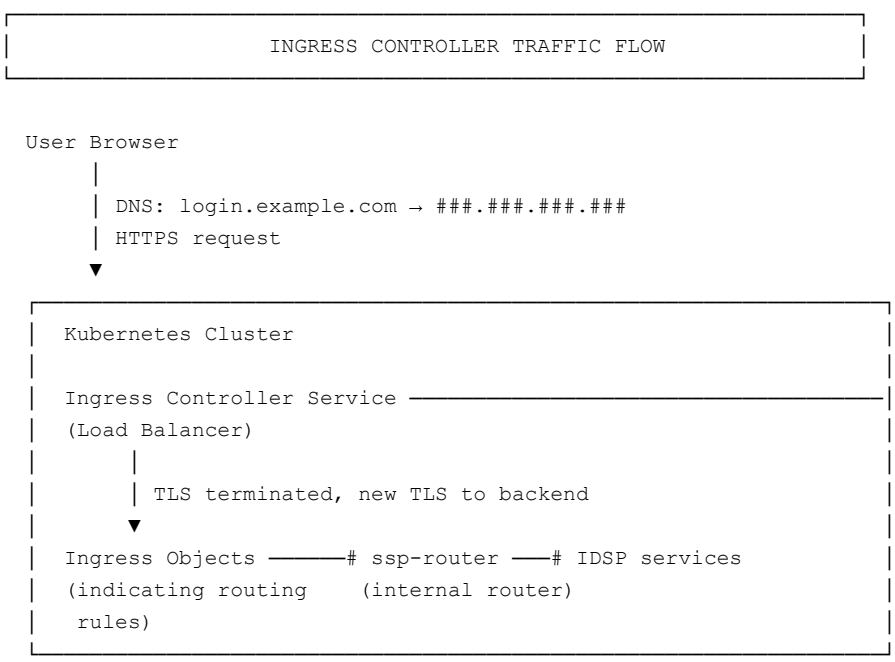
This topic compares the traditional Ingress-based traffic routing model with the newer Gateway API approach in Kubernetes, illustrating how each method directs external HTTPS traffic to IDSP services.

The following diagrams illustrate how traffic routing evolves from the traditional Ingress model to the newer Gateway API approach in Kubernetes. Understanding both models helps teams plan and execute a smooth migration path.

Ingress Traffic Flow

With the Ingress-based model, an Ingress Controller Service acts as the load balancer and Ingress Objects define the routing rules that direct traffic to IDSP services:

This diagram assumes that you have migrated from legacy routes to ssp-router. See IDSP upgrade section (Step 12)

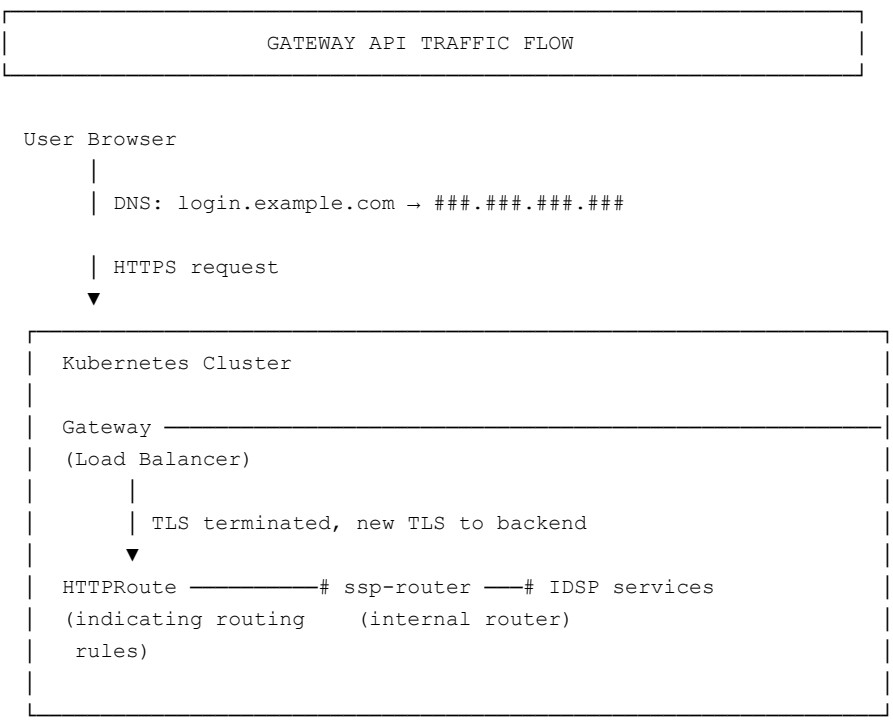


In this model, the key components are:

- **Ingress Controller Service**
  Acts as the external-facing load balancer that receives incoming HTTPS traffic from user browsers. The controller terminates TLS and establishes new TLS connections to backend services within the cluster.
- **Ingress Objects**
  Kubernetes Ingress resources that define routing rules such as hostname matching and path-based routing. These rules determine how traffic is forwarded from the Ingress Controller to the internal ssp-router service.
- **SSP Router**
  IDSP's internal router service that receives traffic from the Ingress Controller and performs tenant extraction, path normalization, and microservice routing to direct requests to the appropriate IDSP services.

Gateway API Traffic Flow

Gateway API is the Kubernetes-native replacement for Ingress that routes external HTTPS traffic to IDSP. Here, a Gateway resource serves as the load balancer and HTTPRoute defines the routing rules:



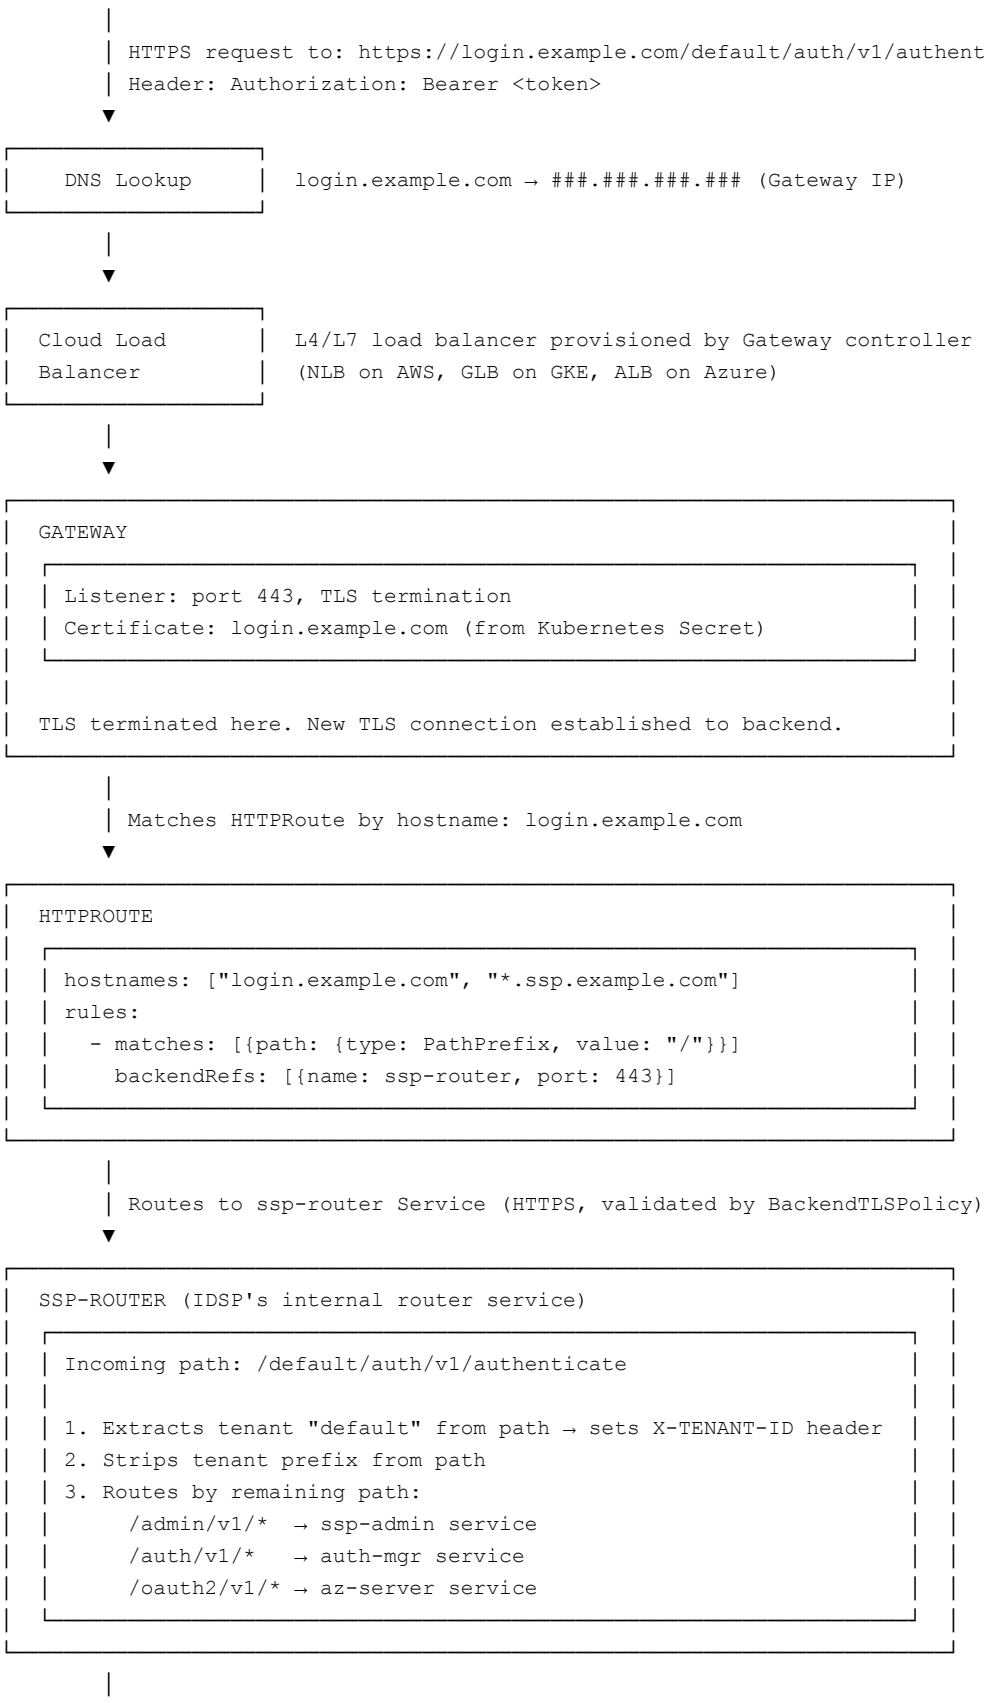
In the Gateway API model, the key components are:

- **Gateway**
  A Gateway API resource that provisions and configures a cloud load balancer. The Gateway listens on ports 80 and 443, holds TLS certificates stored in Kubernetes Secrets, and receives an external IP address for DNS resolution. It terminates TLS and establishes new encrypted connections to backend services.
- **HTTPRoute**
  A Gateway API resource that defines application-layer routing rules. HTTPRoute specifies hostname matching patterns (e.g., `ssp.example.com` , `*.ssp.example.com`), path prefix matching (e.g., `/admin/v1/*` , `/auth/v1/*`), and backend service references pointing to `ssp-router:443` .
- **SSP Router**
  IDSP's internal router service that functions identically in both models — performing tenant extraction, path normalization, and microservice routing to direct requests to the appropriate IDSP services.

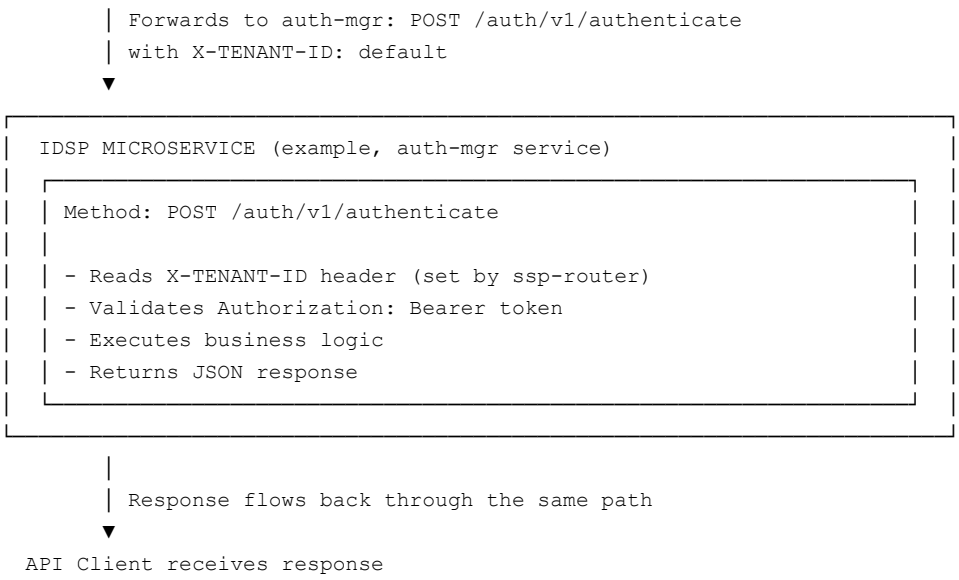
  NOTE
  Both models route traffic to the same internal ssp-router service. The migration from Ingress to Gateway API changes only the external traffic entry point and routing configuration — IDSP's internal routing logic remains unchanged.

End-to-End Request Flow in IDSP

This diagram shows how a request flows from an end user through Gateway API to an IDSP microservice:



HTTPS request to: https://login.example.com/default/auth/v1/authenticate
Header: Authorization: Bearer <token>
DNS Lookup
login.example.com → ###.###.###.### (Gateway IP)
Cloud Load Balancer
L4/L7 load balancer provisioned by Gateway controller
(NLB on AWS, GLB on GKE, ALB on Azure)
GATEWAY
Listener: port 443, TLS termination
Certificate: login.example.com (from Kubernetes Secret)
TLS terminated here. New TLS connection established to backend.
Matches HTTPRoute by hostname: login.example.com
HTTPROUTE
hostnames: ["login.example.com", "*.ssp.example.com"]
rules:
- matches: [{path: {type: PathPrefix, value: "/"}}]
backendRefs: [{name: ssp-router, port: 443}]
Routes to ssp-router Service (HTTPS, validated by BackendTLSPolicy)
SSP-ROUTER (IDSP's internal router service)
Incoming path: /default/auth/v1/authenticate
1. Extracts tenant "default" from path → sets X-TENANT-ID header
2. Strips tenant prefix from path
3. Routes by remaining path:
/admin/v1/* → ssp-admin service
/auth/v1/* → auth-mgr service
/oauth2/v1/* → az-server service



Flow Notes:

- **Single Entry Point**
  All external traffic enters through the Gateway and routes to `ssp-router` .
- **SSP Router as Internal Router**
  IDSP uses its own router (not the Gateway) for microservice routing because:
  – Path-based routing requires IDSP-specific logic (tenant extraction, token validation)
  – Microservices are internal-only and not exposed directly
- **Backend HTTPS**
  Gateway connects to ssp-router over HTTPS (port 443), validated via BackendTLSPolicy.
- **Vanity Domains**
  End-user login portals can use custom domains (for example., `login.example.com`) that route to the same ssp-router.
- **ISK Encryption**
  All intra-cluster communications are encrypted using the Internal Signing Key (ISK), including between the Gateway and IDSP Router (Gateway Backend TLS).

Gateway API Controller Capabilities

This topic compares Gateway API controller capabilities across supported providers, covering routing, TLS validation, mTLS certificate forwarding, and traffic policy controls.

Gateway API Controller Capabilities Comparison

The following table compares all supported ingress controllers and gateway providers across the capabilities that matter most for IDSP deployments. Use it to select the right controller for your environment.

Controller	ingress.type	Platforms	Backend TLS Validation	mTLS Cert Forw
Envoy Gateway	`gatewayapi`	GKE, EKS, AKS, VKS	# Full CA (BackendTLSPolicy)	# XFCC header
GKE L7 Gateway	`gatewayapi`	GKE	HTTPS only, no validation	# Metadata only (fing
Azure AGC	`gatewayapi`	AKS	# Full CA (vendor BackendTLSPolicy)	# Validates but does forward
AWS ALB	`gatewayapi`	EKS	HTTPS only, no validation	# No optional verify m
Avi AKO	`gatewayapi`	VKS, vSphere	# Full CA (RouteBackendExtension)	## Via Avi API (manu may not persist acros reconciliation)
OpenShift HAProxy	`openshiftroute`	OpenShift	HTTPS only, no validation	# X-SSL-Client-DER

NOTE

- **Envoy Gateway:** If the optimal Gateway selection is undetermined, use Envoy Gateway. It operates across all platforms and provides the most complete feature set, including configurable headers, backend TLS validation, and mTLS forwarding.
- **OpenShift:** OpenShift uses its native HAProxy Router with OpenShift Routes (`ingress.type: openshiftroute`) instead of the Gateway API. It supports mTLS via `IngressController.spec.clientTLS` . The default header limit is 24 KB; increase this limit to at least 128 KB for IDSP (see the OpenShift HAProxy Router section below).
- **AWS ALB header limits:** The limits of 16 KB per header and 64 KB total are strict AWS infrastructure constraints that cannot be overridden. OIDC `id_token` values with numerous claims can exceed the 16 KB limit. If this limitation affects the deployment, use Envoy Gateway on EKS, which operates behind a Network Load Balancer (NLB) without header limits.
- **Avi AKO:** Avi AKO is the default choice for VMware Kubernetes Service (VKS). Header size limits and mTLS certificate forwarding are configurable through the Avi Controller REST API (using a custom Application Profile for headers and an HTTP Policy Set for certificate forwarding). However, these require manual modifications to the Avi Virtual Service (VS), and it is undetermined whether AKO reconciliation might revert them. For VKS deployments requiring mTLS, use Envoy Gateway on VKS instead.

Frontend mTLS (Client Certificate Authentication)

IDSP supports OAuth2 `tls_client_auth` — clients authenticate to the `/token` endpoint using a TLS client certificate. This requires two things from the Gateway:

1. **Request/validate the client certificate** during the TLS handshake
2. **Forward the certificate to the backend** via an HTTP header so the authorization server can read it

The backend services expect the client certificate in the `X-CLIENT-CERT` header as URL-encoded PEM. With Gateway API, ssp-router sits between the Gateway and the backend services, so ssp-router must normalize the provider-specific cert header into `X-CLIENT-CERT` before forwarding to backends.

IMPORTANT

The Gateway API standard defines frontendValidation (GEP-91) for client certificate validation at the Gateway level (`Gateway.spec.tls.frontendValidation` , `gateway.networking.k8s.io/v1`). However, this only covers **validation** — it does **not** define how to forward the certificate to backends. Forwarding is entirely implementation-specific. Most implementations have not adopted `frontendValidation` yet and use their own CRDs instead.

For a summary of which controllers support `tls_client_auth` , see the Choose Your Controller table above. The following table provides additional detail on header names, formats, and Helm automation — including OpenShift HAProxy and nginx Ingress which are not Gateway API controllers but also support mTLS.

Controller	Forwards client cert to backend	Validation CRD	Cert header na
Envoy Gateway	# Yes	`ClientTrafficPolicy`	`x-forwarded-client-ce`
AWS LB Controller	# No	N/A	N/A — verify mode has no optic passthrough doesn't validate ch
nginx Ingress	# Yes	`auth-tls-*` annotations	`X-CLIENT-CERT`
OpenShift HAProxy	# Yes	`IngressController.spec.clientTLS`	`X-SSL-Client-DER`
Avi AKO	# No (EVH limitation)	Application Profile + PKI Profile (Avi Controller)	`X-Whole-Cert` (via HTTP P
GKE L7 Gateway	# No	N/A	N/A — only forwards fingerprint
Azure AGC	# No	`FrontendTLSPolicy`	N/A — validates but does not fo

NOTE

- **Why the full certificate PEM is required:** The gateway must forward the full certificate PEM (not just a fingerprint). IDSP needs the full certificate to extract Subject DN and SANs for `tls_client_auth` authentication, and to compute certificate-bound access token claims (`x5t#S256` , `kid`). Controllers that only forward metadata (like GKE's SHA-256 fingerprint) cannot support `tls_client_auth` .
- **Avi AKO mTLS:** Avi Load Balancer can forward client certificates using an HTTP Policy Set, but this requires manual configuration on the Avi Controller. It is not yet Kubernetes-managed through CRDs. For VKS deployments requiring mTLS, Envoy Gateway on VKS is recommended instead.
- **Gateway type naming change:** The `gatewayType` values were renamed to be controller-specific rather than platform-specific. The old names (`eks` , `aks` , `gke`) are still accepted by the Helm chart for backward compatibility. They are silently normalized to the new names (`aws-alb` , `azure-agc` , `gke-l7`).

Helm Configuration

```
ssp:
  ingress:
    mtls:
      # Enable frontend mTLS (client certificate authentication / tls_client_auth).
      # This is the single master gate for mTLS. When enabled:
      #   - Sets SSP_MTLS_ENABLED=true on ssp-router (enables cert extraction)
      #   - For Envoy Gateway: creates ClientTrafficPolicy with clientValidation
      #     and XFCC header forwarding (SanitizeSet mode)
      #   - For AWS ALB: mTLS not supported (use Envoy Gateway on EKS)
      #   - For nginx/openshift: configures client cert request and forwarding
      #   - For "avi" and "custom" providers, the gateway/LB admin must:
      #       1. Configure the gateway to request and forward client certificates
      #       2. Ensure the gateway sanitizes cert headers to prevent spoofing
```

```
#
# The gateway provider is derived automatically from ingress.type + gatewayType.
# ssp-router uses SSP_GATEWAY_IDENTIFICATION to determine which header carries
# the client certificate (e.g., XFCC for Envoy, X-Amzn-Mtls-Clientcert for ALB).
enabled: false
caCertSecretName: ""    # Secret containing CA cert for client validation

# Per-request gateway detection via X-SSP-Gateway-Type header.
# Default (false): ssp-router uses the provider derived from ingress.type + gatewayType
# for all requests (explicit mode — secure, recommended).
# Set to true only for multi-provider setups where ALL providers inject and sanitize
# the X-SSP-Gateway-Type header. NOT safe with aws-alb, azure-agc, openshift, or
# customIngress controllers that cannot set the header.
enableGatewayDetectionByHeader: false

# Custom cert header/regex — only used when provider resolves to "custom".
# certHeader: ""    # Header name containing the client certificate
# certRegex: ""     # Regex to extract cert from header value (group 1)
```

Gateway API Controller Selection and Prerequisites

This topic helps you choose the right Gateway API controller and covers the prerequisites, RBAC permissions, and TLS configuration required before deployment.

Choose Your Controller

The following table compares all supported ingress controllers and gateway providers across the capabilities that matter most for IDSP deployments. Use it to select the right controller for your environment.

Controller	ingress.type	Platforms	Backend TLS Validation	mTLS Cert Forw
Envoy Gateway	`gatewayapi`	GKE, EKS, AKS, VKS	# Full CA (BackendTLSPolicy)	# XFCC header
GKE L7 Gateway	`gatewayapi`	GKE	HTTPS only, no validation	# Metadata only (fing
Azure AGC	`gatewayapi`	AKS	# Full CA (vendor BackendTLSPolicy)	# Validates but does forward
AWS ALB	`gatewayapi`	EKS	HTTPS only, no validation	# No optional verify n
Avi AKO	`gatewayapi`	VKS, vSphere	# Full CA (RouteBackendExtension)	## Via Avi API (manu may not persist acros reconciliation)
OpenShift HAProxy	`openshiftroute`	OpenShift	HTTPS only, no validation	# X-SSL-Client-DER
nginx	`nginx`	Any	# Full CA (proxy-ssl-secret annotation)	# X-CLIENT-CERT h

NOTE

- Not sure?Use **Envoy Gateway** - it works everywhere and has the most features.
- AWS Note:AWS Load Balancer Controller does not support BackendTLSPolicy for backend certificate validation. HTTPS to backends still works (encrypted), but the ALB does not verify the backend's TLS certificate. If backend TLS validation is required, use Envoy Gateway on EKS instead.
- Avi AKO: Default choice for **VKS (VMware Kubernetes Service)**. Also use when you already run Avi and want Gateway API on VKS, vSphere/NSX-T. Backend TLS is configured via Avi's `RouteBackendExtension` CRD rather than the standard BackendTLSPolicy CRD.
- For deploying Envoy Gateway on AKS version older than 1.35, refer to this section, AKS - Envoy Gateway.

Controller Name	Description	Controller Version	Doc URL
Envoy Gateway	Cross-cloud portable Gateway API controller. Supports BackendTLSPolicy, mTLS with client cert forwarding, and configurable header/buffer limits via ClientTrafficPolicy and BackendTrafficPolicy CRDs.	1.6.0 (minimum)	https://gateway.envoyproxy.io/
GKE L7 Gateway	Native Google Cloud Gateway API controller using Google Cloud Load Balancer. Does not support BackendTLSPolicy or mTLS client cert forwarding.	GKE-managed	https://cloud.google.com/kubernetes-engine/docs/concepts/gatewayapi
Azure AGC	Native Azure Gateway API controller using Application Gateway for Containers. Uses Azure-specific BackendTLSPolicy and HealthCheckPolicy CRDs (alb.networking.azure.io/v1). Does not support mTLS.	1.9.13	https://learn.microsoft.com/en-us/azure/application-gateway/for-containers/overview
AWS LB Controller	Native AWS Gateway API controller using Application Load Balancer. Uses LoadBalancerConfiguration and TargetGroupConfiguration CRDs. Does not support BackendTLSPolicy or mTLS.	3.x	https://kubernetes-sigs.github.io/aws-load-balancer-controller/
Avi AKO	Gateway API controller for VMware VKS and vSphere/NSX-T environments. Uses RouteBackendExtension CRD for backend TLS. Default choice for VKS (VMware Kubernetes Service).	1.12+	https://techdocs.broadcom.com/us/en/vmware-security-load-balancing/avi-load-balancer.html
OpenShift HAProxy	OpenShift's built-in HAProxy Router using OpenShift Routes (not Gateway API). Supports mTLS via IngressController.spec.clientTLS. Header buffer sizes are adjustable at the IngressController level.	4.18	https://docs.redhat.com/en/documentation/openshift_container_platform/4.18/html/networking/configuring-routes
nginx Ingress	Kubernetes Ingress controller using nginx. Supports mTLS via auth-tls-* annotations with client cert forwarding in X-CLIENT-CERT header. Used as the legacy/default ingress controller for IDSP.	4.14.3	https://kubernetes.github.io/ingress-nginx/

Prerequisites (All Deployments)

Before deploying IDSP with Gateway API, ensure you have:

Requirement	How to Check	Notes
Gateway API CRDs	`kubectl get crd gateways.gateway.networking.k8s.io`	Install
Gateway Controller	`kubectl get gatewayclass`	Envoy
GatewayClass	`kubectl get gatewayclass`	Must s
TLS Certificate	`kubectl get secret <tls-secret> -n ssp`	For yo
DNS (planned)	-	Know
RBAC Permissions	Information provided in the **Required RBAC Permissions** table	Requi

Install Gateway API CRDs

If Gateway API CRDs are not installed:

```
kubectl apply -f https://github.com/kubernetes-sigs/gateway-api/releases/download/v1.2.0/standard-install.yaml
```

Required RBAC Permissions

The user or service account running `helm install` needs permissions to create Gateway API resources. The **core resources** are required for all controllers; **controller-specific resources** depend on your chosen controller.

Core resources (all controllers):

Resource	API Group	Required When
`Gateway`	`gateway.networking.k8s.io`	`createGatewa`
`HTTPRoute`	`gateway.networking.k8s.io`	Always
`BackendTLSPolicy`	`gateway.networking.k8s.io`	`createBacken`
`Secret`	`core`	Always (for TLS ce
`Service`	`core`	Always

> **NOTE**
> If using an existing Gateway (`createGateway: false`), you only need permissions for `HTTPRoute` and `BackendTLSPolicy`, not `Gateway`.

Each controller's section includes the controller-specific RBAC requirements and ClusterRole YAML. See the section, **Pre-requisite Check** in your chosen controller section.

TLS Certificates

The Gateway requires a TLS certificate for HTTPS termination. Create a Kubernetes Secret with your certificate:

```
# From certificate files
kubectl create secret tls ssp-tls-cert \
  -n ssp \
  --cert=path/to/tls.crt \
  --key=path/to/tls.key

# Verify the secret exists
kubectl get secret ssp-tls-cert -n ssp
```

Certificate requirements:

- Must cover your IDSP hostname(s):
  - Main host (e.g., `idsp.example.com`)
  - Wildcard (e.g., `*.idsp.example.com`) for tenant subdomains
  - Management host if separate (e.g., `mgmt.idsp.example.com`)
- For vanity domains, create separate secrets or use a SAN certificate

Alternative provisioning methods:

- **cert-manager**: Automates certificate issuance from Let's Encrypt or internal CA
- **Cloud provider**: GCP Certificate Manager, AWS ACM, Azure Key Vault
- **Manual**: Upload certificates from your enterprise CA
- **Chart-generated self-signed**: See Self-Signed TLS Certificates below

Self-Signed TLS Certificates

For test and dev environments, the chart can generate self-signed TLS certificates automatically. This removes the need to create certificates manually before deploying.

> **NOTE**
> **Not for production.** Self-signed certificates are not trusted by browsers or clients without explicit CA trust configuration.

How It Works

When `generateSelfSignedCert: true` is set, the chart:

1. Generates a self-signed CA and a TLS certificate signed by that CA
2. Stores the cert, key, and CA in a Kubernetes Secret with a chart-owned name (e.g., `<release>-ssp-tls`)
3. References that Secret in Gateway listeners and/or Ingress TLS sections
4. On upgrades, reuses the existing certificate from the cluster (via Helm `lookup()`) to avoid regeneration

Configuration

Main certificate — covers the primary hostname, wildcard (unless separate), and mgmt (unless separate):

```
ssp:
  ingress:
    tls:
      generateSelfSignedCert: true   # Generates <release>-ssp-tls
      # secretName is ignored when generateSelfSignedCert=true
```

Separate wildcard certificate — use a real cert for the main FQDN but generate a self-signed cert for `*.host` :

```
ssp:
  ingress:
    tls:
      wildcardTls:
        generateSelfSignedCert: true # Generates <release>-ssp-wildcard-tls
```

Separate mgmt certificate — generate a self-signed cert for the management hostname:

```
ssp:
  ingress:
    tls:
      generateSelfSignedCert: true
    mgmt:
```

```
tls:
  generateSelfSignedCert: true # Generates <release>-ssp-mgmt-tls
```

Certificate Names and SANs

The chart uses deterministic naming and automatically adjusts SANs to avoid duplication:

Cert	Generated Secret Name	SANs
Main	`<release>-ssp-tls`	`host` , `*.host` (if no separate wildcard), `mgmt-host`
Wildcard	`<release>-ssp-wildcard-tls`	`*.host`
Mgmt	`<release>-ssp-mgmt-tls`	`mgmt-host`

Resolution Priority

For each cert type, the chart resolves the secret name in this order:

Cert type	generateSelfSignedCert: true	secretName set
Main	`<release>-ssp-tls`	Use `secretName`
Wildcard	`<release>-ssp-wildcard-tls`	Use `wildcardTls.secretName`
Mgmt	`<release>-ssp-mgmt-tls`	Use `mgmt.tls.secretName`
FullVanity	n/a	Per-host `tlsSecretName`
EndUser	n/a	Per-host `tlsSecretName`

NOTE

On AWS, the ALB controller ignores Kubernetes TLS Secrets and uses ACM auto-discovery instead. After deploying with `generateSelfSignedCert: true` , you must import the generated certificate into ACM.

Ingress Configuration Reference

This topic introduces the values.yaml configuration file and provides a complete reference of all ingress parameters for IDSP.

About values.yaml Files

Throughout the documentation, Helm commands reference `-f your-values.yaml` . This file contains your IDSP deployment configuration including:

- Database connection settings
- License and tenant configuration
- Service replicas and resource limits
- Other IDSP-specific settings

The Gateway API settings in this doc are additions to your existing values.yaml, not replacements.

The following table describes the ingress configuration parameters available in the values.yaml file. These parameters control how external traffic is routed to your IDSP services and can be configured based on your specific ingress controller type (nginx, OpenShift Route, or Gateway API).

Ingress Parameters

Parameter	Description
ssp.ingress.enabled	enabled = true | false **Default Value**: true
ssp.ingress.type	• type = "nginx" for nginx ingress controller (IngressAPI) • type = "openshiftroute" for openshift ingress controller (IngressAPI) • type = "gatewayapi" for ingress controllers compatible with Gateway API **Default Value**: nginx
ssp.ingress.ingressClassName	Specifies the ingress class name to be used for the ingress controller. **Default Value**: nginx
ssp.ingress.keepLegacyRoutes	• **Phase 1**: Keep pre-ssp-router legacy routes during migration to ssp-router. • When true, both legacy and ssp-router Ingress routes are created on the same controller. **Default Value**: false
ssp.ingress.previousController.enabled	• **Phase 2**: Previous controller settings (used during migration to a new ingress controller or Gateway API). • When enabled, keeps the current ssp-router Ingress unchanged on the old controller and creates an additional Ingress (named with the new class suffix) on the new controller. • This allows gradual DNS switchover with zero downtime. **Default Value**: false
ssp.ingress.previousController.ingressClassName	• IngressClass of the previous (old) controller (e.g., "nginx"). • Required when enabled=true. **Default Value**: ""
ssp.ingress.additionalLabels	additional labels for ingress objects **Default Value**: {}
ssp.ingress.additionalAnnotations	additional annotations for ingress objects **Default Value**: {}
ssp.ingress.timeoutSecs	• Default timeout in seconds for proxy read/send (used by Gateway API and legacy templates). • For nginx-specific override, use nginx.timeoutSecs. **Default Value**: "60"
ssp.ingress.host	host is an fqdn. For example: `iam.example.com` or `iam.<yourdomain>.com`. **Default Value**: (empty)
ssp.ingress.tls.enabled	Enables or disables TLS configuration for ingress. **Default Value**: true
ssp.ingress.tls.secretName	Name of the TLS secret containing the certificate and private key. **Default Value**: ssp-general-tls
ssp.ingress.tls.host	Host for the TLS certificate. **Default Value**: (empty)

ssp.ingress.tls.generateSelfSignedCert	• Generate a self-signed TLS certificate and store it in the Secret named by secretName. • The cert includes {host} and *.{host} as SANs (unless wildcardTls.secretName is set). • Useful for test/dev environments. Not for production. Has no effect on AWS ALB (uses ACM). **Default Value**: false
ssp.ingress.tls.wildcardTls.secretName	• Separate TLS secret for the wildcard (*.host) Gateway listener. • If empty, the wildcard listener uses the main tls.secretName. • Set this when you have a real cert for the main FQDN but need a self-signed wildcard cert. **Default Value**: ""
ssp.ingress.tls.wildcardTls.generateSelfSignedCert	Generate a self-signed certificate for the wildcard TLS secret. **Default Value**: false
ssp.ingress.mtls.enabled	Enables or disables mutual TLS (mTLS) authentication. **Default Value**: false
ssp.ingress.mtls.caCertSecretName	Name of the secret containing the CA certificate for mTLS authentication. **Default Value**: (empty)
ssp.ingress.gatewayApi.gatewayType	• Gateway controller type: auto, envoy, gke, aks, eks, avi, custom • "auto" detects from gatewayClassName prefix (gke-l7-* → gke, envoy-* → envoy, etc.) **Default Value**: auto
ssp.ingress.gatewayApi.createGateway	If true, Helm creates the Gateway resource **Default Value**: true
ssp.ingress.gatewayApi.existingGateway	Name of pre-existing Gateway (required if createGateway=false) **Default Value**: ""
ssp.ingress.gatewayApi.existingGatewayNamespace	Namespace of pre-existing Gateway (defaults to Release namespace if empty) **Default Value**: ""
ssp.ingress.gatewayApi.gatewayClassName	GatewayClass name (required if createGateway=true) **Default Value**: ""
ssp.ingress.gatewayApi.infrastructureRef	Infrastructure parametersRef for cloud-specific load balancer config (e.g., AWS LoadBalancerConfiguration) **Default Value**: {}
ssp.ingress.gatewayApi.additionalListeners	• Additional listeners to add to the main Gateway (for sharing with other apps). • allowedRoutesFrom defaults to "All" for cross-namespace sharing; a ReferenceGrant in THIS namespace is still required to authorize the cross-namespace reference. **Default Value**: []
ssp.ingress.gatewayApi.httpToHttpsRedirect	• Add an HTTP listener (port 80) and redirect HTTPRoute to automatically redirect HTTP → HTTPS (301). Equivalent to nginx ssl-redirect: "true". • Values: "auto" (default), true, false. • "auto" enables for envoy/custom, disables for cloud controllers (gke/aks/eks/avi) that handle redirect at the infrastructure level. **Default Value**: "auto"

ssp.ingress.gatewayApi.skipWildcardListener	Skip the wildcard (*.host) listener on the Gateway. Set true when the TLS certificate does not cover the sub-wildcard (e.g., cert is *.example.com but host is app.example.com, so *.app.example.com is not covered). Tenant routing still works via ssp-router path-based routing. **Default Value**: false
ssp.ingress.gatewayApi.createBackendTLSPolicy	Create BackendTLSPolicy resource for ssp-router (set false if managing separately) **Default Value**: true
ssp.ingress.gatewayApi.additionalLabels	Labels for Gateway and HTTPRoute resources **Default Value**: {}
ssp.ingress.gatewayApi.envoy.connectionBufferLimitBytes	• Per-connection buffer limit in bytes for Envoy Gateway ClientTrafficPolicy. • Equivalent to nginx proxy-buffer-size × proxy-buffers-number (128k × 4 = 512KB). **Default Value**: 524288
ssp.ingress.gatewayApi.envoy.maxRequestBodySize	• Maximum request body size. Requests exceeding this limit receive HTTP 413. • Equivalent to nginx proxy-body-size: 50m. Set to "" to disable the limit. • Uses Kubernetes resource.Quantity format (e.g., "50Mi", "10Mi"). **Default Value**: "50Mi"
ssp.ingress.gatewayApi.avi.sslProfile	• SSL profile on Avi Controller for backend re-encrypt TLS. • Configures the cipher suites and TLS version for the Avi pool → ssp-router connection. **Default Value**: {}
ssp.ingress.gatewayApi.gatewayAnnotations	Annotations for Gateway resource (e.g., static IP, load balancer settings) **Default Value**: {}
ssp.ingress.gatewayApi.addresses	• Static addresses for the Gateway (standard Gateway API spec.addresses). • Supported by: Envoy Gateway, Istio, Contour, Cilium. • NOT supported by cloud-managed controllers (GKE, AKS AGC, EKS ALB) — use gatewayAnnotations for those instead (e.g., networking.gke.io/static-ip). **Default Value**: []
ssp.ingress.gatewayApi.httpRouteAnnotations	Annotations for HTTPRoute resources (e.g., konghq.com/strip-path) **Default Value**: {}
ssp.ingress.fullVanity.enabled	Enables or disables full vanity host configuration. **Default Value**: false
ssp.ingress.fullVanity.hosts	List of full vanity hosts with their TLS secret names. **Default Value**: []
ssp.ingress.endUsersVanity.enabled	Enables or disables end users vanity host configuration. **Default Value**: false
ssp.ingress.endUsersVanity.ingressClassName	Ingress class name for end users vanity hosts **Default Value**: (empty)
ssp.ingress.endUsersVanity.allowScim	Allow SCIM endpoints on end users vanity hosts **Default Value**: false

ssp.ingress.endUsersVanity.hosts	List of end users vanity hosts with their TLS secret names **Default Value**: []
ssp.ingress.mgmt.enabled	keep mgmt host and/or mgmt tls empty to use values from the main ingress section **Default Value**: true
ssp.ingress.mgmt.ingressClassName	Ingress class name for management interface **Default Value**: (empty)
ssp.ingress.mgmt.host	Host for management interface **Default Value**: (empty)
ssp.ingress.mgmt.tls.enabled	Enables or disables TLS for management interface **Default Value**: true
ssp.ingress.mgmt.tls.secretName	TLS secret name for management interface **Default Value**: (empty)
ssp.ingress.mgmt.tls.host	TLS host for management interface **Default Value**: (empty)
ssp.ingress.mgmt.tls.generateSelfSignedCert	• Generate a self-signed cert for the mgmt hostname. Only used when mgmt has a separate secretName. • If secretName matches the main tls.secretName, the mgmt host is added to the main cert's SANs instead. **Default Value**: false
ssp.ingress.nginx.timeoutSecs	Nginx-specific timeout in seconds for proxy read/send operations. **Default Value**: "60"
ssp.ingress.nginx.proxySslVerifyDepth	Sets the verification depth in the proxied server certificates chain. **Default Value**: 1
ssp.ingress.nginx.configSnippetsEnabled	Enables or disables nginx configuration snippets. **Default Value**: true
ssp.ingress.nginx.clientHeaderBuffersNumber	Sets the number of buffers used for reading large client request headers. **Default Value**: "4"
ssp.ingress.nginx.clientHeaderBufferSize	Sets buffer size for reading client request headers. **Default Value**: "128k"
ssp.ingress.nginx.clientHeaderBusyBufferSize	• Buffer math: clientHeaderBusyBufferSize must be < (clientHeaderBuffersNumber × clientHeaderBufferSize) - clientHeaderBufferSize • Example: 4 × 128k = 512k, so busy-buffers-size must be < 512k - 128k = 384k (256k is valid) **Default Value**: "256k"

ssp.ingress.openShiftRoute.isDefaultTenantInPath	• Note: OpenShift HAProxy does not support per-route header buffer size annotations. • The effective max request header size is headerBufferBytes - headerBufferMaxRewriteBytes (default: 32768 - 8192 = 24KB), which is too small for SSP's large JWT tokens. • Increase at the IngressController level (OpenShift 4.10+): • oc patch ingresscontroller/default -n openshift-ingress-operator --type=merge -p '{"spec":{"tuningOptions": {"headerBufferBytes":131072,"headerBufferMaxRewriteBytes":1638 • Note: Wildcard hosts (*.fqdn) require wildcardPolicy: WildcardsAllowed on the IngressController. • If wildcards are disabled (default in OpenShift 4.x), the wildcard route shows RouteNotAdmitted. • isDefaultTenantInPath:false implies routes uses <defaultTenant>.<ssp-fqdn>/<defaultTenantPlaceholderInPath>, otherwise routing uses <ssp-fqdn>/<defaultTenant> **Default Value**: false
ssp.ingress.openShiftRoute.defaultTenant	Default tenant name for OpenShift route configuration. **Default Value**: default
ssp.ingress.openShiftRoute.defaultTenantPlaceholderInPath	Default tenant placeholder in path for OpenShift route configuration. **Default Value**: common
ssp.ingress.openShiftRoute.timeout	Timeout for OpenShift route connections. **Default Value**: "60s"
ssp.ingress.openShiftRoute.tunnelTimeout	Tunnel timeout for OpenShift route connections. **Default Value**: "1h"

Already Have a Gateway? Use It!

Configuration details for using an existing Gateway, Traffic Policies and mTLS requirements.

If your platform team already manages Gateway resources, IDSP can attach to your existing Gateway, you do not need to create a new one. IDSP creates only the HTTPRoutes and BackendTLSPolicy, attaching them to your existing Gateway.

Quick setup with existing Gateway:

```
ssp:
  ingress:
    type: gatewayapi
    gatewayApi:
      createGateway: false                    # Don't create new Gateway
      existingGateway: "your-gateway-name"    # Name of your existing Gateway
      existingGatewayNamespace: ""            # Namespace of existing Gateway (defaults to release namespace)
      gatewayClassName: "your-gateway-class"  # Required for HTTPRoute parentRef
```

NOTE
Cross-namespace Gateways: If your existing Gateway lives in a different namespace than IDSP, set `existingGatewayNamespace` to that namespace. The Gateway must have `allowedRoutes.namespaces.from: All` (or a matching Selector) for cross-namespace HTTPRoutes to be accepted.

Requirements for your existing Gateway:

Requirement	Details
HTTPS Listener	Must have a listener on port 443 with `protocol: HTTPS`
TLS Certificate	Listener must reference a Secret with TLS cert for IDSP's hostname(s)
Same Namespace	Gateway must be in the same namespace as IDSP (or use `ReferenceGrant` for cross-namespace)
Hostname Coverage	TLS cert must cover: main host, `*.{main-host}` (wildcard for tenants), mgmt host, vanity hosts

NOTE
Vanity Host Impact: When using an externally-managed Gateway (createGateway=false), the chart creates HTTPRoutes but cannot add listeners to the Gateway. Gateway API listeners match HTTPRoutes by hostname, an HTTPRoute is rejected if no listener matches its hostname. This means that adding a new vanity host requires two steps:

1. Edit the Gateway to add a new HTTPS listener for the vanity hostname.
2. Run helm upgrade to create the HTTPRoute.
   Note that the same applies to any additional hostnames (example, sample-app hostnames if sharing the Gateway).

For detailed information on how to create and use Vanity Hosts in IDSP, see Creating Vanity URLs.

Traffic Policies and mTLS with an Existing Gateway

When the chart creates its own Gateway (`createGateway: true`), it automatically creates all controller-specific resources: traffic policies (timeouts, buffer limits, connection settings), health checks, and mTLS configuration. When you bring your own Gateway, **you are responsible for some of these resources**, depending on your setup.

What you may need to create

When the existing Gateway is in the **same namespace** as IDSP, the chart handles everything automatically.

When the existing Gateway is in a **different namespace**, you may need to create:

Resource	When needed	Notes
ReferenceGrant	Cross-namespace Gateway	Authorizes IDSP's HTTPRoute to attach to the Gateway. Set `allowCrossNamespaceCreate: true` to let the chart create or create it manually in the Gateway's namespace
Traffic policies	Cross-namespace Gateway	Controller-specific policies (e.g., Envoy `ClientTrafficPolicy`) must be in the Gateway's namespace. Set `allowCrossNamespaceCreate: true` to let the chart create these, or create them manually
mTLS policies	Cross-namespace Gateway + `mtls.enabled: true`	Same as traffic policies, requires `allowCrossNamespaceCreat` `true`

NOTE
Why `allowCrossNamespaceCreate` ? Controller-specific policies must be in the **same namespace as the Gateway** they target. When `allowCrossNamespaceCreate: true` , the chart creates these resources in the Gateway's namespace. When `false` (default), the Helm service account may not have RBAC outside the release namespace — create the resources manually instead.

NOTE
Mgmt and enduser gateways: For separate management or end-user Gateways using `existingGateway`, traffic policies are only created when you explicitly set `createTrafficPolicies: true`. This is because a shared existing Gateway may already have traffic policies managed by another team.

Per-controller requirements

The chart creates traffic policies automatically — in the release namespace for same-namespace setups, and in the **Gateway's namespace** for cross-namespace setups (when `allowCrossNamespaceCreate: true`). The following table lists the controller-specific resources and their purpose. If you manage these policies yourself (for example, `allowCrossNamespaceCreate: false` with a cross-namespace Gateway), refer to the following examples.

Envoy Gateway:

Resource	Purpose	Required?
`ClientTrafficPolicy`	Connection buffer limits, request timeout, header case preservation	Recommended
`ClientTrafficPolicy` — mTLS section	Client cert validation + XFCC header forwarding	Required for mTLS
`BackendTrafficPolicy`	Backend timeouts, connection idle timeout	Recommended

Example `ClientTrafficPolicy` with mTLS (the chart creates this automatically in the Gateway's namespace):

```
apiVersion: gateway.envoyproxy.io/v1alpha1
kind: ClientTrafficPolicy
metadata:
  name: ssp-client-traffic
  namespace: <gateway-namespace>      # Must match Gateway's namespace
spec:
  targetRef:
    group: gateway.networking.k8s.io
    kind: Gateway
    name: <your-gateway-name>
  connection:
    bufferLimit: 524288               # 512KB — matches nginx proxy-buffer-size × proxy-buffers-number
  timeout:
    http:
      requestReceivedTimeout: 60s
  http1:
    preserveHeaderCase: true
  # --- mTLS section (only needed when mtls.enabled: true) ---
  tls:
    clientValidation:
      caCertificateRefs:
        - kind: Secret
          group: ""
          name: <ca-cert-secret>      # Secret containing CA cert for client validation
      optional: true                  # Accept requests without client cert (optional mTLS)
  headers:
    xForwardedClientCert:
      mode: SanitizeSet               # Strip client-injected XFCC, set from real cert
      certDetailsToAdd:
        - Cert                        # Include full URL-encoded PEM in XFCC header
```

NOTE
How Envoy mTLS forwarding works: When `clientValidation` is configured, Envoy sets the `x-forwarded-client-cert` (XFCC) header with `Cert="<URL-encoded PEM>"` . The `mode: SanitizeSet` ensures the header is sanitized (client-injected values are stripped). ssp-router extracts the cert from the XFCC `Cert=` field and normalizes it to `X-CLIENT-CERT` for backend services.

Example `BackendTrafficPolicy` (create in IDSP's namespace, targets HTTPRoute):

```
apiVersion: gateway.envoyproxy.io/v1alpha1
kind: BackendTrafficPolicy
metadata:
  name: ssp-backend-traffic
  namespace: <idsp-namespace>         # Same namespace as the HTTPRoute
spec:
  targetRefs:
    - group: gateway.networking.k8s.io
      kind: HTTPRoute
      name: <release>-ssp-router-full
  timeout:
    tcp:
      connectTimeout: 15s
    http:
      requestTimeout: 60s
      connectionIdleTimeout: 3600s
```

NOTE
Note: `BackendTrafficPolicy` targets the **HTTPRoute** (not the Gateway), so it is created in IDSP's namespace and works even with cross-namespace Gateways. The chart creates this automatically.

AWS Load Balancer Controller:

Resource	Purpose	Required?
`LoadBalancerConfiguration`	Listener configuration (e.g., idle timeout)	Optional
`TargetGroupConfiguration`	Health check, target type, protocol, timeouts	Recommended

The `LoadBalancerConfiguration` must be in the Gateway's namespace. It is used for listener-level settings (for example, idle timeout). The chart creates it automatically when needed.

NOTE
mTLS note: ALB does not support mTLS for IDSP. ALB's verify mode requires all requests to present a client cert (no optional mode), and passthrough mode does not validate the cert chain. For mTLS on EKS, use Envoy Gateway instead.

The `TargetGroupConfiguration` targets the Service (in IDSP's namespace), the chart creates this automatically.

Avi AKO:

Resource	Purpose	Required?
Application Profile (Avi Controller)	Client cert request mode + PKI Profile	Required for mTLS
HTTP Policy Set (Avi Controller)	Forward cert via `X-Whole-Cert` header	Required for mTLS

Avi mTLS configuration is done on the **Avi Controller** (not through Kubernetes CRDs).

GKE L7 Gateway / Azure AGC:

These controllers do **not** support forwarding client certificates to backends. Use Envoy Gateway instead if you need mTLS. See Frontend mTLS (Client Certificate Authentication) for workarounds.

Quick reference: existing Gateway checklist

Use this checklist when setting up IDSP with an existing Gateway:

- [ ] Gateway has HTTPS listener(s) covering all IDSP hostnames
- [ ] TLS certificate covers main host + wildcard (`*.main-host`) + mgmt host
- [ ] `allowedRoutes.namespaces.from: All` (or matching Selector) if cross-namespace
- [ ] **Cross namespace?** → Set `allowCrossNamespaceCreate: true` to let the chart create resources in the Gateway's namespace
- [ ] **Cross namespace?** → `ReferenceGrant` created by chart (set `createReferenceGrant: false` if managing separately)
- [ ] **Same namespace?** → Traffic policies created automatically by chart
- [ ] **Cross namespace?** → Traffic policies created in Gateway's namespace (requires `allowCrossNamespaceCreate: true`)
- [ ] **mTLS needed?** → mTLS policy included in traffic policies when `mtls.enabled: true`
- [ ] **mTLS needed?** → CA cert Secret accessible from Gateway's namespace
- [ ] Set `ssp.ingress.mtls.enabled: true` and `caCertSecretName` in Helm values

Supported Gateways/Ingress Controllers in IDSP

This topic includes the links to all the supported Gateway platforms:

- AWS Gateway API Controller
- GKE L7 Gateway Controller
- Azure Application Gateway
- AVI AKO Gateway API Controller
- Envoy Gateway
- OpenShift

AWS Gateway API Controller

Amazon Web Services (AWS) provides native Gateway API support through the AWS Load Balancer Controller (v3.x), which provisions Application Load Balancers (ALBs) for Gateway resources in EKS environments.

> **NOTE**
> AWS Load Balancer Controller does **not** support BackendTLSPolicy for backend certificate validation. HTTPS to backend services still works (traffic is encrypted), but the ALB does not verify the backend's TLS certificate. If backend cert validation is required, use Envoy Gateway on EKS instead.

For Official documentation, see:AWS Load Balancer Controller.

Overview

This topic details the configuration and deployment of the Gateway API on Amazon EKS using the AWS Load Balancer Controller. Deploying on AWS introduces unique requirements compared to standard Ingress setups, such as relying on specific custom resources (`LoadBalancerConfiguration` and `TargetGroupConfiguration`) instead of standard annotations, and utilizing AWS Certificate Manager (ACM) for TLS.

To streamline deployment, the IDSP Helm chart auto-detects AWS environments (via the `amazon*` or `aws*` gatewayClassName prefix) and applies necessary AWS-specific workarounds automatically:

- Skips `BackendTLSPolicy` creation, as it is not supported by the AWS Load Balancer Controller.
- Sets `appProtocol: HTTPS` on the ssp-router Service to enable HTTPS backend connections.
- Creates a `TargetGroupConfiguration` resource with the required `targetType: ip` , health check (`/actuator/health`), and deregistration delay settings (provided the CRD exists in the cluster).

Aspect	Details
Gateway API support	GatewayClass (v1), Gateway (v1), HTTPRoute (v1)
BackendTLSPolicy	Not supported — HTTPS to backends works via `appProtocol: HTTPS` but without cert validation
Health Check	`TargetGroupConfiguration` CRD (`elbv2.k8s.aws/v1beta1`) — auto-created by Helm chart
Traffic Policy	`TargetGroupConfiguration` — target type, health check, deregistration delay
Platforms	EKS only
EKS Requirements	AWS LB Controller v3.x with `ALBGatewayAPI` feature gate enabled, IRSA

IMPORTANT
AWS Load Balancer Controller Gateway API mode behaves **very differently** from its Ingress mode. Configuration that works with Ingress (annotations, tag-based subnet discovery) does **not** work with Gateway API. The controller uses dedicated CRDs instead.

Infrastructure Setup for AWS Gateway API Controller

Step-by-Step Setup

1. Set environment variables:
```
export CLUSTER_NAME="<your-eks-cluster-name>"
export REGION="<aws-region>"
export ACCOUNT_ID=$(aws sts get-caller-identity --query Account --output text)
```
2. Verify the OIDC provider is registered. IRSA requires an OIDC provider associated with the EKS cluster. Most EKS clusters have this enabled by default.
```
OIDC_ID=$(aws eks describe-cluster --name $CLUSTER_NAME --region $REGION \
  --query "cluster.identity.oidc.issuer" --output text | cut -d'/' -f5)

# Check if OIDC provider exists in IAM:
aws iam list-open-id-connect-providers | grep $OIDC_ID

# If not found, create it:
# eksctl utils associate-iam-oidc-provider --cluster $CLUSTER_NAME --region $REGION --approve
```
3. Create the IAM policy (if it does not already exist):
```
# Download the official IAM policy document:
curl -o /tmp/iam-policy.json https://raw.githubusercontent.com/kubernetes-sigs/aws-load-balancer-
controller/main/docs/install/iam_policy.json

# Create the policy:
aws iam create-policy \
  --policy-name AWSLoadBalancerControllerIAMPolicy \
  --policy-document file:///tmp/iam-policy.json
```

```
# If policy already exists, note the ARN:
POLICY_ARN=$(aws iam list-policies --scope Local \
  --query "Policies[?PolicyName=='AWSLoadBalancerControllerIAMPolicy'].Arn" --output text)
echo "Policy ARN: $POLICY_ARN"
```

4. Create the IAM role with an IRSA trust policy:

```
OIDC_ISSUER=$(aws eks describe-cluster --name $CLUSTER_NAME --region $REGION \
  --query "cluster.identity.oidc.issuer" --output text)
OIDC_PROVIDER=${OIDC_ISSUER#https://}

cat > /tmp/trust-policy.json <<EOF
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
                "Federated": "arn:aws:iam::${ACCOUNT_ID}:oidc-provider/${OIDC_PROVIDER}"
            },
            "Action": "sts:AssumeRoleWithWebIdentity",
            "Condition": {
                "StringEquals": {
                    "${OIDC_PROVIDER}:aud": "sts.amazonaws.com",
                    "${OIDC_PROVIDER}:sub": "system:serviceaccount:kube-system:aws-load-balancer-
controller"
                }
            }
        }
    ]
}
EOF

ROLE_NAME="AmazonEKSLoadBalancerControllerRole-${CLUSTER_NAME}"

aws iam create-role \
  --role-name $ROLE_NAME \
  --assume-role-policy-document file:///tmp/trust-policy.json

aws iam attach-role-policy \
  --role-name $ROLE_NAME \
  --policy-arn $POLICY_ARN

ROLE_ARN=$(aws iam get-role --role-name $ROLE_NAME --query "Role.Arn" --output text)
echo "Role ARN: $ROLE_ARN"
```

5. Create the Kubernetes service account:

```
cat <<EOF | kubectl apply -f -
apiVersion: v1
kind: ServiceAccount
metadata:
  name: aws-load-balancer-controller
  namespace: kube-system
  annotations:
```

```
    eks.amazonaws.com/role-arn: ${ROLE_ARN}
EOF
```

6. Install the Gateway API CRDs:

```
kubectl apply -f https://github.com/kubernetes-sigs/gateway-api/releases/download/v1.2.0/standard-
install.yaml

# Verify:
kubectl get crd gateways.gateway.networking.k8s.io
```

7. Install the AWS Load Balancer Controller via Helm. Use `controllerConfig.featureGates.ALBGatewayAPI=true` to enable Gateway API support.

```
helm repo add eks https://aws.github.io/eks-charts
helm repo update eks

VPC_ID=$(aws eks describe-cluster --name $CLUSTER_NAME --region $REGION \
  --query "cluster.resourcesVpcConfig.vpcId" --output text)

helm install aws-load-balancer-controller eks/aws-load-balancer-controller \
  -n kube-system \
  --set clusterName=$CLUSTER_NAME \
  --set serviceAccount.create=false \
  --set serviceAccount.name=aws-load-balancer-controller \
  --set region=$REGION \
  --set vpcId=$VPC_ID \
  --set "controllerConfig.featureGates.ALBGatewayAPI=true"

# Verify controller pods are running:
kubectl get pods -n kube-system -l app.kubernetes.io/name=aws-load-balancer-controller

# Verify feature gate is enabled:
kubectl get deployment -n kube-system aws-load-balancer-controller \
  -o jsonpath='{.spec.template.spec.containers[0].args}'
```

8. Create the GatewayClass. The controller does not auto-create a GatewayClass. The `controllerName` must be exactly `gateway.k8s.aws/alb` .

```
cat <<EOF | kubectl apply -f -
apiVersion: gateway.networking.k8s.io/v1
kind: GatewayClass
metadata:
  name: amazon-alb
spec:
  controllerName: gateway.k8s.aws/alb
EOF

# Verify GatewayClass is Accepted:
kubectl get gatewayclass
```

9. Verify the Gateway API controllers are running:

```
kubectl logs -n kube-system -l app.kubernetes.io/name=aws-load-balancer-controller \
  --tail=50 | grep "Starting Controller"
```

You should see `gateway.k8s.aws/alb` and `aws-lbc-gateway-class-controller` among the started controllers.

AWS-Specific CRDs and Configuration

LoadBalancerConfiguration CRD (Required)

The `LoadBalancerConfiguration` CRD controls ALB settings. It is **required** for Gateway API mode.

```
apiVersion: gateway.k8s.aws/v1beta1
kind: LoadBalancerConfiguration
metadata:
  name: <release>-ssp-gateway-config
  namespace: <namespace>
spec:
  scheme: internet-facing               # or "internal"
  loadBalancerSubnets:
    - identifier: subnet-aaaa           # Public subnets with internet gateway
    - identifier: subnet-bbbb
    - identifier: subnet-cccc
  # Optional: use existing security group instead of creating new one
  securityGroups:
    - sg-xxxx
  manageBackendSecurityGroupRules: false
```

Attach it to the Gateway via `spec.infrastructure.parametersRef` :

```
apiVersion: gateway.networking.k8s.io/v1
kind: Gateway
metadata:
  name: <release>-ssp-gateway
spec:
  gatewayClassName: amazon-alb
  infrastructure:
    parametersRef:
      group: gateway.k8s.aws
      kind: LoadBalancerConfiguration
      name: <release>-ssp-gateway-config
  listeners:
    # ...
```

Finding subnets:

```
# List subnets in the cluster VPC
VPC_ID=$(aws eks describe-cluster --name <cluster> --region <region> \
  --query "cluster.resourcesVpcConfig.vpcId" --output text)

aws ec2 describe-subnets --filters "Name=vpc-id,Values=$VPC_ID" \
  --query 'Subnets[].{ID:SubnetId,AZ:AvailabilityZone,CIDR:CidrBlock,Public:MapPublicIpOnLaunch}' \
  --output table
```

Use **public** subnets (MapPublicIpOnLaunch=true) for internet-facing ALBs.

TargetGroupConfiguration CRD (Required)

The `TargetGroupConfiguration` CRD controls how the ALB connects to ssp-router pods.

```
apiVersion: gateway.k8s.aws/v1beta1
kind: TargetGroupConfiguration
metadata:
  name: <release>-ssp-router-tgc
  namespace: <namespace>
spec:
  targetReference:
    group: ""
    kind: Service
    name: <release>-ssp-router
  defaultConfiguration:
    targetType: ip                        # Required: ssp-router uses ClusterIP
    protocol: HTTPS                       # Required: ssp-router listens on HTTPS
    protocolVersion: HTTP1
    healthCheckConfig:
      healthCheckPath: /actuator/health  # Required: must work without Host header
      healthCheckProtocol: HTTPS
      healthCheckInterval: 15
      healthyThresholdCount: 2
      unhealthyThresholdCount: 3
      matcher:
        httpCode: "200-399"
```

Why `targetType: ip` Is Required:

The default target type is `instance` , which requires a NodePort service. ssp-router is a ClusterIP service. Set `targetType: ip` to register pod IPs directly as ALB targets. Without it you get: `TargetGroup port is empty. When using Instance targets, your service must be of type 'NodePort' or 'LoadBalancer'.`

Why `/actuator/health` Is the Health Check Path:

ALB health checks do **not** send a `Host` header. ssp-router requires a valid Host header to resolve the tenant. Without it, any tenant-scoped path returns 403. `/actuator/health` is a Spring Boot actuator endpoint that returns 200 regardless of Host header.

Health Check Path	Works Without Host Header?	Notes
`/`	No (403)	ssp-router returns 403
`/actuator/health`	No (403)	Requires Host header for tenant
`/actuator/health`	**Yes (200)**	Spring Boot actuator, no tenant context needed

AWS-Specific CRDs Summary

CRD	API Group	Purpose	Requir
`LoadBalancerConfiguration`	`gateway.k8s.aws/v1beta1`	ALB settings: subnets, scheme, security groups	**Yes**
`TargetGroupConfiguration`	`elbv2.k8s.aws/v1beta1`	Target settings: IP mode, protocol, health checks	**Yes** (Helm-ma
`ListenerRuleConfiguration`	`gateway.k8s.aws/v1beta1`	Custom listener rule settings	No (not neede IDSP)

NOTE
`TargetGroupConfiguration` is now created by the Helm chart automatically when `gatewayType=eks` (via `ssprouter-traffic-policy.yaml`). It configures `targetType: ip` , health check path `/actuator/health` , and deregistration delay. `LoadBalancerConfiguration` must still be created manually outside the Helm chart, as it contains environment-specific settings (subnet IDs, security groups).

Deploying or Migrating to Gateway API

Learn how to deploy a fresh installation of IDSP using the Gateway API on AWS, or migrate an existing NGINX Ingress deployment to the Gateway API standard.

Pre-requisite Check

NOTE
Before proceeding with the specific checks mentioned in this section, review and complete all items in the Prerequisites for All Deployments list.

Run the following commands to verify all prerequisites are in place before deploying IDSP:

- **Verify Gateway API CRDs are installed:**
  ```
  kubectl get crd gateways.gateway.networking.k8s.io
  ```
- **Verify AWS Load Balancer Controller pods are running:**
  ```
  kubectl get pods -n kube-system -l app.kubernetes.io/name=aws-load-balancer-controller
  ```
- **Verify the ALBGatewayAPI feature gate is enabled:**
  ```
  kubectl get deployment -n kube-system aws-load-balancer-controller \
    -o jsonpath='{.spec.template.spec.containers[0].args}'
  ```
  Expected output: The output should contain `ALBGatewayAPI=true` .
- **Verify the GatewayClass is available and accepted:**
  ```
  kubectl get gatewayclass
  ```
  Expected output: The list should display `amazon-alb` with a status of `Accepted=True` .
- **Verify the LoadBalancerConfiguration is created:**
  ```
  kubectl get loadbalancerconfiguration -n ssp
  ```
- **Verify the TLS certificate Secret exists:**
  ```
  kubectl get secret <tls-secret-name> -n ssp
  ```
- **Verify the ACM certificate exists for hostnames (AWS):**
  ```
  aws acm list-certificates --region <region>
  ```
  If no ACM certificate exists, import your TLS certificate into ACM. The ALB controller auto-discovers ACM certificates by matching Gateway listener hostnames against the certificate SANs.
  ```
  aws acm import-certificate \
    --certificate fileb://tls.crt \
    --private-key fileb://tls.key \
  ```

```
    --certificate-chain fileb://ca.crt \
    --region <region>
```

Minimum ClusterRole for AWS Load Balancer Controller:

```
apiVersion: rbac.authorization.k8s.io/v1
kind: ClusterRole
metadata:
  name: gateway-api-admin
rules:
  - apiGroups: ["gateway.networking.k8s.io"]
    resources: ["gateways", "httproutes"]
    verbs: ["get", "list", "watch", "create", "update", "patch", "delete"]
  - apiGroups: ["elbv2.k8s.aws"]
    resources: ["targetgroupconfigurations"]
    verbs: ["get", "list", "watch", "create", "update", "patch", "delete"]
  - apiGroups: ["gateway.k8s.aws"]
    resources: ["loadbalancerconfigurations"]
    verbs: ["get", "list", "watch", "create", "update", "patch", "delete"]
```

Before You Deploy

NOTE

- Gateway ownership: The Gateway can be created by Helm (`createGateway: true` , default) or pre-created by the platform team (`createGateway: false` + `existingGateway`). To know how to use an already existing Gateway, see Already Have a Gateway? section for details.
- Set these Environment Variables:

```
export RELEASENAME="<SSP_RELEASENAME>"
export NAMESPACE="<SSP_NAMESPACE>"
export HELM_REPO='ssp_helm_charts'
```

- Run the following command to export the current override values of your Helm release to `ssp-override.yaml` . This lets you review, back up, or reuse your existing configuration:

```
helm get values ${RELEASENAME} -n ${NAMESPACE} >ssp-override.yaml
```

Deploy IDSP with Gateway API (Fresh Install)

1. **Ensure AWS LB Controller is installed**
   Verify that the AWS Load Balancer Controller is installed with the `ALBGatewayAPI` feature gate enabled and that the GatewayClass exists. See the Infrastructure Setup section.
2. **Create LoadBalancerConfiguration (manual — not Helm-managed)**
   Create the `LoadBalancerConfiguration` resource with your environment-specific subnet IDs. See the LoadBalancerConfiguration CRD section for the full spec.

```
cat <<EOF | kubectl apply -n ssp -f -
apiVersion: gateway.k8s.aws/v1beta1
kind: LoadBalancerConfiguration
metadata:
  name: <release>-ssp-gateway-config
spec:
  scheme: internet-facing
```

```
    loadBalancerSubnets:
      - identifier: <subnet-1>
      - identifier: <subnet-2>
      - identifier: <subnet-3>
  EOF
```

3. **Deploy IDSP with Gateway API**
   Run the Helm install with Gateway API settings. The chart auto-detects the AWS gateway class and skips `BackendTLSPolicy` creation.

```
helm upgrade --install ${RELEASENAME} ${HELM_REPO}/ssp -n ${NAMESPACE} \
  -f your-values.yaml \
  --set ssp.ingress.type=gatewayapi \
  --set ssp.ingress.gatewayApi.gatewayClassName=amazon-alb \
  --set ssp.ingress.gatewayApi.createGateway=true \
  --set ssp.ingress.gatewayApi.createBackendTLSPolicy=false
```

4. **Verify resources**
   Confirm that the Gateway, HTTPRoute, and TargetGroupConfiguration resources were created.

```
kubectl get gateway,httproute -n ${NAMESPACE}
kubectl get targetgroupconfiguration -n ${NAMESPACE}
```

5. **Verify Gateway references the LoadBalancerConfiguration**
   Check that the Gateway has an `infrastructure.parametersRef` pointing to your `LoadBalancerConfiguration`.

```
kubectl get gateway -n ${NAMESPACE} -o yaml | grep -A5 parametersRef
```

6. **Test connectivity**
   Retrieve the ALB DNS name from the Gateway status and send a test request.

```
ALB_DNS=$(kubectl get gateway -n ${NAMESPACE} -o jsonpath='{.items[0].status.addresses[0].value}')
curl -sk --resolve "your-host:443:$ALB_DNS" \
"https://your-host/default/.well-known/openid-configuration"
```

What Helm creates for EKS:

Resource	Name Pattern	Purpose
Gateway	`<release>-ssp-gateway`	HTTPS listeners with TLS termination
HTTPRoute	`<release>-ssp-router-full`	Routes all traffic to ssp-router
TargetGroupConfiguration	`<release>-ssp-router-tgc`	Target type (IP), health check, deregistration delay

> **NOTE**
> `LoadBalancerConfiguration` must be created manually. See AWS-Specific CRDs section.

Migrate IDSP from Nginx to Gateway API

> **NOTE**
> Before proceeding, complete all steps in the Before You Deploy section.

1. **Upgrade the existing deployment:**
   Run the following command to upgrade an existing NGINX-based IDSP deployment to Gateway API on AWS:

```
helm upgrade ${RELEASENAME} ${HELM_REPO}/ssp -n ${NAMESPACE} \
  -f your-values.yaml \
  --set ssp.ingress.type=gatewayapi \
  --set ssp.ingress.previousController.enabled=true \
  --set ssp.ingress.previousController.ingressClassName=nginx \
  --set ssp.ingress.gatewayApi.gatewayClassName=amazon-alb \
  --set ssp.ingress.gatewayApi.createGateway=true \
  --set ssp.ingress.gatewayApi.createBackendTLSPolicy=false
```

2. **Remove the old controller:**
   After verifying that the Gateway API works and switching your DNS, run the following command to remove the old controller:

```
helm upgrade ${RELEASENAME} ${HELM_REPO}/ssp -n ${NAMESPACE} \
  -f your-values.yaml \
  --set ssp.ingress.type=gatewayapi \
  --set ssp.ingress.previousController.enabled=false \
  --set ssp.ingress.gatewayApi.gatewayClassName=amazon-alb \
  --set ssp.ingress.gatewayApi.createGateway=true \
  --set ssp.ingress.gatewayApi.createBackendTLSPolicy=false
```

Deploy the Sample App to Test Connectivity

Deploy the sample-app with AWS ALB to test connectivity before or alongside IDSP:

1. **Create the LoadBalancerConfiguration (manual — not Helm-managed):**

```
cat <<EOF | kubectl apply -n <namespace> -f -
apiVersion: gateway.k8s.aws/v1beta1
kind: LoadBalancerConfiguration
metadata:
  name: <release>-ssp-sample-app-gateway-config
spec:
  scheme: internet-facing
  loadBalancerSubnets:
    - identifier: <subnet-1>
    - identifier: <subnet-2>
    - identifier: <subnet-3>
EOF
```

2. **Deploy the sample app with Gateway API (EKS):**

```
helm upgrade --install ${RELEASENAME} ${HELM_REPO}/ssp-sample-app -n ${NAMESPACE} \
  -f your-sample-values.yaml \
  --set ingress.type=gatewayapi \
  --set ingress.gatewayApi.gatewayClassName=amazon-alb \
  --set ingress.gatewayApi.createGateway=true \
  --set ingress.gatewayApi.createBackendTLSPolicy=false
```

3. **Verify resources:**

```
kubectl get gateway,httproute,targetgroupconfiguration -n <namespace>
```

4. **Test connectivity:**

```
ALB_DNS=$(kubectl get gateway -n <namespace> -o jsonpath='{.items[0].status.addresses[0].value}')
curl -sk --resolve "your-host:443:$ALB_DNS" "https://your-host/sample-app/"
```

> **NOTE**
> All sample-app services use ClusterIP, so `targetType: ip` is required. The chart creates a TargetGroupConfiguration for each backend service automatically when `gatewayType=aws-alb` is detected.

Troubleshooting AWS Deployments

Condition

The following issues may occur during the deployment or migration of the Gateway API on AWS.

Cause: GatewayClass stays Unknown

Check: Run `kubectl get gatewayclass -o yaml`

Remedy

Verify `controllerName` is exactly `gateway.k8s.aws/alb` and the `ALBGatewayAPI` feature gate is enabled.

Cause: No gateway controllers in logs

Check: Run `kubectl logs ... | grep gateway`

Remedy

Enable the feature gate by running `--set "controllerConfig.featureGates.ALBGatewayAPI=true"` and restart.

Cause: Controller pods CrashLoopBackOff

Check: Run `kubectl logs -n kube-system -l app.kubernetes.io/name=aws-load-balancer-controller`

Remedy

Check IRSA: verify the service account annotation and IAM role trust policy.

Cause: ALB not created after Gateway

Check: Run `kubectl describe gateway <name>`

Remedy

Check IAM permissions (AWSLoadBalancerControllerIAMPolicy), VPC subnets, and security groups.

Cause: Target group unhealthy

Check: Run `aws elbv2 describe-target-health --target-group-arn <arn>`

Remedy

Verify ssp-router pods are running and security groups allow traffic from the ALB.

Cause: Gateway API CRDs not found

Check: Run `kubectl get crd | grep gateway`

Remedy

Install the CRDs by running: `kubectl apply -f https://...gateway-api/.../standard-install.yaml`

Cause: "Evaluated 0 subnets"

Check: Review the Controller logs.

Remedy

Create a `LoadBalancerConfiguration` with explicit subnet IDs — tag-based discovery does not work.

Cause: SecurityGroupLimitExceeded

Check: Review the Controller logs.

Remedy

Specify an existing security group in the `LoadBalancerConfiguration` .

Cause: "no certificate found for host"

Check: Review the Controller logs.

Remedy

Import the certificate to ACM, then trigger reconciliation — see the Verifying ACM Certificates section.

Cause: 502 Bad Gateway after TGC change

Check: Run `aws elbv2 describe-target-health --target-group-arn <arn>`

Remedy

Ensure the TargetGroupConfiguration (TGC) has `protocol: HTTPS` — without it, the ALB connects via HTTP to ssp-router (which is HTTPS-only).

Cause: Gateway Accepted: False

Check: Run `kubectl get gateway <name> -o yaml` and check `status.conditions` .

Remedy

Check the controller logs; this is usually a certificate discovery failure blocking reconciliation.

GKE L7 Gateway Controller

Learn how to configure and deploy the Gateway API on Google Kubernetes Engine (GKE) using the native GKE Gateway Controller.

The GKE L7 Gateway Controller is Google's native implementation of the Kubernetes Gateway API. It provisions Cloud Load Balancing resources to manage HTTP and HTTPS traffic routing into your GKE clusters. By using the Gateway API on GKE, you benefit from a standardized, declarative model for service networking that integrates seamlessly with Google Cloud infrastructure.

> **NOTE**
> ## **Limitation:** GKE L7 Gateway does **not** validate backend certificates. If backend certificate validation is a strict requirement for your deployment, consider using Envoy Gateway on GKE instead.

For comprehensive official documentation on the GKE Gateway API, see: About GKE Gateway Controller.

Overview

When deploying the Identity Security Platform (IDSP) using the GKE L7 Gateway Controller, the deployment leverages native Google Cloud resources. The IDSP Helm chart streamlines this process by automatically detecting the GKE environment and applying several necessary configurations:

- **Backend TLS Policy:** Skips `BackendTLSPolicy` creation (which is not currently supported by GKE) and instead sets `appProtocol: HTTPS` on the `ssp-router` Service to enable encrypted backend connections.
- **Health Checks:** Automatically generates a `HealthCheckPolicy` custom resource (`networking.gke.io/v1`) for native HTTPS health checks to the `ssp-router` .
- **Traffic Policies:** Creates a `GCPBackendPolicy` for managing backend timeouts and connection draining.

The following table summarizes the Gateway API resource support and specific platform configurations when using the GKE Gateway Controller:

Aspect	Details
Gateway API support	GatewayClass (v1), Gateway (v1), HTTPRoute (v1)
BackendTLSPolicy	Not supported. HTTPS to backends works via `appProtocol: HTTPS` but without cert validation
Health Check	`HealthCheckPolicy` CRD (`networking.gke.io/v1`) — auto-created by Helm chart
Traffic Policy	`GCPBackendPolicy` , backend timeout, connection draining
Platforms	GKE only

GatewayClass Options

GKE offers different GatewayClasses depending on your traffic routing needs (such as global, regional, or internal access). Choosing the right GatewayClass determines how the Google Cloud Load Balancer is provisioned and whether a proxy-only subnet is required.

GatewayClass	Type	Proxy Subnet Required	Description
`gke-l7-global-external-managed`	Global External	#	Anycast IP, g
`gke-l7-regional-external-managed`	Regional External	#	Single region
`gke-l7-rilb`	Internal	#	VPC-only acc

Choosing a GatewayClass:

- Use `gke-l7-global-external-managed` for multi-region or when you want the simplest setup (no proxy subnet needed).
- Use `gke-l7-regional-external-managed` when your deployment is single-region and you want a regional external IP. Requires a proxy-only subnet in the same region.
- Use `gke-l7-rilb` for internal-only access within the VPC.

The IDSP Helm chart auto-detects GKE based on the GatewayClass and automatically does the following:

- Creates a `HealthCheckPolicy` for HTTPS health checks
- Sets `appProtocol: HTTPS` on the ssp-router Service
- Skips BackendTLSPolicy creation (not supported by GKE)

Infrastructure Setup for GKE L7 Gateway API Controller
These steps describe how to prepare your Google Kubernetes Engine (GKE) environment for the Gateway API.

1. **Enable Gateway API on GKE cluster:**

```
gcloud container clusters update <CLUSTER_NAME> \
  --gateway-api=standard \
  --zone=<ZONE>
```

2. **Create proxy-only subnet (required for regional/internal only):**

```
gcloud compute networks subnets create proxy-only-subnet \
  --purpose=REGIONAL_MANAGED_PROXY \
  --role=ACTIVE \
  --region=<REGION> \
  --network=<VPC_NAME> \
  --range=<CIDR_RANGE>
```

Deploying or Migrating to GKE L7 Gateway API
Learn how to deploy a fresh installation of the Gateway API on Google Kubernetes Engine (GKE), or migrate an existing Nginx-based deployment to the GKE L7 Gateway API.

Pre-requisite Check

Run the following commands to verify that all prerequisites are correctly configured before deploying IDSP:

1. **Verify GatewayClass:** Ensure that the required GKE GatewayClass (such as `gke-l7-global-external-managed`) is available and has been accepted.
   ```
   kubectl get gatewayclass
   ```
   Expected Output: Look for GKE classes with `Accepted=True` .
2. **Verify TLS Certificate Secret:** Confirm that the secret containing your TLS certificates exists in the `ssp` namespace.
   ```
   kubectl get secret <tls-secret-name> -n ssp
   ```
3. **Check RBAC Permissions:** Ensure you have the necessary permissions to create Gateway API and GKE-specific networking resources.

```
kubectl auth can-i create gateways.gateway.networking.k8s.io -n ssp
kubectl auth can-i create httproutes.gateway.networking.k8s.io -n ssp
kubectl auth can-i create healthcheckpolicies.networking.gke.io -n ssp
kubectl auth can-i create gcpbackendpolicies.networking.gke.io -n ssp
```

4. **Verify Proxy-Only Subnet:** (Required only for regional or internal gateways) Check that a proxy-only subnet exists in your VPC.
   ```
   gcloud compute networks subnets list --filter="purpose=REGIONAL_MANAGED_PROXY"
   ```

Minimum ClusterRole for GKE L7 Gateway:

```
apiVersion: rbac.authorization.k8s.io/v1
kind: ClusterRole
metadata:
  name: gateway-api-admin
rules:
  - apiGroups: ["gateway.networking.k8s.io"]
    resources: ["gateways", "httproutes"]
    verbs: ["get", "list", "watch", "create", "update", "patch", "delete"]
  - apiGroups: ["networking.gke.io"]
    resources: ["healthcheckpolicies", "gcpbackendpolicies"]
    verbs: ["get", "list", "watch", "create", "update", "patch", "delete"]
```

Before You Deploy

NOTE

- Gateway ownership: The Gateway can be created by Helm (`createGateway: true` , default) or pre-created by the platform team (`createGateway: false` + `existingGateway`). To know how to use an already existing Gateway, see Already Have a Gateway? section for details.
- Set these Environment Variables:

```
export RELEASENAME="<SSP_RELEASENAME>"
export NAMESPACE="<SSP_NAMESPACE>"
export HELM_REPO='ssp_helm_charts'
```

- Run the following command to export the current override values of your Helm release to `ssp-override.yaml` . This lets you review, back up, or reuse your existing configuration:

```
helm get values ${RELEASENAME} -n ${NAMESPACE} >ssp-override.yaml
```

Deploying Symantec Identity Security Platform with Gateway API (Fresh Install)

1. Ensure GKE Gateway API is enabled. For regional or internal deployments, also ensure that a proxy-only subnet exists. See the Infrastructure Setup section for details.
2. Deploy Symantec Identity Security Platform with Gateway API. Choose the option that matches your deployment type:

   Option A — Global External (no proxy subnet needed):

```
helm install ${RELEASENAME} ${HELM_REPO}/ssp -n ${NAMESPACE} \
  -f your-values.yaml \
  --set ssp.ingress.type=gatewayapi \
  --set ssp.ingress.gatewayApi.gatewayClassName=gke-l7-global-external-managed \
  --set ssp.ingress.gatewayApi.createGateway=true \
  --set ssp.ingress.gatewayApi.createBackendTLSPolicy=false
```

   Option B — Regional External (requires proxy-only subnet):

```
helm install ${RELEASENAME} ${HELM_REPO}/ssp -n ${NAMESPACE} \
  -f your-values.yaml \
  --set ssp.ingress.type=gatewayapi \
  --set ssp.ingress.gatewayApi.gatewayClassName=gke-l7-regional-external-managed \
  --set ssp.ingress.gatewayApi.createGateway=true \
  --set ssp.ingress.gatewayApi.createBackendTLSPolicy=false
```

3. Verify that the Gateway API resources were created:

```
kubectl get gateway,httproute -n ${NAMESPACE}
kubectl get healthcheckpolicy,gcpbackendpolicy -n ${NAMESPACE}
```

4. Wait for the Gateway to receive an external IP address. This typically takes 2–5 minutes on GKE:

```
kubectl get gateway -n ${NAMESPACE} -w
```

5. Test connectivity through the Gateway:

```
GATEWAY_IP=$(kubectl get gateway -n ${NAMESPACE} -o jsonpath='{.items[0].status.addresses[0].value}')
curl -sk --resolve "your-host:443:$GATEWAY_IP" \
  "https://your-host/actuator/health"
```

What Helm creates for GKE:

Resource	Name Pattern	Purpose
Gateway	`<release>-ssp-gateway`	HTTPS listeners with TLS termination
HTTPRoute	`<release>-ssp-router-full`	Routes all traffic to ssp-router
HealthCheckPolicy	`<release>-ssp-router-healthcheck`	HTTPS health check for ssp-router
GCPBackendPolicy	`<release>-ssp-router-backend-policy`	Backend timeout, connection draining

Migrating Symantec Identity Security Platform from Nginx to Gateway API

> **NOTE**
> Before proceeding, complete all steps in the Before You Deploy section.

If upgrading an existing nginx-based Symantec Identity Security Platform deployment to Gateway API on GKE:

1. Upgrade your deployment (choose Option A or Option B):

   Option A — Global External (no proxy subnet needed):

```
helm upgrade ${RELEASENAME} ${HELM_REPO}/ssp -n ${NAMESPACE} \
  -f your-values.yaml \
  --set ssp.ingress.type=gatewayapi \
  --set ssp.ingress.previousController.enabled=true \
  --set ssp.ingress.previousController.ingressClassName=nginx \
  --set ssp.ingress.gatewayApi.gatewayClassName=gke-l7-global-external-managed \
  --set ssp.ingress.gatewayApi.createGateway=true \
  --set ssp.ingress.gatewayApi.createBackendTLSPolicy=false
```

   Option B — Regional External (requires proxy-only subnet):

```
helm upgrade ${RELEASENAME} ${HELM_REPO}/ssp -n ${NAMESPACE} \
  -f your-values.yaml \
  --set ssp.ingress.type=gatewayapi \
  --set ssp.ingress.previousController.enabled=true \
  --set ssp.ingress.previousController.ingressClassName=nginx \
  --set ssp.ingress.gatewayApi.gatewayClassName=gke-l7-regional-external-managed \
  --set ssp.ingress.gatewayApi.createGateway=true \
  --set ssp.ingress.gatewayApi.createBackendTLSPolicy=false
```

2. After verifying Gateway API works and switching DNS, remove the old controller:

```
# Use the same gatewayClassName you chose above

helm upgrade ${RELEASENAME} ${HELM_REPO}/ssp -n ${NAMESPACE} \
  -f your-values.yaml \
  --set ssp.ingress.type=gatewayapi \
  --set ssp.ingress.previousController.enabled=false \
  --set ssp.ingress.gatewayApi.gatewayClassName=<same-class-as-above> \
  --set ssp.ingress.gatewayApi.createGateway=true \
  --set ssp.ingress.gatewayApi.createBackendTLSPolicy=false
```

Deploying the Sample App to Test Connectivity

Deploy the sample-app with GKE Gateway to test connectivity before or alongside Symantec Identity Security Platform:

Option A — Global External (no proxy subnet needed):

```
helm upgrade --install ${RELEASENAME} ${HELM_REPO}/ssp-sample-app -n ${NAMESPACE} \
  -f your-sample-values.yaml \
  --set ingress.type=gatewayapi \
  --set ingress.gatewayApi.gatewayClassName=gke-l7-global-external-managed \
  --set ingress.gatewayApi.createGateway=true \
  --set ingress.gatewayApi.createBackendTLSPolicy=false
```

Option B — Regional External (requires proxy-only subnet):

```
helm upgrade --install ${RELEASENAME} ${HELM_REPO}/ssp-sample-app -n ${NAMESPACE} \
  -f your-sample-values.yaml \
  --set ingress.type=gatewayapi \
  --set ingress.gatewayApi.gatewayClassName=gke-l7-regional-external-managed \
  --set ingress.gatewayApi.createGateway=true \
  --set ingress.gatewayApi.createBackendTLSPolicy=false

# Wait for Gateway IP (GKE takes 2-5 minutes)
kubectl get gateway -n ${NAMESPACE} -w

# Test connectivity
GATEWAY_IP=$(kubectl get gateway -n ${NAMESPACE} -o jsonpath='{.items[0].status.addresses[0].value}')
curl -sk --resolve "your-host:443:$GATEWAY_IP" "https://your-host/sample-app/"
```

> **NOTE**
> **Note:** GKE does not support BackendTLSPolicy (`createBackendTLSPolicy=false`). GKE uses `appProtocol: HTTPS` on the spi-demo Service to connect via HTTPS. The chart creates a HealthCheckPolicy for spi-demo because it returns 302 on `/` .

Troubleshooting GKE L7 Deployments

"proxy-only subnetwork required" error

Remedy

Create a proxy-only subnet or use `gke-l7-global-external-managed` which does not require one.

Backend unhealthy (503 errors)

Remedy

Check the health check policy and the backend health:

```
kubectl get healthcheckpolicy -n ssp
# For global external:
gcloud compute backend-services get-health <backend-service-name> --global
```

```
# For regional external:
gcloud compute backend-services get-health <backend-service-name> --region=<REGION>
```

Backends showing HTTP instead of HTTPS

Remedy

Check the appProtocol on the service:

```
kubectl get service <release-name>-ssp-router -n ssp -o jsonpath='{.spec.ports[0].appProtocol}'
```

SPI demo returns 503 — health check type or port mismatch

GKE NEG health checks go directly to the pod IP, so the HealthCheckPolicy must use:

- `type: HTTPS` (not `HTTP`) — spi-demo is an HTTPS-only backend
- `port:` set to the **container port** (e.g., 8092), not the service port (e.g., 443)

Remedy

1. Check the GCE health check configuration:

   ```
   gcloud compute health-checks list --filter="name~spi" --format="table(name,type)" --regions=<REGION>
   ```

   If type shows HTTP instead of HTTPS, this is the issue.

2. Check backend health:

   ```
   gcloud compute backend-services get-health <backend-name> --region=<REGION>
   ```

   If healthState is UNHEALTHY, the health check is failing.

3. Verify the HealthCheckPolicy:

   ```
   kubectl get healthcheckpolicy -n <ns> -o yaml
   ```

   Check: config.type should be HTTPS, httpsHealthCheck.port should be the container port.

4. Fix the issue:

   Update the HealthCheckPolicy to use `type: HTTPS` with `httpsHealthCheck` and the container port. The Helm chart (v1034+) does this automatically.

Azure Application Gateway

Learn about Azure Application Gateway for Containers (AGC) and its integration with the Kubernetes Gateway API on AKS.

Overview

Azure Application Gateway for Containers (AGC) is a Microsoft-managed Layer 7 load balancing and traffic management service built specifically for Azure Kubernetes Service (AKS). It natively implements the Kubernetes Gateway API to securely and efficiently route incoming traffic to your applications. By leveraging AGC, you can take advantage of advanced routing capabilities, robust TLS termination, and seamless integration with the Azure ecosystem.

For comprehensive Official documentation, see Application Gateway for Containers.

To streamline the setup process on AKS, the IDSP Helm chart automatically detects the Azure environment via the `azure*` `gatewayClassName` prefix and does the following:

- Creates the Azure-specific BackendTLSPolicy CRD (`alb.networking.azure.io/v1`) for backend TLS validation
- Creates the Azure-specific HealthCheckPolicy CRD (`alb.networking.azure.io/v1`) with HTTPS health checks to `/actuator/health` , **recommended** because AGC's default health check hits `/` which returns 404 on ssp-router (though AGC can also fall back to the Kubernetes readiness probe when no HCP is present)
- Uses `gatewayAnnotations` to link the Gateway to the ApplicationLoadBalancer resource (the ALB instance in Azure)

> **NOTE**
> AGC assigns a unique FQDN (example, #.####.alb.azure.com) to the Gateway instead of a static IP. You must use "`dig`" or "`nslookup`" to resolve it when testing with "`curl --resolve`" .

Aspect	Details
Gateway API support	GatewayClass (v1), Gateway (v1), HTTPRoute (v1), BackendTLSPolicy (Azure CRD)
BackendTLSPolicy	Azure-specific CRD (`alb.networking.azure.io/v1`) — full CA certificate validation
HealthCheckPolicy	Azure-specific CRD (`alb.networking.azure.io/v1`) — **recommended** (AGC falls back to K8s readiness probe without it, but explicit HCP is safer)
Traffic Policy	Managed by Azure — no CRD needed
Platforms	AKS only
AKS Requirements	Azure CNI networking (flat or overlay), Workload Identity enabled
CNI Overlay Support	Requires ALB Controller ≥1.7.9 (recommended ≥1.9.13). Tested and working on both flat and overlay CNI.

Infrastructure Setup for Azure Gateway API Controller
Review the infrastructure requirements for the Azure Gateway API Controller, including required RBAC roles, provider registration, and a step-by-step setup guide for Azure Application Gateway for Containers (AGC).

Introduction

Before deploying the Gateway API, your Azure Kubernetes Service (AKS) cluster and Azure subscription must be properly configured. The following sections detail the mandatory Role-Based Access Control (RBAC) assignments for the ALB Controller's managed identity, the required subscription-level registration for the `Microsoft.ServiceNetworking` provider, and a complete step-by-step deployment procedure to provision the Azure Application Gateway for Containers (AGC) from scratch.

RBAC Roles Required

The ALB Controller managed identity needs **three** roles (not two — this is a common pitfall):

#	Role	Scope	Purpose
1	**AppGw for Containers Configuration Manager**	**MC resource group** (not AGC subnet)	Create and manage Traffic Controller resources (`Microsoft.ServiceNetworking/trafficCo` `write`). If scoped to the subnet, the ALB CR fails with `AuthorizationFailed.`
2	**Network Contributor**	AGC subnet	Manage network interfaces in the AGC subnet
3	**Reader**	MC resource group	Read resource group properties (required for AGC provi

NOTE

- **Critical:** Role #1 must be scoped to the **MC resource group**, not the AGC subnet. Many Azure docs and tutorials show the subnet scope, but this causes `403 AuthorizationFailed` when the controller tries to create the Traffic Controller resource. The error appears in the ApplicationLoadBalancer CR status (not in controller logs). .
- **CNI Overlay Note:** Azure CNI Overlay works with AGC. The ALB Controller (≥1.7.9) detects overlay automatically and manages overlay tunnels via `OverlayExtensionConfig` . Network Contributor scoped to the AGC subnet is sufficient — VNet scope is not required. If backends are UNHEALTHY on an overlay cluster, check the BackendTLSPolicy port first .

Microsoft.ServiceNetworking Provider

The `Microsoft.ServiceNetworking` resource provider must be registered at the subscription level. If not, the ALB controller fails with a `403` error about `Microsoft.ServiceNetworking/register/action` .

```
# Check registration status
az provider show --namespace Microsoft.ServiceNetworking --query registrationState -o tsv

# Register if needed (takes 1-2 minutes)
az provider register --namespace Microsoft.ServiceNetworking

# Wait for registration to complete
az provider show --namespace Microsoft.ServiceNetworking --query registrationState -o tsv
# Expected: Registered
```

After registering, restart the ALB controller to pick up the change:

```
kubectl rollout restart deployment alb-controller -n azure-alb-system
```

Step-by-Step Setup

Follow these steps to set up Azure AGC:

1. **Set Environment Variables**
   Define the environment variables used throughout the remaining steps.

   ```
   export RESOURCE_GROUP="<your-resource-group>"
   export AKS_NAME="<your-aks-cluster-name>"
   export LOCATION="<region>"
   export ALB_IDENTITY_NAME="alb-identity"
   ```

2. **Verify OIDC Issuer and Workload Identity**
   Both OIDC Issuer and Workload Identity must be enabled on the AKS cluster for the ALB Controller to authenticate to Azure.
   a. Check the current status:

      ```
      az aks show -g $RESOURCE_GROUP -n $AKS_NAME \
        --query "{oidcEnabled:oidcIssuerProfile.enabled,
       workloadIdentity:securityProfile.workloadIdentity.enabled}"
      ```

   b. If either value is `false` , enable them:

```
az aks update -g $RESOURCE_GROUP -n $AKS_NAME \
  --enable-oidc-issuer --enable-workload-identity
```

3. **Install Gateway API CRDs**
   a. Install the standard Gateway API Custom Resource Definitions:

```
kubectl apply -f https://github.com/kubernetes-sigs/gateway-api/releases/download/v1.2.0/standard-
install.yaml
```

   b. Verify the CRDs are installed:

```
kubectl get crd gateways.gateway.networking.k8s.io
```

4. **Create Managed Identity for ALB Controller**
   a. Create a user-assigned managed identity that the ALB Controller uses to manage Azure resources:

```
az identity create -g $RESOURCE_GROUP -n $ALB_IDENTITY_NAME -l $LOCATION
```

   b. Retrieve the identity details for use in later steps:

```
ALB_IDENTITY_CLIENT_ID=$(az identity show -g $RESOURCE_GROUP -n $ALB_IDENTITY_NAME --query clientId -o
 tsv)
ALB_IDENTITY_PRINCIPAL_ID=$(az identity show -g $RESOURCE_GROUP -n $ALB_IDENTITY_NAME --query
 principalId -o tsv)
echo "Client ID:    $ALB_IDENTITY_CLIENT_ID"
echo "Principal ID: $ALB_IDENTITY_PRINCIPAL_ID"
```

5. **Create Federated Credential for Workload Identity**
   Link the managed identity to the ALB Controller's Kubernetes service account via a federated credential.
   a. Retrieve the OIDC Issuer URL for your AKS cluster:

```
AKS_OIDC_ISSUER=$(az aks show -g $RESOURCE_GROUP -n $AKS_NAME --query "oidcIssuerProfile.issuerUrl" -o
 tsv)
```

   b. Create the federated credential:

```
az identity federated-credential create \
  --name alb-federated-credential \
  --identity-name $ALB_IDENTITY_NAME \
  -g $RESOURCE_GROUP \
  --issuer "$AKS_OIDC_ISSUER" \
  --subject system:serviceaccount:azure-alb-system:alb-controller-sa
```

6. **Create AGC Subnet**
   AGC requires a dedicated subnet with `Microsoft.ServiceNetworking/trafficControllers` delegation. The subnet must have at least 250 IPs (/24 or larger).
   a. Get the AKS node resource group and VNet name:

```
AKS_NODE_RG=$(az aks show -g $RESOURCE_GROUP -n $AKS_NAME --query nodeResourceGroup -o tsv)
AKS_VNET=$(az network vnet list -g $AKS_NODE_RG --query "[0].name" -o tsv)
```

b. Check if an AGC subnet already exists:

```
az network vnet subnet list -g $AKS_NODE_RG --vnet-name $AKS_VNET \
  --query "[?delegations[0].serviceName=='Microsoft.ServiceNetworking/trafficControllers'].name" -o tsv
```

c. If no subnet exists, create one (adjust the address prefix to avoid conflicts with existing subnets):

```
az network vnet subnet create \
  -g $AKS_NODE_RG \
  --vnet-name $AKS_VNET \
  -n agc-subnet \
  --address-prefixes 10.225.0.0/24 \
  --delegations Microsoft.ServiceNetworking/trafficControllers
```

d. Get the AGC subnet ID (replace `<agc-subnet-name>` with your subnet name):

```
AGC_SUBNET_ID=$(az network vnet subnet show -g $AKS_NODE_RG --vnet-name $AKS_VNET \
  -n <agc-subnet-name> --query id -o tsv)
echo "AGC Subnet ID: $AGC_SUBNET_ID"
```

7. **Register Microsoft.ServiceNetworking Provider**
   The `Microsoft.ServiceNetworking` resource provider is required at the subscription level. Without it, the ALB controller logs show `403` for `Microsoft.ServiceNetworking/register/action`.
   a. Check the registration status:

```
az provider show --namespace Microsoft.ServiceNetworking --query registrationState -o tsv
```

   b. If the status is `NotRegistered`, register it (takes 1-2 minutes):

```
az provider register --namespace Microsoft.ServiceNetworking
```

   c. Wait and verify registration is complete:

```
az provider show --namespace Microsoft.ServiceNetworking --query registrationState -o tsv
# Expected: Registered
```

8. **Assign RBAC Roles to ALB Identity**

   IMPORTANT
   This step requires **Owner** or **User Access Administrator** permissions. If you do not have these permissions, ask your Azure admin to run these commands.

   Three roles are needed: **Reader** (MC resource group), **AppGw for Containers Configuration Manager** (MC resource group), and **Network Contributor** (AGC subnet).
   a. Get the subscription ID:

```
SUBSCRIPTION_ID=$(az account show --query id -o tsv)
```

   b. Assign **Role 1: Reader** on the MC resource group (required for `Microsoft.Resources/subscriptions/resourcegroups/read`, which is NOT included in the Configuration Manager role):

```
az role assignment create \
  --assignee-object-id $ALB_IDENTITY_PRINCIPAL_ID \
  --assignee-principal-type ServicePrincipal \
  --role "Reader" \
  --scope /subscriptions/$SUBSCRIPTION_ID/resourceGroups/$AKS_NODE_RG
```

c. Assign **Role 2: AppGw for Containers Configuration Manager** on the MC resource group.

> **IMPORTANT**
> **Critical:** Scope this role to the **MC resource group**, not the AGC subnet. Scoping to the subnet causes `403 AuthorizationFailed` when the controller tries to create `Microsoft.ServiceNetworking/trafficControllers` resources. The error appears in the ApplicationLoadBalancer CR status, not in logs.

```
az role assignment create \
  --assignee-object-id $ALB_IDENTITY_PRINCIPAL_ID \
  --assignee-principal-type ServicePrincipal \
  --role "AppGw for Containers Configuration Manager" \
  --scope /subscriptions/$SUBSCRIPTION_ID/resourceGroups/$AKS_NODE_RG
```

d. Assign **Role 3: Network Contributor** on the AGC subnet (for standard Azure CNI flat networking):

```
az role assignment create \
  --assignee-object-id $ALB_IDENTITY_PRINCIPAL_ID \
  --assignee-principal-type ServicePrincipal \
  --role "Network Contributor" \
  --scope $AGC_SUBNET_ID
```

e. Verify all three roles are assigned:

```
az role assignment list --assignee $ALB_IDENTITY_PRINCIPAL_ID --all \
  --query "[].{role:roleDefinitionName, scope:scope}" -o table
# Expected: Reader, AppGw for Containers Configuration Manager, Network Contributor
```

9. **Install ALB Controller via Helm**

a. Install the ALB Controller using the Microsoft container registry Helm chart:

> **NOTE**
> Use v1.9.13 or later. Versions older than v1.7.9 do not support Azure CNI Overlay networking.

```
helm install alb-controller oci://mcr.microsoft.com/application-lb/charts/alb-controller \
  --namespace azure-alb-system --create-namespace \
  --version 1.9.13 \
  --set albController.podIdentity.clientID=$ALB_IDENTITY_CLIENT_ID
```

b. Verify ALB Controller pods are running:

```
kubectl get pods -n azure-alb-system
```

c. Verify GatewayClass is created and accepted:

```
kubectl get gatewayclass
# Expected:
```

```
# NAME                 CONTROLLER                                ACCEPTED
# azure-alb-external   alb.networking.azure.io/alb-controller   True
```

10. **Create ApplicationLoadBalancer Resource**
    This creates the AGC instance in Azure. RBAC roles (Step 8) must be assigned before this step.
    a. If you previously deleted an ApplicationLoadBalancer CR, verify the Azure resource is fully deleted before proceeding:

CAUTION
The Kubernetes CR status can show `Deployment: True` while the Azure resource is still stuck in `provisioningState: Deleting`. Recreating the CR while the Azure resource is still deleting causes a failure loop: the controller tries to create child resources (frontends) under a deleting parent, Azure rejects with "PUT is not allowed as previous operation on parent resource was DELETE", and the Gateway stays in Unknown state.

```
az network alb show --resource-group $AKS_NODE_RG --name <alb-name>
# Must return "ResourceNotFound" before proceeding.
# If you don't know the ALB name, list all traffic controllers:
az network alb list --resource-group $AKS_NODE_RG -o table
```

    b. Create the ApplicationLoadBalancer resource:

```
cat <<EOF | kubectl apply -f -
apiVersion: alb.networking.azure.io/v1
kind: ApplicationLoadBalancer
metadata:
  name: idsp-alb
  namespace: azure-alb-system
spec:
  associations:
    - $AGC_SUBNET_ID
EOF
```

    c. Wait for AGC to be provisioned (3-5 minutes):

```
kubectl get applicationloadbalancer -n azure-alb-system -w
```

    d. If the `DEPLOYMENT` column stays empty, check controller logs for RBAC errors:

```
kubectl logs -n azure-alb-system deployment/alb-controller --tail=20
```

11. **Verify Setup Is Complete**
    Run the following commands to confirm all infrastructure components are ready.
    a. Confirm GatewayClass is accepted:

```
kubectl get gatewayclass
```

    b. Confirm ALB Controller pods are running:

```
kubectl get pods -n azure-alb-system
```

c. Confirm ApplicationLoadBalancer is provisioned:

```
kubectl get applicationloadbalancer -n azure-alb-system
```

Azure Specific CRD's
Review the Azure-specific Custom Resource Definitions (CRDs), including their associated API groups, purposes, and creation methods.

Overview

The following table outlines the Azure-specific CRDs used in the configuration:

CRD	API Group	Purpose	Create
`ApplicationLoadBalancer`	`alb.networking.azure.io/v1`	AGC instance in Azure	Manu
`BackendTLSPolicy`	`alb.networking.azure.io/v1`	Azure-specific backend TLS config	Helm
`HealthCheckPolicy`	`alb.networking.azure.io/v1`	HTTPS health check for ssp-router backend	Helm
`GatewayClass`	`gateway.networking.k8s.io/v1`	`azure-alb-external` / `azure-alb-internal`	ALB C

NOTE
Note: The `ApplicationLoadBalancer` resource is created manually outside the Helm chart, as it contains environment-specific settings (subnet associations). The ALB Controller automatically creates the GatewayClass resources. The `HealthCheckPolicy` is required because AGC's default health check hits `/` which returns 404 on ssp-router.

Deploying or Migrating to Azure Gateway API
Learn to deploy a fresh instance of IDSP or migrate an existing configuration of IDSP to use the Azure Gateway API.

Introduction

This topic outlines the necessary steps to successfully deploy or migrate to the Azure Gateway API. It covers strict pre-deployment checks, fresh installation procedures, Nginx to Gateway API migration logic, and a sample app validation.

Pre-requisite Check

NOTE
Before proceeding with the specific checks mentioned in this section, review and complete all items in the Prerequisites for All Deployments list.

Run these commands to verify all prerequisites are in place before deploying IDSP:

- **ALB Controller pods running:**
  `kubectl get pods -n azure-alb-system`
- **GatewayClass available and accepted** (Expected: `azure-alb-external` with `Accepted=True`):
  `kubectl get gatewayclass`
- **ApplicationLoadBalancer provisioned** (`DEPLOYMENT` must be `True` . If `False` , check controller logs for RBAC errors - Gotcha #16):
  `kubectl get applicationloadbalancer -n azure-alb-system`
- **OverlayExtensionConfig exists in correct namespace** (CNI Overlay clusters only. Expected: one entry in `azure-alb-system` with `Succeeded` status):

```
kubectl get overlayextensionconfigs -A
```

- **Microsoft.ServiceNetworking provider registered** (Expected: `Registered`):
  ```
  az provider show --namespace Microsoft.ServiceNetworking --query registrationState -o tsv
  ```
- **RBAC roles assigned** (3 roles needed. Expected: `Reader`, `AppGw for Containers Configuration Manager`, `Network Contributor`):
  ```
  az role assignment list --assignee <ALB_IDENTITY_PRINCIPAL_ID> --all \
    --query "[].{role:roleDefinitionName, scope:scope}" -o table
  ```
- **TLS certificate Secret exists:**
  ```
  kubectl get secret <tls-secret-name> -n ssp
  ```
- **RBAC permissions:**
  ```
  kubectl auth can-i create gateways.gateway.networking.k8s.io -n ssp
  kubectl auth can-i create httproutes.gateway.networking.k8s.io -n ssp
  kubectl auth can-i create healthcheckpolicies.alb.networking.azure.io -n ssp
  kubectl auth can-i create backendtlspolicies.alb.networking.azure.io -n ssp
  ```

Minimum ClusterRole for Azure AGC:

```
apiVersion: rbac.authorization.k8s.io/v1
kind: ClusterRole
metadata:
  name: gateway-api-admin
rules:
  - apiGroups: ["gateway.networking.k8s.io"]
    resources: ["gateways", "httproutes", "backendtlspolicies"]
    verbs: ["get", "list", "watch", "create", "update", "patch", "delete"]
  - apiGroups: ["alb.networking.azure.io"]
    resources: ["healthcheckpolicies", "backendtlspolicies"]
    verbs: ["get", "list", "watch", "create", "update", "patch", "delete"]
```

Before You Deploy

NOTE

- Gateway ownership: The Gateway can be created by Helm (`createGateway: true`, default) or pre-created by the platform team (`createGateway: false` + `existingGateway`). To know how to use an already existing Gateway, see Already Have a Gateway? section for details.
- Set these Environment Variables:
  ```
  export RELEASENAME="<SSP_RELEASENAME>"
  export NAMESPACE="<SSP_NAMESPACE>"
  export HELM_REPO='ssp_helm_charts'
  ```
- Run the following command to export the current override values of your Helm release to `ssp-override.yaml`. This lets you review, back up, or reuse your existing configuration:
  ```
  helm get values ${RELEASENAME} -n ${NAMESPACE} >ssp-override.yaml
  ```

Deploying Symantec Identity Security Platform with Gateway API (Fresh Install)

1. **Ensure Azure ALB Controller is installed and GatewayClass exists.**
   See Infrastructure Setup.

2. **Deploy IDSP with Gateway API**
   a. Run the helm upgrade command with inline `--set` arguments (note: the escaped dots are required for the command line):

```
helm upgrade --install ${RELEASENAME} ${HELM_REPO}/ssp -n ${NAMESPACE} \
  -f your-values.yaml \
  --set ssp.ingress.type=gatewayapi \
  --set ssp.ingress.gatewayApi.gatewayClassName=azure-alb-external \
  --set ssp.ingress.gatewayApi.createGateway=true \
  --set ssp.ingress.gatewayApi.createBackendTLSPolicy=true \
  --set ssp.ingress.gatewayApi.gatewayAnnotations."alb\.networking\.azure\.io/alb-name"=<alb-name> \
  --set ssp.ingress.gatewayApi.gatewayAnnotations."alb\.networking\.azure\.io/alb-namespace"=azure-alb-
system
```

   b. Alternatively, `gatewayAnnotations` can be set via a values override file (recommended for readability). Override file example (`gateway-overrides.yaml`):

```
ssp:
  ingress:
    type: gatewayapi
    gatewayApi:
      gatewayClassName: azure-alb-external
      createGateway: true
      gatewayAnnotations:
        alb.networking.azure.io/alb-name: <alb-name>
        alb.networking.azure.io/alb-namespace: azure-alb-system
```

3. **Verify resources**

```
kubectl get gateway,httproute,backendtlspolicy,healthcheckpolicy -n ssp
```

4. **Wait for Gateway to be Programmed**
   AGC takes 3-5 minutes on first deploy. Wait until STATUS shows `Programmed=True` and ADDRESS shows an FQDN.

```
kubectl get gateway -n ssp -w
```

5. **Verify all policies are accepted**

```
kubectl get backendtlspolicy -n ssp -o jsonpath='{range .items[*]}{.metadata.name}:
 Accepted={.status.conditions[?(@.type=="Accepted")].status}{"\n"}{end}'
kubectl get healthcheckpolicy -n ssp -o jsonpath='{range .items[*]}{.metadata.name}:
 Accepted={.status.conditions[?(@.type=="Accepted")].status}{"\n"}{end}'
```

   Expected: `Accepted=True` for both.
6. **Test connectivity**
   AGC returns FQDN, not IP — you must resolve it first.

```
GATEWAY_FQDN=$(kubectl get gateway -n ssp -o jsonpath='{.items[0].status.addresses[0].value}')
GATEWAY_IP=$(dig +short $GATEWAY_FQDN | head -1)
curl -sk --resolve "your-host:443:$GATEWAY_IP" \
```

```
"https://your-host/actuator/health"
```

What Helm creates for Azure AGC:

Resource	Name Pattern	Purpose
Gateway	`<release>-ssp-gateway`	HTTPS listeners with TLS termination
HTTPRoute	`<release>-ssp-router-full`	Routes all traffic to ssp-router
HTTPRoute	`<release>-ssp-router-mgmt`	Management hostname route (if mgmt enab
BackendTLSPolicy	`<release>-ssp-router-backend-tls`	Azure-specific CA validation for HTTPS to s
HealthCheckPolicy	`<release>-ssp-router-health-check`	HTTPS health check (required — AGC defa

Migrating Symantec Identity Security Platform from Nginx to Gateway API

NOTE
Before proceeding, complete all steps in the " Before you Deploy" section.

1. If upgrading an existing nginx-based Symantec Identity Security Platform deployment to Gateway API on Azure, run the following:

```
helm upgrade ${RELEASENAME} ${HELM_REPO}/ssp -n ${NAMESPACE} \
  -f your-values.yaml \
  --set ssp.ingress.type=gatewayapi \
  --set ssp.ingress.previousController.enabled=true \
  --set ssp.ingress.previousController.ingressClassName=nginx \
  --set ssp.ingress.gatewayApi.gatewayClassName=azure-alb-external \
  --set ssp.ingress.gatewayApi.createGateway=true \
  --set ssp.ingress.gatewayApi.createBackendTLSPolicy=true \
  --set ssp.ingress.gatewayApi.gatewayAnnotations."alb\.networking\.azure\.io/alb-name"=<alb-name> \
  --set ssp.ingress.gatewayApi.gatewayAnnotations."AZ_ALB}alb\.networking\.azure\.io/alb-namespace"=azure-
alb-system
```

2. After verifying Gateway API works and switching DNS, remove the old controller:

```
helm upgrade ${RELEASENAME} ${HELM_REPO}/ssp -n ${NAMESPACE} \
  -f your-values.yaml \
  --set ssp.ingress.type=gatewayapi \
  --set ssp.ingress.previousController.enabled=false \
  --set ssp.ingress.gatewayApi.gatewayClassName=azure-alb-external \
  --set ssp.ingress.gatewayApi.createGateway=true \
  --set ssp.ingress.gatewayApi.createBackendTLSPolicy=true \
  --set ssp.ingress.gatewayApi.gatewayAnnotations."alb\.networking\.azure\.io/alb-name"=<alb-name> \
  --set ssp.ingress.gatewayApi.gatewayAnnotations."alb\.networking\.azure\.io/alb-namespace"=azure-alb-
system
```

Deploying the Sample App to Test Connectivity

1. Deploy the sample-app with Azure AGC to test connectivity before or alongside Symantec Identity Security Platform:

```
helm upgrade --install ${RELEASENAME} ${HELM_REPO}/ssp-sample-app -n ${NAMESPACE} \  -f your-sample-
values.yaml \
  --set ingress.type=gatewayapi \
  --set ingress.gatewayApi.gatewayClassName=azure-alb-external \
  --set ingress.gatewayApi.createGateway=true \
  --set ingress.gatewayApi.createBackendTLSPolicy=true \
  --set ingress.gatewayApi.gatewayAnnotations."alb\.networking\.azure\.io/alb-name"=<alb-name> \
  --set ingress.gatewayApi.gatewayAnnotations."alb\.networking\.azure\.io/alb-namespace"=azure-alb-system

# Verify resources
kubectl get gateway,httproute,backendtlspolicy,healthcheckpolicy -n
${NAMESPACE}
```

NOTE
Note: The chart creates a HealthCheckPolicy for spi-demo (which returns 302 on `/`) pointing to `/actuator/health` .

Troubleshooting Azure Deployments

General Diagnostics

If you encounter issues during your Azure AGC deployment, use these diagnostic commands to check the state of your resources:

ALB Controller not creating resources:

```
kubectl logs -n azure-alb-system deployment/alb-controller --tail=50
```

Check Gateway status:

```
kubectl get gateway -n ssp -o yaml
kubectl describe gateway <gateway-name> -n ssp
```

Verify BackendTLSPolicy and HealthCheckPolicy:

```
kubectl get backendtlspolicy -n ssp -o yaml
kubectl get healthcheckpolicy -n ssp -o yaml
```

Testing connectivity with curl:

AGC requires proper TLS SNI. Use `--resolve` (not `-H Host:`):

```
# Get Gateway FQDN and resolve to IP
GATEWAY_FQDN=$(kubectl get gateway -n ssp -o jsonpath='{.items[0].status.addresses[0].value}')
GATEWAY_IP=$(dig +short $GATEWAY_FQDN | head -1)

# CORRECT - uses --resolve for proper SNI:
curl -sk --resolve "your-host:443:$GATEWAY_IP" \
  "https://your-host/actuator/health"

# WRONG - -H Host: does NOT set TLS SNI, AGC resets the connection:
curl -sk -H "Host: your-host" "https://$GATEWAY_IP/actuator/health"
```

Cause: 403 AuthorizationFailed / Missing Reader Role

The ALB controller logs report a `403 AuthorizationFailed` specifically for `Microsoft.Resources/subscriptions/resourcegroups/read`.

Remedy

Cluster Administrator

1. Ensure the ALB Managed Identity has the **Reader** role assigned to the AKS node resource group (MC resource group).
2. Ensure the user running the RBAC commands has Owner or User Access Administrator permissions.
3. Restart the ALB controller to pick up the cached RBAC changes: `kubectl rollout restart deployment alb-controller -n azure-alb-system`

Cause: 403 AuthorizationFailed / ServiceNetworking Registration

The ALB controller logs report a `403 AuthorizationFailed` specifically for `Microsoft.ServiceNetworking/register/action`.

Remedy

Cluster Administrator

1. Run the following command to register the required provider: `az provider register --namespace Microsoft.ServiceNetworking`
2. Restart the ALB controller: `kubectl rollout restart deployment alb-controller -n azure-alb-system`

Cause: 403 AuthorizationFailed / Traffic Controller Not Provisioning

Running `kubectl get applicationloadbalancer -o yaml` shows an `AuthorizationFailed` error, and the Traffic Controller fails to provision.

Remedy

Cluster Administrator

Verify that the **AppGw for Containers Configuration Manager** role is scoped correctly to the **MC resource group**, and NOT the AGC subnet.

Cause: 503 "no healthy upstream" / Stale AGC Data Plane State

Curl returns a 503 error. All backends show `UNHEALTHY` but pods are running, responsive, and policies are `Accepted=True`.

Remedy

Cluster Administrator

1. Delete all AGC objects (HTTPRoute, BackendTLSPolicy, HealthCheckPolicy) to clear the stale data plane state.
2. Wait 5 minutes for full deprovisioning and verify entries are gone from the API.
3. Recreate the objects from scratch.

Cause: 503 "no healthy upstream" / BackendTLSPolicy Port Mismatch

Curl returns a 503 error. All backends show `UNHEALTHY` even after a clean recreate of AGC objects (on either flat CNI or CNI Overlay).

Remedy

Cluster Administrator

1. Check the `port` configured in your BackendTLSPolicy. It must be set to the service port (`443`), not the container port (e.g., `8095`).
2. Verify the policy has `verify.caCertificateRef` pointing to the correct CA secret if using self-signed certificates.

Cause: 503 "no healthy upstream" / BackendTLSPolicy Name Collision

Curl returns a 503 error, but all resources and policies read as `Accepted=True` .

Remedy

Cluster Administrator

1. Run `kubectl get backendtlspolicies.alb.networking.azure.io -A` and look for duplicate names across namespaces.
2. If duplicates exist, AGC uses the wrong CA certificate. Fix by ensuring your BackendTLSPolicy names include the namespace to make them unique.

Cause: HealthCheckPolicy Rejected

Running `kubectl describe healthcheckpolicy -n <ns>` shows the policy state as `Accepted=False` .

Remedy

Cluster Administrator

Check the protocol schema in your HealthCheckPolicy yaml. You must use `http` + `useTLS: true` instead of `https` .

Cause: Gateway Not Accepted / Missing Annotations

Running `kubectl describe gateway` reports that the Gateway "does not have annotation".

Remedy

Cluster Administrator

Ensure you have added the `alb.networking.azure.io/alb-name` and `alb.networking.azure.io/alb-namespace` annotations to the Gateway via the `gatewayAnnotations` block in your Helm values.

Cause: OverlayExtensionConfig Issues

The `OverlayExtensionConfig` is not created, logs report `nodenetworkconfigs` watch errors, `overlayextensionconfigs.acn.azure.com is forbidden`, or `extension IP range overlaps with existing`.

Remedy

Cluster Administrator

1. Verify your ALB controller is version ≥1.7.9. Upgrade if older.
2. Run `kubectl get clusterrole alb-controller-cluster-role -o yaml` and ensure the `watch` verb exists for `nodenetworkconfigs.acn.azure.com`.
3. Check the ClusterRoleBinding target namespace: `kubectl get clusterrolebinding alb-controller-cluster-role-binding -o yaml | grep namespace`. If it points to `kube-system` but the controller runs in `azure-alb-system`, create a supplementary binding.
4. If overlapping IP ranges are reported, check for stale configurations across namespaces using `kubectl get overlayextensionconfigs -A`. Delete the stale config, delete the failed one in `azure-alb-system`, and restart the controller.

Cause: Stuck Traffic Controller / Gateway Unknown Status

The Gateway is stuck in `Unknown` status, or ALB controller logs report "Failed to parse Frontend" / "invalid frontend" after recreating an ALB CR. `az network alb show` indicates the Azure resource is stuck in `Deleting` state.

Remedy

Cluster Administrator

1. Remember that ALB CR status can be stale—always verify actual Azure ARM resource state.
2. Wait for the Traffic Controller to fully finish deleting and return a `ResourceNotFound` response via the Azure CLI.
3. Once fully deleted, recreate the ALB CR in Kubernetes.
4. Restart the ALB controller.

Cause: ALB Controller CrashLoopBackOff

The ALB controller pods fail to start or crash repeatedly.

Remedy

Cluster Administrator

Verify that the federated credential matches the ALB Controller service account name and namespace exactly.

Cause: AGC Subnet Creation Fails

Attempts to create the `agc-subnet` using the Azure CLI fail.

Remedy

Cluster Administrator

1. Run `az network vnet subnet list -g $AKS_NODE_RG --vnet-name $AKS_VNET` to review the existing subnets.
2. Check for address space conflicts and adjust the `--address-prefixes` parameter in your create command to use a non-overlapping CIDR block.

AVI AKO Gateway API Controller

Review the features, requirements, and architecture mapping of the Avi AKO Gateway API Controller.

Overview

Avi AKO is Broadcom's Kubernetes operator for Avi (NSX Advanced Load Balancer). It implements Gateway API by translating Gateway API resources into Avi Controller objects (Virtual Services, Pools, Pool Groups, SSL profiles).

> **NOTE**
> Avi AKO is the **default and recommended** Gateway API controller for **VKS (VMware Kubernetes Service)**.

Aspect	Details
Gateway API support	GatewayClass (v1), Gateway (v1), HTTPRoute (v1). Supported from AKO 1.12.1+. Enable via `featureGates.GatewayAPI: true` in values.yaml.
Default GatewayClass	`avi-lb` with `controllerName: ako.vmware.com/avi-lb` (installed when Gateway API is enabled).
Gateway	HTTP/HTTPS listeners; TLS termination with `certificateRefs` to Kubernetes Secrets; optional static IP via `spec.addresses` (single IPv4).
HTTPRoute	Hostname, path (including `PathPrefix` , `RegularExpression`), and header matching; traffic splitting (canary/blue-green).
HTTPRoute filters	RequestHeaderModifier, RequestRedirect, URLRewrite (path/hostname), ResponseHeaderModifier. `ExtensionRef` filters under `backendRefs` are supported for `RouteBackendExtension` .
Backend TLS	Backend HTTPS and certificate validation are configured via Avi's `RouteBackendExtension` CRD (referenced as an `ExtensionRef` filter in HTTPRoute `backendRefs`), not the standard BackendTLSPolicy CRD. Requires the AKO CRD Operator to be enabled.
Platforms	Kubernetes on VMware vSphere/NSX-T; supports ClusterIP, NodePort, NodePortLocal; CNI: Calico, Antrea.
Limitation	AKO High Availability (HA) is not supported when Gateway API is enabled. GRPCRoute, TLSRoute, TCPRoute, UDPRoute, and ReferenceGrant are not supported.

For Official documentation, see Avi Kubernetes Operator – Gateway API v1.

Avi Architecture: How Gateway API Maps to Avi Objects

```
Gateway (K8s)
  └── Parent VS (Avi) — VS_TYPE_VH_PARENT
        ├── VSVIP — holds the VIP (e.g., 172.30.128.214)
        ├── SSL Certs — from Gateway listener TLS secretRef
        ├── Port 443, enable_ssl=true
        └── Child VS entries (one per HTTPRoute)
              ├── Child VS 1 — VS_TYPE_VH_CHILD, vh_type=VS_TYPE_VH_ENHANCED
```

```
│     ├── vh_matches: [{host: "app.example.com", rules: [...]}]
│     └── pool_group_ref → Pool → Servers (NPL node:port pairs)
└── Child VS 2 — VS_TYPE_VH_CHILD
      └── ...
```

Key points:

- One parent VS per Gateway, one child VS per HTTPRoute
- Parent handles SSL termination; children handle host/path matching and backend routing
- AKO uses **EVH mode** for Gateway API regardless of the `enableEVH` AKO config setting
- Child VS uses `vh_matches` (not `vh_domain_name`) — this is the EVH-specific field
- With NodePortLocal (NPL), pool servers are `node_IP:NPL_port` pairs, not pod IPs

Infrastructure Setup for AVI ACO Gateway API Controller
Review the configuration steps required to enable and set up Gateway API support for the Avi Kubernetes Operator (AKO), including feature gate configuration, CRD installation, and ConfigMap verification.

Introduction

Configure the necessary infrastructure to support the AVI AKO Gateway API Controller. The following steps cover enabling Gateway API support in your Helm values, installing the required RouteBackendExtension Custom Resource Definition (CRD) for backend TLS, and verifying the final ConfigMap settings.

Setup Steps

1. **Enable Gateway API Support**
   To enable Gateway API support in AKO, set `featureGates.GatewayAPI: true` in the AKO Helm values:

   ```
   # AKO Helm values
   featureGates:
     GatewayAPI: true
   ```

   This automatically creates the `avi-lb` GatewayClass:

   ```
   apiVersion: gateway.networking.k8s.io/v1
   kind: GatewayClass
   metadata:
     name: avi-lb
   spec:
     controllerName: ako.vmware.com/avi-lb
   ```

2. **Install RouteBackendExtension CRD (required for backend TLS)**
   If you need backend TLS re-encryption (i.e., `createBackendTLSPolicy: true`), the `RouteBackendExtension` CRD must be installed. This CRD is part of the AKO CRD Operator and is **not** included in the base AKO Helm chart.

   WARNING
   If the CRD is not installed, the IDSP Helm chart silently skips creating the `RouteBackendExtension` resource and the corresponding `ExtensionRef` filter in the HTTPRoute. **ssp-router serves HTTPS only** — without backend TLS, the Avi pool connects with plain HTTP, ssp-router rejects the connection, and all requests return **503**. This is the most common cause of 503 errors with AKO Gateway API. The RouteBackendExtension CRD is effectively **required**, not optional.

   a. To install, deploy the AKO CRD Operator Helm chart (available from the same AKO distribution):

   ```
   helm install ako-operator oci://projects.packages.broadcom.com/ako/helm-charts/ako-operator \
     -n avi-system --version <ako-version>
   ```

b. Alternatively, apply the CRD YAML directly from the AKO release artifacts:

```
kubectl apply -f https://raw.githubusercontent.com/vmware/load-balancer-and-ingress-services-for-kubernetes/master/ako-crd-operator/config/crd/bases/ako.vmware.com_routebackendextensions.yaml
```

c. Verify the CRD is installed:

```
kubectl get crd routebackendextensions.ako.vmware.com
```

3. **Verify AKO ConfigMap settings**
(especially on VKS with Antrea CNI):

```
kubectl get configmap avi-k8s-config -n avi-system -o yaml | grep -E "serviceType|cniPlugin|enableEVH"
# Expected for VKS: serviceType=NodePortLocal, cniPlugin=antrea
```

Deploying or Migrating to AVI ACO Gateway API

Review the deployment and migration steps for the AVI AKO Gateway API, including prerequisite validation, fresh installations, Nginx migrations, and sample app connectivity testing.

Introduction

Deploy or migrate to the AVI AKO Gateway API using the end-to-end process outlined below. The following sections cover essential prerequisite validations, configuration steps for both fresh installs and Nginx migrations, and a sample application deployment to verify connectivity.

Pre-requisite Check

Execute the following steps to verify that your cluster and resources are properly configured before attempting a deployment.

1. Check that the AKO pods are running:

```
# AKO pods running
kubectl get pods -n avi-system -l app.kubernetes.io/name=ako
```

2. Verify the GatewayClass is available and accepted:

```
# GatewayClass available and accepted
kubectl get gatewayclass avi-lb
```

3. Ensure the TLS certificate Secret exists:

```
# TLS certificate Secret exists
kubectl get secret <tls-secret-name> -n ssp
```

4. Confirm the RouteBackendExtension CRD is installed (required because ssp-router is HTTPS-only):

```
# RouteBackendExtension CRD installed (required — ssp-router is HTTPS-only)
kubectl get crd routebackendextensions.ako.vmware.com
```

5. After deployment, verify backend TLS is active:

```
# Verify RouteBackendExtension has backendTLS (not null/missing)
kubectl get routebackendextension -n ssp
kubectl get routebackendextension <release>-ssp-router-backend-ext -n ssp -o jsonpath='{.spec.backendTLS}'
# Expected: {} or {"hostCheckEnabled":...}
# If empty/missing: ssp-router returns 503
```

6. Ensure your ClusterRole meets the minimum requirements for Avi AKO:

```
apiVersion: rbac.authorization.k8s.io/v1
kind: ClusterRole
metadata:
  name: gateway-api-admin
rules:
  - apiGroups: ["gateway.networking.k8s.io"]
    resources: ["gateways", "httproutes"]
    verbs: ["get", "list", "watch", "create", "update", "patch", "delete"]
  - apiGroups: ["ako.vmware.com"]
    resources: ["routebackendextensions"]
    verbs: ["get", "list", "watch", "create", "update", "patch", "delete"]
```

Before You Deploy

Review and configure the following environmental considerations before executing the IDSP Helm installation.

NOTE

- Gateway ownership: The Gateway can be created by Helm (`createGateway: true` , default) or pre-created by the platform team (`createGateway: false` + `existingGateway`). To know how to use an already existing Gateway, see Already Have a Gateway? section for details.
- Set these Environment Variables:

```
export RELEASENAME="<SSP_RELEASENAME>"
export NAMESPACE="<SSP_NAMESPACE>"
export HELM_REPO='ssp_helm_charts'
```

- Run the following command to export the current override values of your Helm release to `ssp-override.yaml` . This lets you review, back up, or reuse your existing configuration:

```
helm get values ${RELEASENAME} -n ${NAMESPACE} >ssp-override.yaml
```

Deploying Symantec Identity Security Platform with Gateway API (Fresh Install)

Perform the following steps to deploy a fresh instance of Symantec Identity Security Platform using the Gateway API with Avi.

1. Run the Helm upgrade command to deploy the application:

```
helm upgrade --install ${RELEASENAME} ${HELM_REPO}/ssp -n ${NAMESPACE} \
  -f your-values.yaml \
  --set ssp.ingress.type=gatewayapi \
  --set ssp.ingress.gatewayApi.gatewayClassName=avi-lb \
  --set ssp.ingress.gatewayApi.createGateway=true \
  --set ssp.ingress.gatewayApi.gatewayType=avi
  # createBackendTLSPolicy defaults to true — creates RouteBackendExtension for Avi
```

2. Verify the Gateway and HTTPRoute resources were successfully created:

```
# Verify resources
kubectl get gateway,httproute -n ssp
```

Migrating Symantec Identity Security Platform from Nginx to Gateway API

Follow these steps if you are upgrading an existing nginx-based <keyword keyref="pnameShort"/> deployment to the Gateway API using Avi AKO.

1. Upgrade the deployment while leaving the previous Nginx controller enabled:

```
helm upgrade ${RELEASENAME} ${HELM_REPO}/ssp -n ${NAMESPACE} \
  -f your-values.yaml \
  --set ssp.ingress.type=gatewayapi \
  --set ssp.ingress.previousController.enabled=true \
  --set ssp.ingress.previousController.ingressClassName=nginx \
  --set ssp.ingress.gatewayApi.gatewayClassName=avi-lb \
  --set ssp.ingress.gatewayApi.createGateway=true \
  --set ssp.ingress.gatewayApi.gatewayType=avi
```

2. After verifying Gateway API works and switching DNS, run the upgrade command again to remove the old controller:

```
helm upgrade ${RELEASENAME} ${HELM_REPO}/ssp -n ${NAMESPACE} \
  -f your-values.yaml \
  --set ssp.ingress.type=gatewayapi \
  --set ssp.ingress.previousController.enabled=false \
  --set ssp.ingress.gatewayApi.gatewayClassName=avi-lb \
  --set ssp.ingress.gatewayApi.createGateway=true \
  --set ssp.ingress.gatewayApi.gatewayType=avi
```

Deploying the Sample App to Test Connectivity

Perform these steps to deploy a sample application with Avi AKO to test connectivity before or alongside IDSP.

1. Install the sample application using Helm:

```
helm upgrade --install ${RELEASENAME} ${HELM_REPO}/ssp-sample-app -n ${NAMESPACE} \
  -f your-sample-values.yaml \
  --set ingress.type=gatewayapi \
  --set ingress.gatewayApi.gatewayClassName=avi-lb \
  --set ingress.gatewayApi.createGateway=true \
  --set ingress.gatewayApi.gatewayType=avi
```

2. Verify the created resources:

```
# Verify resources
kubectl get gateway,httproute -n ${NAMESPACE}
```

3. Retrieve the Gateway VIP and test connectivity:

```
# Get Gateway VIP and test
GATEWAY_VIP=$(kubectl get gateway -n ${NAMESPACE} -o jsonpath='{.items[0].status.addresses[0].value}')
curl -sk --resolve "your-host:443:$GATEWAY_VIP" "https://your-host/sample-app/"
```

NOTE
Note: Avi AKO does not use BackendTLSPolicy or HealthCheckPolicy CRDs. spi-demo health checks use Avi's default TCP health monitor.

Backend TLS with AVI ACO
Review the configuration, verification, and troubleshooting steps for setting up backend TLS with the Avi Kubernetes Operator (AKO) using the RouteBackendExtension CRD.

Introduction

Review the concepts and prerequisites for configuring backend TLS with Avi AKO.

Avi AKO does **not** use the standard BackendTLSPolicy CRD. Instead, backend TLS is configured via Avi's **RouteBackendExtension** CRD, which is attached to the HTTPRoute as an `ExtensionRef` filter on the `backendRefs` entry.

Pre-requisite: The `RouteBackendExtension` CRD must be installed via the AKO CRD Operator (see Section 5.2 for installation instructions).

The Helm chart automatically creates the `RouteBackendExtension` resource and references it from the HTTPRoute when `createBackendTLSPolicy: true` and `gatewayType: avi` . The chart gates this on CRD availability — if the CRD is not installed, the resource and the ExtensionRef filter are silently skipped.

> **NOTE**
> **Critical:** The `backendTLS` field in the RouteBackendExtension **must** be present (even as empty `{}`). Without it, the Avi pool has no `ssl_profile_ref` and connects to ssp-router with plain HTTP. Since ssp-router is HTTPS-only, this results in **503 errors** — and is extremely hard to diagnose because the Gateway shows `Programmed=True` , the VS is `OPER_UP` , and the pool servers are healthy (TCP health checks pass, but application-layer communication fails). If you see 503 with everything else looking healthy, check the RouteBackendExtension first.

How backendTLS works — toggle by existence

Understand how the presence of the `backendTLS` field functions as a toggle to enable HTTPS to the backend.

The `backendTLS` field acts as a **toggle**: its *presence* enables HTTPS to the backend, not its contents. The optional sub-fields only refine TLS validation strictness:

`backendTLS` state	Avi pool behavior
Absent or `null`	No `ssl_profile_ref` → **plain HTTP** to backend → **503** (ssp-router is HTTPS-only)
`{}` (present, empty)	Adds `ssl_profile_ref: System-Standard` → **HTTPS** to backend (default validation)
`{pkiProfile: ...}`	HTTPS + CA certificate pinning / mutual TLS
`{hostCheckEnabled: true}`	HTTPS + SNI hostname verification against backend cert
`{domainName: [...]}`	HTTPS + expected SAN/CN matching

For most deployments, `backendTLS: {}` is sufficient — it enables re-encryption with Avi's default `System-Standard` SSL profile without imposing additional certificate validation requirements.

Resource Configurations

Review the YAML configurations created by Helm for the RouteBackendExtension and HTTPRoute.

RouteBackendExtension resource (created by Helm):

```
apiVersion: ako.vmware.com/v1alpha1
kind: RouteBackendExtension
metadata:
  name: <release>-ssp-router-backend-ext
  namespace: ssp
```

```
spec:
  backendTLS: {}   # presence enables HTTPS; sub-fields are optional refinements
```

HTTPRoute ExtensionRef filter (added by Helm to backendRefs):

```
backendRefs:
  - name: <release>-ssp-router
    port: 8095
    filters:
      - type: ExtensionRef
        extensionRef:
          group: ako.vmware.com
          kind: RouteBackendExtension
          name: <release>-ssp-router-backend-ext
```

For full details, see: AKO RouteBackendExtension

How to Verify Backend TLS is Working

Execute the following steps to confirm that backend TLS is properly enabled and functioning.

1. **Check RouteBackendExtension exists and has backendTLS:**

   ```
   kubectl get routebackendextension -n <namespace>
   kubectl get routebackendextension <name> -n <namespace> -o yaml
   # Verify: spec.backendTLS is present (not missing or null-without-fields)
   ```

2. **Check the Avi pool has ssl_profile_ref:**
   Log into Avi Controller → Applications → Pools → find the pool → check SSL Profile. Or verify via API:

   ```
   curl -sk -b cookies.txt "https://<avi-controller>/api/pool/<pool-uuid>?fields=name,ssl_profile_ref" \
     -H 'X-Avi-Version: 30.2.4'
   # ssl_profile_ref should be a non-empty URL
   ```

3. **Perform a quick backend protocol test (from inside a router pod):**

   ```
   kubectl exec -n <namespace> <router-pod> -- wget -qO- --no-check-certificate https://localhost:8095/
   actuator/health
   # Should return: {"status":"UP",...}

   kubectl exec -n <namespace> <router-pod> -- wget -qO- http://localhost:8095/actuator/health
   # Should fail with: "error getting response" (confirms HTTPS-only)
   ```

When backendTLS Can Go Missing

Identify scenarios where the `backendTLS` field may go missing and apply the necessary fixes.

There are three scenarios where the pool ends up without `ssl_profile_ref` :

1. **Old chart version** — the IDSP chart template was updated to include `backendTLS` in the RouteBackendExtension. Deployments from an older chart version have the RouteBackendExtension without `backendTLS` .

2. **AKO full rebuild** — when AKO recreates all Avi objects from scratch (after VS deletion + AKO restart), it reads the current K8s objects. If the RouteBackendExtension doesn't have `backendTLS` , the new pool won't have SSL. Previous pool SSL settings are NOT preserved across recreation.
3. **Manual RouteBackendExtension edits** — if someone patches the CRD and removes `backendTLS` , AKO updates the pool accordingly.

To resolve a missing `backendTLS` configuration, perform one of the following fixes:

1. **Emergency fix (without Helm upgrade):**
   Apply a merge patch to the resource. Note that `hostCheckEnabled:false` is just a carrier field — the merge-patch requires at least one key to create the backendTLS object. `backendTLS:{}` is what matters.

```
kubectl patch routebackendextension <name> -n <namespace> \
  --type=merge -p '{"spec":{"backendTLS":{"hostCheckEnabled":false}}}'
```

2. **Template fix (already applied):**
   The Helm chart template was fixed to render `backendTLS: {}` (empty object) instead of `backendTLS:` (YAML null) when no AVI-specific sub-fields are configured. YAML null is treated as "field not present" by the CRD, which means backend TLS is not enabled. The empty object `{}` correctly signals "enable backend TLS with defaults".

Troubleshooting AVI ACO Deployments

General Diagnostics and Maintenance

Use the following commands and procedures to check the general health of your Avi AKO deployment, force reconciliations, or enable debug logging.

Check AKO logs (AKO runs two containers — `ako` for Ingress and `ako-gateway-api` for Gateway API):

```
# Gateway API container logs (filter out NPL noise)
kubectl logs -n avi-system -l app.kubernetes.io/name=ako -c ako-gateway-api | grep -v "annotation not found"

# Main AKO container logs
kubectl logs -n avi-system -l app.kubernetes.io/name=ako -c ako
```

Verify GatewayClass:

```
kubectl get gatewayclass avi-lb
```

Check Gateway status:

```
kubectl get gateway -n ssp -o wide
kubectl describe gateway <gateway-name> -n ssp
```

Check HTTPRoute status:

```
kubectl get httproute -n ssp
kubectl describe httproute <name> -n ssp
```

Verify Virtual Service in Avi Controller:

- Log into Avi Controller UI
- Navigate to Applications > Virtual Services
- Verify the VS corresponding to your Gateway is created and healthy

Nudge AKO to re-reconcile a Gateway or HTTPRoute:

AKO sometimes caches stale state (e.g., after another Gateway is deleted, hostname conflict checks may not re-evaluate). To trigger re-processing without restarting AKO:

```
kubectl annotate gateway <name> -n <ns> ako.vmware.com/reconcile=$(date +%s) --overwrite
# Or for an HTTPRoute:
kubectl annotate httproute <name> -n <ns> ako.vmware.com/reconcile=$(date +%s) --overwrite
```

Enable debug logging:

```
# Set log level to DEBUG (shows AKO internal model and REST API payloads)
kubectl patch configmap avi-k8s-config -n avi-system \
  --type=merge -p '{"data":{"logLevel":"DEBUG"}}'

# Trigger reconciliation (e.g., delete and re-create an HTTPRoute)
kubectl delete httproute <name> -n <ns>
kubectl apply -f /tmp/httproute-backup.yaml

# Read debug logs
kubectl logs -n avi-system -l app.kubernetes.io/name=ako -c ako-gateway-api --tail=200

# IMPORTANT: Reset to WARN when done
kubectl patch configmap avi-k8s-config -n avi-system \
  --type=merge -p '{"data":{"logLevel":"WARN"}}'
```

In debug logs, look for:

- `AviVsNode` graph dumps — verify `VHMatches` has correct hostnames
- `REST API POST/PUT` payloads — verify `vh_matches` and `pool_group_ref`
- `servers for port` — verify NPL resolution found servers with correct ports

Cause: 503 errors with Gateway Programmed=True

This is most commonly caused by missing `backendTLS` on the RouteBackendExtension. The Avi pool connects to ssp-router with plain HTTP instead of HTTPS. Everything else looks healthy — the Gateway is Programmed, the VS is OPER_UP, the pool servers pass health checks (TCP-only).

Remedy

Cluster Administrator

1. Verify the RouteBackendExtension has backendTLS and patch it if it is missing.

   ```
   # 1. Verify RouteBackendExtension has backendTLS
   kubectl get routebackendextension <release>-ssp-router-backend-ext -n ssp -o jsonpath='{.spec.backendTLS}'
   # If empty/null: this is the cause. Fix with:
   # (hostCheckEnabled:false is just a carrier — any field works; backendTLS:{} is
   #  what matters, but kubectl merge-patch requires at least one key)
   kubectl patch routebackendextension <release>-ssp-router-backend-ext -n ssp \
     --type=merge -p '{"spec":{"backendTLS":{"hostCheckEnabled":false}}}'
   ```

2. Verify the Avi pool has `ssl_profile_ref` via the Avi Controller UI or API.

   ```
   # 2. Verify the Avi pool has ssl_profile_ref (via Avi Controller UI or API)
   # Navigate to: Applications > Pools > find the pool > check SSL Profile is set
   ```

Cause: "no servers for port" in AKO logs

NPL port resolution failure. The HTTPRoute references a service port that differs from the container port, and AKO can't find the NPL annotation.

Remedy

Cluster Administrator

1. Check which port the HTTPRoute uses.

```
# Check which port the HTTPRoute uses
kubectl get httproute <name> -n <ns> -o yaml | grep -A2 backendRefs
# Should show port: 8095 (not 443)
```

2. Ensure the HTTPRoute references the `https-direct` port (8095) where `port == targetPort` . The IDSP chart handles this automatically for `gatewayType: avi` .

Cause: "no listeners matching" in AKO logs

An HTTPRoute's hostname doesn't match any Gateway listener hostname.

Remedy

Cluster Administrator

Ensure the Gateway has a listener for every hostname used in HTTPRoutes. For shared gateways, add listeners via `additionalListeners` .

Cause: Gateway shows Programmed=True but no VIP

IPAM/DNS allocation failure. Avi IPAM might be exhausted or misconfigured.

Remedy

Cluster Administrator

Check the AKO gateway-api container logs to diagnose IPAM issues.

```
# Check AKO gateway-api container logs
kubectl logs -n avi-system -l app.kubernetes.io/name=ako -c ako-gateway-api | grep -i "ipam\|vsvip\|address"
```

Cause: Child VS has empty vh_matches

AKO cache corruption. The child VS was created from stale internal state.

Remedy

Cluster Administrator

Use the AKO Disaster Recovery procedure — delete the Gateway, clean up Avi, restart AKO, and recreate.

Known Issues in AVI ACO Deployments

Review known issues related to AVI AKO Gateway API deployments, including NPL resolution failures, missing CRDs, and cached hostname conflicts, along with their respective workarounds.

Introduction

Familiarize yourself with the common known issues and behaviors when deploying the AVI AKO Gateway API Controller.

NPL (NodePortLocal) with Gateway API

Understand the known issue regarding NodePortLocal resolution and how the Helm chart automatically mitigates it.

Issue: When AKO uses `AKOSettings.serviceType: NodePortLocal` (common on VKS with Antrea CNI), the Gateway API code path has a known issue where service port → targetPort resolution does not work correctly for NPL annotation lookup. If the service port differs from the container/target port (e.g., `port: 443, targetPort: 8095`), AKO logs `no servers for port` and creates an empty pool, resulting in 503 errors.

Workaround: This is handled automatically by the Helm chart — no manual configuration needed.

1. The ssp-router Service includes a second port where `port == targetPort` (e.g., `8095 → 8095`).
2. The HTTPRoute references this port when `gatewayType: avi` .

```
# ssp-router Service (automatic)
ports:
  - name: https          # Used by nginx Ingress
    port: 443
    targetPort: 8095
  - name: https-direct   # Used by AVI Gateway API (NPL workaround)
    port: 8095
    targetPort: 8095
```

RouteBackendExtension CRD not installed

Review the consequences of a missing RouteBackendExtension CRD and how to prevent it.

Issue: If the AKO CRD Operator is not enabled, the `RouteBackendExtension` CRD is not present in the cluster. The Helm chart detects this automatically and skips creating the CRD resource and the ExtensionRef filter. **This results in 503 errors** — ssp-router is HTTPS-only and rejects plain HTTP connections from Avi.

Workaround:

1. The RouteBackendExtension CRD must be installed before deploying IDSP with `gatewayType: avi` .

AKO Caches Hostname Conflicts Across Gateways

Learn how to force AKO to re-evaluate listener hostnames when conflicts are cached.

Issue: When two Gateways in the same namespace have overlapping listener hostnames, AKO rejects the duplicate listeners. If you later delete the conflicting Gateway, AKO does **not** automatically re-evaluate the rejected listeners.

Workaround:

1. You must nudge the Gateway to trigger a manual re-evaluation:

```
kubectl annotate gateway <name> -n <ns> ako.vmware.com/reconcile=$(date +%s) --overwrite
```

Envoy Gateway

Envoy Gateway provides a complete Gateway API implementation with full BackendTLSPolicy support and consistent behavior across all platforms.

Overview

Envoy Gateway supports GatewayClass, Gateway, HTTPRoute, and BackendTLSPolicy (all v1). It provides configurable buffers and header sizes via ClientTrafficPolicy, mTLS with XFCC forwarding, backend timeouts via BackendTrafficPolicy, and uses Kubernetes readiness probes for health checks. It runs on any Kubernetes cluster including GKE, EKS, AKS, and on-premises environments.

The following table summarizes the key aspects and supported capabilities of Envoy Gateway.

Aspect	Details
Gateway API support	GatewayClass (v1), Gateway (v1), HTTPRoute (v1), BackendTLSPolicy (v1)
GatewayClass	`envoy-gateway-class` with `controllerName: gateway.envoyproxy.io/gatewayclass-controller`
BackendTLSPolicy	Full support — standard `gateway.networking.k8s.io/v1` CRD with CA certificate validation. **Required** for backend HTTPS (`appProtocol` alone is not sufficient). Alternative: Envoy Gateway `Backend` resource with `tls` config.
Traffic Policy	`ClientTrafficPolicy` (buffer limit, header preservation, mTLS with XFCC) + `BackendTrafficPolicy` (timeouts)
Health Checks	Uses Kubernetes readiness probes by default (no extra CRD needed)
Platforms	Any Kubernetes cluster: GKE, EKS, AKS, on-premises

NOTE

Envoy Gateway version: Minimum **v1.6.0**. This is the first Envoy Gateway release to support the stable `gateway.networking.k8s.io/v1` BackendTLSPolicy schema. Earlier versions (v1.4.x, v1.5.x) were built against older Gateway API versions and only support `v1alpha3` for BackendTLSPolicy, which our Helm templates do not target. Get releases from: https://github.com/envoyproxy/gateway/releases

Infrastructure Setup for Envoy Gateway API Controller

Install the Gateway API CRDs, deploy the Envoy Gateway controller, and create the GatewayClass for your platform.

Complete the following steps to set up the Envoy Gateway infrastructure on your Kubernetes cluster.

Step 1: Install Gateway API CRDs

Install the standard Gateway API Custom Resource Definitions:

```
kubectl apply -f https://github.com/kubernetes-sigs/gateway-api/releases/download/v1.4.0/standard-install.yaml
```

Step 2: Install Envoy Gateway

Install the Envoy Gateway Helm chart for your platform.

GKE / AKS / On-premises:

```
helm install eg oci://docker.io/envoyproxy/gateway-helm --version v1.6.0 \
  -n envoy-gateway-system --create-namespace --skip-crds
```

EKS (internet-facing):

```
helm install eg oci://docker.io/envoyproxy/gateway-helm --version v1.6.0 \
  -n envoy-gateway-system --create-namespace \
  --set service.annotations.service\.beta\.kubernetes\.io/aws-load-balancer-scheme="internet-facing" \
  --set service.annotations.service\.beta\.kubernetes\.io/aws-load-balancer-type="external" \
  --set service.annotations.service\.beta\.kubernetes\.io/aws-load-balancer-nlb-target-type="ip" \
  --skip-crds
```

EKS (internal, behind DMZ):

```
helm install eg oci://docker.io/envoyproxy/gateway-helm --version v1.6.0 \
  -n envoy-gateway-system --create-namespace \
  --set service.annotations.service\.beta\.kubernetes\.io/aws-load-balancer-scheme="internal" \
  --set service.annotations.service\.beta\.kubernetes\.io/aws-load-balancer-type="external" \
  --set service.annotations.service\.beta\.kubernetes\.io/aws-load-balancer-nlb-target-type="ip" \
  --skip-crds
```

Step 3: Apply Oversized CRD (GKE and AKS)

The `envoyproxies` CRD exceeds the 262KB annotation size limit used by `kubectl apply` (client-side apply). Since Helm applies CRDs from the `crds/` directory using client-side apply, this CRD may fail to install or update. Apply it separately using server-side apply:

```
kubectl apply --server-side -f https://raw.githubusercontent.com/envoyproxy/gateway/v1.6.0/charts/gateway-helm/crds/generated/gateway.envoyproxy.io_envoyproxies.yaml
```

Run this **after** the `helm install` command above. If you are upgrading Envoy Gateway, run it after `helm upgrade` as well. The other Envoy Gateway CRDs are small enough to work with standard client-side apply.

Step 4: Create GatewayClass

Envoy Gateway's Helm chart may auto-create a GatewayClass named `eg` . Verify with `kubectl get gatewayclass` . If no GatewayClass exists, or you want a custom name, create one:

```
apiVersion: gateway.networking.k8s.io/v1
kind: GatewayClass
metadata:
  name: envoy-gateway-class
spec:
  controllerName: gateway.envoyproxy.io/gatewayclass-controller
```

Deploying or Migrating to Envoy Gateway API Controller

Verify prerequisites, deploy Symantec Identity Security Platform with Envoy Gateway API, or migrate an existing nginx-based deployment to Gateway API.

Pre-requisite Check

> **NOTE**
> Before proceeding with the specific checks mentioned in this section, review and complete all items in the Prerequisites for All Deployments list.

Run these commands to verify all prerequisites are in place before deploying Symantec Identity Security Platform:

1. Verify Gateway API CRDs are installed:
   ```
   kubectl get crd gateways.gateway.networking.k8s.io
   ```
2. Verify Envoy Gateway pods are running:

```
kubectl get pods -n envoy-gateway-system
```

3. Verify GatewayClass is created and accepted:

```
kubectl get gatewayclass
# Expected: envoy-gateway-class with Accepted=True
```

4. Verify BackendTLSPolicy CRD has v1 version (required by Envoy Gateway v1.6+):

```
kubectl get crd backendtlspolicies.gateway.networking.k8s.io \
  -o jsonpath='{.spec.versions[*].name}'
# Expected: should include "v1". If only "v1alpha3" is listed,
# upgrade Gateway API CRDs to v1.4.0+
```

5. Verify TLS certificate Secret exists:

```
kubectl get secret <tls-secret-name> -n ssp
```

6. Verify RBAC permissions (current user can create Gateway API resources):

```
kubectl auth can-i create gateways.gateway.networking.k8s.io -n ssp
kubectl auth can-i create httproutes.gateway.networking.k8s.io -n ssp
kubectl auth can-i create backendtlspolicies.gateway.networking.k8s.io -n ssp
kubectl auth can-i create clienttrafficpolicies.gateway.envoyproxy.io -n ssp
kubectl auth can-i create backendtrafficpolicies.gateway.envoyproxy.io -n ssp
```

Minimum ClusterRole for Envoy Gateway:

```
apiVersion: rbac.authorization.k8s.io/v1
kind: ClusterRole
metadata:
  name: gateway-api-admin
rules:
  - apiGroups: ["gateway.networking.k8s.io"]
    resources: ["gateways", "httproutes", "backendtlspolicies"]
    verbs: ["get", "list", "watch", "create", "update", "patch", "delete"]
  - apiGroups: ["gateway.envoyproxy.io"]
    resources: ["clienttrafficpolicies", "backendtrafficpolicies"]
    verbs: ["get", "list", "watch", "create", "update", "patch", "delete"]
```

Before You Deploy

Complete the following before deploying or migrating Symantec Identity Security Platform with Gateway API.

NOTE

1. Gateway ownership: The Gateway can be created by Helm (`createGateway: true` , default) or pre-created by the platform team (`createGateway: false` + `existingGateway`). To know how to use an already existing Gateway, see Already Have a Gateway? section for details.
2. Set these Environment Variables:

```
export RELEASENAME="<SSP_RELEASENAME>"
export NAMESPACE="<SSP_NAMESPACE>"
export HELM_REPO='ssp_helm_charts'
```

3. Run the following command to export the current override values of your Helm release to `ssp-override.yaml` . This lets you review, back up, or reuse your existing configuration:

```
helm get values ${RELEASENAME} -n ${NAMESPACE} >ssp-override.yaml
```

Deploying Symantec Identity Security Platform with Gateway API (Fresh Install)

Follow these steps to deploy Symantec Identity Security Platform with Envoy Gateway API on a fresh installation.

1. Ensure Envoy Gateway is installed and GatewayClass exists (see Infrastructure Setup section).

2. Deploy Symantec Identity Security Platform with Gateway API:

```
helm upgrade --install ${RELEASENAME} ${HELM_REPO}/ssp -n ${NAMESPACE} \
  -f your-values.yaml \
  --set ssp.ingress.type=gatewayapi \
  --set ssp.ingress.gatewayApi.gatewayClassName=envoy-gateway-class \
  --set ssp.ingress.gatewayApi.createGateway=true \
  --set ssp.ingress.gatewayApi.createBackendTLSPolicy=true
```

3. Verify resources:

```
kubectl get gateway,httproute,backendtlspolicy -n ${NAMESPACE}
kubectl get clienttrafficpolicies,backendtrafficpolicies -n ${NAMESPACE}  # Envoy-specific
```

4. Test connectivity:

```
GATEWAY_IP=$(kubectl get gateway -n ${NAMESPACE} -o jsonpath='{.items[0].status.addresses[0].value}')
curl -sk --resolve "your-host:443:$GATEWAY_IP" \
  "https://your-host/actuator/health"
```

What Helm creates for Envoy:

Resource	Name Pattern	Purpose
Gateway	`<release>-ssp-gateway`	HTTPS listeners with TLS termination
HTTPRoute	`<release>-ssp-router-full`	Routes all traffic to ssp-router
HTTPRoute	`<release>-ssp-router-mgmt`	Management hostname route (if mgmt enabled)
BackendTLSPolicy	`<release>-ssp-router-backend-tls`	CA validation for HTTPS to ssp-router
ClientTrafficPolicy	`<release>-ssp-client-traffic`	Buffer limit (512KB), client timeout, header preservation, mTLS client validation
BackendTrafficPolicy	`<release>-ssp-backend-traffic`	Backend request timeout, idle timeout

NOTE

Envoy mTLS — how cert forwarding works:

Client validation: When `mtls.enabled=true` , the `ClientTrafficPolicy` includes `tls.clientValidation` with `optional: true` (allows requests without client certs) and a CA certificate bundle for validation.

Certificate forwarding: Envoy forwards the validated client certificate via the `x-forwarded-client-cert` (XFCC) header using the following settings:

- `forwardClientCertDetails: SanitizeSet` — sanitizes any client-injected XFCC values.
- `setCertificateDetails: Cert` — includes the full URL-encoded PEM in the XFCC header as `Cert="<URL-encoded PEM>"` .

Header normalization: ssp-router extracts the PEM from the XFCC header and normalizes it into the `X-CLIENT-CERT` header for backend services.

Migrating Symantec Identity Security Platform from Nginx to Gateway API

Follow these steps to migrate an existing nginx-based Symantec Identity Security Platform deployment to Envoy Gateway API.

NOTE
Before proceeding, complete all steps in the Before You Deploy section.

1. Deploy with both nginx and Gateway API active using `previousController.enabled: true` to maintain both paths during transition:

```
helm upgrade ${RELEASENAME} ${HELM_REPO}/ssp -n ${NAMESPACE} \
  -f your-values.yaml \
  --set ssp.ingress.type=gatewayapi \
  --set ssp.ingress.previousController.enabled=true \
  --set ssp.ingress.previousController.ingressClassName=nginx \
  --set ssp.ingress.gatewayApi.gatewayClassName=envoy-gateway-class \
  --set ssp.ingress.gatewayApi.createGateway=true \
  --set ssp.ingress.gatewayApi.createBackendTLSPolicy=true
```

2. After verifying Gateway API works and switching DNS, remove the old controller:

```
helm upgrade ${RELEASENAME} ${HELM_REPO}/ssp -n ${NAMESPACE} \
  -f your-values.yaml \
  --set ssp.ingress.type=gatewayapi \
  --set ssp.ingress.previousController.enabled=false \
  --set ssp.ingress.gatewayApi.gatewayClassName=envoy-gateway-class \
  --set ssp.ingress.gatewayApi.createGateway=true \
  --set ssp.ingress.gatewayApi.createBackendTLSPolicy=true
```

Deploying the Sample App to Test Connectivity

Deploy the sample-app with Envoy Gateway to test connectivity before or alongside Symantec Identity Security Platform.

1. Deploy the sample-app:

```
helm upgrade --install ${RELEASENAME} ${HELM_REPO}/ssp-sample-app -n ${NAMESPACE} \
  -f your-sample-values.yaml \
  --set ingress.type=gatewayapi \
  --set ingress.gatewayApi.gatewayClassName=envoy-gateway-class \
  --set ingress.gatewayApi.createGateway=true \
  --set ingress.gatewayApi.createBackendTLSPolicy=true
```

2. Verify resources:

```
kubectl get gateway,httproute,backendtlspolicy -n ${NAMESPACE}
```

3. Get Gateway IP and test:

```
GATEWAY_IP=$(kubectl get gateway -n ${NAMESPACE} -o jsonpath='{.items[0].status.addresses[0].value}')
curl -sk --resolve "your-host:443:$GATEWAY_IP" "https://your-host/sample-app/"
```

Troubleshooting Envoy Deployments

Condition

Issues with Envoy Gateway deployments including Gateway IP assignment, HTTPRoute routing, backend TLS, ClientTrafficPolicy status, pod readiness, and NLB target health.

Cause: Gateway not getting IP address

Remedy

Run the following commands:

```
kubectl get gateway -n ssp -o yaml
kubectl describe gateway <gateway-name> -n ${NAMESPACE}
kubectl get gatewayclass
```

Cause: HTTPRoute not routing traffic

Remedy

Run the following commands:

```
kubectl get httproute -n ssp -o yaml
kubectl get httproute -n ssp -o custom-columns='NAME:.metadata.name,PARENT:.spec.parentRefs[0].name'
```

Cause: Backend TLS errors

Remedy

Run the following commands:

```
kubectl get backendtlspolicy -n ${NAMESPACE} -o yaml
kubectl get secret ${RELEASENAME}-ssp-keys-isk-ca -n ${NAMESPACE}
```

Cause: ClientTrafficPolicy has no status (mTLS not working despite correct config)

This is a known race condition: if the Envoy Gateway controller starts **before** the `ClientTrafficPolicy` CRD is installed on the cluster, it skips the CTP watch entirely. CTP resources are created and appear correct (`kubectl get ctp -A` shows them), but they have **no status conditions** — meaning the controller never processed them. The data plane won't apply any CTP settings (mTLS client validation, XFCC forwarding, buffer limits, etc.).

Symptoms:

- `kubectl get ctp -A` shows the resource but no `ACCEPTED` or `PROGRAMMED` status
- Controller log: `ClientTrafficPolicy CRD not found, skipping ClientTrafficPolicy watch`
- Client certificates not forwarded to backends despite correct CTP config

Remedy

1. Restart the Envoy Gateway controller so it re-discovers the CRD:

   ```
   kubectl rollout restart deployment/envoy-gateway -n envoy-gateway-system
   ```

2. After restart, verify the CTP is processed:

   ```
   kubectl get ctp -A
   # STATUS should show Accepted: True / Programmed: True
   ```

Cause: Envoy Gateway pods not ready (EKS)

Remedy

Run the following commands:

```
kubectl get pods -n envoy-gateway-system
```

```
kubectl describe pod -n envoy-gateway-system -l app.kubernetes.io/name=envoy-gateway
```

Cause: Verify NLB target health (EKS)

Remedy

Run the following command:

```
aws elbv2 describe-target-health --target-group-arn <target-group-arn>
```

AKS - Envoy Gateway
Describes how to configure Envoy Gateway on Azure Kubernetes Service (AKS) to support client certificate forwarding and backend TLS, including workarounds for BackendTLSPolicy CRD limitations on Kubernetes versions 1.34 and earlier.

> **NOTE**
> Azure AGC cannot forward client certificates. Use Envoy Gateway on AKS instead.

AKS prerequisite — BackendTLSPolicy CRD

Envoy Gateway v1.6+ requires the standard BackendTLSPolicy CRD (`gateway.networking.k8s.io/v1`), which became GA in Gateway API v1.4.0. On AKS, the available Gateway API CRDs are tied to the Kubernetes version via a managed validating webhook (`managed-gateway-api-ccp-validating-webhook`). This webhook blocks manual installation of Gateway API CRDs.

AKS with K8s 1.35+

Gateway API v1.4.1 is bundled — BackendTLSPolicy is available automatically. No action needed.

AKS with K8s ≤1.34

The bundled Gateway API version does not include BackendTLSPolicy.

> **WARNING**
> In this case, the Helm chart skips creating the BackendTLSPolicy resource and displays a warming message. This results in Envoy Gateway NOT connecting to ssp-router over HTTPS, which fails with 503 upstream connect errors. Envoy Gateway does not use `appProtocol` for backend TLS; it requires either a BackendTLSPolicy or a Backend resource.

Two options:

Option A — Delete the managed webhook and install CRDs manually

1. Delete the managed webhook (takes over CRD lifecycle from AKS):
   ```
   kubectl delete validatingwebhookconfiguration managed-gateway-api-ccp-validating-webhook
   ```
2. Install Gateway API v1.4.0 CRDs (includes BackendTLSPolicy):

   ```
   kubectl apply -f https://github.com/kubernetes-sigs/gateway-api/releases/download/v1.4.0/standard-install.yaml
   ```

> **CAUTION**
> After deleting the managed webhook, AKS no longer manages Gateway API CRD upgrades automatically. You are responsible for keeping the CRDs up to date when upgrading Envoy Gateway.

Option B — Use an Envoy Gateway Backend resource (no webhook change required)

Instead of BackendTLSPolicy, use Envoy Gateway's own Backend CRD for backend TLS. This CRD ships with Envoy Gateway and is not affected by the AKS managed webhook.

Follow these steps:

1. **Enable the Backend API in Envoy Gateway**:
   In the **Envoy Gateway Helm chart deployment** (not the IDSP chart), enable the Envoy Gateway Backend API support:
   ```
   --set config.envoyGateway.extensionApis.enableBackend=true
   ```
2. **Create a Backend resource for ssp-router:**
   ```
   apiVersion: gateway.envoyproxy.io/v1alpha1
   kind: Backend
   metadata:
     name: ssp-router-backend
     namespace: <namespace>
   spec:
     endpoints:
       - fqdn:
           hostname: <release>-ssp-router.<namespace>.svc.cluster.local
           port: 8095
     tls:
       sni: <release>-ssp-router.<namespace>.svc
       caCertificateRefs:
         - group: ""
           kind: Secret
           name: <release>-ssp-keys-isk-ca   # Secret with ca.crt key
   ```

   IMPORTANT
   The `sni` field must be set to the ssp-router service's short name (`<release>-ssp-router.<namespace>.svc`) to match the router certificate's SAN (`*.<namespace>.svc`). If you omit `sni` , Envoy uses the full FQDN (`...svc.cluster.local`) which does not match the certificate's wildcard SAN, causing `CERTIFICATE_VERIFY_FAILED` errors.

   NOTE
   Troubleshooting: If you need to temporarily bypass backend certificate validation (e.g., to isolate TLS issues), you can replace the `tls` block with `tls: { insecureSkipVerify: true }` .
3. The **IDSP Helm chart deployment** should route HTTPRoutes to the Backend instead of the Service:

   ```
   ssp:
     ingress:
       gatewayApi:
         createBackendTLSPolicy: false
         backendRef:
           group: gateway.envoyproxy.io
           kind: Backend
           name: ssp-router-backend
           port: 8095
   ```

Constructing the Service FQDN

Learn how to construct the Service FQDN by specifying the domain, and the service-hostname. Decide on a Releasename and Namespace that can be used in the commands throughout the release process by creating environment variables.

- Setup steps assume that you specify a root domain <DOMAIN> in the Configuring the Environment Variables section. For example, the domain could look like this- "myiam.example.com". By default, the deployment steps assume services are deployed under the same DNS domain name, and the services FQDN is added to the DNS (or configured in /etc/hosts) in the form of "<service-hostname>.<DOMAIN>".
- Setup steps assume that you specify the value for "<PREFIX>" in the Configuring the Environment Variables section. The <PREFIX> specifies the Symantec Identity Security Platform service-hostname which results in the FQDN in the form of "<PREFIX>.<DOMAIN>".
- It is recommended that you acquire a TLS certificate signed by a well-known and trusted Certificate Authority (CA), for example; Let's Encrypt, Digicert. The commands in the following sections use a wildcard certificate for *. <DOMAIN> (for example, "*.myiam.example.com"). However, you could also use host-specific certificates.

  NOTE
  If you do not provide a certificate, the deployment uses a self-signed certificate for all ingress objects. However, note that not all clients are able to work with self-signed certificates. For example, some clients may reject self-signed SSL connections unless those clients have a way to enable the "ignoreSSL" capability.
- The key file and the certificate that is used in the deployment steps refer to the key file as (.key) and the cert file as (.crt), as provided by the CA. Once you have obtained the issuer certificate package containing the CA public certificate series, copy the contents of the package to the bottom of the issued .crt file (domain certificate) and save it as a separate .crt file.
- <RELEASENAME> refers to the helm Release-Name and <NAMESPACE> refers to the Kubernetes Namespace of the IDSP deployment.

The FQDN is used during the creation of environment variables for the deployment of IDSP. See Configuring the Environment Variables section.

Symantec Identity Security Platform Components and URLs

Includes the URLs of the Symantec Identity Security Platform Components.

The following table displays the IDSP components and their respective URLs:

Service	Description	Kubernetes Namespace	Service URL
IDSP	IDSP Services	<user-defined>	https://<PREFIX>.<DOMAIN>/default/<API>
SignIn UI	IDSP SignIn UI	<user-defined>	https://<PREFIX>.<DOMAIN> /default/ui/v1/adminconsole/
Admin Console	IDSP Admin Console	<user-defined>	https://<PREFIX>.<DOMAIN> /default/ui/v1/adminconsole/
IDSP Swagger	IDSP Swagger Documentation	<user-defined>	https://<PREFIX>.<DOMAIN> /default/swagger-ui/index.html
Kibana	Logging of IDSP APIs and 3rd party components	Logging	https://kibana.<DOMAIN>
Grafana	Monitoring of IDSP APIs health and Cluster health	Monitoring	https://grafana.<DOMAIN>
Alert Manager	Alerting based on IDSP KPIs	Monitoring	https://alertmanager.<DOMAIN>

Ingress	Ingress	Ingress	n/a

Master Encryption Key

Creating a master encryption key and backing it up for future retrievals

This topic includes the following sub-sections:

- Backing-up and Restoring the MEK
- New deployment with existing database
- Disaster Recovery deployment

- The Master Encryption Key is used to encrypt the tenants' data encryption keys of the VIP Authentication Hub. Every VIP Authentication Hub installation requires an MEK. The MEK is stored as a Kubernetes secret in a file called, "mek.key" which contains the MEK key value.
- If you do not provide an MEK during deployment, an MEK is dynamically generated as a Kubernetes secret name -"`<RELEASENAME>-ssp-keys-mek`" where the "<RELEASENAME> is the name of the release that is used during the deployment of IDSP helm chart.
- To use an existing MEK, create a Kubernetes secret that contains a file that is called "mek.key" which contains the MEK key and specify `--set ssp.keys.mek.existingSecret="<name of the Kubernetes Secret containing MEK.key>"` parameter during the IDSP helm chart deployment.
  The following command is an example of creating a MEK secret named "ssp-mek-secret" in a namespace called "ssp" with the MEK value of "Th1s!sMyT0pS3cretM3K":
  ```
  kubectl create secret generic ssp-mek-secret -n ssp --from-literal=mek.key='Th1s!sMyT0pS3cretM3K'
  ```
  Once the secret is created, add `--set ssp.keys.mek.existingSecret="ssp-mek-secret"` to your Authentication Hub helm chart deployment command.

  NOTE

  - It is important to create a backup of the MEK because it is the only key that can be used to decrypt the solution's encrypted data stored in the Authentication Hub database. If you lose the MEK, there is no other way to recover the encrypted data.
  - If you are pointing to a replicated instance of an existing Authentication Hub database or restoring an existing database from a backup, ensure to use that MEK.

Important: If you are upgrading from 2021.April.01 or a prior release to the current release, VIP Authentication Hub automatically generates a MEK (if a name of a MEK existing Kubernetes secret was not provided), and this MEK re-encrypts the tenant data encryption key.

Backing-up and Restoring the MEK

It is important to back up your MEK into a safe place for future retrievals. If you have created your own MEK, make sure you save it in a secure location. If the MEK was automatically generated by IDSP during the deployment of the Authentication Hub, ensure to export and save it.

There are two ways to back up the MEK:

- Export the complete secret object using the following command:
  ```
  kubectl get secret ${RELEASENAME}-ssp-keys-mek -n ${NAMESPACE} -o yaml >mek-secret_backup.yaml
  ```
  This command saves the content of the MEK secret into a yaml file called, mek-secret_backup.yaml. In the future when you want to restore it, use the following command:
  ```
  kubectl apply -f <mek secret yaml file> -n ${NAMESPACE}
  ```
- Export the MEK value only, using the following command:
  ```
  kubectl get secret ${RELEASENAME}-ssp-keys-mek -n ${NAMESPACE} -o jsonpath="{.data.mek\.key}" | base64 --
  decode; echo
  ```
  In the future, when you want to restore the MEK value only, use the following command:

```
kubectl create secret generic <secretname> -n ${NAMESPACE} --from-literal=mek.key=<mek value>
```

New Deployment with Existing Database

The MEK is the key to unlock the Authentication Hub database. If you are pointing to a replicated instance of an existing Authentication Hub database or restoring an existing database from a backup, ensure to use that database's MEK.

1. Before deploying the new instance of the Authentication Hub, create a Kubernetes secret, using the MEK value of the existing deployment in the new Authentication Hub deployment location (deployment cluster and Kubernetes namespace). To perform this step, follow the restore steps mentioned in the section- **Backing-up and Restoring the MEK**.
2. Create an Authentication Hub deployment, pointing to the database of the existing deployment and to the MEK secret created in the previous step, by adding the following parameter to the Authentication Hub helm chart install command:

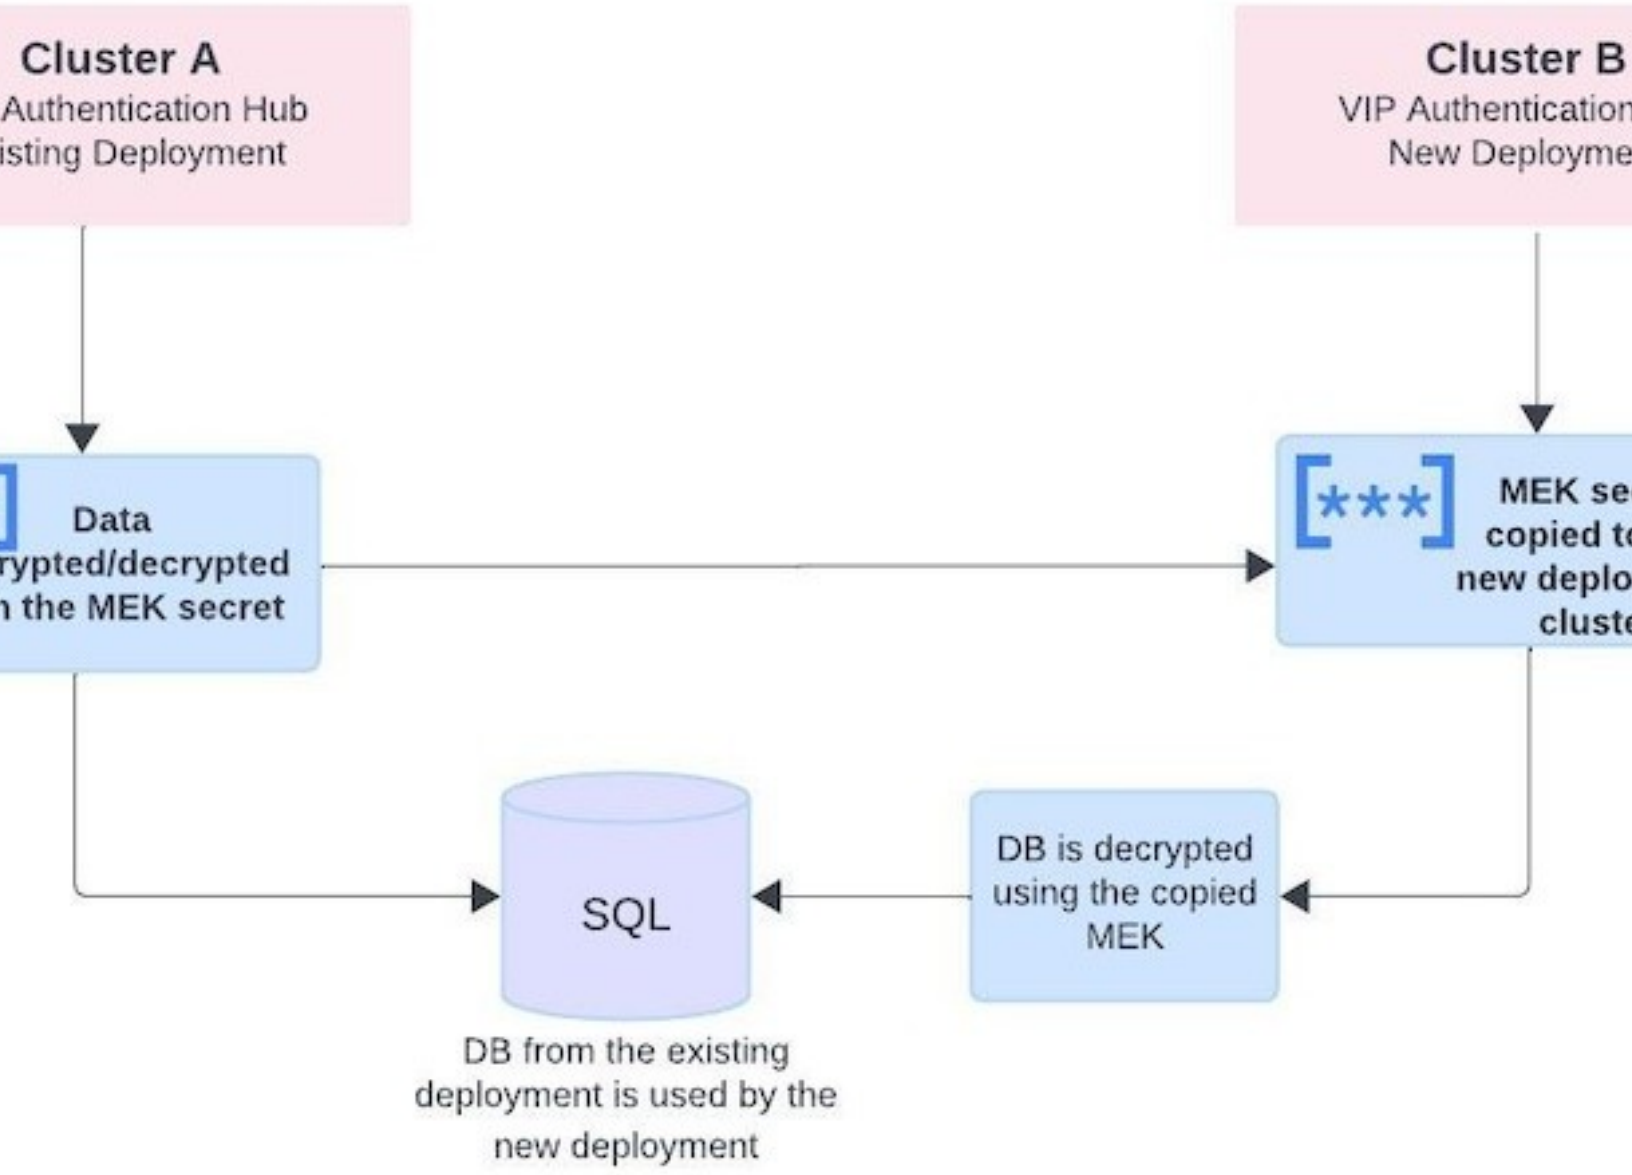
```
--set ssp.global.drSite=true --set ssp.keys.mek.existingSecret="<name of the Kubernetes Secret containing
 MEK.key>"
```

NOTE

- When adding the parameter, ssp.global.drSite=true, no updates are made to the existing database.
- When performing an Authentication Hub version upgrade or deployment changes that require an update to the database, always perform the update or the upgrade on the primary deployment, and not on a DR deployment site (where ssp.global.drSite=true).

Two separate deployments that are using the same database, with the same MEK value

The following image illustrates the process of securely managing database access in a VIP Authentication Hub deployment with two clusters (Cluster A and Cluster B). Cluster A is the existing deployment, while Cluster B is the new deployment. Both clusters use the same database, which is encrypted with a Master Encryption Key (MEK). The MEK secret is copied from Cluster A to Cluster B, allowing Cluster B to decrypt and access the same database.



Disaster Recovery (DR) setup for the VIP Authentication Hub using a load balancer

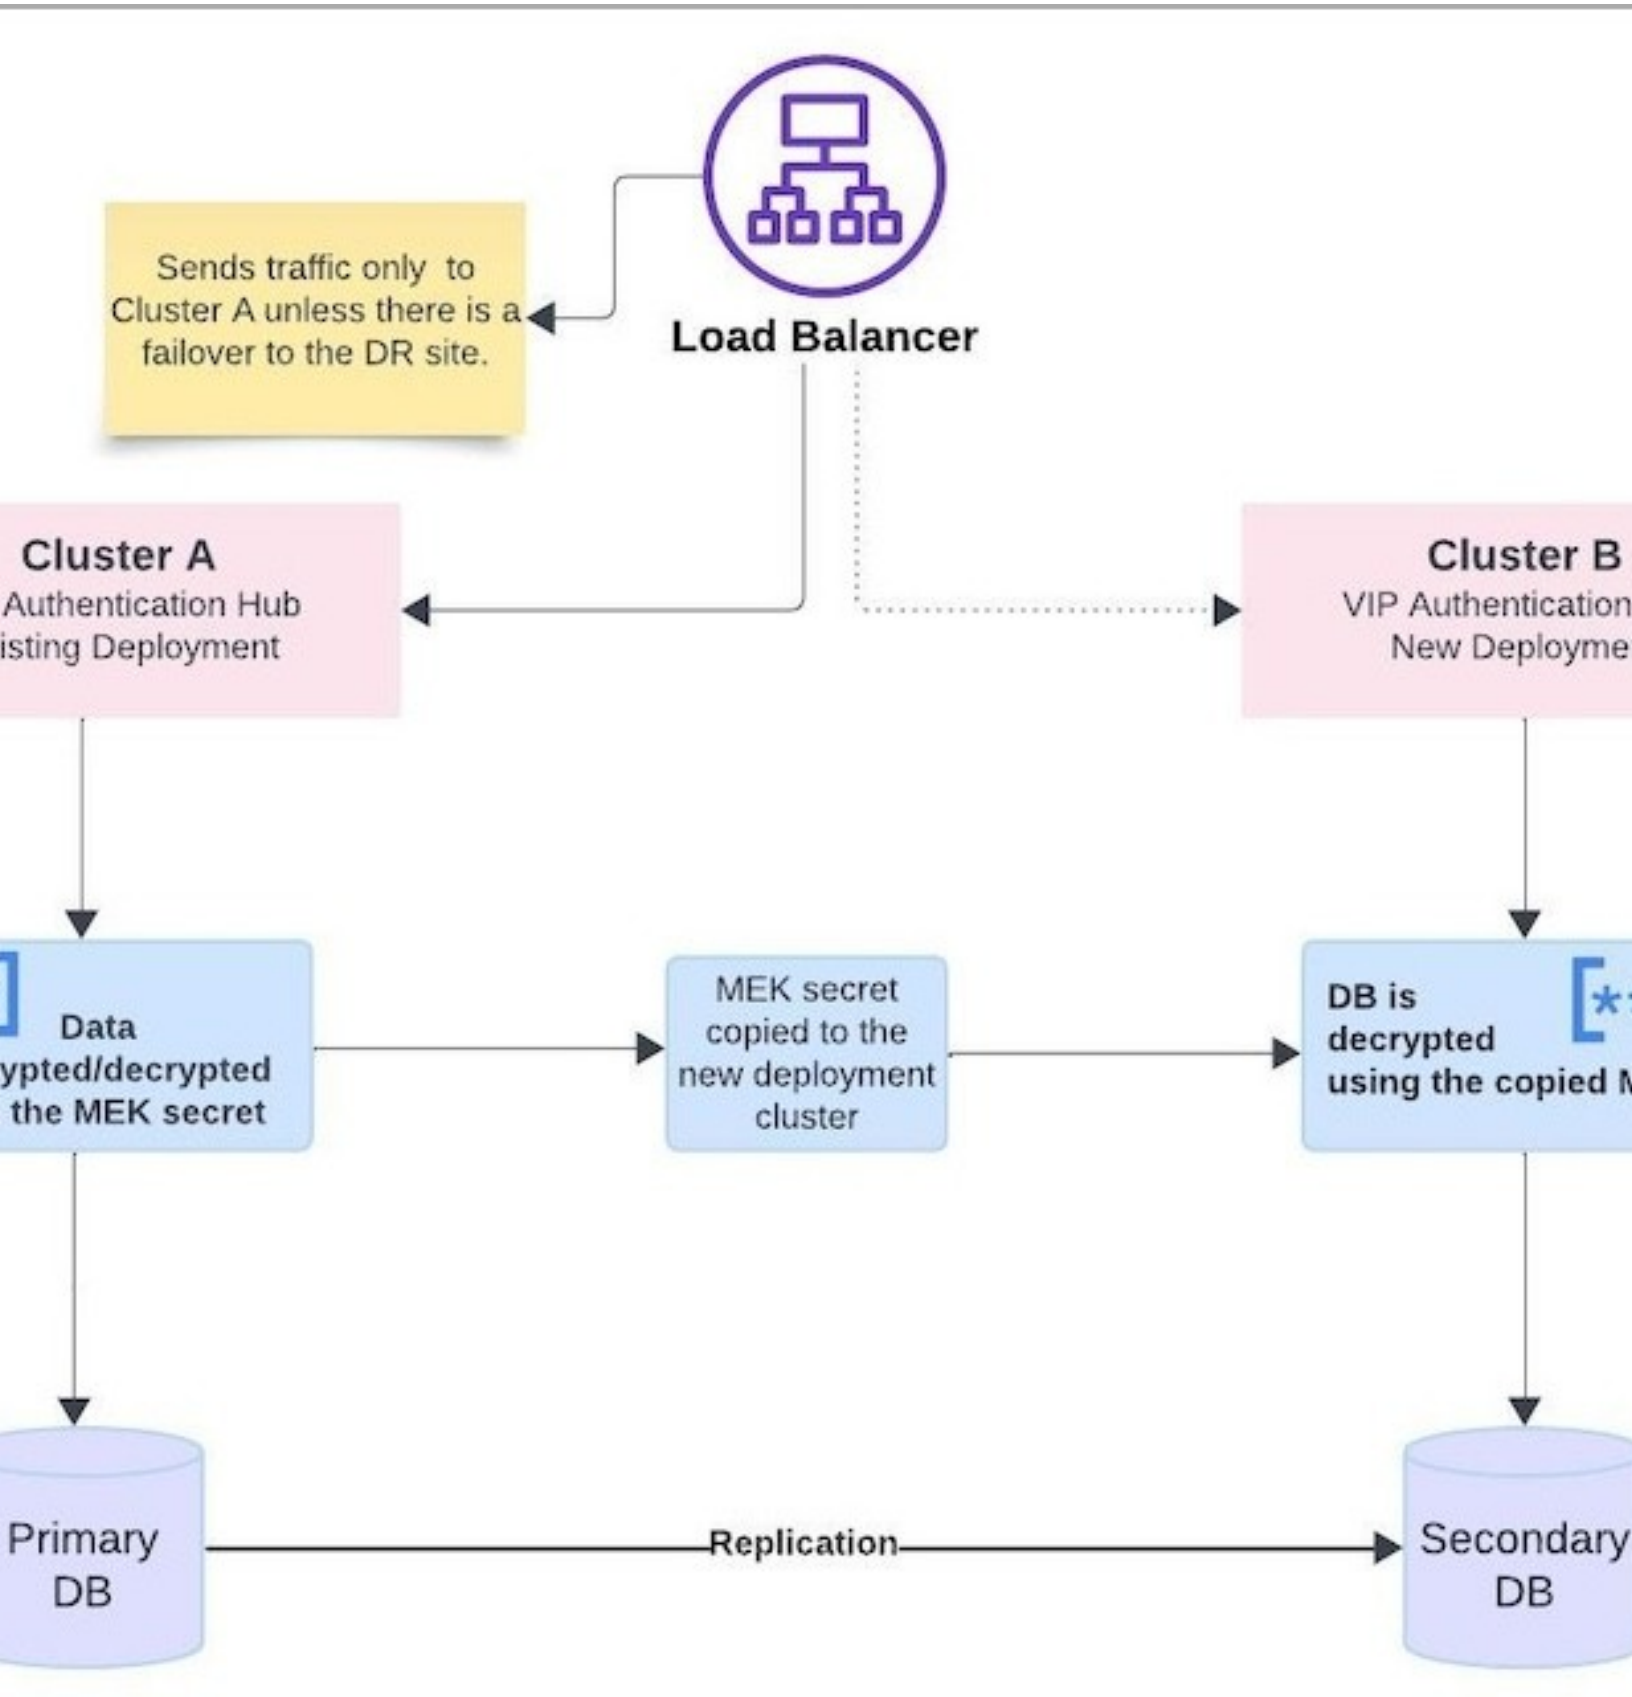
The following image illustrates a DR setup for the VIP Authentication Hub using a load balancer to manage traffic between two clusters (Cluster A and Cluster B). Cluster A uses the primary db serving as the active deployment that handles all traffic unless a failover occurs. Data in the primary database is encrypted using a Master Encryption Key (MEK) secret. This MEK secret is copied to Cluster B, the DR deployment, which uses the same MEK.

In case of a failover, the secondary db must be promoted to a standalone primary db, only then the load balancer starts sending traffic to Cluster B. When Cluster A is available again, a failback procedure should take place which includes the following steps:

1. Creating Cluster A's db as a replica of Cluster B's db.
2. Promote Cluster B's db to primary and switchover load balancer to send traffic to Cluster A.
3. Recreate Cluster B as a readonly db of Cluster A.

IMPORTANT

- The MEK is copied to the DR cluster because both clusters use the same MEK, which is essential for encrypting and decrypting sensitive data in the database.
- If the secondary database is a read-only replica of the primary database, set the parameter, "***drsite=true***" during Authentication Hub deployment to prevent Authentication Hub from updating the database during installation and upgrades.
- In the following diagram, Cluster A and Cluster B are deployed in two separate regions. These clusters should be created as multi-zone clusters to leverage cloud providers infrastructure to get better resiliency within their region.



Sends traffic only to Cluster A unless there is a failover to the DR site.
Load Balancer

DR Deployment Steps

View information about the Disaster Recovery (DR) deployent steps.

This section describes the steps taken for testing Cloud SQL MySQL failover to another cross-region.

Assume a primary instance is deployed in **us-east-1**, and a replica is deployed in **us-west-1.**

The following steps simulate an instance that "stopped" in **us-east-1**.

General Approach:

1. Ensure that a cross-region replica has been created and can be accessed from the cluster.
2. Capture a fresh backup to ensure that no data has been lost.
3. Simulate a Disaster Recovery (DR) Scenario.
4. Implement DR.
5. Delete the old primary instance (Clean-up).

Detailed Steps:

Step	Steps Description	Detailed Steps
1	Create a cross-region replica from the primary instance, in this scenario, a replica is created in us-west-1	This can be done either directly in the console or by using the following `gcloud` command: `gcloud sql instances create $cross_region_replica_name \ --master-instance-name=$primary_name \ --region=$cross_region_replica_region`

1a	Confirm if us-west-1 Replica instance can be connected from mysql client pod	Create MySQL Pod in preprod jumphost (jumphost that is used for the testing environment) by running the following command:
		`kubectl run mysql-client -n ssp --image=mysql:5.7 -it --rm --restart=Never -- /bin/bash`
		In POD, connect by running the following command:
		`mysql -u iamauth -p '=*HA@=_z@<8qht$.' -h 10.254.91.2`
		k delete pod mysql-client

2	Capture a backup of the primary instance	Either click "Create Backup" in the console or run the following gcloud command: `gcloud sql backups create --async --instance=$primary_name`
2a	List the Backup ID created in the previous step and confirm if backup has created successfully.	Use the following command to output the Backup ID and check the status, which should be shown as SUCCESSFUL: `gcloud sql backups list --instance sample-ah-db-prd`
3	Disable the deletion protection of the primary instance.	Edit the master instance and click "Disable Deletion Protection." This must be done before the instance is stopped, as GCP will not allow you to edit the instance afterward.
3a	Remove the cross-region replica from the primary instance by running the following command:	`gcloud sql instances patch sample-ah-db-prd-replica --no-enable-database-replication` After the command executes successfully, the replica state should display as "replication disabled."

Step	Steps Description	Detailed Steps
3b	Stop the primary database instance	Click `STOP` or run the following gcloud command: `gcloud sql instances patch $primary_name --activation-policy NEVER`
4	Promote the cross-region read replica to a standalone instance	Click `Promote` or run the following gcloud command: `gcloud sql instances promote-replica $cross_region_replica_name`
4a	Start the new primary (the replica that was promoted in step 4).	The `$primary_name` now refers to the replica name that was promoted in step 4. Use the following command to set the activation policy to ALWAYS: `gcloud sql instances patch $primary_name --activation-policy ALWAYS`
4b	Enable the new primary as an HA Regional instance.	The`$primary_name` is now the replica name that was promoted in step 4. `gcloud sql instances patch $primary_name \ --availability-type REGIONAL \ --enable-bin-log \ --backup-start-time=$backup_start_time`
4c	Update the values.yaml file with the new host IP address (replica address).	1. Navigate to the correct branch (environment) in the repository sample-authhub-cd, specifically in the Symantec Identity Security Platform branch. For example: `pipeline_ssp_int_gke-authhub-$ENVNAME-$ENVREGION-int` 2. Update the `spec.db.serviceHost` field to the new primary (replica) address.
4d	Create a cross-region read-replica in a different region (us-east).	Click `Create Replica` or run the following gcloud command `gcloud sql instances create $cross_region_replica_name \ --master-instance-name=$primary_name \ --region=$cross_region_replica_region`
4e	Ensure the dataseed pod in the IDSP namespace is marked as "COMPLETED" and that new IDSP pods are spinning up. Additionally, verify that the admin console is still accessible and that you can log in.	See the following output, all IDSP pods are in a RUNNING state. Use the following command: `kubectl get pods -n ssp`
5	Delete the old primary instance	Click Delete or run the following gcloud command:
5a	(Optional) If you're creating a standalone instance and want to back up data from a previous instance, run the following command:	`gcloud sql backups restore $BACKUP_ID \ --restore-instance=TARGET_INSTANCE_NAME \ --backup-instance=SOURCE_INSTANCE_NAME`

IDSP Deployment Steps (DR Setup for Failover Cluster)

Ensure the Cloud SQL MySQL read-replica are functioning properly and can access the cluster. Then, deploy IDSP in the failover cluster.

Step	Steps Description	Detailed Steps
1	Retrieve the following secrets from the primary cluster: • sample-authhub-ssp-prd-ssp-east-ssp-keys-mek • sample-authhub-ssp-prd-ssp-east-ssp-keys-isk-ca • sample-authhub-ssp-prd-ssp-east-ssp-keys-isk • hazelcast-ssp-keys-isk With IDSP v 3.2, the IDSPchart supports DR deployment mode which automates all Kubernetes provisioning steps. It including generating local ISK secrets, while skipping data loading since the DR DB is assumed to be in read-only mode. Therefore, no ISK secrets must be copied. When deploying the chart, ensure you set the `drSite` parameter: `ssp.global.drSite=true` and `ssp.db.dataseed.enabled=true` . When "drSite=true", the database operates in a read-only mode, preventing any schema or data updates. However, dataseed must still be run to manage (includes create and update) Kubernetes secrets (isk/ssl secrets).	Retrieve the secrets into a file using the following command: `kubectl get $SECRET_NAME -n ssp -o yaml > $FILE_NAME`
2	Apply the secrets retrieved from step 1.	Update the values for the following secrets to align with the current environment: `ssp-isk-ca` ,`ssp-keys-isk` , and `ssp-keys-mek` . The `hazelcast-ssp-keys-isk` must have the same name as in the primary cluster. `kubectl apply -f $FILE_NAME -n ssp`

3	Add the following values to values.yaml and deploy IDSP helm chart in the failover cluster.	`global:`
		`  helmOfflineMode: true`
		`ssp:`
		`  global:`
		`  drSite: true`
		`  keys:`
		`  mek:`
		`  existingSecret: <sample-authhub-ssp-prd-ssp-west-ssp-keys-mek>`
		`  db:`
		`  dataseed:`
		`  enabled: true`
		
		`  featureFlags:`
		`  scheduler:`
		`  enabled: false`

Troubleshooting Steps

Error	Steps Taken to Resolve
failed exit status 1: Error: execution error at (ssp/templates/mek-secret.yaml:84:3): ***** Existing Master Encryption Key (MEK) secret specified (ssp-keys-mek) but does not exist\n\nUse --debug flag to render out invalid YAML" kubectl logs POD_NAME	Set dataseed to false and recreate the secrets from primary to failover (see section 2 step 2).
{"timestamp":"2024-04-25T17:36:11.349651Z","type":"log","level":"error","thread":"main","msg":"(conn=103) The MySQL server is running with the --super-read-only option so it cannot execute this statement","tid":"e202f42f-95fc-48dd-83b5-e72ec36d5c71","tname":"system"}	Make sure that the primary cluster is not pointed to the read/write db d.

Cache Considerations

Learn about Hazelcast configurations required during Symantec Identity Security Platform deployment.

IDSP uses Hazelcast (Cache) Enterprise version 5.2.1 which supports configuring the role-binding and service account during the IDSP deployment.

By default, the IDSP does not require Role-based access control (RBAC) for discovering Hazelcast cache instances for cache replication ("dns" discovery mode). Hazelcast maintains a backup for each replica in another instance. When running in a multi-zone cluster, "kubeapi" discovery mode is recommended. "kubeapi" discovery mode supports two modes, using a Kubernetes cluster role or a Kubernetes local role. It is recommended to use the Kubernetes cluster role. Granting the ClusterRole permissions to the Hazelcast service account improves data loss prevention by allowing Hazelcast to get information about the NODE and ZONE of each cache instance. Hazelcast uses this information to make a better decision about where to store replicas' backups (trying to avoid storing a replica's backup on the same node or the same zone as the replica itself).

Switching to "kubeapi" discovery mode can be done by setting the following parameters when deploying the IDSP helm chart to create the Hazelcast service account and grant permissions to it:

```
--set ssp.global.cache.discoveryMode=kubeapi
--set hazelcast-enterprise.rbac.create=true
--set hazelcast-enterprise.rbac.useClusterRole=true
```

Switching to "kubeapi" discovery mode can also be done ***manually*** by creating the proper Kubernetes RBAC Role or ClusterRole, binding it to the service account, and specifying that service account by adding the following parameters to the IDSP helm chart:

```
--set hazelcast-enterprise.serviceAccount.create=false \
--set hazelcast-enterprise.serviceAccount.name=<serviceaccount-name> \
--set "ssp.global.cache.discoveryMode"="kubeapi"
```

See HAZELCAST documentation for more information.

The following table shows the <parameter_name> and describes the <value> that can be passed into the IDSP helm chart using `--set <parameter_name>="<value>"` helm command.

Parameter Name	Default	Description
hazelcast-enterprise.rbac.create	false	Possible Values: • true - Creates a cluster role, and cluster role binding (or role and role binding depending on the value of hazelcast-enterprise.rbac.useClusterRole). • false - Does not create cluster role, and cluster role binding (or role and role binding)
hazelcast-enterprise.rbac.useClusterRole	false	Possible Values: • true - Set this parameter to "true" to create a cluster role. • false - Set this parameter to "false" to create a Kubernetes Role instead of a Kubernetes Cluster Role. When this parameter is set to false, some of the discovery features are unavailable.
hazelcast-enterprise.serviceAccount.create	true	Possible Values: • true: Set this parameter to true to enable creation of the Service Account. • false: Set this parameter to false to disable creation of the Service Account. In this case, you must specify the service account name to be used by specifying it in the parameter: hazelcast-enterprise.serviceAccount.name=<serviceaccount-n

Deploying Enclave Services

Enclave (observability) services refer to a group of external services (such as Elasticsearch, Kibana, Prometheus, Grafana) that are plugged into Symantec Identity Security Platform to collect information that is related to search, logging, and monitoring from services that are running in the IDSP Kubernetes cluster.

> **NOTE**
> Support for cloud-native "**Elastic" / "Kibana"** and "**Prometheus" / "Grafana"** in the cloud-native IDSP is provided on a best-effort basis. While customers typically have their own enterprise observability stacks, we aim to deliver an out-of-the-box observability experience using robust open-source alternatives, allowing them the flexibility to choose the appropriate tool for their specific environment.
> We certify major releases of both these platforms for compatibility with the IDSP, but the responsibility for upgrading these platforms to address vulnerabilities or use new features lies with our customers, following the general guidelines based on our certifications.

This page includes the following topics:

- Prerequisites
- Read Me First
- Configuring Environment Variables

Prerequisites

Before setting up the enclave services, ensure that you have gone through the Prerequisites and installed all the required software.

Read Me First

- Constructing the DNS domain name:
  - Setup steps assume a root domain, <DOMAIN> that is set by you in the section-Configuring Environment Variable and again while configuring */etc/hosts or the DNS entries.* By default, the deployment steps assume that services

are hosted under one DNS domain. For example, the domain value can be "myiam.example.com" and the services Fully Qualified Domain Name can be *kibana.myiam.example.com* or *grafana.myiam.example.com.*

- It is recommended that you acquire a TLS certificate signed by a well-known and trusted Certificate Authority (CA), for example; Let us Encrypt, Digicert. The following commands use a wildcard certificate for *. <DOMAIN> (for example, "*.myiam.example.com"), but you could also use host-specific certs.

  NOTE
  If you do not provide a certificate, the deployment uses a self-signed certificate for all ingress objects. However not all clients are able to work with self-signed certificates. For example, some clients reject self-signed SSL connections unless those clients have a way to enable the "ignoreSSL" capability.
- The key file and the certificate that is used in the deployment steps refer to the key file (.key) and the cert file (.crt) as provided from the Certificate Authority (CA). If you also receive an issuer certificate package containing the CA public certificate series, copy the contents of the package to the bottom of the issued .crt file (domain certificate) and save it as a separate .crt file.

Configuring Environment Variables

Set up your system environment variables so that you can use them in the commands that are used in deploying the enclave services.

These commands can be executed from your on-premise workstation or in the case of GCP, you could also use a cloud shell:

Follow these steps:

1. Configure environment variables to point to your DNS domain.
   ```
   export DOMAIN="<DOMAIN>"
   ```
   NOTE
   Example of <DOMAIN> name: myiam.example.com, iam.example.com
2. If you have a wildcard certificate from a trusted Certificate Authority (CA), configure the environment variables to point to the key and cert files.
   ```
   export KEYFILE="<keyfile>"
   export CERTFILE="<certfile>"
   ```

See the following topics:

- Deploying Elasticsearch and Kibana for Logging
- Deploying Prometheus for monitoring

Deploying Elastic Operator and Kibana

Learn to setup a basic Elasticsearch deployment (non-production) to index and analyze all the Symantec Identity Security Platform logs, view them in the Kibana interface, and configure a data retention policy in Elastic Search.

This topic includes the following sections:

- Deploying Elasticsearch and Kibana for Logging
- Publishing the Kibana Endpoint

Deploying Elastic Search and Kibana

NOTE

- Elasticsearch requires a persistent volume for storing logs and configurations. ***Refer to the official documentation and best practices provided by*** elastic.co for guidance on persistent volume requirements.
- If you already have a log storage system, skip this step.
- The default sizing used in this topic is for a minimal deployment. If the observability stack is used for production, then the replica counts must be 3 for Elastic.

Follow these steps to deploy Elastic Operator to use Elastic Search capabilities of indexing and analyzing all the IDSP logs and view them in the Kibana interface:

1. Deploy Elastic Cloud on Kubernetes (ECK) operator globally or for managing objects under the **logging** namespace. Follow the instructions at https://www.elastic.co/guide/en/cloud-on-k8s/master/k8s-install-helm.html.
   For example:
   a. Load the elastic chart repository:
   ```
   helm repo add elastic https://helm.elastic.co
   helm repo update
   ```
   b. To deploy Elastic Operator without specifying image registry credentials, use this command. This is a sample helm command for a default global deployment of an Elastic operator under the logging namespace:
   NOTE
   The following command can be used by all the IDSP supported cloud providers (including OpenShift) to install the elastic operator.
   ```
   kubectl create ns logging
   helm install elastic-operator elastic/eck-operator -n logging --create-namespace --version=3.2.0
   ```
   c. To deploy Elastic Operator by creating a secret to authenticate to your container-registry to pull images, create a Kubernetes secret of type docker-registry by running the following command:
   ```
   kubectl create secret docker-registry <registry-secret-name> -n logging \
   --docker-server="https://index.docker.io/v2/" \
   --docker-username="<dockerhub-username>" \
   --docker-password="<dockerhub-password>" \
   --docker-email="<your-email-address>"
   ```
   d. Add the preceding created secret to the helm install command that is used to install the Elastic operator by adding the parameter, `--set imagePullSecrets[0].name="<registry-secret-name>"`.
   For example:
   ```
   helm install elastic-operator elastic/eck-operator -n logging \
   --set imagePullSecrets[0].name="<registry-secret-name>" \
   --version=3.2.0
   ```
2. Using the Elastic operator, deploy Elastic Search by creating an Elasticsearch instance.
   a. To set your own password for the elastic default user, create a secret (for example, kibana-user)
   ```
   kubectl create secret generic kibana-user  -n logging \
   --from-literal roles=superuser \
   --from-literal username=kibana \
   --from-literal password=changeme
   ```
   Next, pass the secret (kibana-user) in the Elastic Operator configuration object by uncommenting the line "#-secretName: kibana-user".
   b. To set the registry, pull secret in the Elastic Operator configuration object, uncomment the following lines:
   ```
   #imagePullSecrets:
   #- name: <registry-secret-name>
   ```

An ***example*** of the Elastic Operator configuration object. This example object is not configured for HA and resilience.

```
cat <<EOF | kubectl apply -f -
apiVersion: elasticsearch.k8s.elastic.co/v1
kind: Elasticsearch
metadata:
name: elasticsearch
labels:
app: elasticsearch-master
namespace: logging
spec:
version: 9.2.1
#image: docker.elastic.co/elasticsearch/elasticsearch:9.2.1
http:
service:
 metadata:

   metadata:
     labels:
       app: elasticsearch-master
   spec:
     #imagePullSecrets:
     #- name: <registry-secret-name>
     containers:
     - name: elasticsearch
       resources:
         requests:
           memory: 4Gi
           cpu: 1
         limits:
           memory: 4Gi
           cpu: 1
 volumeClaimTemplates:
 - metadata:
     name: elasticsearch-data
   spec:
     #storageClassName: fast
     accessModes:
     - ReadWriteOnce
     resources:
       requests:
         storage: 20Gi
 name: default
 count: 1
volumeClaimDeletePolicy: DeleteOnScaledownOnly
auth:
fileRealm:
```

```
#To create new elastic users, see: https://www.elastic.co/guide/en/cloud-on-k8s/master/k8s-users-and-roles.html
#    - secretName: kibana-user ##uncomment if you want to create users/set password in elastic.
EOF
```

c. Verify that all persistent volume claims in the logging namespace are showing the *STATUS* as *Bound,* by running this command:

```
kubectl get pvc -n logging
```

The following image is a sample displaying a PVC with the "*STATUS"* reported as "*Bound"*:

NAME	STATUS	VOLUME	CAPACITY	ACCESS MODES	STORAGECLASS
elasticsearch-data-elasticsearch-es-default-0	Bound	pvc-d81aabb1-f3fc-435a-a074-e20b3a2f1874	20Gi	RWO	standard

d. Verify that the pods are Ready (1/1) and in Running State by running this command:

```
kubectl get pods -n logging
```

NOTE
If you want to start with an empty data set after uninstalling elastic, then delete all the Elastic's PVC using this command: `kubectl delete pvc <elastic-pvc-name> -n logging`

3. To set a data retention policy for the log and audit messages in Elastic Search, see the steps that are described in the Setting up data retention policy for Elastic Search section.
4. Deploy Kibana by creating a Kibana cluster instance using the deployed Elastic operator.
   a. To add your own trusted certificate signed by the Certificate Authority (CA), run this command:

```
kubectl create secret tls logging-general-tls \
--cert "${CERTFILE}" \
--key "${KEYFILE}" -n logging
```

If you do not have a certificate, you can skip creating the "logging-general-tls" secret. The ingress-nginx ingress controller uses its built-in self-signed certificate if the "logging-general-tls" secret is not provided.

   b. To set the registry, pull secret in the Elasticsearch configuration object, uncomment the following lines:

```
#imagePullSecrets:
#- name: <registry-secret-name>
```

An ***example*** of the Kibana configuration object. The following example requires that the environment variable DOMAIN is set.

```
cat <<EOF | kubectl apply -n logging -f -
apiVersion: kibana.k8s.elastic.co/v1
kind: Kibana
metadata:
name: kibana
namespace: logging
spec:
version: 9.2.1
#image: docker.elastic.co/kibana/kibana:9.2.1
elasticsearchRef:
name: elasticsearch
namespace: logging
serviceName: elasticsearch-es-http
http:
service:
 spec:
   type: ClusterIP
tls:
 selfSignedCertificate:
   subjectAltNames:
   - dns: kibana.${DOMAIN}
podTemplate:
```

```
    metadata:
     labels:
       app: kibana
    spec:
     #imagePullSecrets:
     #- name: <registry-secret-name>
     containers:
       - name: kibana
         resources:
           requests:
             memory: 1Gi
             cpu: 0.5
           limits:
             memory: 2Gi
             cpu: 1
    count: 1
    EOF
```

c. Verify that the pods are Ready (1/1) and in Running State by running this command:

```
kubectl get pods -n logging
```

The following image is a sample displaying the logging pods with the STATUS-Running:

```
NAME                          READY   STATUS    RESTARTS
elastic-operator-0            1/1     Running   4 (12h ago)
elasticsearch-es-default-0    1/1     Running   0
kibana-kb-868977bf88-skvjw    1/1     Running   0
```

5. Expose the Kibana service. The default deployment does not create an Ingress object to expose the Kibana service. Use the following command to create an Ingress object. The following example requires that the environment variable "DOMAIN" is configured.

```
cat <<EOF | kubectl apply -n logging -f -
apiVersion: networking.k8s.io/v1
kind: Ingress
metadata:
name: kibana
namespace: logging
annotations:
nginx.ingress.kubernetes.io/backend-protocol: "HTTPS"
spec:
ingressClassName: nginx
rules:
- host: kibana.${DOMAIN}
 http:
   paths:
     - path: /
       pathType: Prefix
       backend:
         service:
           name: kibana-kb-http
           port:
             number: 5601
tls:
- hosts:
 - kibana.${DOMAIN}
```

```
  secretName: logging-general-tls
EOF
```

6. Connect to Kibana.
   a. Ensure that the Kibana FQDN defined in the ingress object is registered along with the ingress IP in your DNS.
   b. From your browser, go to the Kibana URL. For example, https://kibana.${DOMAIN}/
   c. If you created a Kibana user as specified above, use it to log in to Kibana.
   d. Otherwise, log in using the default user: ***elastic*** with the password that can be obtained with the following command:

```
kubectl get secret -n logging elasticsearch-es-elastic-user -o=jsonpath='{.data.elastic}' | base64 --
decode; echo
```

Publishing Kibana Service IP

Perform these steps to ensure that the FQDN of the Kibana service is resolvable to the Ingress IP Address. This could be done by adding its FQDN and its Ingress IP Address to your Cloud DNS or your local DNS.

1. The FQDNs of the Kibana service are:
   – Kibana.<DOMAIN>

   NOTE
   Replace the <DOMAIN>, with the name of the domain as mentioned in the environment section.
2. Use the following command to get the Ingress IP Address:

```
kubectl get ingress -n <NAMESPACE>
```

   NOTE
   If you are using a BareMetal cluster that is fronted by HAPROXY, then this IP Address would be of the machine running HAPROXY. Otherwise, the IP Address is the external IP Address of your Ingress service as returned by the following command:

```
kubectl get svc -n ingress ingress-nginx-controller
```

3. Update the DNS with the preceding host name and IP Address. If you are unable to update the DNS, and want to access the services from your local machine, add the following line to your "**/etc/host**" file:

```
<ingress-ip> kibana.<DOMAIN>
```

   NOTE

   - Replace the <DOMAIN>, with the name of the domain as mentioned in the environment section.
   - Replace the <ingress-ip> with the IP Address that you retrieved in the previous step.

Setting up Data Retention Policy in Elastic Search

Setting-Up Data Retention Policy in Elastic Search

This topic outlines the process of setting up a data retention policy in Elasticsearch to manage log indexes and prevent disk space issues. It covers creating lifecycle policies and index templates for different log types (ssp-audit, ssp-log, ssp-tp-log) to ensure automated cleanup and efficient storage.

The IDSP enclave deployment instructions and the IDSP infra deployment steps provide examples of configuring fluent-bit to use elastic search as a log storage repository. Without proper maintenance of these indexes, the system can run out of disk space which would cause it to fail and not start. To prevent this, a lifecycle policy has to be defined in elastic

which would take care of data retention and would clean up these indexes. The log retention policy that is defined in this section is configured to leave logs in a "hot" state (readily available and indexed for fast search) for two days before being deleted.

Defining log retention in Elastic Search requires the creation of two objects (_ilm/policy and _index_template) per log type. Notice that the following example creates a retention policy for 3 types of logs, ssp-audit (with a retention policy of 30 days), ssp-log (with a retention policy of 10 days), and ssp-tp-log (third-party log - with a retention policy of 7 days). These values can be adjusted as needed.

1. Create a Lifecycle Policy:

   NOTE
   The lifecycle policy that is created in this example is shown for all the three types of logs; ssp_audit, ssp_log, and ssp_tp_log.

```
kubectl exec -n logging elasticsearch-es-default-0 -c elasticsearch -- curl --insecure -u "elastic:
$(kubectl get secret -n logging elasticsearch-es-elastic-user -o=jsonpath='{.data.elastic}' | base64 --
decode; echo)" -s -XPUT \
 "https://elasticsearch-es-http.logging.svc:9200/_ilm/policy/ssp_audit_lifecycle_policy" \
 -H 'Content-Type: application/json' \
 -d '{
"policy": {
"phases": {
 "hot": {
   "min_age": "0ms",
   "actions": {
     "set_priority": {
       "priority": 100
     },
     "rollover": {
       "max_age": "1d",
       "max_primary_shard_size": "50gb"
     }
   }
 },
 "delete": {
   "min_age": "30d",
   "actions": {
     "delete": {
       "delete_searchable_snapshot": true
     }
   }
 }
}
}
}'

kubectl exec -n logging elasticsearch-es-default-0 -c elasticsearch -- curl --insecure -u "elastic:
$(kubectl get secret -n logging elasticsearch-es-elastic-user -o=jsonpath='{.data.elastic}' | base64 --
decode; echo)" -s -XPUT \
 "https://elasticsearch-es-http.logging.svc:9200/_ilm/policy/ssp_log_lifecycle_policy" \
 -H 'Content-Type: application/json' \
 -d '{
"policy": {
"phases": {
 "hot": {
```

```
    "min_age": "0ms",
    "actions": {
      "set_priority": {
        "priority": 100
      },
      "rollover": {
        "max_age": "1d",
        "max_primary_shard_size": "50gb"
      }
    }
  },
  "delete": {
    "min_age": "10d",
    "actions": {
      "delete": {
        "delete_searchable_snapshot": true
      }
    }
  }
}
}
}'

kubectl exec -n logging elasticsearch-es-default-0 -c elasticsearch -- curl --insecure -u "elastic:
$(kubectl get secret -n logging elasticsearch-es-elastic-user -o=jsonpath='{.data.elastic}' | base64 --
decode; echo)" -s -XPUT \
 "https://elasticsearch-es-http.logging.svc:9200/_ilm/policy/ssp_tp_log_lifecycle_policy" \
 -H 'Content-Type: application/json' \
 -d '{
"policy": {
"phases": {
 "hot": {
   "min_age": "0ms",
   "actions": {
     "set_priority": {
       "priority": 100
     },
     "rollover": {
       "max_age": "1d",
       "max_primary_shard_size": "50gb"
     }
   }
 },
 "delete": {
   "min_age": "7d",
   "actions": {
     "delete": {
       "delete_searchable_snapshot": true
     }
   }
 }
}
}
```

```
}'
```

2. Create an Index Template that associates the Lifecycle Policy with the index:

   NOTE
   The Index Template created in this step is shown for all the three types of logs; ssp_audit, ssp_log, and ssp_tp_log.

```
kubectl exec -n logging elasticsearch-es-default-0 -c elasticsearch -- curl --insecure -u"elastic:
$(kubectl get secret -n logging elasticsearch-es-elastic-user -o=jsonpath='{.data.elastic}' | base64 --
decode; echo)" \
-s -XPUT "https://elasticsearch-es-http.logging.svc:9200/_index_template/ssp_audit" \
-H 'Content-Type: application/json' \
-d '{
"template": {
"settings": {
  "index": {
    "lifecycle": {
      "name": "ssp_audit_lifecycle_policy",
      "rollover_alias": "ssp_audit_alias"
    }
  }
},
"aliases": {
  "ssp_audit_alias": {
    "is_write_index": true
  }
}
},
"index_patterns": [
"ssp_audit*"
],
"composed_of": []
}'

kubectl exec -n logging elasticsearch-es-default-0 -c elasticsearch -- curl --insecure -u"elastic:
$(kubectl get secret -n logging elasticsearch-es-elastic-user -o=jsonpath='{.data.elastic}' | base64 --
decode; echo)" \
-s -XPUT "https://elasticsearch-es-http.logging.svc:9200/_index_template/ssp_log" \
-H 'Content-Type: application/json' \
-d '{
"template": {
 "settings": {
   "index": {
     "lifecycle": {
       "name": "ssp_log_lifecycle_policy",
       "rollover_alias": "ssp_log_alias"
     }
   }
 },
 "aliases": {
   "ssp_log_alias": {
     "is_write_index": true
   }
 }
```

```
},
"index_patterns": [
 "ssp_log*"
],
"composed_of": []
}'

kubectl exec -n logging elasticsearch-es-default-0 -c elasticsearch -- curl --insecure -u"elastic:
$(kubectl get secret -n logging elasticsearch-es-elastic-user -o=jsonpath='{.data.elastic}' | base64 --
decode; echo)" \
-s -XPUT "https://elasticsearch-es-http.logging.svc:9200/_index_template/ssp_tp_log" \
-H 'Content-Type: application/json' \
-d '{
"template": {
  "settings": {
    "index": {
      "lifecycle": {
        "name": "ssp_tp_log_lifecycle_policy",
        "rollover_alias": "ssp_tp_log_alias"
      }
    }
  },
  "aliases": {
    "ssp_tp_log_alias": {
      "is_write_index": true
    }
  }
},
"index_patterns": [
  "ssp_tp_log*"
],
"composed_of": []
}'
```

3. Create an empty initial (writable) index with the pattern: <ssp_audit-messaegs-{now/d}-000001>

```
kubectl exec -n logging elasticsearch-es-default-0 -c elasticsearch -- curl --insecure -u"elastic:
$(kubectl get secret -n logging elasticsearch-es-elastic-user -o=jsonpath='{.data.elastic}' | base64 --
decode; echo)" \
-s -XPUT "https://elasticsearch-es-http.logging.svc:9200/%3Cssp_audit-messaegs-%7Bnow%2Fd%7D-000001%3E" \
-H 'Content-Type: application/json' \
-d '{}'

kubectl exec -n logging elasticsearch-es-default-0 -c elasticsearch -- curl --insecure -u"elastic:
$(kubectl get secret -n logging elasticsearch-es-elastic-user -o=jsonpath='{.data.elastic}' | base64 --
decode; echo)" \
-s -XPUT "https://elasticsearch-es-http.logging.svc:9200/%3Cssp_log-messaegs-%7Bnow%2Fd%7D-000001%3E" \
-H 'Content-Type: application/json' \
-d '{}'

kubectl exec -n logging elasticsearch-es-default-0 -c elasticsearch -- curl --insecure -u"elastic:
$(kubectl get secret -n logging elasticsearch-es-elastic-user -o=jsonpath='{.data.elastic}' | base64 --
decode; echo)" \
```

```
-s -XPUT "https://elasticsearch-es-http.logging.svc:9200/%3Cssp_tp_log-messaegs-%7Bnow%2Fd%7D-000001%3E" \
-H 'Content-Type: application/json' \
-d '{}'
```

4. Elastic Search requires the creation of a new index to pick the new Index-Template. To retain the old logs, configure Fluent Bit to append the date to the index name. If you have created Kibana's dataview using the <index_name>* pattern, it picks both old and new indexes for log viewing. After about three weeks, manual deletion of the old indexes is required using the Kibana Index Management section. The following example shows the fluent-bit configuration's output:

```
[OUTPUT]
Name  es
Match *
Host  elasticsearch_host
Port  9200
Index ssp_audit_alias
```

Deploying Prometheus

Includes links to deploy Prometheus and Grafana in OpenShift and in Non-Openshift Clusters.

Symantec Identity Security Platform services expose performance monitoring data in a Prometheus metrics format. The endpoint exposing the Prometheus metrics is indicated using the IDSP service's label. If you have a Prometheus Operator deployed in your cluster, IDSP creates the proper serviceMonitor object to communicate this information to Prometheus.

If you plan to use another tool to scrape the Prometheus endpoints exposed by IDSP services, skip the deployment steps, and refer to the following information:

- Every service with the label `ssp-prometheus-metrics=actuator` exposes the endpoint `/actuator/prometheus` over TLS (port-443, HTTPS).
- Every service with the label `ssp-prometheus-metrics=metrics` exposes the endpoint `/metrics` over TLS (port-443, HTTPS).

Otherwise, follow the steps to deploy/configure Prometheus and Grafana outlined based on your cluster type.

See the following links based on your cluster requirement.

- Deploying Prometheus in Non-Openshift Cluster
- Deploying Prometheus in Openshift Cluster

Deploying Prometheus and Grafana in a Non-Openshift Cluster

Learn the steps to deploy Prometheus, AlertManager, and Grafana in Symantec Identity Security Platform using a Non-OpenShift Cluster to view performance data in Prometheus metrics format.

This topic includes the following sections:

- Deploying Prometheus
- Deploying Grafana
- Publishing the Grafana Service IP

> **NOTE**
> Prometheus requires a persistent volume to store its time series database containing metrics data. ***Refer to the official documentation and best practices provided by*** **Prometheus** for guidance on persistent volume usage.

Deploying Prometheus

Follow these steps to deploy Prometheus in a Non-OpenShift Cluster:

1. Create a monitoring namespace.
   ```
   kubectl create ns monitoring
   ```
2. Load the bitnami charts repository.

   NOTE

   - Please be aware that as of August 28th, 2025, Bitnami is archiving its OCI registry of charts and images on Docker Hub. Most older or versioned tags and non-hardened images are being migrated to the Bitnami Legacy repository (docker.io/bitnamilegacy) and will no longer receive updates. Refer to Bitnami official documentation for more information.
   - Based on these changes, the deployment command in step 3 (iii) has been updated.

   ```
   helm repo add bitnami https://charts.bitnami.com/bitnami
   helm repo update
   ```
3. Deploy Prometheus Operator to set up Prometheus, AlertManager, and Grafana.
   a. Deploy Prometheus under the monitoring namespace.
      a. If you are required to authenticate to your container-registry to pull images, then create a Kubernetes secret of type docker-registry as follows:
         ```
         kubectl create secret docker-registry <registry-secret-name> -n monitoring \
         --docker-server="https://index.docker.io/v2/" \
         --docker-username="<dockerhub-username>" \
         --docker-password="<dockerhub-password>" \
         --docker-email="<your-email-address>"
         ```
         Next, add this secret by adding the following parameters to the helm install command that is used to install the Prometheus operator.
         ```
         --set global.imagePullSecrets[0].name="<registry-secret-name>"
         --set grafana.image.pullSecrets[0]="<registry-secret-name>"
         ```
      b. When enabling TLS, alert manager uses a TLS secret by the name <alertmanager.ingress.hostname>**-tls,** if this secret is not found, the ingress controller uses its own self-signed certificate. You can also have the chart create this secret by passing the certificates using ***alertmanager.ingress.secrets.certificate*** and ***alertmanager.ingress.secrets.key***, or use ***alertmanager.ingress.selfSigned=true*** to have helm generate new self-signed certificates. For example,
         ```
         kubectl create secret tls alertmanager.${DOMAIN}-tls --cert ${CERTFILE} --key ${KEYFILE} -n
          monitoring
         ```
      c. Deploy the prometheus-operator under the monitoring namespace.

         ```
         helm install prometheus-operator bitnami/kube-prometheus -n monitoring \
         --set alertmanager.ingress.enabled=true \
         --set alertmanager.ingress.ingressClassName=nginx \
         --set alertmanager.ingress.hostname=alertmanager.${DOMAIN} \
         --set alertmanager.ingress.tls=true \
         --set prometheus.persistence.enabled=true \
         --set alertmanager.persistence.enabled=true \
         --set prometheus.scrapeInterval=1m \
         --set prometheus.evaluationInterval=1m \
         --set blackboxExporter.image.repository=bitnamilegacy/blackbox-exporter \
         --set kube-state-metrics.image.registry=bitnamilegacy \
         --set kube-state-metrics.image.repository=kube-state-metrics \
         --set operator.image.repository=bitnamilegacy/prometheus-operator \
         --set prometheus.image.repository=bitnamilegacy/prometheus \
         ```

```
--set alertmanager.image.repository=bitnamilegacy/alertmanager \
--set node-exporter.image.registry=bitnamilegacy \
--set node-exporter.image.repository=node-exporter \
--set global.security.allowInsecureImages=true \
--version=11.3.10
```

d. Verify that all persistent volume claims are bound for this namespace and that the pods are ready.

```
kubectl get pvc -n monitoring
kubectl get pods -n monitoring
```

e. Post the deployment of the Prometheus Operator, configure the resource allocation for your Prometheus Operator deployment by selecting an environment size (Small, Medium, Large, or Custom), based on which the CPU and memory limits are applied using a kubectl patch..

```
"Select your environment size:"
 "  1) Small    (< 100 targets)   - 1Gi/2Gi memory"
 "  2) Medium   (100-500 targets) - 2Gi/4Gi memory  [RECOMMENDED]"
 "  3) Large    (500+ targets)    - 4Gi/8Gi memory"
 "  4) Custom   (specify your own values)"
 ""
SIZE_CHOICE=2

case $SIZE_CHOICE in
    1)
        CPU_REQ="250m"
        CPU_LIMIT="1000m"
        MEM_REQ="1Gi"
        MEM_LIMIT="2Gi"
        ;;
    2)
        CPU_REQ="500m"
        CPU_LIMIT="2000m"
        MEM_REQ="2Gi"
        MEM_LIMIT="4Gi"
        ;;
    3)
        CPU_REQ="1000m"
        CPU_LIMIT="4000m"
        MEM_REQ="4Gi"
        MEM_LIMIT="8Gi"
        ;;

    4) Choose your own CPU and MEM REQ and LIMIT.
```

Apply this Kubectl patch:

```
kubectl patch prometheus $PROMETHEUS_NAME -n $NAMESPACE --type=merge -p "
{
  \"spec\": {
    \"resources\": {
      \"requests\": {
        \"cpu\": \"$CPU_REQ\",
        \"ephemeral-storage\": \"8Gi\",
        \"memory\": \"$MEM_REQ\"
      },
      \"limits\": {
        \"cpu\": \"$CPU_LIMIT\",
```

```
            \"ephemeral-storage\": \"8Gi\",
            \"memory\": \"$MEM_LIMIT\"
          }
        }
      }
    }"
```

Deploying Grafana

1. Deploy Grafana.
   a. If you want to add your own trusted certificate signed by the Certificate Authority (CA), run this command:
   ```
   kubectl create secret tls monitoring-general-tls \
   --cert "${CERTFILE}" \
   --key "${KEYFILE}" -n monitoring
   ```
   If you do not have a certificate, you can skip this step as the Monitoring ingress uses the self-signed certificate.
   b. To change the default password, update the value of the ***grafana.config.security.admin_password*** parameter in the grafana-operator helm install command.
   c. Deploy the Grafana operator using the following helm command. The Grafana Operator chart creates and deploys a Grafana instance.
   ```
   helm install grafana-operator bitnami/grafana-operator -n monitoring \
   --set operator.containerSecurityContext.readOnlyRootFilesystem=true \
   --set operator.image.repository=bitnamilegacy/grafana-operator \
   --set grafana.image.repository=bitnamilegacy/grafana \
   --set grafana.config.security.admin_password=prom-operator \
   --set grafana.ingress.enabled=true \
   --set grafana.ingress.ingressClassName=nginx \
   --set grafana.ingress.host=grafana.${DOMAIN} \
   --set grafana.ingress.tls=true \
   --set grafana.ingress.tlsSecret=monitoring-general-tls \
   --set-string grafana.labels.dashboards="ssp-grafana" \
   --version=4.9.37
   ```

2. Configure Grafana to use the local Prometheus by creating a Grafana DataSource object.
   Run this command to create a Grafana datasource object on the native cloud providers.
   ```
   cat <<EOF | kubectl apply -n monitoring -f -
   apiVersion: grafana.integreatly.org/v1beta1
   kind: GrafanaDatasource
   metadata:
     name: prometheus-datasource
   spec:
     datasource:
       name: Prometheus
       type: prometheus
       access: proxy
       editable: true
       isDefault: true
       url: 'http://prometheus-operator-kube-p-prometheus.monitoring.svc:9090'
       jsonData:
         timeInterval: 5s
     instanceSelector:
       matchLabels:
         dashboards: "ssp-grafana"
   ```

```
EOF
```

a. To install the IDSP dashboard through the Grafana operator, run this command:

```
cat <<EOF | kubectl apply -n monitoring -f -
apiVersion: grafana.integreatly.org/v1beta1
kind: GrafanaDashboard
metadata:
  name: ssp-monitoring-dashboard
spec:
  datasources:
    inputName: "DS_PROMETHEUS"
    datasourceName: "Prometheus"
  instanceSelector:
    matchLabels:
      dashboards: "ssp-grafana"
  grafanaCom:
    id: 25306
EOF
```

3. Delete the existing Grafana Pod so that the monitoring namespace configuration is read in.

```
kubectl delete pod -l app.kubernetes.io/name=grafana-operator -n monitoring
```

4. Verify your Prometheus/Grafana deployment:
   From your browser, you can now access Grafana using the Ingress URL that you have configured. For example: https://grafana.openshift.clusters.demo.dev-ssp.com
   – Default user: admin
   – Default Password: prom-operator

Publishing Grafana Service IP

Perform these steps to ensure that the FQDN of the Grafana service is resolvable to the Ingress IP Address. This could be done by adding its FQDN and its Ingress IP Address to your Cloud DNS or your local DNS.

1. The FQDNs of the Grafana service are:
   – Grafana.<DOMAIN>

   NOTE
   Replace the <DOMAIN>, with the name of the domain as mentioned in the environment section.
2. The Ingress IP Address can be retrieved from the "Address" column of the Grafana Ingress object when using the following command:

```
kubectl get ingress -n monitoring
```

3. Update the DNS with the preceding host names and IP Address. If you are unable to update the DNS, and want to access the services from your local machine, add the following line to your "**/etc/host**" file:

```
<ingress-ip> grafana.<DOMAIN>
```

   NOTE

   - Replace the <DOMAIN>, with the name of the domain as mentioned in the environment section.
   - Replace the <ingress-ip> with the IP Address that you retrieved in the previous step.

Next Step

Deploying IDSP

Deploying Prometheus and Grafana in an OpenShift Cluster

Learn the steps to deploy Prometheus and Grafana in Symantec Identity Security Platform using an OpenShift Cluster to view performance data in Prometheus metrics format.

This topic includes the following sections:

- Deploying Prometheus
- Deploying Grafana and AlertManager Service IP
- Publishing the Grafana Service IP

> **NOTE**
> In an OpenShift cluster, both Prometheus Operator and Grafana may require persistent volumes, depending on the specific deployment and usage requirements. While both Prometheus Operator and Grafana can function without persistent volumes, using them can enhance data reliability and availability. ***Refer to the official documentation and best practices provided by OpenShift and the Prometheus, and Grafana tools*** for guidance on persistent volume usage in your specific deployment scenario.

Deploying Prometheus

Follow these steps to deploy Prometheus in an OpenShift Cluster:

1. Deploy Prometheus Operator to set up Prometheus (including AlertManager), and Grafana on OpenShift.
   a. Given that OpenShift already includes a Prometheus operator deployment, there is no requirement to perform an additional deployment. However, it is necessary to grant the required permissions to Prometheus to enable it to scrape metrics from the IDSP (SSP) namespace.
   b. Enable Prometheus to Scrape IDSP (SSP) Services' Information:

      > **NOTE**
      > Ensure that the environment variable, NAMESPACE is set to the name of the Kubernetes namespace where IDSP (SSP) was deployed. If IDSP is not deployed yet, you can perform this step anytime after the IDSP (SSP) namespace is created.

```
kubectl label ns ${NAMESPACE} openshift.io/cluster-monitoring="true"

cat <<EOF | kubectl apply -n ${NAMESPACE} -f -
apiVersion: rbac.authorization.k8s.io/v1
kind: Role
metadata:
  name: prometheus-k8s
rules:
- apiGroups:
  - ""
  resources:
  - services
  - endpoints
  - pods
  verbs:
  - get
  - list
  - watch

---

apiVersion: rbac.authorization.k8s.io/v1
kind: RoleBinding
```

```
  metadata:
    name: prometheus-k8s
  roleRef:
    apiGroup: rbac.authorization.k8s.io
    kind: Role
    name: prometheus-k8s
  subjects:
  - kind: ServiceAccount
    name: prometheus-k8s
    namespace: openshift-monitoring
  EOF
```

c. Perform the following steps to ensure that OpenShift's "monitoring for user-defined projects" is enabled:
   a. Edit the cluster-monitoring-config configmap.
      ```
      kubectl -n openshift-monitoring edit configmap cluster-monitoring-config
      ```
   b. Enable enableUserWorkload by adding enableUserWorkload: true to the config.yaml. For example:
      ```
      data:
       config.yaml: |
          enableUserWorkload: true
      ```
      NOTE
      If you get an error "Error from server (NotFound): configmaps "cluster-monitoring-config" not found" (configmap not found), create ConfigMap using the following command:
      ```
      cat <<EOF | kubectl create -f -
        apiVersion: v1
        kind: ConfigMap
        metadata:
          name: cluster-monitoring-config
          namespace: openshift-monitoring
        data:
          config.yaml: |
            enableUserWorkload: true
      EOF
      ```
   Next step is to deploy Grafana.

Deploying Grafana and AlertManager Service IP

1. Create a monitoring namespace.
   ```
   kubectl create ns monitoring
   ```
2. Load the bitnami charts repository.
   ```
   helm repo add bitnami https://charts.bitnami.com/bitnami
   helm repo update
   ```
3. Deploy Grafana.
   a. If you want to add your own trusted certificate signed by the Certificate Authority (CA), run this command:
      ```
      kubectl create secret tls monitoring-general-tls \
      --cert "${CERTFILE}" \
      --key "${KEYFILE}" -n monitoring
      ```
      If you do not have a certificate, you can skip this step as the Monitoring ingress uses the self-signed certificate.
   b. To change the default password, update the value of the ***grafana.config.security.admin_password*** parameter in the grafana-operator helm install command.
   c. Deploy the Grafana operator. Note that the Grafana Operator chart will also create and deploy a grafana instance.
      a. Set the following environment variables.

```
read -d '/' -r GRAFANA_UID < <(kubectl get ns monitoring -o
 jsonpath='{.metadata.annotations.openshift\.io/sa\.scc\.uid-range}') || GRAFANA_UID=1000650000
read -d '/' -r GRAFANA_GID < <(kubectl get ns monitoring -o
 jsonpath='{.metadata.annotations.openshift\.io/sa\.scc\.supplemental-groups}') ||
 GRAFANA_GID=1000650000

export GRAFANA_FSGROUP=${GRAFANA_GID}
```

b. Using the following command, deploy Grafana:

```
helm install grafana-operator bitnami/grafana-operator -n monitoring \
--set operator.containerSecurityContext.readOnlyRootFilesystem=true \
--set grafana.image.repository=bitnami/grafana \
--set grafana.config.security.admin_password=prom-operator \
--set grafana.ingress.enabled=true \
--set grafana.ingress.ingressClassName=nginx \
--set grafana.ingress.host=grafana.${DOMAIN} \
--set grafana.ingress.tls=true \
--set grafana.ingress.tlsSecret=monitoring-general-tls \
--set operator.containerSecurityContext.runAsUser=${GRAFANA_UID} \
--set operator.containerSecurityContext.runAsGroup=${GRAFANA_GID} \
--set operator.podSecurityContext.fsGroup=${GRAFANA_FSGROUP} \
--set grafana.containerSecurityContext.runAsUser=${GRAFANA_UID} \
--set grafana.podSecurityContext.runAsUser=${GRAFANA_UID} \
--set grafana.podSecurityContext.fsGroup=${GRAFANA_FSGROUP} \
--version=2.7.3
```

4. Configuring Grafana to use the local Prometheus by creating a Grafana DataSource object.
   Follow these instructions to create a Grafana datasource object on OpenShift:
   a. **Use this command for OpenShift version 4.16**
      Get the token from the openshift-user-workload-monitoring secret (see obtain the OpenShift's "prometheus-user-workload-token" bearer token from the "openshift-user-workload-monitoring" namespace secret)

```
SECRET_NAME=`kubectl get secret -n openshift-user-workload-monitoring | grep  prometheus-user-workload-
token | head -n 1 | awk '{print $1 }'`
TOKEN=`echo $(kubectl get secret $SECRET_NAME -n openshift-user-workload-monitoring -o json | jq -r
 '.data.token') | base64 -d`
```

      Use this command for OpenShift version 4.17 and higher as the secret will no longer be available
      You need a user (or a service account) in your cluster which has the "cluster-monitoring-view" cluster role granted. Acquire a bearer token for that user. Login as the user and use the following command to generate a bearer token for the user. (This is a short-lived token which needs to be refreshed periodically) :

```
TOKEN=$(oc whoami -t)
```

   b. Create the Grafana datasource object.

```
cat <<EOF | kubectl apply -n monitoring -f -
  apiVersion: integreatly.org/v1alpha1
  kind: GrafanaDataSource
  metadata:
    name: grafana-datasource
  spec:
    name: grafana-datasource.yaml
    datasources:
      - name: Prometheus
        type: prometheus
        version: 1
        access: proxy
        editable: true
```

```
            isDefault: true
            url: 'https://prometheus-k8s.openshift-monitoring.svc:9091'
            jsonData:
              timeInterval: 5s
              tlsSkipVerify: true
              httpHeaderName1: 'Authorization'
            secureJsonData:
              httpHeaderValue1: "Bearer ${TOKEN}"
    EOF
```

c. Delete the existing Grafana Pod so that the monitoring namespace configuration is read in.

```
kubectl delete pod -l app=grafana -n monitoring
```

5. Expose the Grafana service.
   When running on OpenShift, the default deployment creates a Route object. If you want to expose Grafana through your nginx ingress controller, create an ingress object use the following command:

```
cat <<EOF | kubectl apply -n monitoring -f -
apiVersion: networking.k8s.io/v1
kind: Ingress
metadata:
  name: grafana
  namespace: monitoring
spec:
  ingressClassName: nginx
  rules:
    - host: grafana.${DOMAIN}
      http:
        paths:
          - path: /
            pathType: Prefix
            backend:
              service:
                name: grafana-service
                port:
                  number: 3000
  tls:
    - hosts:
      - grafana.${DOMAIN}
      secretName:  monitoring-general-tls
EOF
```

6. Verify your Prometheus/Grafana deployment:
   From your browser, you can now access Grafana using the Ingress URL that you have configured. For example: https://grafana.openshift.clusters.demo.dev-ssp.com
   – Default user: admin
   – Default Password: prom-operator

Publishing the Grafana Service IP

Perform these steps to ensure that the FQDN of the Grafana service is resolvable to the Ingress IP Address. This could be done by adding its FQDN and its Ingress IP Address to your Cloud DNS or your local DNS.

1. The FQDNs of the Grafana service is:
   – grafana.<DOMAIN>

NOTE
Replace the <DOMAIN>, with the name of the domain as mentioned in the environment section.

2. Exposing the Grafana Service:
   – If you choose to expose the Grafana Service using an ***NGINX Ingress Controller***, the Ingress IP Address can be retrieved from the "Address" column of the Grafana Ingress object when using the following command:
   ```
   kubectl get ingress -n monitoring
   ```
   – If you choose to expose the Grafana Service using ***OpenShift Ingress Controller (using route)***, the IP Address is displayed under the "EXTERNAL IP" column of your OpenShift Ingress service as returned by the following command:
   ```
   kubectl get svc -n openshift-ingress
   ```
3. Update the DNS with the above host names and IP Address. If you are unable to update the DNS, and want to access the services from your local machine, add the following line to your "**/etc/host**" file:
   ```
   <openshift-ingress-ip> grafana.<DOMAIN>
   ```

   NOTE
   - Replace the <DOMAIN>, with the name of the domain as mentioned in the environment section.
   - Replace the <ingress-ip> with the IP Address that you retrieved in the previous step.

Next Step

Deploying IDSP

Deploying Symantec Identity Security Platform

Learn how to deploy Symantec Identity Security Platform solution on a Kubernetes environment.

This topic provides a streamlined deployment guide with the following sections:

- Understanding Deployment Modes
- Configuring the Environment Variables
- Configuring the Helm Repo
- Quick Deployment Summary
- Verifying the Deployment
- Retrieving Initial Security Credentials From Kubernetes Secrets
- Next Step - Configuring Administrative Access

Understanding the Deployment Modes

The IDSP offers two distinct modes of deployment to cater to different operational needs:

- **"custom" Mode (Default mode)**:
  – Provides flexibility to configure each service's pod count and allocate CPU and memory resources to suite your production environment's requirements. To learn about the IDSP deployment guidelines, see Sizing the Deployment.
  – You can override the default "values.yaml" file with your own specifications. If this file is provided, the deployment uses the custom values from this file.
  – If no override file is provided, the deployment uses the default values from the standard "values.yaml" file.
- **"demo" Mode**:

- Designed for Proof-of-Concept (POC) scenarios, allowing customers to test functionalities before committing to full-scale development environment deployments.
- In this mode, the pod count is fixed to 1 for each service.
- CPU and memory resources per pod are minimized, and database sizes are optimized, specifically for Proof-of-Concept (POC) environments.
  The following table shows how the resources are utilized optimally in this mode.

Table 32: Resources Table

Resources	CPU	Memory
limits	600m	2Gi
requests	400m	1Gi

- This mode should not be used for production environment.
- To deploy IDSP in demo mode, the following parameters must be passed along with the IDSP Helm deployment command:

```
--set ssp.deployment.size="demo" \
--set hazelcast-enterprise.cluster.memberCount=1
```

Configuring the Environment Variables

Once you installed the software that has been mentioned in the earlier section, you must set up your system environment from where you are managing your cluster.

These commands can be executed from your on-premise work station or cloud shell using bash shell:

1. Configure environment variables to point to your DNS domain.

```
export PREFIX="<PREFIX>"
export DOMAIN="<DOMAIN>"
export SSP_FQDN="${PREFIX}.${DOMAIN}"
```

   For **Ingress Nginx** deployment, configure the following environment variable:

```
export SSP_MGMT_FQDN="mgmt-${SSP_FQDN}"
```

   NOTE
   The mgmt-${SSP_FQDN} is the default FQDN. This could be overridden by specifying the management hostname in the parameter, "ssp.ingress.mgmt.host".

   For **OpenShift Routes** deployment, configure the following environment variable:

```
export SSP_MGMT_FQDN="system.${SSP_FQDN}"
```

   NOTE
   For example,

   - <PREFIX> can be replaced by "myssp" and,
   - <DOMAIN> can be replaced by "myiam.example.com"

   Resulting in FQDN for IDSP as - "myssp.myiam.example.com". This FQDN is used to access the IDSP service.

2. Configure the environment variables to point to the HELM release name and Kubernetes namespace. These names enable decoupling between deployments.

```
export RELEASENAME="<RELEASENAME>"
export NAMESPACE="<NAMESPACE>"
```

   Where,

- The ***Release Name*** is a Lifecycle Management (LCM) construct, representing a versionable instance of a deployment with specific configuration that can be upgraded, rolled back, and so on.
- The ***Namespace*** is a Kubernetes construct representing an operational partition aggregating specific permissions, seclists, network rules, quotas, and so on.
- Both names can be given the same value such as "ssp-dev", "ssp-prod".

3. Set the environment variables to indicate the HELM REPO and HELM REPO URL for IDSP helm charts deployment. For example,

```
export HELM_REPO='ssp_helm_charts'
export HELM_REPO_URL=https://ssp_helm_charts.storage.googleapis.com
```

4. If you have a wildcard certificate from a trusted Certificate Authority (CA), configure the environment variables to point to the key and cert files.

```
export KEYFILE="<keyfile>"
export CERTFILE="<certfile>"
```

Configuring Helm Chart Repo

These set of commands use the environment variable values created in the previous section.

1. Load the IDSP pods with the given release name and namespace (this may take several minutes).
   a. Create the IDSP namespace.
      ```
      kubectl create ns ${NAMESPACE}
      ```
   b. Configure the IDSP Helm chart repo.
      ```
      helm repo add "${HELM_REPO}" "${HELM_REPO_URL}"
      ```
   c. Get the latest Helm chart updates.
      ```
      helm repo update
      ```
   d. Check for all the available versions of IDSP Helm charts.
      ```
      helm search repo ssp_helm_charts --versions
      ```
      NOTE
      This command displays all the charts available in the repository. The first (latest) version of the chart is deployed by default unless a particular version is specified using --version=<*chart-version*>

Quick Deployment Summary

For a basic deployment with default settings, follow these essential steps:

1. **Deploy Infra Chart:**
   ```
   helm install "infra-${RELEASENAME}" "${HELM_REPO}/ssp-infra" -n "${NAMESPACE}" --set
    sspReleaseName="${RELEASENAME}"
   ```
2. **Wait for Database Creation:**
   ```
   kubectl wait jobs.batch --namespace "${NAMESPACE}" --selector "app.kubernetes.io/name=ssp-infra-create-db-
   job" --for 'condition=complete' --timeout '5m'
   ```
3. **Deploy SSP Chart:**
   ```
   helm install "${RELEASENAME}" -n "${NAMESPACE}" "${HELM_REPO}/ssp" --set ssp.ingress.host="${SSP_FQDN}" --
   timeout=120m
   ```
4. **Verify Deployment:**
   ```
   kubectl get pods -n "${NAMESPACE}"
   ```

For advanced configurations, refer to the detailed configuration guides below.

Additional Configuration Topics

For advanced deployment scenarios and customizations, refer to these detailed configuration topics:

- **IDSP Infra Chart Configuration** - Detailed configuration options for the Infra chart including database, fluent-bit, and OpenShift settings
- **IDSP Main Chart Configuration** - Comprehensive configuration options for the main IDSP chart including database connectivity, ingress, and feature flags
- **IDSP OpenShift Configuration** - OpenShift-specific configurations and deployment examples
- **IDSP SSP-Data Chart Deployment** - Deploying the SSP-Data chart to load network risk data

Verifying the deployment

To verify that your deployment has been successful, check that all the IDSP pods are in the running and ready state. This may take a few minutes.

- Use the following command to check the status of the pods:
  ```
  kubectl get pods -n "${NAMESPACE}"
  ```
- Use the following command to verify the status of the pods and services:
  ```
  kubectl get pods,svc,ing -n "${NAMESPACE}" -o wide
  ```
- Use the following command to view events of the deployment:
  ```
  kubectl get events -n "${NAMESPACE}"
  ```

NOTE

- The output shows a column named READY with values such as 0/1, 1/1, 1/2, 2/2. The number on the right shows the total number of containers in the pod, while the number on the left shows the number of containers in the pod that are considered ready. The pod is considered ready when the number of ready containers equals to the total number of containers in the pod.
- Unlike the pods, it is expected that upon completion, the *jobs* have their status changed to Completed and not show as ready.

The following image shows how a successful deployment would look when all the pods are *Ready* (1/1) and in *Running* state:

```
NAME                                                              READY   STATUS    RESTARTS   AGE
ssp-hazelcast-0                                                   1/1     Running   0          39h
ssp428-infra-fluent-bit-dcmdj                                     1/1     Running   0          40h
ssp428-infra-fluent-bit-t74mw                                     1/1     Running   0          40h
ssp428-infra-fluent-bit-x58qw                                     1/1     Running   0          40h
ssp428-infra-fluent-bit-xvnck                                     1/1     Running   0          40h
ssp428-infra-ssp-infra-percona-xtradb-cluster-operator-5f7tjsxk   1/1     Running   0          40h
ssp428-ssp-admin-f9bb6bc9d-mldkv                                  1/1     Running   0          40h
ssp428-ssp-adminconsole-66477f6cfd-qbh2s                          1/1     Running   0          40h
ssp428-ssp-auth-mgr-586d76c9b4-99vws                              1/1     Running   0          40h
ssp428-ssp-azserver-84bc44589-z6qvn                               1/1     Running   0          40h
ssp428-ssp-db-metrics-exporter-5d6d85b466-hvm74                   1/1     Running   0          40h
ssp428-ssp-db-pxc-0                                               1/1     Running   0          39h
ssp428-ssp-factor-79ccb56865-s67kp                                1/1     Running   0          40h
ssp428-ssp-iarisk-6bd69c47c8-q7j4t                                2/2     Running   0          40h
ssp428-ssp-opa-6c4f6d8869-lg867                                   1/1     Running   0          40h
ssp428-ssp-signin-79598f4ddf-blq4q                                1/1     Running   0          40h
ssp428-ssp-swagger-69b97f978c-cr5tt                               1/1     Running   0          40h
```

To validate the deployment, run the following command which invokes the openId discovery API call and in addition requests IDSP to return the IP Address as identified by it:

```
curl --insecure https://"${SSP_FQDN}"/default/.well-known/openid-configuration?sspinfo=true
```

Ensure that the IDSP detects the real client IP. If the client is accessing IDSP through the Internet, this IP would be the IP from which the client accesses the Internet.
In the following example, the "xxx.xxx.xxx.xxx" represents the IP Address of the client as identified by IDSP.

```
curl -k https://${SSP_FQDN}/default/.well-known/openid-configuration?sspinfo=true
```

```
{
.
.
.
"clientIp" : "xxx.xxx.xxx.xxx",
"userIp" : "xxx.xxx.xxx.xxx"
}
```

Compare the IP address listed as clientIP in the output above with the IP address of the machine from which you ran the curl command. Notice that when connecting to IDSP through the Internet, the IP address should be the Public IP address that your machine is identified with while connecting to the Internet.

To find out what this IP is, use the following command:

```
$ curl https://ifconfig.me
```

NOTE
If the validation fails, make sure to restart the ingress pods. Due to specific SSL configurations in the Ingress objects, sometimes these settings may require a restart of the ingress pods.

```
kubectl rollout restart deployment ingress-nginx-controller -n ingress
```

NOTE

- Now you can deploy and integrate the Demo Application. Click here to navigate to the demo section.
- To know more about logs generated by the solution and enclave services, click here.

Retrieving Initial Security Credentials from Kubernetes secrets

The solution by default provisions a few system and tenant-level clients and an admin user to help you to get started with the solution's capabilities. To know more about these seeded default credentials, see Administrative Model.

Next Step

See Configuring Administrative Access

IDSP Infra Helm Chart Configuration

Configuring IDSP Infra helm chart parameters and options.

This topic provides detailed information about all configuration options available for the IDSP Infra helm chart deployment.

Overview

The IDSP Infra chart serves to deploy a demo database and deploy fluent-bit for streaming IDSP logs and audit messages. If your preference is to use an external database and forgo the deployment of fluent-bit for log streaming, you have the option to skip the infra chart deployment and proceed directly to the IDSP deployment.

Demo Database Configuration

The demo database is deployed by default. If you do not intend to use the demo database, use the following command:

```
--set db.enabled=false
```

Fluent-bit Configuration

The fluent-bit is deployed by default. If you do not intend to use the fluent-bit to stream IDSP logs into the log storage, use the following parameter:

```
--set fluent-bit.enabled=false
```

You must provide a new customConfig parameters section under the fluent-bit section in the ***IDSP infra chart values yaml*** file to configure where to stream the IDSP log and audit messages. To know more about it, see Logs and Security Audit Data section.

Using Private Image Registry

To deploy IDSP infra chart using images stored in your private image registry:

```
--set fluent-bit.image.repository=<PRIVATE_IMAGE_REGISTRY>/fluent/fluent-bit
```

For more information, see the Using Private Image Registry section.

If you are using the internal demo database with images stored in your private image registry, add these values to your values.yaml:

```
db:
  image:
    pxc:
      repository: <PRIVATE_IMAGE_REGISTRY>percona/percona-xtradb-cluster
      tag: 8.0.29-21.1
    operator:
      repository: <PRIVATE_IMAGE_REGISTRY>percona/percona-xtradb-cluster-operator
      tag: 1.12.0
    haproxy:
      repository: <PRIVATE_IMAGE_REGISTRY>percona/percona-xtradb-cluster-operator
      tag: 1.12.0-haproxy
    proxysql:
      repository: <PRIVATE_IMAGE_REGISTRY>percona/percona-xtradb-cluster-operator
      tag: 1.12.0-proxysql
    pmm:
      repository: <PRIVATE_IMAGE_REGISTRY>percona/pmm-client
      tag: 2.32.0
    backup:
      repository: <PRIVATE_IMAGE_REGISTRY>percona/percona-xtradb-cluster-operator
      tag: 1.12.0-pxc8.0-backup
    mysqld_exporter:
      repository: <PRIVATE_IMAGE_REGISTRY>prom/mysqld-exporter
      tag: v0.12.1
```

Using External Database

If you are using a customer database (external db mode), pass this parameter in the IDSP infra helm install command:

```
--set db.enabled=false
```

Container Runtime Configuration

If the container runtime is "containerd" or "cri-o", add this parameter in the IDSP infra helm install command. If the parser parameter is not specified, it defaults to "cri".

Possible values include "cri" or "docker".

To find out which container runtime is used in your cluster nodes, run:

```
kubectl get nodes -o wide
```

Then add the appropriate parameter:

```
--set sspfbService.parser=cri
```

Docker Registry Authentication

By default, IDSP Infra helm chart pulls images from the Docker Hub registry which requires authentication. Create a docker-registry secret to store the registry credentials:

```
kubectl create secret docker-registry ssp-infra-registrypullsecret -n ${NAMESPACE} \
  --docker-server="https://index.docker.io/v2/" \
  --docker-username="<dockerhub-username>" \
  --docker-password="<dockerhub-password>" \
  --docker-email="<your-email-address>"
```

Once the secret is created, specify the secret by adding these parameters to the IDSP infra helm chart deployment command:

```
--set global.registry.existingSecrets[0].name='ssp-infra-registrypullsecret' \
--set fluent-bit.imagePullSecrets[0].name="ssp-infra-registrypullsecret"
```

> **NOTE**
> If you decide to use your own private registry (recommended) and your registry requires authentication as well, you can use a similar command using your own docker server URL and credentials.

Ingress Nginx Logs Streaming

To stream the Ingress Nginx logs in third-party dashboards, such as Kibana dashboard, pass the following parameter:

```
--set sspfbService.ingressLogsIncluded=true
```

For more information, see the Observing Nginx Ingress Traffic section.

Custom Log Configuration

To stream the IDSP log and audit messages (ssp_log, ssp_audit, ssp_tp_log) to log storage systems available in your environment, pass this parameter:

```
-f customConfig_sspinfra.yaml
```

For more information, see the Logs and Security Audit Data section.

Infra Helm Chart Deployment Command

Deploy IDSP Infra helm chart using the following command, adding to it any additional parameters that you may need as indicated in the previous sections:

```
helm install "infra-${RELEASENAME}" "${HELM_REPO}/ssp-infra" -n "${NAMESPACE}" --set
 sspReleaseName="${RELEASENAME}"
```

> **NOTE**
> When you are using the out-of-the-box demo database, ensure that the database is completely created by **waiting** until the database creation job shows "**completed**" status before proceeding with the IDSP deployment. You can check the status of the database creation job by running this command:
>
> ```
> kubectl wait jobs.batch \
> --namespace "${NAMESPACE}" \
> --selector "app.kubernetes.io/name=ssp-infra-create-db-job" \
> --for 'condition=complete' \
> ```

```
--timeout '5m'
```

IDSP OpenShift Configuration

Learn how to deploying IDSP on OpenShift with specific configurations and requirements.

This topic provides detailed information about OpenShift-specific configurations required for IDSP deployment.

Overview

Deploying IDSP on OpenShift requires specific security context configurations and ingress settings. This topic covers all OpenShift-specific parameters and configurations.

OpenShift Environment Setup

Before deploying on OpenShift, set the following environment variables:

```
read -d '/' -r SSP_UID < <(kubectl get ns ${NAMESPACE} -o jsonpath='{.metadata.annotations.openshift\.io/sa
\.scc\.uid-range}')
read -d '/' -r SSP_GID < <(kubectl get ns ${NAMESPACE} -o jsonpath='{.metadata.annotations.openshift\.io/sa
\.scc\.supplemental-groups}')
export SSP_FSGROUP=${SSP_GID}
```

Infra Chart OpenShift Configuration

Security Context for Infra Chart:

Pass the following additional parameters in the IDSP infra helm install command:

```
--set global.securityContext.runAsUser=${SSP_UID} \
--set global.securityContext.runAsGroup=${SSP_GID} \
--set global.securityContext.fsGroup=${SSP_FSGROUP} \
--set fluent-bit.serviceAccount.create=true \
--set fluent-bit.openShift.enabled=true \
--set fluent-bit.openShift.securityContextConstraints.create=true \
#Note that --set fluent-bit.securityContext.privileged=true is required if using tail log db
```

See Additional Parameters to consider in OpenShift.

Prometheus Configuration:

Enable Prometheus to Scrape IDSP Service's Information. For more information, see Enabling Promethues in OpenShift.

```
kubectl label ns ${NAMESPACE} openshift.io/cluster-monitoring="true"

cat <<EOF | kubectl apply -n ${NAMESPACE} -f -
apiVersion: rbac.authorization.k8s.io/v1
kind: Role
metadata:
  name: prometheus-k8s
rules:
- apiGroups:
  - ""
  resources:
  - services
  - endpoints
  - pods
```

```
  verbs:
  - get
  - list
  - watch

---

apiVersion: rbac.authorization.k8s.io/v1
kind: RoleBinding
metadata:
  name: prometheus-k8s
roleRef:
  apiGroup: rbac.authorization.k8s.io
  kind: Role
  name: prometheus-k8s
subjects:
- kind: ServiceAccount
  name: prometheus-k8s
  namespace: openshift-monitoring
EOF
```

IDSP Chart OpenShift Configuration

Security Context for SSP Chart:

To deploy in OpenShift, pass the additional parameters in the helm chart install command:

```
--set ssp.global.securityContext.fsGroup=${SSP_FSGROUP} \
--set ssp.global.securityContext.runAsGroup=${SSP_GID} \
--set ssp.global.securityContext.runAsUser=${SSP_UID} \
--set hazelcast-enterprise.securityContext.fsGroup=${SSP_FSGROUP} \
--set hazelcast-enterprise.securityContext.runAsGroup=${SSP_GID} \
--set hazelcast-enterprise.securityContext.runAsUser=${SSP_UID}
```

See Ingress in OpenShift for more information.

Ingress Type Configuration

OpenShift Routes:

If you intend to use OpenShift routes when deploying IDSP, pass these additional parameters in the IDSP helm deployment command. Note that OpenShift Route requires OpenShift version 4.11 and above.

```
--set ssp.ingress.type="openshiftroute" \
--set ssp.ingress.ingressClassName="openshift-default"
```

Default Nginx Ingress:

If you intend to use Nginx Ingress which is the default ingress used when deploying IDSP, pass these additional parameters in the IDSP helm deployment command:

```
--set ssp.ingress.type="nginx" \
--set ssp.ingress.ingressClassName="nginx"
```

See Ingress in OpenShift for more information.

SSP Data Chart OpenShift Configuration

For OpenShift deployment, the following additional parameters must be passed in the "ssp-data" helm install command:

```
--set ssp.global.securityContext.runAsUser=${SSP_UID} \
--set ssp.global.securityContext.runAsGroup=${SSP_GID} \
--set ssp.global.securityContext.fsGroup=${SSP_FSGROUP}
```

For information on deploying IDSP Data chart, see Deploying IDSP Data Chart .

Complete OpenShift Deployment Example

1. Set Environment Variables:

```
export PREFIX="myssp"
export DOMAIN="myiam.example.com"
export SSP_FQDN="${PREFIX}.${DOMAIN}"
export SSP_MGMT_FQDN="system.${SSP_FQDN}"
export RELEASENAME="ssp-prod"
export NAMESPACE="ssp-prod"
export HELM_REPO='ssp_helm_charts'
export HELM_REPO_URL=https://ssp_helm_charts.storage.googleapis.com

read -d '/' -r SSP_UID < <(kubectl get ns ${NAMESPACE} -o jsonpath='{.metadata.annotations.openshift\.io/sa
\.scc\.uid-range}')
read -d '/' -r SSP_GID < <(kubectl get ns ${NAMESPACE} -o jsonpath='{.metadata.annotations.openshift\.io/sa
\.scc\.supplemental-groups}')
export SSP_FSGROUP=${SSP_GID}
```

2. Deploy Infra Chart:

```
helm install "infra-${RELEASENAME}" "${HELM_REPO}/ssp-infra" -n "${NAMESPACE}" \
  --set sspReleaseName="${RELEASENAME}" \
  --set global.securityContext.runAsUser=${SSP_UID} \
  --set global.securityContext.runAsGroup=${SSP_GID} \
  --set global.securityContext.fsGroup=${SSP_FSGROUP} \
  --set fluent-bit.serviceAccount.create=true \
  --set fluent-bit.openShift.enabled=true \
  --set fluent-bit.openShift.securityContextConstraints.create=true
```

3. Deploy SSP Chart:

```
helm install "${RELEASENAME}" -n "${NAMESPACE}" "${HELM_REPO}/ssp" \
  --set ssp.ingress.host="${SSP_FQDN}" \
  --set ssp.ingress.type="openshiftroute" \
  --set ssp.ingress.ingressClassName="openshift-default" \
  --set ssp.global.securityContext.fsGroup=${SSP_FSGROUP} \
  --set ssp.global.securityContext.runAsGroup=${SSP_GID} \
  --set ssp.global.securityContext.runAsUser=${SSP_UID} \
  --set hazelcast-enterprise.securityContext.fsGroup=${SSP_FSGROUP} \
  --set hazelcast-enterprise.securityContext.runAsGroup=${SSP_GID} \
  --set hazelcast-enterprise.securityContext.runAsUser=${SSP_UID} \
  --timeout=120m
```

Deploying IDSP Data Chart

Learn to deploy the IDSP-Data chart to load network watchlist and fraud IP data into the IDSPdatabase.

Overview

NOTE

- You can install the "ssp-data" chart, only after installing the IDSP.
- The "ssp-data" chart is updated once a week, therefore to get the most recent data, upgrade to the latest helm chart. The ssp-data charts recent version is 1.0.2023.<week_number>.
- The Geo Location service is used to managing Network Location data which is deployed by default. Search for Geolocation Service in this link.

The solution provides a separate helm chart called, "ssp-data" to load the network watchlist, and fraud IP data into the IDSP database. The solution uses this data to access risk. When this helm chart is deployed, it loads approximately 250K records of data.

Data Sources

The data that is loaded by the "ssp-data" chart comes from the following sources:

Data Type	Source
Unallocated Network	Bogons
Anonymizer/Fraud IP	Neustar

Database Requirement

The database should have 100 MB (megabytes) of space to hold the network data information.

Deploying the latest "ssp-data" Chart

To deploy the latest "ssp-data" chart into the solution's database, use the following set of commands:

1. Get the latest Helm chart updates:
   ```
   helm repo add ssp_helm_charts https://ssp_helm_charts.storage.googleapis.com
   helm repo update
   ```
2. Perform the following steps to deploy the ssp-data chart:
   a. The "ssp-data" helm chart uses SSL mode set to "REQUIRED" as a default.
   When using Customer Provided database, add the attribute, **--set ssp.db.sslMode=<ssl mode>**, and change <ssl mode> to one of the supported values: DISABLED, PREFFERED, REQUIRED, VERIFY_CA, VERIFY_IDENTITY. When using VERIFY_CA and VERIFY_IDENTIFY, you are required to specify a CA certificate(s) that will be used to verify the DB server certificate by passing the SSL certificate(s) secret name, **"--set ssp.db.existingSslSecret=<secret name>".** See DB in SSL mode for more information.
   b. If you want IDSP to use the ***customer provided database***, pass the following database parameters to the "ssp-data" helm chart:
   ```
   --set sspReleaseName=${RELEASENAME} \
   --set ssp.db.serviceHost=<db host name, e.g. sspdb.mysql.database.azure.com> \
   --set ssp.db.servicePort=3306 \
   --set ssp.db.user="<db user name>" \
   --set ssp.db.existingSecret=<secret name>"
   ```
   The existing secret should point to the existing database secret used by IDSP Helm chart.
   c. Following is the helm install command to deploy the "ssp-data" helm chart:

```
helm install "${RELEASENAME}-data" -n "${NAMESPACE}" "${HELM_REPO}/ssp-data" \
--set sspReleaseName="${RELEASENAME}" \
--set ssp.global.ssp.registry.existingSecrets[0].name=ssp-registrypullsecret
```

NOTE
For OpenShift deployment, the following additional parameters must be passed in the "ssp-data" helm install command.

```
--set ssp.global.securityContext.runAsUser=${SSP_UID} \
--set ssp.global.securityContext.runAsGroup=${SSP_GID} \
--set ssp.global.securityContext.fsGroup=${SSP_FSGROUP}
```

This downloads the latest ssp-data helm chart. Once downloaded, the "ssp-data-networkdataload-job" will start automatically and upload the data into the solution's database.

Verifying SSP Data Chart Deployment

To verify that the SSP-Data chart has been deployed successfully:

1. Check the status of the data loading job:
   ```
   kubectl get jobs -n "${NAMESPACE}" | grep ssp-data-networkdataload
   ```
2. Monitor the job logs:
   ```
   kubectl logs -n "${NAMESPACE}" -l job-name=ssp-data-networkdataload-job
   ```
3. Verify the job completion:
   ```
   kubectl wait jobs.batch \
   --namespace "${NAMESPACE}" \
   --selector "app.kubernetes.io/name=ssp-data-networkdataload-job" \
   --for 'condition=complete' \
   --timeout '10m'
   ```

Once the job shows "Completed" status, the network data has been successfully loaded into your IDSP database.

Reference Link:

Additional parameters to pass in OpenShift environment, see here.

Post-Installation Checklist

Consider the tasks in the checklist after deploying the Symantec Identity Security Platform (SSP) helm chart.

After you have installed IDSP, review the following information and perform the post-installation tasks.

#	Post-installations Tasks
1.	Verify your IDSP installation, check that all the Kubernetes Pods are up and running, and ensure that your network components are See Verifying the deployment section.
2.	The solution by default provisions a few system and tenant-level clients and an admin user to help you to get started with the solutio credentials, see Administrative Model section.
3.	Take a backup of all the user-specified values that were used in the deployment of IDSP charts for recovery installation purposes. S
4.	Use a curl command to access the open id discovery url to obtain information needed to interact with the OAuth Authorization Serve section.
5.	Take a backup of the Master Encryption Key for future retrievals as this is the only key that can be used to decrypt the solution's enc there is no other way to recover the encrypted data. See Master Encryption Key.
6.	Retrieve the IDSP client secrets to administer the solution. To know more about the seeded default credentials, see Configuring Adm

7.	If you have deployed the enclave services, (such as Elasticsearch, Kibana, Prometheus, Grafana) into IDSP to monitor logs, configu Configuring Enclave Services section.
8.	You can optionally deploy the Sample Web Application provided by IDSP to test multiple scenarios and use cases in the solution. Se
9.	Broadcom provides a postman collection that can be downloaded and configured to test the demo environment. If you are using pos IDSP solution: 1. Set the environment variables. 2. Acquire the access token. 3. Update the CORS setting to update your "allowedOrigins". 4. Configure your ID Store. 5. Update the Tenant Admin AuthZ policy to add an admin user and a group. 6. Generate Tenant Admin access token / User access token to get the appropriate privileges to access the IDSP APIs. • IDSP **v4.0** Postman Collection is available for download from the Support Portal > My Downloads. • For the basic steps to get started with the IDSP Postman collection, see Using IDSP postman collection. • The Custom Claims SPI yaml can also be downloaded from the Support Portal > My Downloads

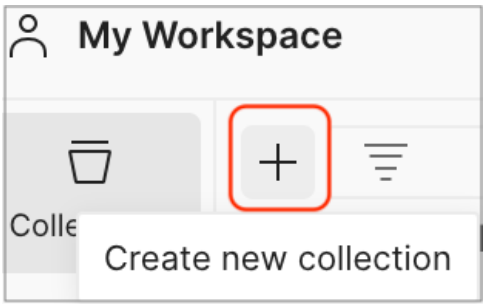
Using the Symantec Identity Security Platform postman collection

When you are setting up the Symantec Identity Security Platform Postman collection to manage your environments, it is a good practice to follow these steps to streamline the process and make things easier for the future.

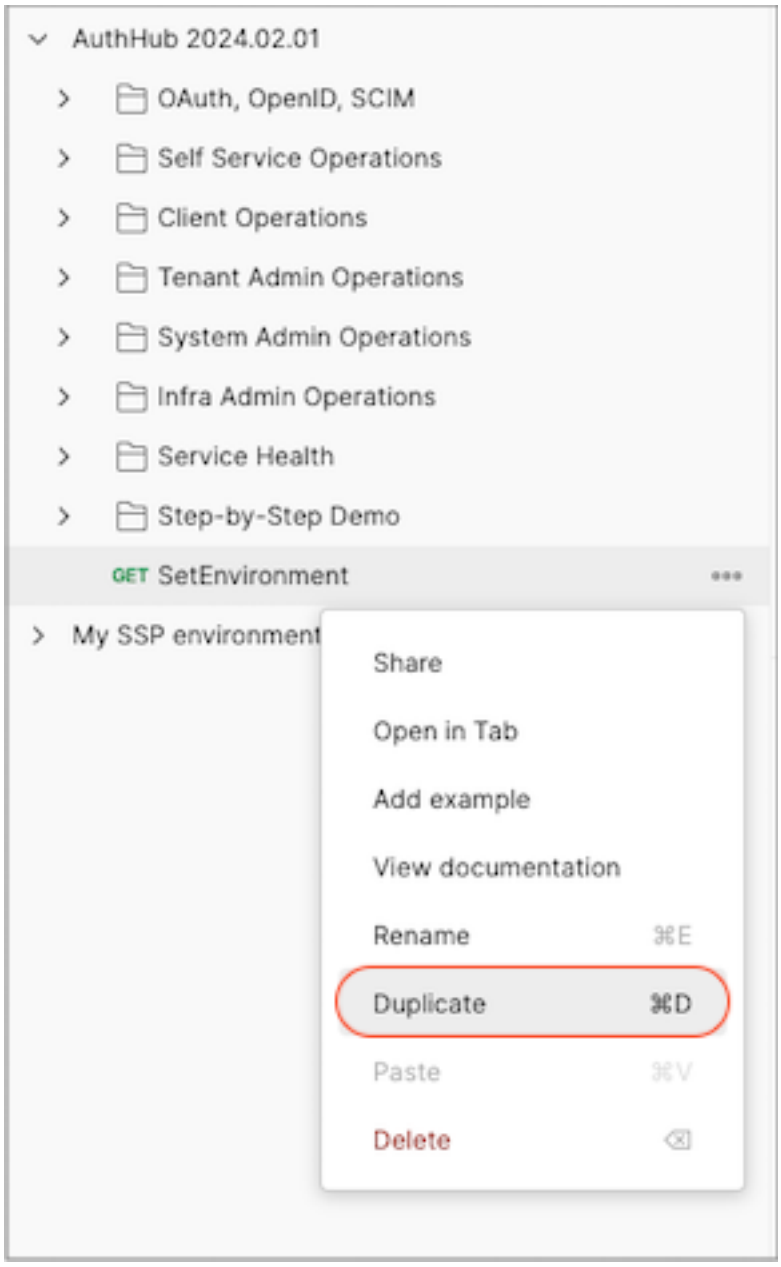
Follow these steps:

1. Import the IDSP API Collection into Postman.

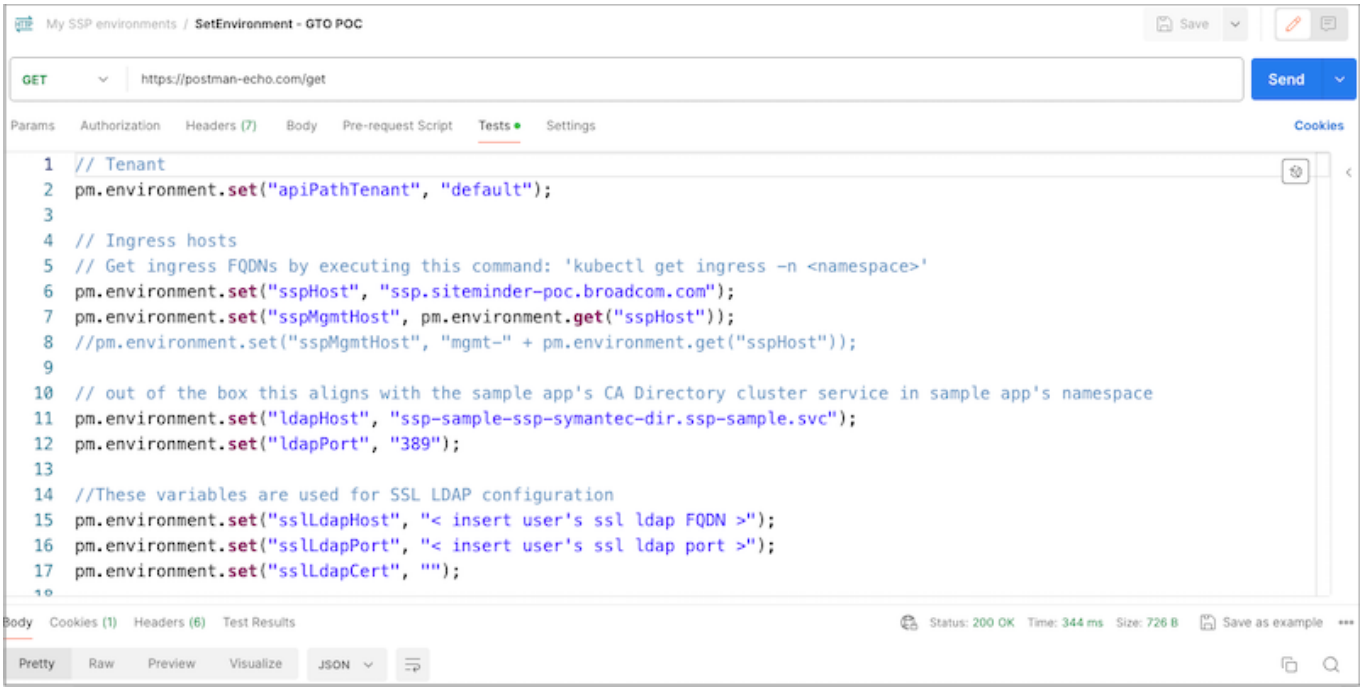
2. Create a new Blank collection by clicking the + sign.



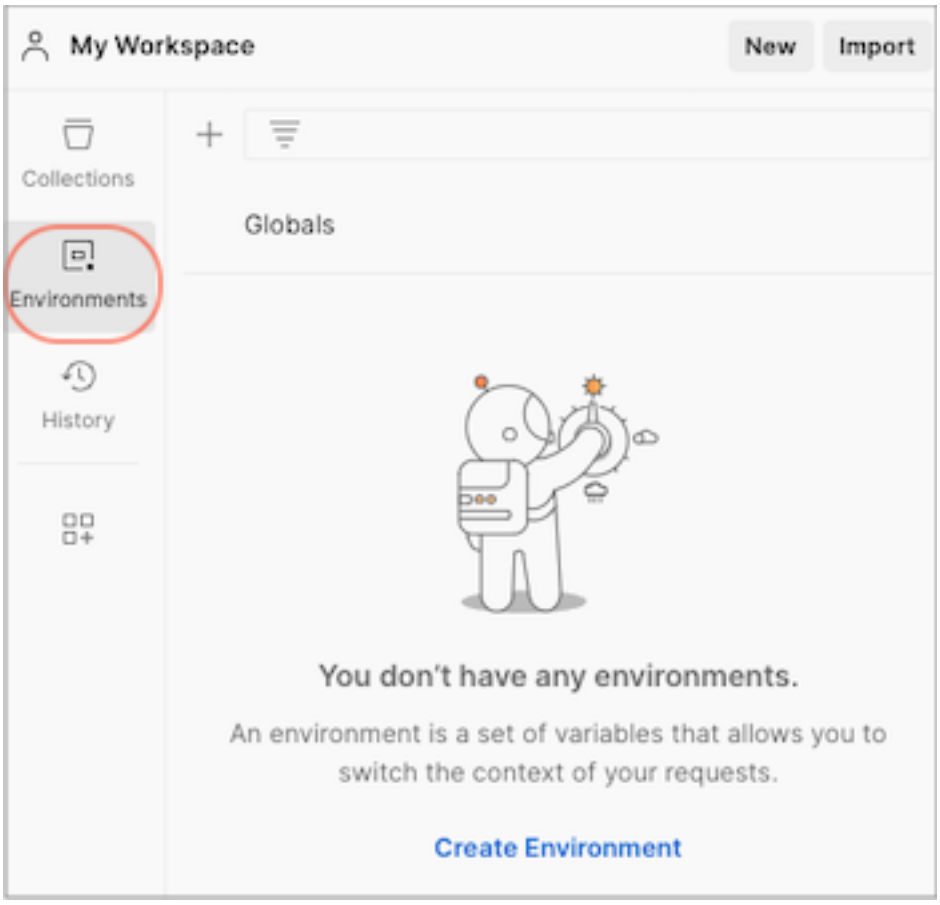
3. Rename the new collection. For instance, you might name the folder as "My SSP environments".
4. Duplicate the SetEnvironment API request (item) from the IDSP collection.



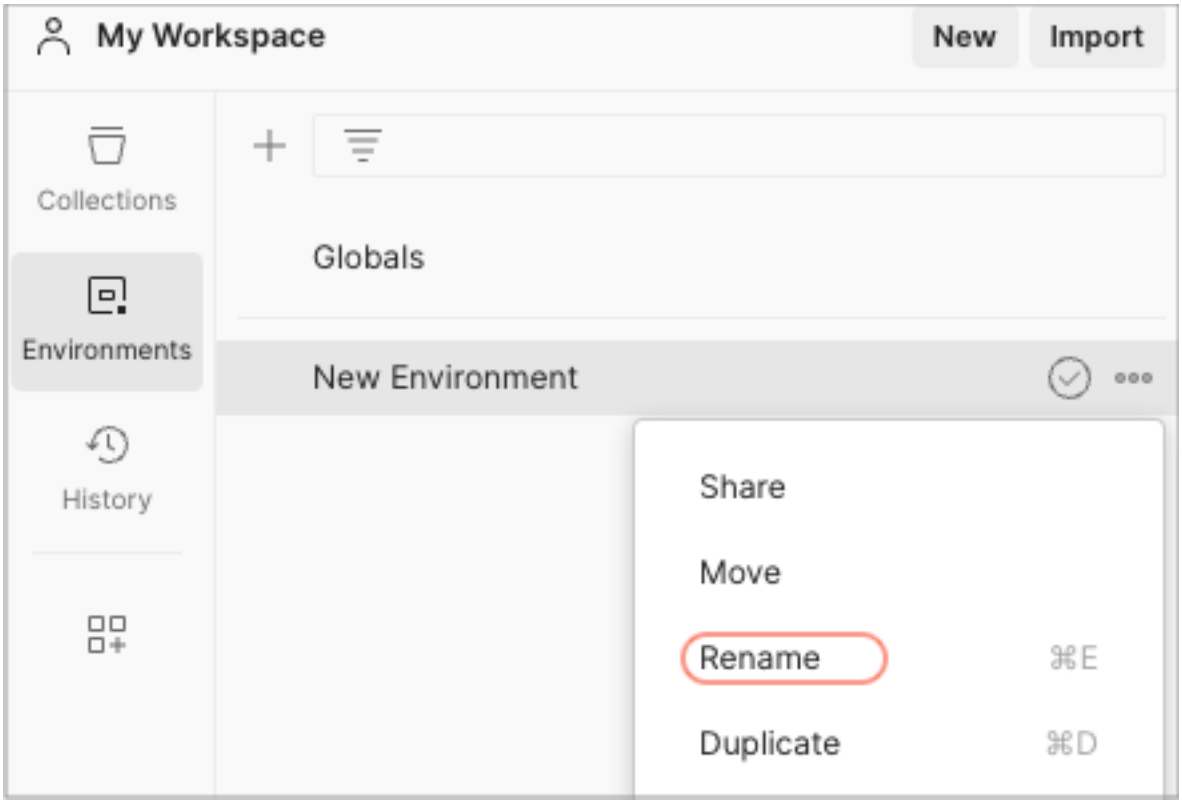
5. Drag the duplicate SetEnvironment item (SetEnvironment Copy) to the new collection you created ("My SSP environments").
6. Rename the "SetEnvironment Copy" to indicate the ssp environment name that you are planning to manage to use the API. For instance, "SetEnvironment - ah-admin-example.com"
7. Edit the Tests/Scripts section of the duplicated "SetEnvironment" item to update the environment information to include the following details:
   a. The environment's sspHost (For instance, ah-admin-example.com).
   b. Your admin client defaultTenantClientID and defaultTenantClientSecret.



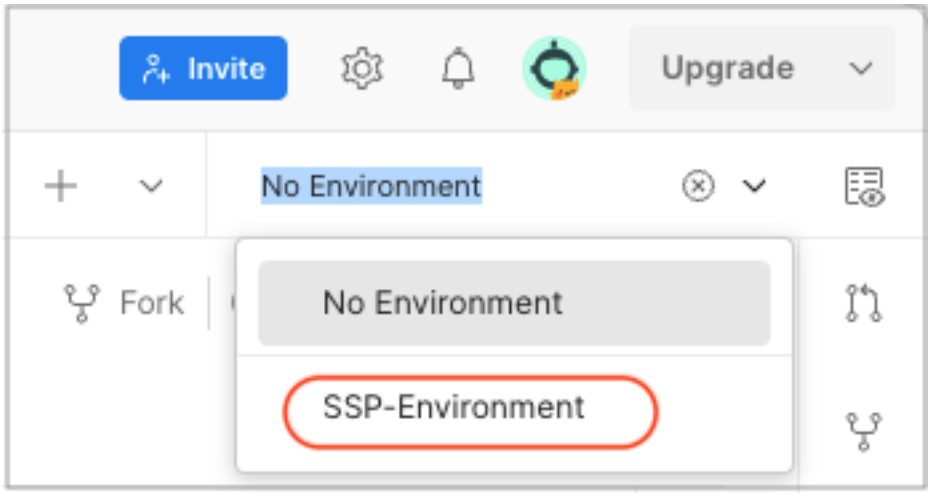
8. If you do not have an environment already created, follow these steps to create it:
   a. Go to the environment section (on the left navigation).



b. Create an environment by clicking the + sign.
c. Once created, click the ellipsis (...) and choose "Rename" to rename the environment (For instance, "SSP environment")



d. On the top left, select the environment that you created.



9. Navigate back to the ssp environment request you edited previously in step7 and invoke the request by clicking `Send`.
10. As you use the collection, you notice that most of the requests within the collection are set to carry context from one command to another by setting additional variables as needed.
For instance, acquiring an access token with one request, and using it with other requests of the same folder.

Configuring Enclave Services to Show Symantec Identity Security Platform Content

Learn how to configure Enclave Services to show Symantec Identity Security Platform content.

This page includes the following topics:

- Configuring Data Views in Kibana to Monitor Logs - 9.1.3
- Configuring Grafana to show the IDSP Dashboard

NOTE

- This configuration procedure and the reference screenshots are of Kibana 9.1.3. For information about the procedure on later versions of Kibana, see the Elasticsearch documentation.
- Ensure that the IDSP is installed before configuring the enclave services.

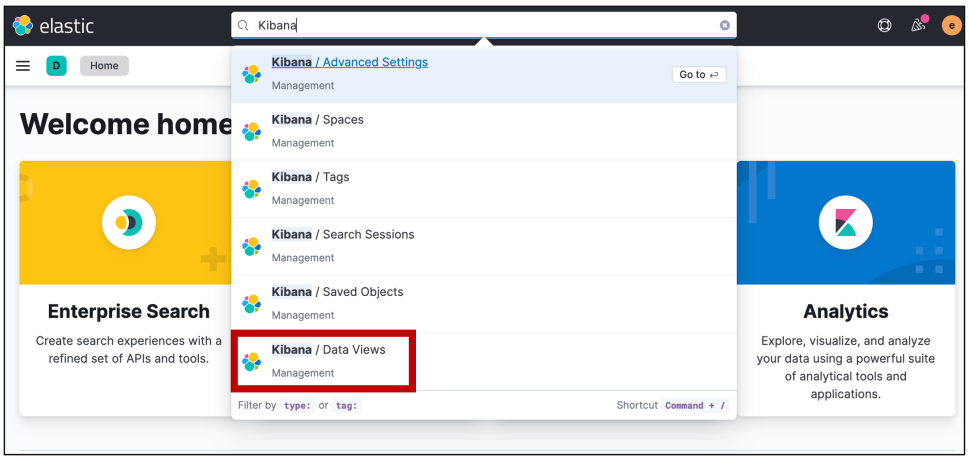
Configuring Data Views in Kibana to Monitor Logs - 9.1.3

To view IDSP logs, use the Kibana monitoring dashboard.

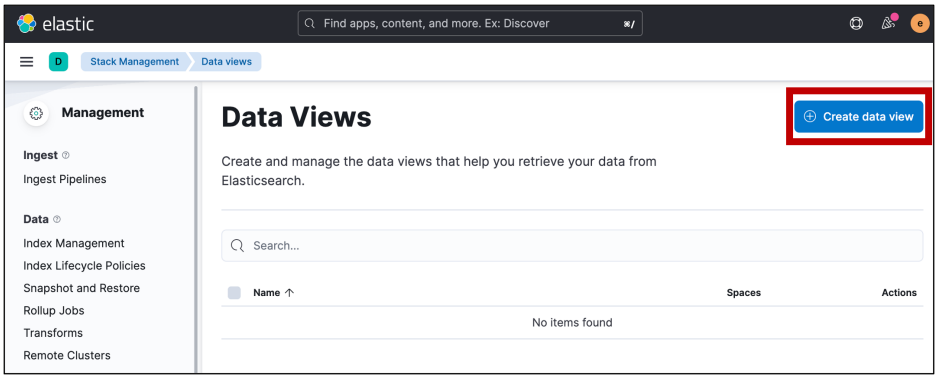
1. Access the Kibana service at the following location. Replace <DOMAIN> with the value that you have set in your environment during deployment, before running this command:

   ```
   http://kibana.<DOMAIN>
   ```

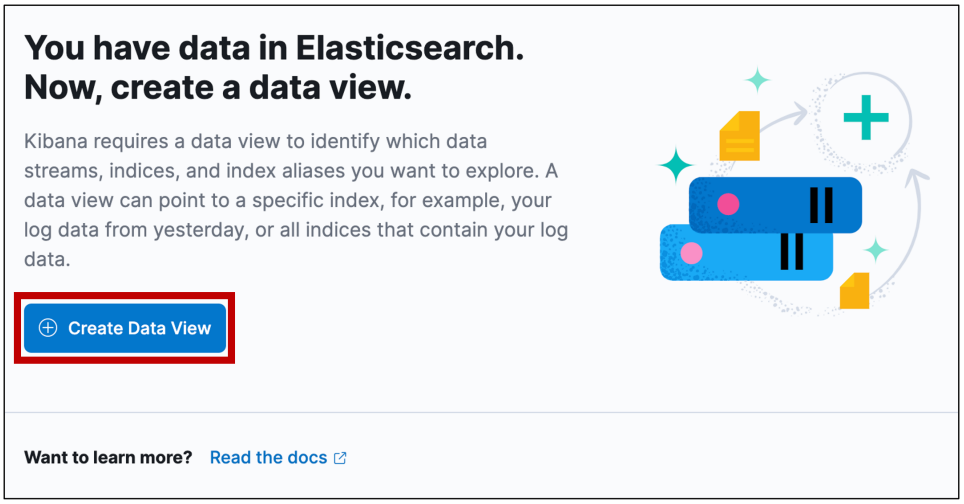
   This displays the Kibana home page.
2. In the home page, search for and click **Kibana / Data Views.**



3. In the **Data Views** page, click **Create data view.**



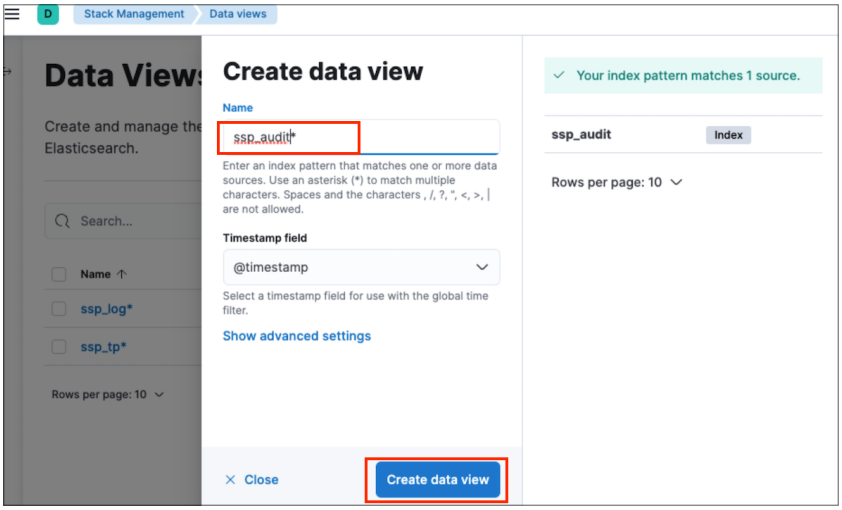
4. In the page that appears next, click **Create Data View.**



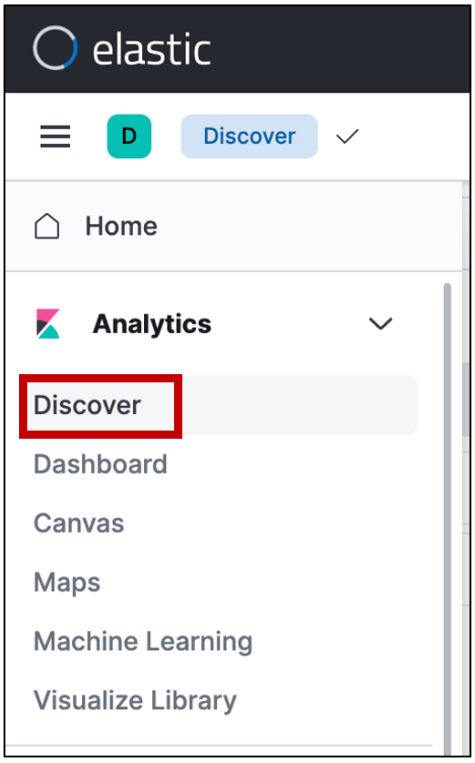
5. In the **Create data view** page, enter an Index pattern name (for example, ssp_log*, ssp_audit*, ssp_tp_log*) in the **Name** field, select the **Timestamp field** as **@timestamp**, and click **Create data view.**

   NOTE

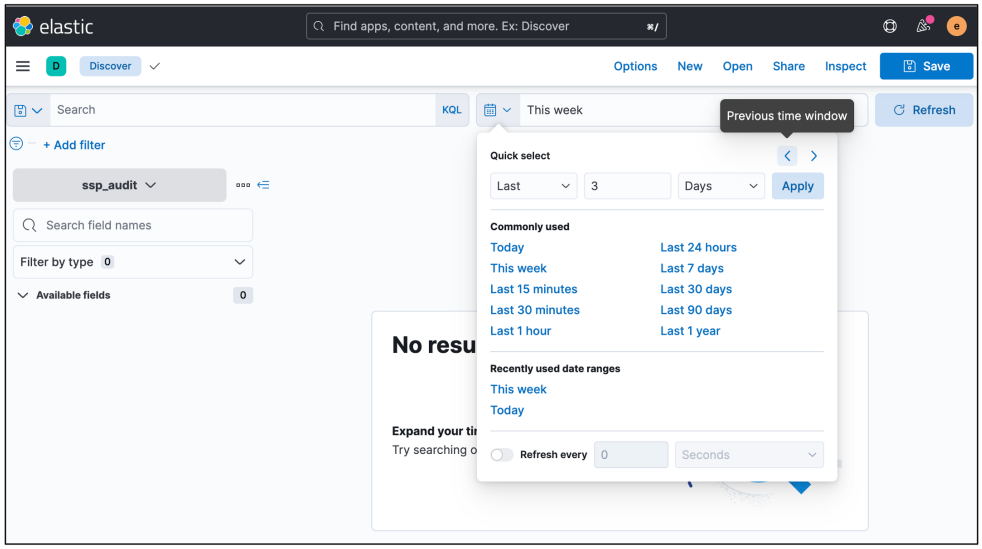
   Repeat step from 2 through 5 for each of the Index pattern names that you want to create.



6. In the Hamburger menu icon on the top-left of the page, click **Discover.**



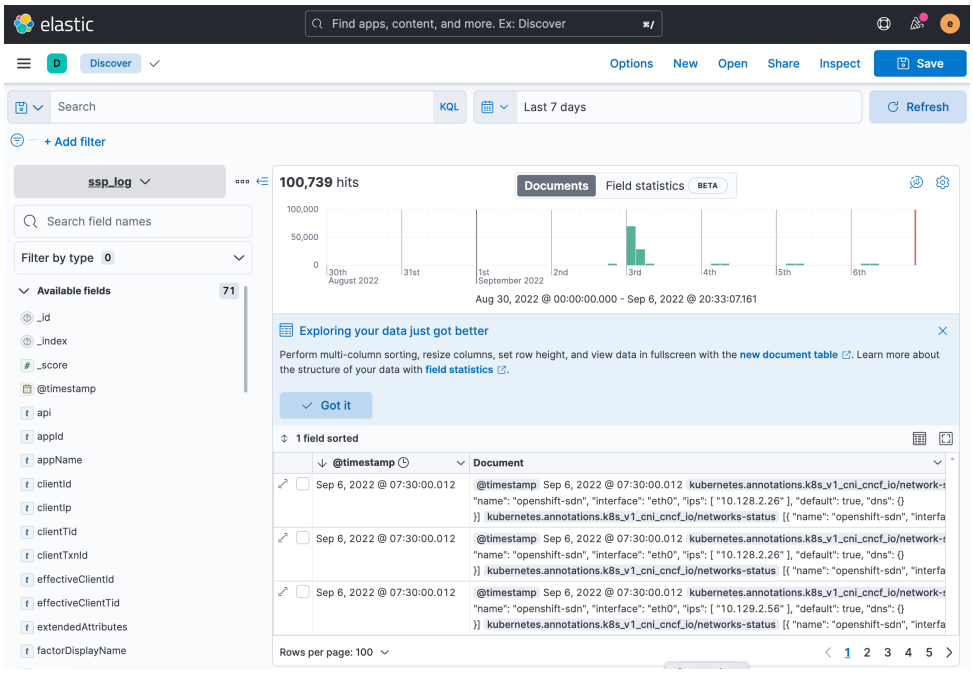
7. You can use the date filter on the top right to retrieve logs from a specific time.



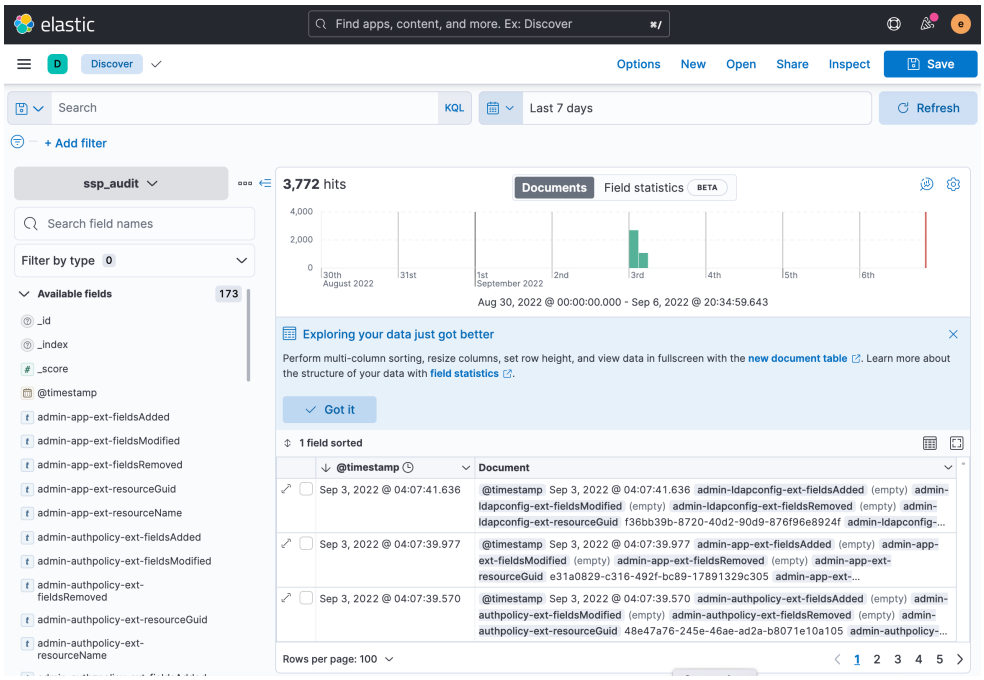
NOTE
Initially, the logs may display empty data. However, after you select the right filter option the data will be populated.

See sample images of the IDSP logs.

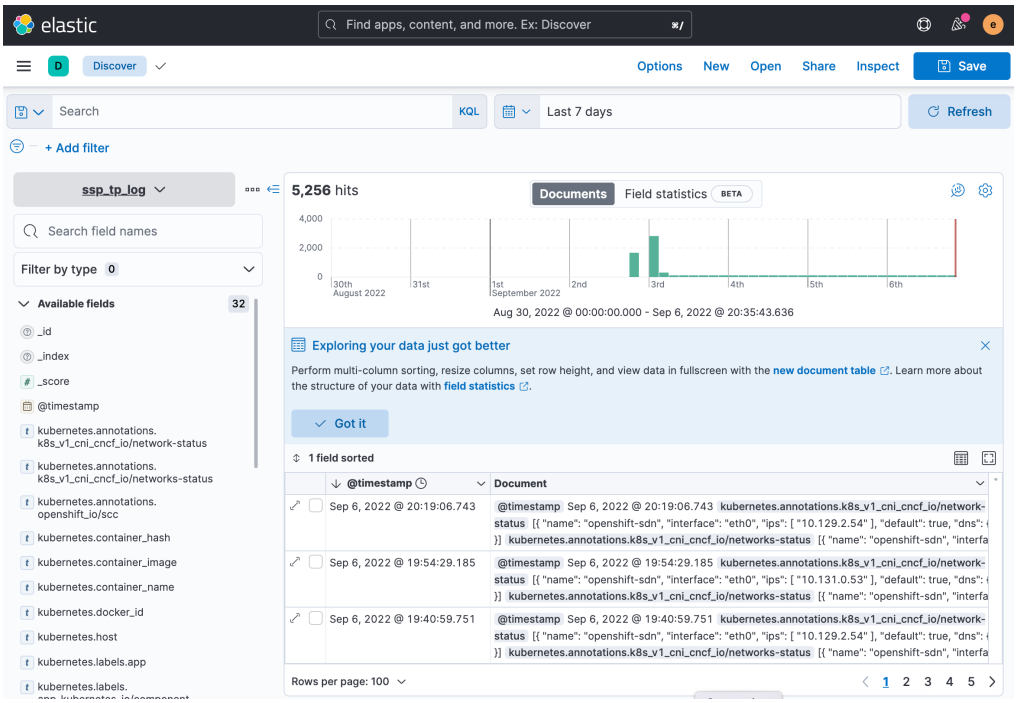
ssp_log



ssp_audit



ssp_tp_log



Configuring Grafana to show the IDSP Dashboard

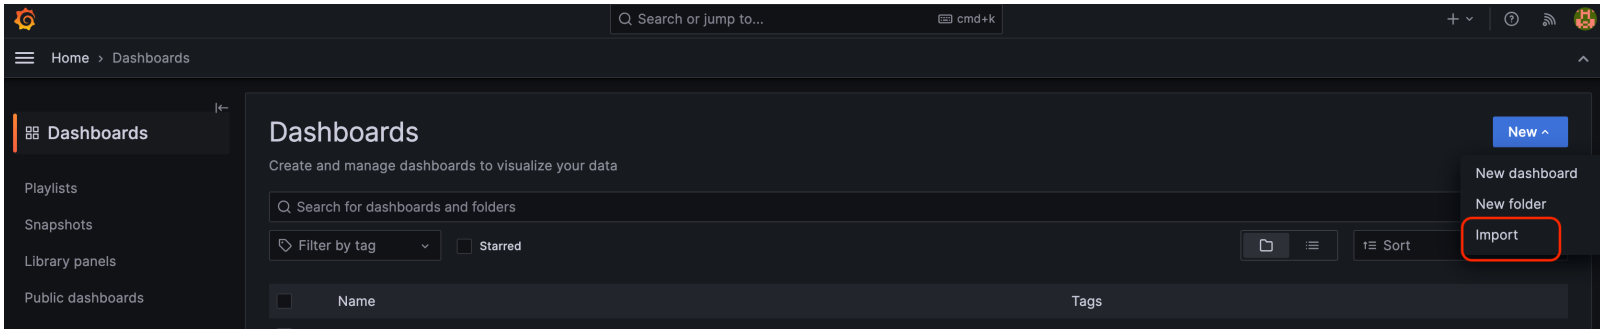
1. Access the Grafana UI at the following location.

   `http://grafana.<DOMAIN>`

   NOTE

   - In the command above, replace <DOMAIN> with the value that you have set in your environment during deployment, before running this command.
   - If you are unable to access Grafana, ensure that the Grafana FQDN is resolvable as described in the section, Publishing the Enclave Endpoints.
   - The default Username and Password to access Grafana are:
     Username: admin
     Password: prom-operator

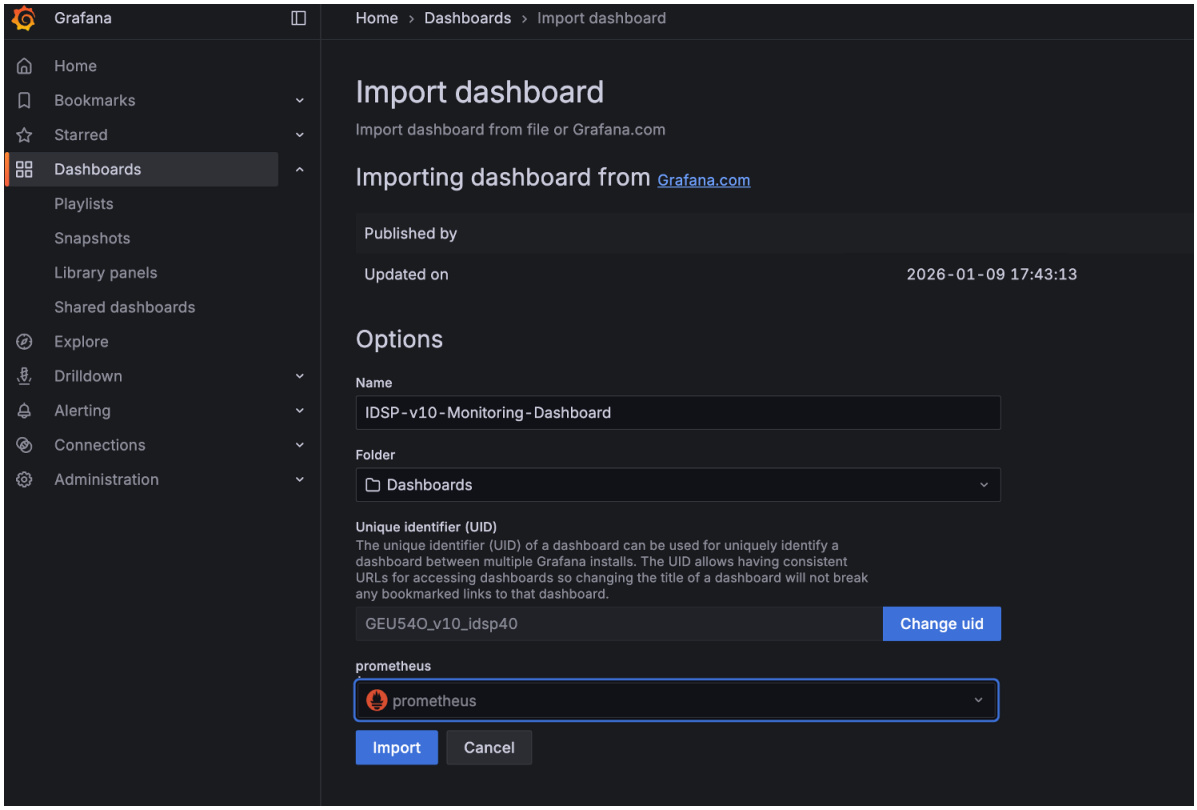
2. Navigate to Grafana dashboard > Import.



3. Under **Import via grafana.com** selector, enter the IDSP Monitoring Dashboard template Id-25306.
   Use the following Dashboard template Id to import the dashboard:
   – ***IDSP Monitoring Dashboard*** - 25306
4. Click **Load.**

The *SSP-v9-Monitoring-Dashboard* gets loaded. Similarly, other dashboards also get loaded if you import them in the same manner.

5. From the *Prometheus* drop-down, select **Prometheus** and click **Import.**

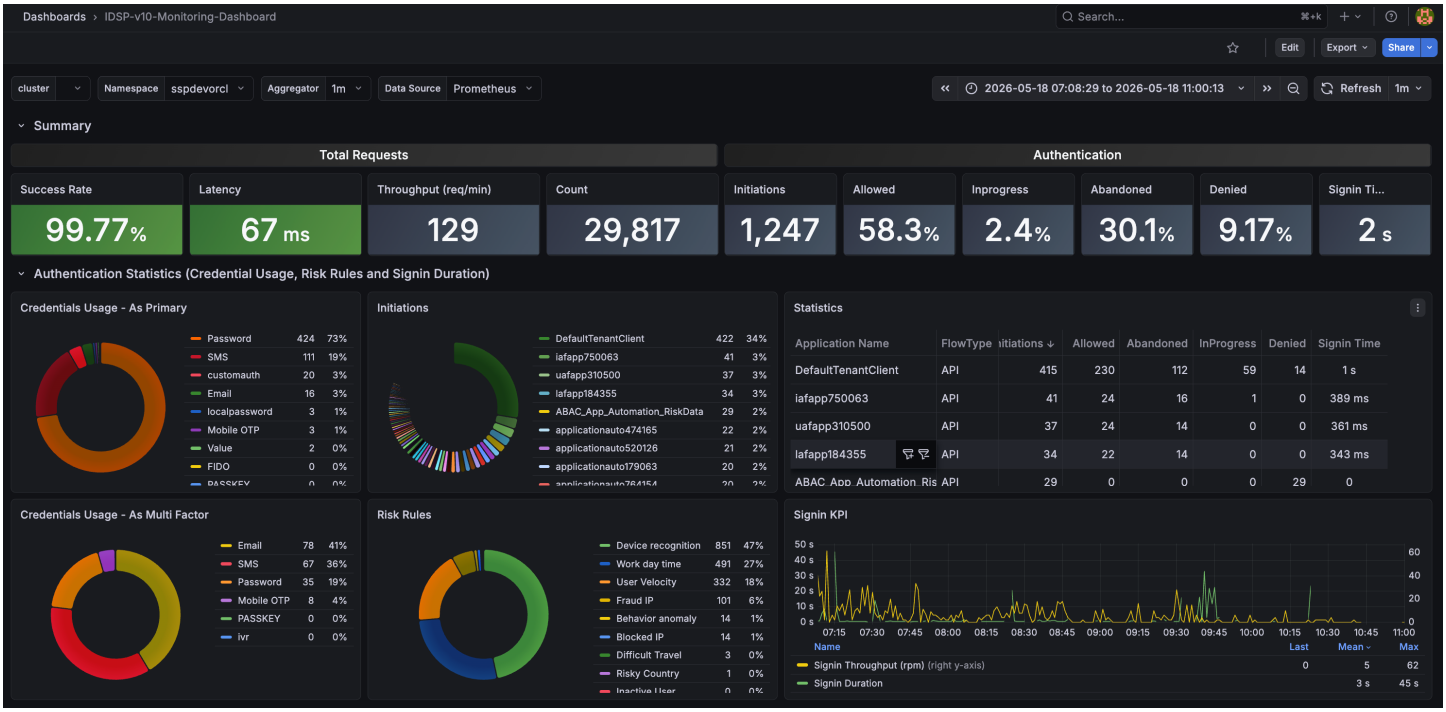


NOTE

Ensure that you verify the "Namespace" field at the top left of the dashboard page to have the name of the namespace where you have deployed the IDSP chart.

This is a sample image showing the IDSP Monitoring Dashboard:

Figure 7: Sample monitoring dashboard"

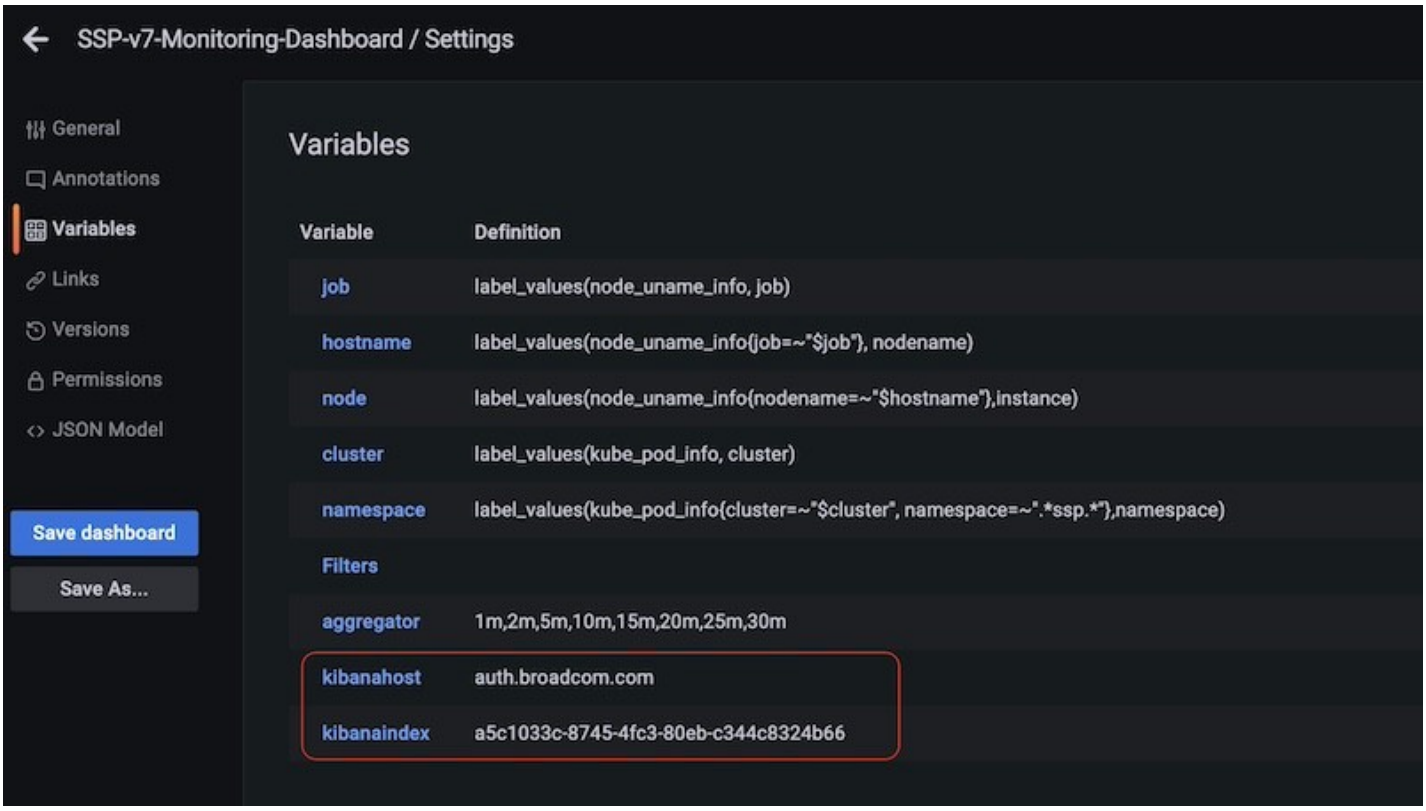


NOTE
Grafana could also be used to view generic cluster dashboards like Kubernetes Cluster Metrics (11074), JVM Metrics (9568), NGINX Ingress Controller Metrics (9614).

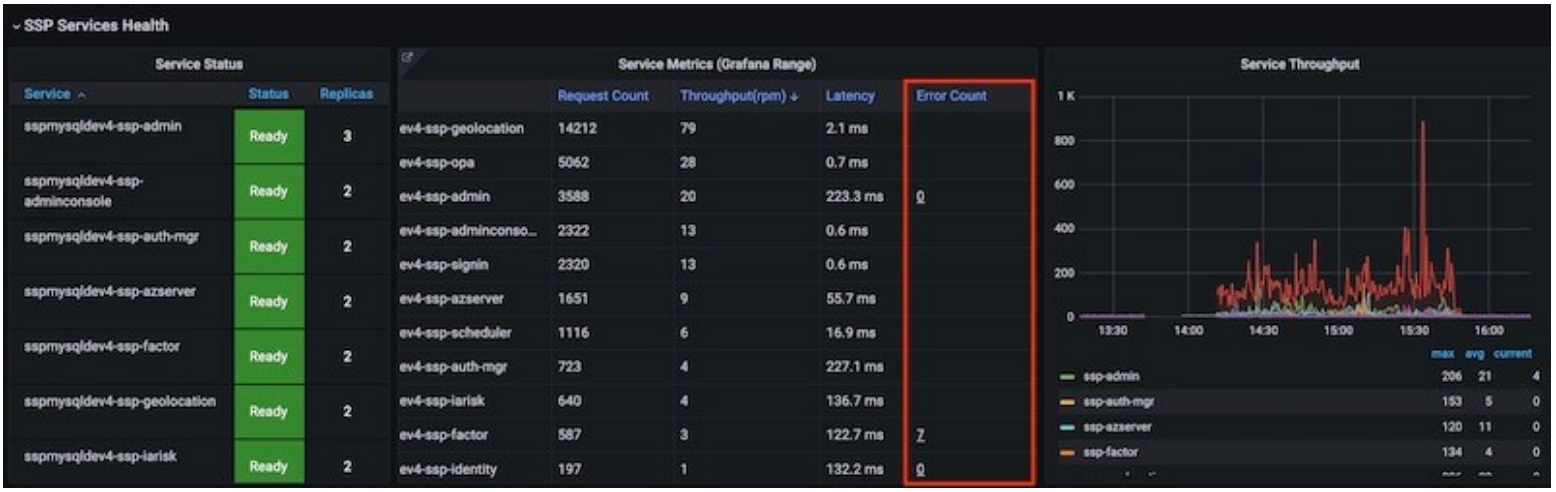
To view the IDSP (SSP) Service's health, and access it's error logs in Kibana, add the "kibanahost" and "kibanaindex" variables to the Grafana Dashboard.

Perform these steps in Grafana Dashboard page:

1. Click the ***Dashboard Settings*** (gear icon) on top right of the Monitoring Dashboard page.
2. On the Dashboard Settings, click ***Variables*** and add the values for the two new parameters, "***kibanahost***" and "***kibanaindex***" as highlighted in the following image:



3. Navigate back to the Monitoring Dashboard page, and expand the IDSP Services Health drop-down.
4. To view IDSP errors listed in the "Error Count" column, click a number to see detailed error information in the Kibana logs as highlighted in the following image.



For troubleshooting tips on monitoring, click here.

Next Step -

Integrate the Demo Application

Configuring Administrative Access

Covers the initial security credentials for the admin clients (Infra client, System client, Default Tenant client and defaultTenantAdminUser), recovery of these credentials after 48 hours, setting up an admin identity and granting permission to the admin role. All of these are provided out-of-the-box by Symantec Identity Security Platform during the initial deployment.

This topic includes the following sections:

- Retrieving Initial Credentials for the clients
- Recovering Initial Credentials after 48 hours (Break-Glass Recovery)
- Setting Up Your Admin Identity
- Granting administrative privileges to the Tenant Admin Role

Retrieving Initial Credentials for the clients'

NOTE
The commands to retrieve the initial credentials use environment variables that are expected to be set in your environment. Before running those commands, ensure that these environment variables are set for your terminal session. You can do so by running the following command:

```
echo RELEASENAME=\'${RELEASENAME}\', NAMEPSPACE=\'${NAMESPACE}\' ; if [ -z "${RELEASENAME}" ] || [ -z
 "${NAMESPACE}" ]; then echo "***** ERROR: RELEASENAME or NAMESPACE environment variables are not set
 *****" ;fi
```

The following initial credentials can be retrieved within 48 hours from the time of deployment by using the following commands:

Client	Role (AZ Policy)	Tenant Name	Steps to acquire Client ID
InfraClient	Infra Admin	System	kubectl get secret ${RELEASENAME}-ssp-secre jsonpath="{.data.clientId}" | base64 --decode; ech kubectl get secret ${RELEASENAME}-ssp-secre jsonpath="{.data.clientSecret}" | base64 --decode
SystemClient	System Admin	System	kubectl get secret ${RELEASENAME}-ssp-secre jsonpath="{.data.clientId}" | base64 --decode; ech kubectl get secret ${RELEASENAME}-ssp-secre jsonpath="{.data.clientSecret}" | base64 --decode
DefaultTenantClient	Tenant Admin	Default	kubectl get secret ${RELEASENAME}-ssp-secre jsonpath="{.data.clientId}" | base64 --decode; ech kubectl get secret ${RELEASENAME}-ssp-secre jsonpath="{.data.clientSecret}" | base64 --decode
DefaultTenantAdminUser You can use this user to login to the admin console and configure the default tenant. The validity of this admin user is limited to 48 hours by default, starting from the deployment time.	Tenant Admin User	Default	echo TENANT_ADMIN_USER=$(kubectl get sec defaulttenantadminuser -n ${NAMESPACE} -o js echo TENANT_ADMIN_USER_PASSWORD=$(k secret-defaulttenantadminuser -n ${NAMESPACE decode)

NOTE
To know more about these bootstrap clients, see Administrative Model.

Recovery of Credentials after 48 hours (Break-Glass Recovery)

If the credentials are not retrieved or an alternate administrative identity was not created and stored within the 48-hour validity period, an administrators can perform a break-glass recovery procedure to enable the default tenant admin user, reset its password and recreate its Kubernetes secret (which is again valid for the next 48 hours only).

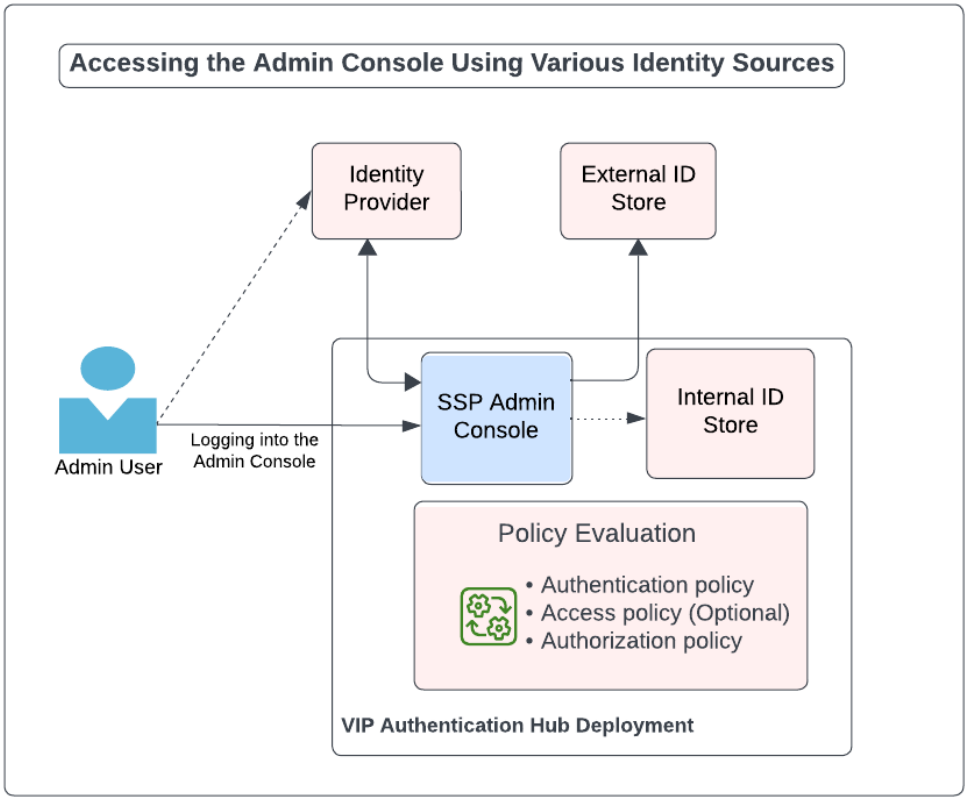
See Recovering Initial Admin Credentials section to perform a break-glass procedure.

Now, access the IDSP Admin Console by authenticating with the admin user and password retrieved in the previous step. After accessing the admin console, you will be required to ***change the admin user's password*** and ***setup the new admin identity.***

To know how to ***change the admin user's password*** and ***setup the new admin identity***, see Managing Tenant Admin Access to the Admin Console with a new user.

Setting-Up Your Admin User Identity

Admin user identities can originate from various sources to access the IDSP Admin Console. This has been explained in the following illustration along with its flow description.



Flow Description:

1. An admin user identity can come from the following user identity sources to log in to the Admin Console:
   - **Internal Identity store** - The internal identity store is deployed automatically as part of the IDSP deployment. The incoming user identity (users or groups) is stored in the IDSP database.
   - **External Identity Provider (BYOI)** - The user identity can come from an external SAML or OIDC Identity provider. The user could be JIT-created in the internal ID store, or configured to use a Zero Footprint (ZFP) mode.
   - **External Identity store (LDAP/SCIM)** - The user Identity can come from an LDAP or a SCIM configured Identity store.

2. Once the user identity is identified, it is evaluated against the Authentication policy, Access policy (if enabled), and Authorization policy.

   NOTE
   Before the policy evaluation takes place, ensure that the user is created in one of the previously stated identity sources and linked to the Authentication policy, Access policy (if enabled), and Authorization policy. Only when the user details are added to these policies, the evaluation is successful.
3. Upon evaluation, the user is provided with a list of authentication factors. Once the user authenticates successfully, access is granted to the admin console.

Use one of the following ways to set up the new admin identity:

- ***Use an existing Identity Store***: Use the Admin Console UI to define an Identity Store pointing to your existing Identity Store. The identity store can be accessed using LDAP or SCIM protocols.
- ***Use IDSP's Internal Identity Store:*** To create a user in the Internal Identity Store- see the Creating Users topic or you can view Create a new user and group in IDSP Internal Identity Store topic to check how to perform these steps from the Admin Console UI.
- ***Use Federated Identity***: Use the Admin Console UI to define an Identity Provider (OpenID or SAML) to be used as the Identity Source in a ZeroFootPrint configuration. See Using Identity Federation to Access the Admin Console.

Granting administrative privileges to the Tenant Admin Role

Based on the identity source type that you have chosen above to set up your administrative identity, use the Admin Console UI or the IDSP APIs to perform the following:

1. Identify the "***user***" or a "***group"*** from the ID store or IDP configured in the previous step to which you want to grant administrative privileges.
2. Grant administrative privileges (Tenant Admin Role) to the user or group. See an example of Granting Admin Privileges (with API usage) here, and to know more about the Authorization APIs, see Authorization Policy APIs. For Admin Console UI usage, see Managing Tenant Admin Access Using Admin Console.
3. Update the Authentication Policy (AdminLoginPolicy) for the Admin Console. See an example of Updating the Authentication Policy for Admin Console using the IDSP API here, and to know more about the Authentication APIs, see Authentication Policy APIs. For Admin Console UI usage, see here .

   NOTE
   Ensure that the identity store configured as your admin identity is correctly mapped to the "Admin Console Identity Store Assignment" tenant setting in the admin console. In the API context, this setting is called "***adminConsoleIdStoreToBeUsed***" and is detailed on the Managing Settings page.

Managing Tenant Administrator Access Using Admin Console

Following these steps ensures seamless administration by transitioning from the "DefaultTenantAdminUser" to a newly created Admin User/Group with assigned TenantAdministrator privileges.

The "**DefaultTenantAdminUser**" is an administrative user with Tenant Administrator privileges, created during Symantec Identity Security Platform deployment. For security reasons, this user is automatically disabled after 48 hours, and its credentials stored in Kubernetes secrets, are also deleted.

To ensure uninterrupted operations, a new user with the same privileges should be created before the "**DefaultTenantAdminUser**" is disabled.

This document outlines the steps to:

- Create a new user and group in IDSP Internal Identity Store
- Assign TenantAdministrator permissions to the new group
- Update the Authentication Policy to recognize the new administrator group
- Log in using the newly created administrator user

Creating a User and Group in IDSP Internal Identity Store

Log in to the IDSP Admin Console.

1. Log in to the IDSP Admin Console (https://${SSP_FQDN}/default/ui/v1/adminconsole/) using the default credentials for the DefaultTenantAdminUser.
   - Username: DefaultTenantAdminUser
   - Password: (Stored in Kubernetes secret)
2. To get the DefaultTenantAdminUser's password, use the following kubectl command:
   ```
   kubectl get secret ${RELEASENAME}-ssp-secret-defaulttenantadminuser -n ${NAMESPACE} -o
   jsonpath="{.data.userPassword}" | base64 --decode
   ```
3. Click Sign In.
   The Change Password dialog is displayed.
4. Enter a New Password, confirm it, and click Change Password.
   You are now logged into the IDSP Admin Console Dashboard.

Creating an Admin Group

1. Navigate to Group from the left panel.
2. Select Groups and click Add Group.
3. Enter a Group Name (for example, Admins).
4. Click Save.

Creating a New User

1. Navigate to Users from the left panel.
2. Select Users and click Add User.
3. Provide the required details:
   - First Name: Your first name.
   - Last Name: Your last name
   - Username: This is the name used to login to the Admin Console. By default the "Use Primary Email as the Username" option is selected.
   - Email: Your email address.
   - Phone Number: This is required if your SMTP provider is not configured yet. To receive the password reset link, specify a phone number that is capable of receiving text messages.
4. Click Save.
   The newly created user appears in the Users page.

Adding the Newly Created User to "Admins" Group

1. Navigate to Groups from the left panel.
2. In the search bar, type Admins and click Submit.
   The newly created "Admins" group gets displayed.

   NOTE
   You can search for the user by specifying the initial letters of the username ("starts with" filter), or choose "Show Filters" to add additional filters.
3. Click "Admins" and then click Add.
4. On the Add Users to Admin Group page, search for the newly added user by its name or first few letters of the name.
5. Select newly added user and click Add.
   The user now becomes the member of "Admins" group.

Assigning the Tenant Administrator Role to "Admins" Group

Steps to assign Tenant Administrator Role

1. Navigate to Settings > Administrators Roles > Roles.
2. In the search bar, search for the Tenant Admin Role.
   The Tenant Admin Role is displayed.
3. Select User Group.
4. Choose internal (Internal Identity Store) as the Identity Provider.
5. Enter "Admins" or click Select Group to search for it.
6. Click Grant.
   The "Admins" group is now listed as a Tenant Administrator.

Updating the Authentication Policy to Assign "Admins" group as the Tenant Administrator

Steps to update the Authentication Policy with the new administrator user/group so that it is recognized for future logins

1. Navigate to Authentication Policies in the left panel.
2. Select the "AdminLoginPolicy".
3. Click Add Rule.
4. Add a description and select authentication rule type, click Next.
5. Click Add Conditions, and select Groups.
6. Select the Identity Store as Internal.
7. Add the group by clicking on Select Group option.
8. Select "Admins", click Select, and click Next.
9. On the Result page, click Next.
10. In Authentication Factors, select the required methods, and click Next.
11. Review the Summary for Authentication Rule and click Done.
12. Click Save Policy.

Logging into the Admin Console with the New User

Steps to Log in as the newly created user in the Admin Console.

1. Wait 30 seconds for the changes to refresh.
2. Log in to the Admin Console using the user's username that you selected during the user creation.
3. The user is locked by default. Click Unlock Account.
   The Unlock Your Account and Reset Password page appears.
4. Select a password reset method:
   - Email: The password reset link would be sent to your email address. This option would only work if you already configured your SMTP provider. (SMTP Configuration)
   - SMS: The password reset link would be sent to your phone number that was provided during the user creation.
5. Follow the reset link from the SMS to update the password.
6. Once reset, return to the Admin Console Sign-In page.
7. Log in with the updated password.
   You are logged into the Admin Console and the dashboard page is displayed.

Upgrading Symantec Identity Security Platform

Learn how to upgrade and rollback Symantec Identity Security Platform deployment.

The In-place IDSP upgrade enables you to upgrade the solution's deployment and handles database schema updates automatically.

To know more about database upgrade, see the Database Considerations page.

Prerequisite for upgrading IDSP charts

- Ensure to upgrade your Ingress-Nginx to version 4.14.3 by using the following command:

```
helm get values ingress-nginx -n ingress >ingress-override.yaml
helm upgrade ingress-nginx -n ingress ingress-nginx/ingress-nginx --version=4.14.3 -f ingress-override.yaml
 \
--set controller.allowSnippetAnnotations=true \
--set controller.config.annotations-risk-level=Critical
```

  For information on why "--set controller.config.annotations-risk-level=Critical" should be added, see Deploying Ingress Controller.
- **Prior to upgrading Symantec Identity Security Platform, you must do the following**
  - Get the user-supplied current IDSP Infra Helm deployment values as instructed in step 7.
  - Get the user-supplied current IDSP Helm deployment values as instructed in step 11.
  - If you intend to upgrade the IDSP Data (ssp-data) helm chart, get the user-supplied current IDSP Helm deployment values as instructed in step 15.

Upgrade Considerations

IMPORTANT

- **IDSP Supports Incremental Upgrades**:
  IDSP facilitates incremental upgrade paths. If you plan to upgrade to the latest release, IDSP v4.0.2, and you are currently using an earlier version, it is advisable to first upgrade to the latest patch of the subsequent minor release before moving on to IDSP 4.0.2.
  IDSP uses the following format for naming release versions: MAJOR.MINOR.PATCH. For example, in the release version 4.0.x, "4" is the MAJOR version, "0" is the MINOR version, and "x" is the PATCH version.
  Upgrade Use Cases:
  - ***Upgrade Scenario 1***: Upgrade from IDSP v3.3 to IDSP v4.0
    Recommended Upgrade Path: You should follow this upgrade path- **3.3.x > 3.4.x > 4.0.2**
    Example: 3.3.6 > 3.4.8 > 4.0.2
  - ***Upgrade Scenario 2***: Upgrade from IDSP v3.4.x to IDSP v4.0.x
    Recommended Upgrade Path: You can directly proceed with the upgrade to v4.0.2 without any intermediate steps.
    Example: 3.4.8 > 4.0.2
- The dataseed job may take longer than usual during the upgrade due to the `ALTER TABLE` statement on the `T_USER` table. The duration depends on the number of records in the table. Plan the maintenance window accordingly.
- **Oracle SQL file Updates**: This release includes Oracle database schema changes that may require manual SQL file updates for environments with separate database administration. For detailed upgrade procedures and SQL file application order, see the Oracle SQL File Updates.

See Upgrading Symantec Identity Security Platform.

Retrieving Environment Variable values required for managing IDSP deployment

- To retrieve the values for Release Name and Namespace that were used during the deployment, use the following command:

```
helm ls --all-namespaces
```

In the returned result, look for a deployment that uses the IDSP(IDSP) chart to find the Release Name (NAME Column), and the Namespace (NAMESPACE Column).

After retrieving these values, set them as environment variables using these commands:

```
export RELEASENAME="<RELEASENAME>"
export NAMESPACE="<NAMESPACE>"
```

- To retrieve the value for IDSP(IDSP) Version, use the following command:

```
#use this command to extract and save the current version of the IDSP chart
export SSP_VERSION=$(helm list --filter="${RELEASENAME}$" -n ${NAMESPACE} -o yaml |grep chart:| cut -d'-' -f2-)&&echo version=${IDSP_VERSION}
```

Perform a version upgrade of the IDSP

Follow these steps:

1. As a precaution, it is always recommended to take a backup of the mysql operation db before the upgrade. If you are using a DB service at your cloud provider, refer to the cloud provider's documentation to find out how to involve an On-demand backup. It is also a good practice to periodically perform a restore-from-backup into a non-production environment to ensure your backups are good and that you are familiar with the restore procedure. For example:
   - GCP - https://cloud.google.com/sql/docs/mysql/backup-recovery/backing-up#console
   - AWS - https://aws.amazon.com/getting-started/hands-on/amazon-rds-backup-restore-using-aws-backup/ or https://docs.aws.amazon.com/AmazonRDS/latest/AuroraUserGuide/USER_CreateSnapshotCluster.html
   - Azure - https://learn.microsoft.com/en-us/azure/mysql/flexible-server/how-to-trigger-on-demand-backup
   - Percona MySQL DB - https://docs.percona.com/percona-operator-for-mysql/pxc/backups-ondemand.html
2. Set the Release Name and Namespace of the IDSP service that was used during the deployment as environment variables:

   ```
   export RELEASENAME="<RELEASENAME>"
   export NAMESPACE="<NAMESPACE>"
   ```

   where,

   The ***Release Name*** and ***Namespace*** values match the ones that were used during the solution's deployment.

   See Configuring the Environment Variables for more details.

   NOTE

   In case you do not remember the values for Release name and Namespace that were used during the deployment, use the following command to get those values:

   helm ls --all-namespaces
3. To get the versions of the charts that are currently deployed, run this command:

   ```
   helm ls -n ${NAMESPACE}
   ```

```
# helm ls -n ssp1
NAME            NAMESPACE       REVISION        UPDATED                                 STATUS          CHART                   APP VERSION
db-ssp          ssp1            1               2021-11-15 04:43:21.932623178 -0500 EST deployed        mysql-1.6.7             5.7.30
ssp634          ssp1            1               2021-11-15 04:45:01.433356477 -0500 EST deployed        ssp-1.0.2430            1.0.2430
ssp634-infra    ssp1            1               2021-11-15 04:44:30.726934371 -0500 EST deployed        ssp-infra-1.0.2430      1.0.2430
```

4. Ensure that the helm is pointing to the correct IDSP helm repository where the charts can be found:

   ```
   helm repo add ssp_helm_charts https://ssp_helm_charts.storage.googleapis.com
   ```

   NOTE

   It is safe to run the preceding command more than once even if the repo was already added before.
5. Get the latest information about the IDSP charts from the chart repositories using this command:

   ```
   helm repo update
   ```
6. To get the list of all available helm chart versions in the IDSP helm chachart repo, run this command:

   ```
   helm search repo ssp_helm_charts --versions
   ```

```
# helm search repo ssp helm charts --versions
NAME                                    CHART VERSION   APP VERSION     DESCRIPTION
ssp_helm_charts/ssp                     1.0.2430        1.0.2430        2021.Nov.01 - Helm chart to deploy Security Ser...

```

7. To get the user-supplied deployment values that were used during the deployment of the IDSP infra chart and save it in the *"infra-override.yaml" file, run this command:*

   ```
   helm get values infra-${RELEASENAME} -n ${NAMESPACE} >infra-override.yaml
   ```

   NOTE
   The infra-${RELEASENAME} is the helm release name of the ssp-infra deployment.

8. To switch to using the new log outputs configuration parameters, perform these steps:

   NOTE
   The old log output configuration parameters are deprecated and will not be supported in future releases. Although not required during the upgrade, ensure you switch to using the new configuration parameters before upgrading to the next release.

   a. Back up the existing config map using this command:

      ```
      kubectl get configmap ssp-infra-config -n ${NAMESPACE} -o yaml >fluent-bit-config.yaml
      ```

   b. Edit the ***infra-override.yaml*** file created in the previous step to include the new customConfig configuration parameters under the fluent-bit section. See Logs and Security Audit Data.

   c. Add the annotation, `configVersion: 1.0` to the existing fluent-bit config map (deployed by the IDSP Infra helm chart).
      This annotation indicates to the chart to start using the new customConfig configuration parameters.

      ```
      kubectl annotate configmap ssp-infra-config -n ${NAMESPACE} configVersion=1.0
      ```

9. To upgrade to the latest version of IDSP infra chart, run this command:

   ```
   helm upgrade infra-${RELEASENAME} ssp_helm_charts/ssp-infra -n ${NAMESPACE}  -f infra-override.yaml
   ```

   To upgrade to the latest infra chart using new docker credentials, run this command:

   ```
   helm upgrade infra-${RELEASENAME} ssp_helm_charts/ssp-infra -n ${NAMESPACE}  -f infra-override.yaml \ --
   set
    ssp.global.ssp.registry.credentials.username=<DockerHubUserName>,ssp.global.ssp.registry.credentials.password=<Doc
   ```

   To upgrade to a specific version of IDSP infra chart, run this command:

   ```
   helm upgrade infra-${RELEASENAME} ssp_helm_charts/ssp-infra -n ${NAMESPACE}  -f infra-override.yaml --
   version <CHART VERSION>
   ```

   <CHART VERSION> -This is the value that appears in the output of the helm search (helm search repo ssp_helm_charts --versions) command.

10. Check if the Prometheus adapter is deployed in your cluster, if yes, uninstall it from the cluster.

    a. Assuming that the namespace used to deploy Prometheus adapter is "prometheus-adapter", run this command:

       ```
       helm ls -n prometheus-adapter
       ```

NOTE
If you are not sure about the namespace, run "helm ls -A" to get a list of all the helm charts deployed in your cluster.

b. If the Prometheus adapter is deployed, uninstall it by running this command:

```
helm uninstall <prometheus-adapter-releasename> -n <proemtheus-adapter-namespace>
```

NOTE
The default behavior when using helm without specifying any "--set" options in the upgrade command is to reuse the previously specified values (--reuse-values).

11. To get the user-supplied deployment values that were used during the deployment of the IDSP chart and save it in the *"ssp-override.yaml" file, run this command:*

```
helm get values ${RELEASENAME} -n ${NAMESPACE} >ssp-override.yaml
```

12. If you are upgrading from an older version to IDSP 4.0.2 or newer, you must migrate your legacy direct backend routes (`oauth2` , `identitysvc` , `adminsvc` , etc.) to the new `ssp-router` architecture to avoid downtime.
The `ssp-router` architecture is highly recommended as it simplifies configuration into a single route, centralizes cluster routing, ensures consistent path rewriting, and is required for Gateway API support.
Step by step migration:
    a. **Deploy with parallel routes**: Run your initial upgrade with `keepLegacyRoutes: true` . This safely creates both routing sets,(Both legacy + ssp-router routes are active).

```
ssp:
  ingress:
    type: nginx
    ingressClassName: nginx
    keepLegacyRoutes: true
```

    b. **Validate**: Test the environment to ensure the new `ssp-router` routes are handling traffic properly.
    c. **Clean up legacy routes**: Run a final upgrade with `keepLegacyRoutes: false` to remove the old direct backend routes (Only ssp-router routes remain active).

```
ssp:
  ingress:
    type: nginx
    ingressClassName: nginx
    keepLegacyRoutes: false
```

13. **Choose one of the following upgrade types:**
    – (**Latest version Upgrade**) - To upgrade to the latest version of IDSP chart, run this command:

```
helm upgrade ${RELEASENAME} ssp_helm_charts/ssp -n ${NAMESPACE}  -f ssp-override.yaml --set
 ssp.featureFlags.dataseed.enabled=true --timeout=120m
```

    – (**Specific Version Upgrade**) To upgrade to a specific version of IDSP chart, run this command:

```
helm upgrade ${RELEASENAME} ssp_helm_charts/ssp -n ${NAMESPACE}  -f ssp-override.yaml --version <CHART
 VERSION> --set ssp.featureFlags.dataseed.enabled=true --timeout=120m
```

    Where,<CHART VERSION> -This is the value that appears in the output of the helm search (helm search repo ssp_helm_charts --versions) command.
    – (**Oracle DB SQL Manual Updates**) - The database schema is typically upgraded automatically as part of the dataseed job. In some instances, the **Oracle DB instance must be updated manually** outside of the regular process because the database administration is separate from the IDSP deployment.
    If manual updates of the schema are required, ensure to run the DB schema files (as discussed Oracle SQL File Updates) before upgrading IDSP. Once the DB files have run successfully, now you can upgrade the IDSP chart by enabling the property, "ssp.featureFlags.dataseed.skipSchemaInit" as shown here:

```
helm upgrade ${RELEASENAME} ssp_helm_charts/ssp -n ${NAMESPACE}  -f ssp-override.yaml --set
 ssp.featureFlags.dataseed.enabled=true --set ssp.featureFlags.dataseed.skipSchemaInit=true --
timeout=120m
```

NOTE

- When running the "helm upgrade" to upgrade to a new version of IDSP, the command must have the "ssp.featureFlags.dataseed.enabled" set to true. The "dataseed" job takes care of updating the database schema and the IDSP configuration data.
- The "--timeout=120m" parameter increases the helm timeout for running the "dataseed" job. This is done to ensure that the helm upgrade does not time out prematurely if the database upgrade steps take longer due to high volumes of data in database tables or slowness of the database. In case the helm command times out, it is important to check the status of the dataseed job and wait until it completes, before running the upgrade command again.
- When the IDSP deployment is in progress, **refrain from interrupting it**. You can open another terminal to watch the status of the dataseed job by running the command given in this section. If the deployment timeout expires before the dataseed job pod completes, let the job's pod continue to run, and you could watch the status of the dataseed job by using this command:

  ```
  kubectl get pods -n ${NAMESPACE} -l job-name=${RELEASENAME}-ssp-dataseed-job
  ```

  To get the Pod details, use this command:

  ```
  kubectl describe pods -n ${NAMESPACE} -l job-name=${RELEASENAME}-ssp-dataseed-job
  ```

  To get the log of the schema update container, use this command:

  ```
  kubectl logs -n ${NAMESPACE} -l job-name=${RELEASENAME}-ssp-dataseed-job -c ssp-db-init --
  tail=-1
  ```

  To get the log of the data update container, use this command:

  ```
  kubectl logs -n ${NAMESPACE} -l job-name=${RELEASENAME}-ssp-dataseed-job -c ssp-db-dataseed --
  tail=-1
  ```

- If the dataseed encounters an error, capture the logs and share them with support. The Job ID numbers in the logs confirm that the deployer checked the logs for details on the error. If the dataseed fails to start (for example, due to an incorrect registry secret), it is not treated as an error since no logs get generated. Once the initial issue is identified and resolved, delete the dataseed pod using

  ```
  kubectl delete pods -n ${NAMESPACE} -l job-name=${RELEASENAME}-ssp-dataseed-job
  ```

  and redeploy the IDSP helm chart.

14. To verify that the IDSP chart was upgraded to the desired version, run this command:

    ```
    helm ls -n ${NAMESPACE}
    ```

15. To validate the deployment, run the following command:

    ```
    curl --insecure https://"${SSP_FQDN}"/default/.well-known/openid-configuration
    ```

    NOTE

    If the validation fails, make sure to restart the ingress pods. Due to specific SSL configurations in the Ingress objects, sometimes these settings may require a restart of the ingress pods. Use the command:

    ```
    kubectl rollout restart deployment ingress-nginx-controller -n ingress
    ```

16. To get the user-supplied deployment values that were used during the deployment of the IDSP data chart and save it in the *"ssp-data-override.yaml" file, run this command:*

    ```
    helm get values ${RELEASENAME}-data -n ${NAMESPACE} >ssp-data-override.yaml
    ```

17. To upgrade the "ssp-data" chart to the latest version, run this command:

    NOTE

    - The "ssp-data" chart is updated once a week, therefore to receive the most recent data, follow the procedures that are outlined here and upgrade to the most recent chart.
    - Ensure that the database has at least 20GB of space to hold the network data information.

```
helm upgrade ${RELEASENAME}-data ssp_helm_charts/ssp-data -n ${NAMESPACE}  -f ssp-data-override.yaml
```

18. To verify that the "ssp-data" chart was upgraded to the desired version, run this command:

```
helm ls -n ${NAMESPACE}
```

The steps to perform a version upgrade of the IDSP chart are complete.

Perform a configuration update of the IDSP helm chart

To know about performing a Configuration update of the IDSP helm chart, see Managing Configuration Updates to the Symantec Identity Security Platform Helm Chart.

Steps to rollback IDSP deployment

Helm maintains a full history of the different revisions of each deployment. A revision can be a ***version-upgrade,*** or just a deployment ***configuration update*** (upgrade to the same version with a config change). Helm allows you to revert to any previous revision of the deployment. Helm does not distinguish between helm upgrade revisions that were used to update the deployment configuration and those that performed a version upgrade.

IDSP supports a rolling back for a single version upgrade, which means that even if the database has already been migrated to the new version, you can roll back the chart to the previous version. This limitation is only referring to an IDSP version rollback. You can revert (rollback) as many "configuration update" revisions as you need, but you should ensure that you are not reverting more than **one "version upgrade"**.

Follow these steps:

1. If you choose to revert to the previous version of the IDSP at any point following the upgrade, you must roll back the Helm version by running these commands:

```
#get history of revisions deployed
helm history <SSP_RELEASE_NAME> -n <SSP_NAMESPACE>

#rollback to the previous (or a specific revision)
helm rollback <SSP_RELEASE_NAME> [REVISION] -n <SSP_NAMESPACE>
```

   Where,

   - the ***<SSP_RELEASE_NAME>*** and ***<SSP_NAMESPACE>*** values should match with the ones that were used during the solution's deployment.

     NOTE
     In case you do not remember the values for Release name and Namespace that were used during the deployment, use the following command to get those values:
     helm ls --all-namespaces
   - ***[REVISION]*** should be replaced with the specific number of the IDSP deployment in the Kubernetes environment you want to roll back to.

2. To verify that you have rolled back to the intented version of IDSP and that the rollback was completed successfully, run the following commands:

```
#check the revision list again
helm history ${RELEASENAME} -n ${NAMESPACE}

#check the current version deployed
helm ls -n -n ${NAMESPACE}

#ensure that all the pods are in ready state
kubectl get pods -n ${NAMESPACE}
```

   The following command lists all the pods in the namespace with their current version:

```
kubectl get pods -n ssp -l app.kubernetes.io/part-of=ssp --template='{{range .items}}{{.metadata.name}}
      {{"\t"}}{{index .metadata.labels "app.kubernetes.io/version"}} {{"\t"}}{{.status.phase}}{{"\n"}}
{{end}}'| column -t -s $'\t'
```

Uninstalling the Solution and Enclave Services

Learn how to uninstall Symantec Identity Security Platform Services.

This topic describes the procedure to uninstall IDSP and enclave services from your Kubernetes environment.

Includes the following sections:

- Uninstalling SSP Data Chart
- Uninstalling IDSP
- Uninstalling Logging Service
- Uninstalling Monitoring Service
- Uninstalling Ingress Service

Uninstalling SSP Data Chart

The ssp-data chart depends on the IDSP chart. If you want to uninstall both charts, delete the ssp-data chart first, then the IDSP chart. If you simply want to uninstall the IDSP chart, see the "Uninstalling IDSP" section and follow the instructions.

To uninstall ssp-data chart from your environment, follow this step:

1. Run this command to uninstall ssp-data (network data loader) chart:
   ```
   helm uninstall ${RELEASENAME}-data -n ${NAMESPACE}
   ```

Uninstalling IDSP

To uninstall IDSP from your environment, follow these steps:

1. Run this command to uninstall IDSP release:
   ```
   helm uninstall <RELEASENAME> -n <NAMESPACE>
   ```
2. Run this command to uninstall the Infra helm chart:
   ```
   helm uninstall infra-<RELEASENAME> -n <NAMESPACE>
   ```
   NOTE
   Ensure that you uninstall the infra helm chart before deleting the namespace as mentioned in the steps.
3. Run this command to get the list of all namespaces deployed in the VIP cluster:
   ```
   helm ls --all-namespaces
   ```
4. After getting the list of namespaces, select the namespace that you want to delete. In this case, select a IDSP namespace and run this command to delete:
   ```
   kubectl delete ns <NAMESPACE>
   ```

Uninstalling Logging Service

To uninstall Kibana and Elastic Search from your environment, follow these steps:

1. Run this command to uninstall the Kibana service:
   ```
   helm uninstall kibana -n logging
   ```
2. Run this command to uninstall Elastic search:
   ```
   helm uninstall elasticsearch -n logging
   ```
3. Run this command to delete the logging namespace:
   ```
   kubectl delete ns logging
   ```

NOTE
If you want to start with an empty data set after uninstalling elastic, then delete all the Elastic's PVC using this command: `kubectl delete pvc <elastic-pvc-name> -n logging`

Uninstalling Monitoring Service

To uninstall Prometheus services from your environment, follow these steps:

1. Run this command to uninstall the Prometheus service:
   ```
   helm uninstall prometheus-operator -n monitoring
   ```
2. Run this command to delete the monitoring namespace:
   ```
   kubectl delete ns monitoring
   ```

Uninstalling Ingress Service

To uninstall Ingress services from your environment, follow these steps:

1. Run this command to uninstall the NGINX -Ingress service:
   ```
   helm uninstall nginx-ingress -n ingress
   ```
2. Run this command to delete the Ingress namespace:
   ```
   kubectl delete ns ingress
   ```

NOTE
When using a cloud provider (such as GKE, AKS, EKS) with the external load balancer, the next ingress installation will generate a new external IP address.

Operating

The Operating section guides you to perform your functions correctly and efficiently.

Operating the Symantec Identity Security Platform deployment involves a number of processes.

This topic includes the following sub-topics:

- Hardening the environment - see the Security Considerations section for guidelines to be applied on day one of the deployments.
- To integrate third-party tools with IDSP to capture and visualize operational and security audit data - see Managing Observability section.
- To choose the topology strategy that best suits your deployment environment, see Managing Deployments section.
- Troubleshooting the environment - see Troubleshooting section.

Security Considerations

Checklist for Securing and Hardening the Symantec Identity Security Platform Environment.

This is the checklist for Securing and Hardening IDSP environment.

Area	Consideration	Overview	Recommendation
Infrastructure	Kubernetes	Kubernetes security enables protecting a cluster from accidental or malicious access. Applicable Docs: • Overview of Cloud-Native Security • Securing a Cluster	• Understand & follow Kubernetes security best practices • Partner with Kubernetes security SME to develop and follow security guidelines
	External Ingress Access	An ingress controller is deployed to expose solution endpoints. By default, a single ingress exposes both the business services and management services. A separate ingress controller can be deployed to expose management services Applicable Docs: Deploying Ingress	• Obtain and deploy an external ingress certificate for your public-facing host. • If you intend to create air gap between the public-facing external ingresses and internal admin and/or management ingress, then obtain and deploy external ingress certificate for internal ingresses.
	Communications to external Operational Database (MySQL)	SSL-based connection with the following options: • DISABLED • PREFERRED • REQUIRED (**default**) • VERIFY_CA • VERIFY_IDENTITY Applicable Docs: Using Database in SSL Mode.	• Ensure SSL is enabled using the highest security setting supported by the database server. • Mutual SSL for MySQL to validate client certificate is not supported.
	Native AWS Authentication to AWS Aurora MySQL	Replaces DB password by AWS IAM as per IAM Database Authentication Applicable Docs: Configuring Connectivity to AWS MySQL DB Without Using a DB Password	• Use this AWS feature to eliminate the use of static DB passwords.

Use of Instance Metadata Service Version 2 (IMDSv2)	IDSP supports both IMDSv1 and IMDSv2 instances in an AWS cluster. However, it is recommended to use IMDSv2 for its enhanced security.	• Use IMDSv2 instances in an AWS cluster for its enhanced security.
Master Data Encryption Key (MEK	MEK is used to encrypt the Tenant Encryption keys which in turn encrypt tenant-specific data, including the system tenant. By default, MEK is auto-generated during the initial deployment. A custom MEK can be specified during the initial deployment. It is not possible for the solution to use the Operational Database without the matching MEK. Applicable Docs: Masterkey Encryption	• If using an automatic MEK created during initial deployment, must have it backed up and stored in a secure location immediately after the deployment. • If using a custom MEK, ensure it is being backed up in a secure location. • If restoring the Operational Database to another location, the original MEK must also be deployed in that location. MEK rollover is not supported.
Internal cluster communications	All internal communications traffic between micro-services is authenticated using an Access Token signed by the internal signing key (ISK). All internal communications traffic between internal microservices is SSL/VERIFY_CA using Internal Signing Key & Certificate. All internal communications traffic between ingress and micro-services is SSL/VERIFY_CA with additional server namespace verification by ingress. Internal services leverage the TLS certificate signed by the internal, self-signed root CA. A custom TLS key/certificate and CA certificate can be specified. Applicable Docs: Intra Cluster Communication	• If an SSL cluster communication uses your own CA, during the SSP helm chart deployment, specify the name of the Kubernetes secret that contains the following files, which represent the ISK: – tls.key file that holds your private key in PKCS8 format – tls.crt file that holds one or more server certificates in PKCS8 format – ca.crt file that holds one or more trusted CA certificates in PKCS8 format **Note**: The PKCS8 format uses the "BEGIN PRIVATE KEY / END PRIVATE KEY" and "BEGIN CERTIFICATE / END CERTIFICATE" header/footer separator lines.
External rate limiting	As an experimental feature, SSP cluster supports rate limiting to protect against cluster overloading from malicious actors. Contact your IDSP team for instructions configuring the NGINX ingress controller.	Access to the IDSP cluster should be rate limited to protect against DDOS attacks on the cluster.

Infra Admin Access	The initial deployment seeds the "Infra admin" client (root) principal with the least amount of privileges required in "break glass" situations when a system admin account is inoperative due to lockout, mistaken policy changes, etc. The client id/secret is exposed to the deployer through the Kubernetes secret for a limited period of time after the initial deployment, and then removed automatically. This Kubernetes secret may be re-created for a limited period of time by re-running the deployment chart with specific values requesting this secret to be re-recreated. Applicable Docs: Administrative Model	• Back up and save the Infra client id/ secret in a vault after the deployment, then delete the Kubernetes secret.
System Admin Access	The initial deployment seeds the "system admin" client principal with Cross Tenant and Tenant Admin functional roles. This client is used to execute system APIs to configure the system, configure system admins, etc. Additionally, this client is used to invoke tenant-level APIs when troubleshooting/fixing tenant-level configuration issues. The client id/secret is exposed to the deployer through the Kubernetes secret for a limited period of time after the initial deployment, and then removed automatically. This Kubernetes secret may be re-created for a limited period of time by re-running the deployment chart with specific values requesting this secret to be re-recreated. Applicable Docs: • Administrative Model • Signing Keys • Deploying Ingress Controller	• Disallow invoking of system-level APIs through the external ingress (see security settings table). • Configure a dedicated ingress network interface for system management operations and use firewall rules to constrain this ingress to internal IPs. Use distinct ingress controller class to set up the management ingress, and deploy the IDSP helm chart with "--set ssp.ingress.mgmt.ingressClassName=<managemen ingress-class-name>"

	System Settings	Various security settings are available to configure the behavior of the system, such as allowSystemOpsOnExternalIngress, accessTokenExpiryMaxMins, idTokenExpiryMaxMins, etc. See table below. Applicable Docs: Settings Configurations	• Configure allowSystemOpsOnExternalIngress=false system setting to disallow system operations on the business ingress object created by the SSP helm chart. • Configure the Issuer Signing Key for the system tenant by importing the Key and Certs signed by a trusted CA. This deletes the self-signed system signing key. • Configure a CORS system setting in the system tenant to accept API requests from specific hosts. • Review and configure various security settings as applicable in your environment for system-level operations and to provide defaults to tenant-level operations.
	Functional	Tenant Admin Access	During the creation of a tenant, the process seeds the "tenant admin" client principal with a Tenant Admin functional role. This client is used to configure the tenant such as to define protected apps, manage authentication/authorization policies, etc. Access by end users can be configured. Applicable Docs: Configuring the Solution • Set up MFA access by end-user admins to ensure user-specific accountability and security. Such admins are configured in the tenant admin signin policy and are granted the Tenant Admin role. • Allow admins to federate against corporate IDP (setup SAML IDP via UI/ API or OIDC OP via API). Restricting the Tenant Admin console to the internal-only network is not supported.
	Tenant Admin Console MFA Warning	Audit event "admin.authpolicy.mfa.warning" is issued when a single rule in an authentication policy protecting the Admin Console does not contain multiple factors.	Multifactor Authentication may be achieved by having multiple policiesor rules, but as a best practice a single rule should be used to secure the Admin Console.
	Tenant Data Encryption Key (TDEK)	Currently hardcoded for the auto-created "default" tenant. A custom TDEK can be provided when creating a tenant.	TDEK rollover is not supported.

	Signin UI Frame Hardening	Harden the Signin UI application by using the deployment-time feature flag "ssp.featureFlags.uiframe.option" specified through the helm chart: • --set ssp.featureFlags.uiframe.option=UNSET (signin UI is rendered with without x-frame-options header) • --set ssp.featureFlags.uiframe.option=DENY (signin UI is rendered with X-Frame-Options: DENY header) • --ssp.featureFlags.uiframe.option: SAMEORIGIN (signin UI is rendered with X-Frame-Options: SAMEORIGIN header) Applicable Docs: • Deployment Time Property	Assess based on security requirements
	Tenant Issuer Signing Key	Each tenant has a signing key used for non-repudiation (sign issued tokens) and confidentiality (decrypt incoming tokens). A newly created tenant is initialized with a self signed key. Applicable Docs: • Signing Keys	Whenever creating a tenant, or after initial deployment, make sure to configure the Issuer Signing Key for the business tenant by importing the Key and Cert signed by a trusted CA. This deletes the previously self-signed tenant signing key.
	Anti snooping In-Transit data confidentiality (also helps in anti replay MITM)	Use in-transit data encryption to ensure end2end confidentiality of the user data collected by the signin app during the user's signin ceremony, **without** depending on SSL. Tenant Setting "fieldsToBeEncryptedInAuthFlow" (csv field containing multiple values) controls whether certain security credentials transmitted by the signin app have additional encryption when the source of SSL termination cannot be trusted. • password - user password collected by sign-in app • devicesignature - device signature collected by sign-in app Applicable Docs: • Encypting Data in Transit	Enabled additional confidentiality capability.

	Tenant Settings for Security Artifacts	Various security settings are available to configure the behavior of the tenant. Tenant Settings overwrite matching System Settings, if any.overwrit, • azCodeExpirySecs • trackAccessToken • trackIdentityToken • etc Applicable Docs: • Settings Configurations	• Configure a CORS system setting in the system tenant to accept API requests from specific hosts. • Review tenant settings to ensure alignment with applicable operational policies. Update settings at the tenant level or at the system level to align with desired settings. • Pay special attention to settings marked in the doc with "Security" tag.
	OAuth Client Authentication	As a best practice, require connecting clients to use PKI for authentication. Applicable Docs: • Client Assertion	• Use JWT Assertion as a means to authenticate OAuth clients, instead of relying on Client ID and Secret. Applies to "/token" and "/introspect" endpoints only.
	Password Storage	User Secrets to store passwords Applicable Docs: • Managing Secrets	• Instead of storing passwords as part of the resource (such as /LDAPconfigs), store the password in a Secret pointed to by an Alias
	End-User Disclosure	Prevent attackers from identifying user accounts whether valid or invalid. Applicable to user-visible signin flows, error messages, API calls made by clients executing in user browsers. Applicable Docs: • End-User Disclosure of Authentication Failures	• Enable an anti-disclosure mode to prevent attackers from identifying user accounts
	KMS-Enabled Password Encryption	Prevent accidental/targeted disclosure of credentials via password encryption done by an external KMS service. Applicable Docs: • Password Encryption	• Take advantage of the Trusted Credential Feature enabling end2end transport security and credential encryption using an external KMS

	Anti Replay Man-in-the-middle (MITM) Attack Prevention	Prevent the MITM attack on artifacts used in various flows. If mitigation is enabled, unexpected changes to such artifacts will be detected. • User Browser's "user-agent" value is made available to the server on every request via an http header. • User's IP Address as is seen by the server. This protection applies to the sign-in flow. • User's Admin Console session as is maintained by the server. This ensures that unexpected changes in user browser's User-Agent, or user's IP Address, or the user's Admin Console session will cause the server to reject incoming requests and terminate the current Admin Console session. Applicable Docs: • Protection against MITM	• Enable MITM protection to guard against replay attacks by the routing tier. • Enable MITM protection to guard against reuse of artifacts copied from another end-user device. • Enable MITM protection to guard against use of bearer tokens copied from the Admin Console session.

<table>
<tr>
<td></td>
<td>Initial Security Credentials</td>
<td>Working with bootstrap credentials:
Due to security concerns with exposing sensitive AuthHub credentials for prolonged periods of time, it is a best practice to remove K8S containing such credentials after 48 hours after the deployment. If required, such bootstrap credentials can be republished into K8S secrets by re-deploying the chart with specific flags to cause K8S secrets to be re-created for another 48-hour period.
To recreate secrets, rerun the helm chart with the CLI values as necessary to re-create the K8S secrets. While doing so, the dataseed does not need to be executed as this would not be a data upgrade, but rather just a configuration update (--set ssp.featureFlags.dataseed.enabled=false).
Helm flags controlling publishing of bootstrap credentials:
<pre>ssp:
  global:
    seedData:
      disclosureExpiryHours: "48"
      defaultTenant:
        seededOnInstall: true
        adminUser:
          seededOnInstall: true
          seededOnUpgrade: false
        adminClient:
          seededOnInstall: true
          disclosedOnInstall:
true
          disclosedOnUpgrade:
false
        demoClient:
          seededOnInstall: true
          disclosedOnInstall:
true
          disclosedOnUpgrade:
false
      systemClient:
        disclosedOnInstall: true
        disclosedOnUpgrade: false
      infraClient:
        disclosedOnInstall: true
        disclosedOnUpgrade: false</pre>
Applicable Docs:
• Configuring Administrative Access</td>
<td>• Immediately after initial deployment, save the infra and system client's credentials in a secure location.
• Make a note of the admin client (defaultTenantClient) and adminUser (defaultTenantAdminUser) for the "default" tenant bootstrapped by the initial deployment. This admin client and admin user have access to the "default" tenant seeded during deployment. If the default admin user credential is requested to be re-published later, the user account will be reset to require a password change at the initial signin.</td>
</tr>
<tr>
<td>Integration</td>
<td>Outbound SMTP provider</td>
<td>Can be configured with or without SSL</td>
<td>• Use SSL.
VERIFY_CA SSL mode is not supported.</td>
</tr>
</table>

	Outbound SMS Provider (Twilio)	SSL is enabled by default	VERIFY_CA SSL mode is not supported.
	LDAP Directory	Can be configured with or without SSL/ VERIFY_CA Applicable Docs: LDAP Configuration	• Use SSL.
	SiteMinder-AuthHub Integration	Integration between SiteMinder and IDSP is over SSL and involves the exchange of JWT-based Identity Tokens in either direction. By default, these tokens are not encrypted, but the use of JWE to encrypt these JWTs is supported. Applicable Docs: SiteMinder Integration with IDSP	• Configure JWE to encrypt Identity Token JWTs exchanged between SiteMinder and AuthHub.
	Web Hooks - SPI hooks, SCIM ID Store	External integration using HTTP APIs should be secured using strong client authentication + transport security methods, when communicating with external Business API Resource Servers and Token STS endpoints. • SSL with at least CA Verification for transport security • For APi authentication, preference should be given to OAuth2-based Client Security using PKI-based Client Assertion, rather than using client id/ secret, API key, or Basic Auth methods, whenever possible. Applicable Docs: • SCIM ID Store • User Change Event Hook	• Use Client Assertion authentication for STS integration • Use SSL in VerifyCA/VerifyIdentity Modes for end2end verification
	Database Password	When connecting to the operational database whose password is being rotated on a regular basis, there is a way for IDSP to read the database password from the Kubernetes secret when it opens a database connection. Applicable Docs: Database Considerations/Vault Handling Database Password Rotation	• Enable database password rotation to harden database connectivity.
	IP-based and Country-based policies	Verify your IDSP installation, and ensure that your network components are configured to preserve the client IP address. This is required for IP-based and Country-based policies to function correctly. Applicable Docs: Use the procedure mentioned in Verifying the deployment section to verify that the client IP address has been preserved.	

Operations/Governance	Operational Log	The operational log receives operational messages indicating ongoing operations. The log can be routed using Fluent Bit configuration to one or more upstream collector/analyzer such as Elastic, Splunk, database, etc. using the "log" data stream By default, the log is "info" with a granularity of {error, warning, info, debug, trace} supported via system-level setting. Applicable Docs: Configuring Enclave Services to Show IDSP content	• Enable operational logging by routing log data into Elastic, Splunk, etc. • Keep the log level = "info" for normal operations. Out of the box, SSL connectivity to an upstream operational log collector is not supported but is field configurable.
	Security Audit Log	The security audit log receives audit messages corresponding to ongoing operations. The log can be routed using Fluent Bit configuration to one or more upstream collector/analyzer such as Elastic, Splunk, database, etc. using the "audit" data stream. By default, the log is "info" with a granularity of {error, warning, info, debug, trace} supported via system-level setting. Applicable Docs: Configuring Enclave Services to Show IDSP content	• Enable security audit by routing audit data into Elastic, Splunk, etc. Out of the box, SSL connectivity to an upstream audit log collector is not supported but is field configurable.
	Observability / Metrics	The operational and performance metrics are emitted for collection by Prometheus Server (or compatible). The Grafana dashboard is provided to visualize such metrics. Applicable Docs: Configuring Enclave Services to Show IDSP content	• Enable observability by routing metrics data into Prometheus. Out of the box, SSL connectivity to an upstream Prometheus Server instance (or compatible) is not supported but is field configurable.

Non Disclosure of User Authentication Failures

Disclosing a reason for authentication failure is considered to be a security vulnerability. IDSP has added the following tenant-level configuration to prevent attackers from determining if a user account is legitimate or invalid:

"hideAuthenticationFailureReason" = "true"/"false"

The Administrator can decide whether to disclose complete error messages regarding authentication failures by setting the above tenant configuration.

When the "***hideAuthenticationFailureReason***" configuration is set to the following:

- if ***true*** - The reason for the failure of the authentication is not disclosed to the user.
- if ***false*** - The user is informed of the reasons for the authentication failure.

This tenant configuration is covered in Global/Tenant Settings.

The following table shows the scenarios and changes in the display of information to the user based on the tenant configuration, "hideAuthenticationFailureReason"= true/false.

Scenario	hideAuthenticationFailureReason=false	hideAuthenticationFailureReason=true

User disambiguation fails (Unique user not found)	{
	"errorCode": "8800004",

Managing Observability

This topic helps us in understanding how to integrate third-party tools with Symantec Identity Security Platform to capture and visualize operational and security audit data.

This topic includes the following sub-topics:

- Logs and Security Audit Data
  - Observing Nginx Ingress Traffic
- Operational Metrics Data

Logs and Security Audit Data

Managing Symantec Identity Security Platform logs and audit events

Gathering of logs on a regular basis is crucial to understand the nature of security incidents, establishing benchmarks, and identifying operational trends. IDSP uses Fluent Bit as the open source tool to collect logs and audit events, and forward them to any of the supported fluentbit log outputs, for example, logs can be streams to elastic search and views in Kibana. However, if you are already using a solution to stream logs from the Kubernetes nodes, you can use it instead of configuring fluent-bit in IDSP Infra chart. To disable the deployment of fluent-bit in the IDSP Infra chart, add "--set fluent-bit.enabled=**false**" to the Infra chart install command.

Configuring Target Log and Audit Messages

To configure the IDSP log outputs to stream log and audit messages to your log repository, create a helm values file as described below and use it when deploying the IDSP Infra Helm chart. The following example uses Kibana to display logs and audit data and the type of logs displayed are: ***ssp_log***, ***ssp_tp_log***, and ***ssp_audit***.

> **NOTE**
> For each log type certain parameters must be configured. The details of these parameters are provided here.

New customConfig configuration parameters

The new customConfig configuration parameters under the fluent-bit section in the ***IDSP infra chart values yaml*** file uses the following format:

```
fluent-bit:
  customConfig:
    outputs:
    - tags:
      <list of log tags to apply the following output  (ssp_log, ssp_audit, ssp_tp_log). >
      template: |
          Name <fluent-bit output plug-in name>
          <configuration parameters as taken from fluent-bit's outputs configuration documentation https://
docs.fluentbit.io/manual/pipeline/outputs>

   - tags:
      <list of log tags to apply the following output (ssp_log, ssp_audit, ssp_tp_log)>
      template: |
          Name <fluent-bit output plug-in name>
          <configuration parameters as taken from fluent-bit's outputs configuration documentation https://
docs.fluentbit.io/manual/pipeline/outputs>
```

Example of the customConfig configuration parameters in the *IDSP infra chart values yaml* file

Based on the new customConfig configuration parameters stated in the previous section, the following example shows the log types: ***ssp_log***, ***ssp_tp_log***, and ***ssp_audit*** that are sent to elastic search to render respective outputs in Kibana. In addition, the ***ssp_audit*** log is also sent to splunk.
Note that the Host name (elasticsearch-es-http.logging.svc) in the following example is same as the Service name and Namespace of the elastic search service.

```
sspfbService:
  ingressLogsIncluded: false
fluent-bit:
  customConfig:
```

```
    outputs:
    - tags:
      - ssp_log
      - ssp_tp_log
      - ssp_audit
      template: |
          Name es
          Host  elasticsearch-es-http.logging.svc
          Port  9200
          tls On
          tls.verify Off
          Suppress_Type_Name On
          Replace_Dots On
          Index ${tag}-%Y.%m.%d
          HTTP_User elastic
          HTTP_Passwd $(kubectl get secret -n logging elasticsearch-es-elastic-user -
o=jsonpath='{.data.elastic}' | base64 --decode; echo)
   - tags:
     - ssp_audit
     template: |
       Name splunk
       Host mysplunkhost.local
       Port  8088
       TLS   on
       TLS.Verify   off
       Splunk_Token a6c401cd-e521-413e-a690-58dba6418a06
       Splunk_Send_Raw off
       event_source http:ssp_logs
       event_sourcetype _json
```

NOTE
When creating the values yaml file from a Linux shell using a construct like 'cat << EOF', you must escape the $ sign by prepending it with a '\' to avoid **'$' sign from being interpreted as an indicator of a shell variable**, as shown in the following example:

```
cat << EOF >  logging-infra-values.yaml
sspfbService:
  parser: cri
fluent-bit:
  enabled: true
  customConfig:
    outputs:
    - tags:
      - ssp_log
      - ssp_audit
      - ssp_tp_log
      template: |
        Name es
        Host  elasticsearch-es-http.logging.svc
        Port  9200
        tls   on
        tls.verify   off
        Suppress_Type_Name On
        Replace_Dots On
```

```
                Index \${tag}-%Y.%m.%d
                HTTP_User elastic
                HTTP_Passwd $(kubectl get secret -n logging elasticsearch-es-elastic-user -
        o=jsonpath='{.data.elastic}' | base64 --decode; echo)
        EOF
```

The IDSP Infra helm chart deployment requires that you override the customConfig section with your own output configuration parameters. Once the values yaml file is created, use the "-f " parameter followed by the name of the values yaml file in the IDSP Infra Helm chart deployment command, for example:

```
-f customConfig_sspinfra.yaml
```

See Additional Parameters to add to the IDSP Infra Chart Deployment section.

Setting Environment Variables in Fluent-Bit

Some output configuration requires an environment variable to be set (see AWS credentials required by the S3 output plug-in). The following example shows how an environment variable can be set (existing feature in fluent-bit chart).

```
  fluent-bit:
   env: []
   #  - name: FOO
   #    value: "bar"

   # The envWithTpl array below has the same usage as "env", but is using the tpl function to support
  templatable string.
   # This can be useful when you want to pass dynamic values to the Chart using the helm argument "--set
  <variable>=<value>"
   # https://helm.sh/docs/howto/charts_tips_and_tricks/#using-the-tpl-function
   envWithTpl: []
   #  - name: FOO_2
   #    value: "{{ .Values.foo2 }}"
   #
   # foo2: bar2

   envFrom: []
```

See the following Example:

```
fluent-bit:
      - env:
        - name: AWS_REGION
          value: ap-southeast-2
        - name: AWS_ACCESS_KEY_ID
          valueFrom:
            secretKeyRef:
              name: fluentbit-s3-key
              key: AWS_ACCESS_KEY_ID
        - name: AWS_SECRET_ACCESS_KEY
          valueFrom:
            secretKeyRef:
              name: fluentbit-s3-key
              key: AWS_SECRET_ACCESS_KEY
```

Mounting Certificates in Fluent-Bit

To enable "tls.verify" in IDSP, you must configure Elasticsearch's CA certificate. This can be accomplished by adding "tls.ca_file /etc/certs/ca.crt" to the output parameters mentioned above, and then using "extraVolumes" and "extraVolumeMounts" to mount the configmap or secret containing the certificate.

Example of the value yaml configuration parameters required to mount a certificate from a secret:

```
fluent-bit:
    extraVolumes:
      - name: tlsconfigs
        secret:
          name: fluent-general-tls
    extraVolumeMounts:
      - name: tlsconfigs
        mountPath: /etc/certs/ca.crt
        subPath: ca.crt
```

Observing Nginx Ingress Traffic

It is critical to monitor the Kubernetes Ingress traffic to detect and manage potential issues that may occur in real time. Using third-party tools like Kibana to display log data on the dashboard helps in tracking the status of services and delving further into any analysis.

Externalizing Ingress log outputs

In Symantec Identity Security Platform, if you intent to externalize the ingress log outputs, you should create a custom config map with the required parameters.

The following example shows a sample of how to create the Ingress config map:

```
kind: ConfigMap
apiVersion: v1
metadata:
  name: ingress-nginx-controller
  namespace: ingress
data:
  error-log-level: "warn"
  log-format-upstream:
  '{"level":"info","type":"log","timestamp": "$time_iso8601", "remoteAddr": "$proxy_protocol_addr",
    "userIP": "$proxy_add_x_forwarded_for", "requestId": "$req_id", "remoteUser":
    "$remote_user", "bytes_sent": "$bytes_sent", "requestTime": "$request_time", "status":
    "$status", "vhost": "$host", "protocol": "$server_protocol", "path": "$uri","api": "$uri",
    "reqLength": "$request_length", "method": "$request_method", "httpReferrer": "$http_referer",
 "userAgent": "$http_user_agent", "contentType": "$http_content_type",
    "clientTxnId": "$upstream_http_x_client_transaction_id", "txnId": "$upstream_http_x_transaction_id",
 "msg": "$server_protocol $request_method $uri processed"
    }'
```

Once the Ingress config map is created, this map should be updated in the Ingress by using this command:

> **NOTE**
> The following command assumes that the config file is named as "**ingress-nginx-controller.yaml**". Once the config map update is complete, the Ingress pod is reloaded with the new configurations.

```
kubectl apply -f ingress-nginx-controller.yaml -n ingress
```

The following example shows a sample output with the modified logging format:

```
{"level":"info","type":"log","timestamp": "2021-09-22T06:21:05+00:00", "remoteAddr": "-", "userIp":

report processed" }
```

Accessing the Ingress Logs

To access the Ingress logs in the third-party dashboard, for example, the Kibana dashboard, perform the following steps.

1. Include the following parameter in your IDSP "ssp-infra" helm chart install/upgrade command:

   ```
   --set sspfbService.ingressLogsIncluded=true
   ```

   For reference to deploy and upgrade commands, see here, Infra Helm deployment command and Infra Helm upgrade command (see step 9-Infra Upgrade).

   NOTE
   If the names of your ingress pods do not use the pattern "ingress-nginx-controller-*", use the following **customConfig > additionalInputs** section in your values yaml file, and replace "ingress-nginx-controller-*" with the pattern that matches your ingress-nginx-controller name and set the ingressLogsIncluded to false, as shown in this example:

```
sspfbService:
    ingressLogsIncluded=false
fluent-bit:
  customConfig:
    additionalInputs:
    - logFileFilter: ingress-nginx-controller-*.log
      tagWith: ssp_msg
```

See Additional Parameters to add to the IDSP Infra Chart Deployment section.

Operational Metrics Data

The operational metrics data helps in measuring efficiency, productivity, and quality of the processes running within the Symantec Identity Security Platform solution. External monitoring tools like Prometheus Operator can be integrated with the solution to monitor the health and get key performance indicators of the deployment.

> **NOTE**
> If you are using out-of-the-box enclave services provided by IDSP, you need not perform the steps mentioned in this topic. The following information is only required if you intend to connect your existing Prometheus solution with IDSP.

IDSP supports exposing metrics information to an external collector. Each of IDSP's micro services exposes a metrics endpoint in a Prometheus format. The information about these endpoints is provided using Prometheus Operator objects called ***ServiceMonitor***.

When integrating the IDSP solution with Prometheus, you should examine the configuration of the monitoring tool to see how this monitoring service is configured to identify **ServiceMonitor** objects that it must serve. This can be done by using a specific label on the serviceMonitor object or on a namespace.

To see the labels that are used by Prometheus for the serviceMonitor object, use the following command:

```
kubectl get prometheus -o yaml
```

The following example shows the labels that are used as a selector for the serviceMonitor object:

```
serviceMonitorSelector:
 matchLabels:
   team: frontend
```

To ensure that such a similar label exists on the IDSP created **serviceMonitor** object, add the following command to the IDSP (ssp) helm chart deployment command:

```
--set-string ssp.global.monitoring.prometheusOperator.serviceMonitor.additionalLabels.<label-name>="<label-value>"
```

- where, the <label-name> and <label-value> should be replaced with appropriate label and value.

After replacing the <label-name> and <label-value>, the configuration would look similar to this example:

```
--set-string ssp.global.monitoring.prometheusOperator.serviceMonitor.additionalLabels.team=frontend
```

- Custom Metrics Supported by IDSP

Custom Metrics Exposed by Symantec Identity Security Platform

Symantec Identity Security Platform exposes custom metrics that provide insight into the health of the business services.

The following table summarizes the custom metrics (counters/timers) exposed by IDSP services.

Table 33: Custom Metrics exposed by IDSP

Metrics	Type	Description	Events	Tags
`ssp_auth_total`	Counter	Metrics published by the authentication orchestrator service (auth-mgr) for various authentication events	• auth-mgr.auth.initiate • auth-mgr.auth.success • auth-mgr.auth.failure	• eventId • tenant • appName
`ssp_azserver_total`	Counter	Metrics published by authorization server (azserver) for OIDC/OAuth2 events	• azserver.token.success • azserver.token.failure • azserver.token.revoke.success	• eventId • tenant • **grantType**
`ssp_factor_total`	Counter	Metrics published by factors service (factor) for various authentication events	• factor.me.register.initiate.success • actor.me.register.initiate.failure • factor.me.register.complete.success • factor.me.register.complete.failure • factor.me.auth.initiate.success • factor.me.auth.initiate.failure • factor.me.auth.complete.success • factor.me.auth.complete.failure • factor.me.auth.lock.success • factor.me.auth.lock.failure	• eventId • tenant • **factorCount** • **factorType**
`ssp_risk_total`	Counter	Metrics published by risk service (factor) for risk evaluation operations	• risk.eval.success • risk.eval.failure	• eventId • tenant • **riskScore** • **riskReason**
`ssp_idstore`	Timer	Timer for idstore events generated by IDSP	• operation= USER_GET • operation=PASSWORD_AUTH	• tenant • idstore • type • operation • status

Metrics	Type	Description	Events	Tags
`ssp_identity`	Counter	Metrics published by Identity Service and SCIM	**User metrics** • identity.scim.user.create.success • identity.scim.user.create.failure • identity.scim.user.update.success • identity.scim.user.update.failure • identity.scim.user.delete.success • identity.scim.user.delete.failure **Group metrics** • identity.scim.group.create.success • identity.scim.group.create.failure • identity.scim.group.update.success • identity.scim.group.update.failure • identity.scim.group.delete.success • identity.scim.group.delete.failure • identity.scim.group.members.update.success -extended attrs contain users being added or removed • identity.scim.user.groups.members.update.failure -extended attrs contain users being added or removed **Password and unlock metrics** • identity.scim.user.password.update.success • identity.scim.user.password.update.failure • identity.me.password.reset.initiate.success • identity.me.password.reset.initiate.failure • identity.password.reset.initiate.success • identity.password.reset.initiate.failure • identity.me.unlock.success • identity.me.unlock.failure	• eventId • tenant • type • idstore="internal"

`ssp_message_delivery_seconds_count`
`ssp_message_delivery_seconds_max`
`ssp_message_delivery_seconds_sum`
	Timer	Metrics published by message delivery service	• Message delivery events where channel is - EMAIL/SMS/PUSH/IVR	• tenant
				• deliveryChannel
				• providerName
				• **status**

Metrics	Type	Description	Events	Tags
ssp_admin_total	Counter	Metrics published by admin service for various administration events	• admin.me.cred.update.success • admin.me.cred.delete.success • admin.me.cred.update.failure • admin.me.cred.delete.failure • • admin.user.cred.update.success • admin.user.cred.delete.success • admin.user.cred.update.failure • admin.user.cred.delete.failure • • admin.user.device.create.success • admin.user.device.update.success • admin.user.device.delete.success • admin.user.device.create.failure • admin.user.device.update.failure • admin.user.device.delete.failure • • admin.me.device.create.success • admin.me.device.update.success • admin.me.device.delete.success • admin.me.device.create.failure • admin.me.device.update.failure • admin.me.device.delete.failure • • admin.cert.create.success • admin.cert.update.success • admin.cert.delete.success • admin.cert.create.failure • admin.cert.update.failure • admin.cert.delete.failure • • admin.app.create.success • admin.app.update.success • admin.app.delete.success • admin.app.create.failure • admin.app.update.failure • admin.app.delete.failure • • admin.app.activate.success • admin.app.activate.failure • admin.app.deactivate.success • admin.app.deactivate.failure • • admin.authpolicy.create.success • admin.authpolicy.update.success • admin.authpolicy.delete.success • admin.authpolicy.create.failure • admin.authpolicy.update.failure • admin.authpolicy.delete.failure • • admin.authzpolicy.create.success • admin.authzpolicy.update.success	• tenant • eventId
			• admin.authzpolicy.delete.success • admin.authzpolicy.create.failure • admin.authzpolicy.update.failure • admin.authzpolicy.delete.failure •	

Metrics	Type	Description	Events	Tags
ssp_identity_stats	Gauge	Static metrics published by the scheduler service	N/A	• type • tenant • provider="internal"

The following table displays the custom metrics and associated samples.

Table 34: Custom Metrics and Samples

Metrics	Sample
ssp_auth_total	ssp_auth_total{ container="ssp-auth-mgr", endpoint="https", eventId="auth-mgr.auth.initiate", instance="10.40.0.195:8086", job="ssp-1737-ssp-auth-mgr", namespace="ssp1", pod="ssp-1737-ssp-auth-mgr-9f684cfff-kq65p", service="ssp-1737-ssp-auth-mgr", tenant="default", appName="defaultClient"} codeph>

Symantec Identity Security Platform Monitoring Information in Grafana Dashboard

The Symantec Identity Security Platform panels that are represented in Grafana dashboard provides insights into the performance and health of IDSP and its integrated components.

This document provides links to all the IDSP panels, providing a centralized view of key metrics for Authentication Statistics, Integrations, Resource Statistics, Policy Usage Statistics, and overall Services Health. It also provides the operational status of your environment with dedicated panels for Insights, Cache Health, Database Health, Policy Engine (OPA) Health, and KPI, alongside Enclave Services Health.

Top Bar Controls

`Cluster / Namespace / Aggregator Filters` : These controls allow filtering of data by cluster, namespace, and time interval aggregation (1m)

`Time Range Selector` : This controls the time window for the data displayed. Set the time selector to include metrics information from the various options available. For example, select "Last 24 hours".

The following IDSP panels are displayed in Grafana Dashboard:

- Summary
- Authentication Statistics
- Integrations
- IDSP Resource Statistics
- IDSP Policy Usage Statistics
- IDSP Services Health
- IDSP Insights
- IDSP Cache Health
- IDSP Database Health
- IDSP Policy Engine (OPA) Health
- IDSP KPI
- Enclave Services Health
- Kubernetes Cluster

Summary

Symantec Identity Security Platform Summary panels - Overview and Metrics

The Summary panels serve as high-level KPIs for monitoring the performance and behavior of authentication events.

- Total Requests
- Authentication

Total Requests

This panel summarizes the overall system-level performance metrics.

Table 35: Total Requests Panel

Metric	Description
Success Rate	API success percentage
Latency	The average response time (in milliseconds) for each API request
Throughput	The average API requests per minute
Count	Total number of API requests

Authentication

This panel summarizes the metrics of the authentication flows.

Table 36: Authentication Panel

Metric	Description
Initiations	Number of initiated authentication flows
Allowed	Percentage of successful authentications
In Progress	Percentage of authentications currently in progress
Abandoned	Percentage of authentications abandoned
Denied	Percentage of authentications denied

Metric	Description
Sign-in Duration	Average sign-in time

Authentication Statistics

The Authentication Statistics panels provide an overview of authentication behavior, analyzing credential usage (primary and multi-factor), risk rule triggers, and authentication outcomes.

The Authentication Statistics dashboard contains panels to analyze authentication behavior of Symantec Identity Security Platform.

The following panels are included:

- Credentials Usage - As Primary
- Credentials Usage - As Multi Factor
- Initiations
- Risk Rules
- Statistics
- Sign-In KPI

Credentials Usage - As Primary

This panel displays the metrics of credential types that are used as the primary authentication factor, measured in value and percentage.

- `Value` - The count of how many times a specific credential type was used during the selected time range. For example, the Password or SMS OTP was used for "x" number of times.
- `Percentage` - The percentage of each credential type's usage compared to the total count of factors for that panel.

Credentials Usage - As Multi Factor

This panel displays the metrics of credential types that are used in multi factor authentication, measured in value and percentage.

- `Value` - The count of how many times a specific credential type was used during the selected time range. For example, the Email and SMS OTP has been used for "x" number of times.
- `Percentage` - The percentage of each credential type's usage compared to the total count of factors for that panel.

Initiations

This panel displays metrics on distribution of authentication initiations across different applications.

- `Value` - The count of how many times a specific application has been initiated during the selected time range.

Risk Rules

This panel displays metrics on distribution of the triggered risk rules. It indicates the rules that are triggered the most and the least.

- `Value` - The count of how many times a specific risk rule type was triggered during the selected time range.
- `Percentage` - The percentage of each risk rule type's that were triggered compared to the total count of risk rules triggered for that panel.

Statistics

This panel displays the metrics to help correlate authentication outcomes with specific applications.

Table 37: Statistics Panel

Attributes	Description
Application Name	Lists each application involved in authentication.
Initiations	Number of initiated authentication attempts for the application.
Allowed	Number of successful authentications
Abandoned	Number of authentications that were abandoned before completion.
In Progress	Number of authentications currently ongoing.
Denied	Number of failed or denied authentications.
Sign-in Duration	Time taken (in seconds or ms) to complete the sign-in process per application.

Sign-In KPI (Key Performance Indicator)

This panel provides key performance indicators (KPIs) for the signin process. It helps assess both the duration and throughput of user signins over time.

The panel includes:

- A **time-series line graph** visualizing the KPIs.
- A **table** summarizing metrics on sign-in duration and sign-in throughput.

Graph Type: Time-series line graph

X-Axis Unit: Represents time (chronological series)

Y-Axis Unit: Represents the number of sign-in requests per minute

Table 38: Sign-In KPI Panel

Metric	Description
Sign-in Duration	Average time it takes for a user to complete the sign-in process
Sign-in Throughput	Rate at which sign-in requests are processed over time

Integrations

Symantec Identity Security Platform Integrations - provides insight into the performance of core backend integration services.

The "Integrations" panels provides real-time monitoring of the core backend integration services that support authentication flows in IDSP.

This topic includes the following panels:

- Message Delivery, Risk, Decryption Providers
- Identity Stores

Message Delivery, Risk, Decryption Providers

This panel provides insight into the performance of various backend integration services.
It captures the following key metrics for each service:

- **Success Rate** - The percentage of successful responses from the service.
- **Request Count** - The total number of requests made to the service.
- **Latency** - The average response time (in milliseconds) for each service.

Table 39: Service Descriptions

Service	Description
SMS	SMS provider used to deliver OTPs
Email	Email provider used to deliver OTPs
Push & TOTP (VIP)	Push notification or time-based OTP delivery via VIP
SPI (SMS, Email, IVR, Risk)	Custom service provider interface supporting multiple channels
Risk Engine	Evaluates risk based on behavior, device, etc
Decryption	Service responsible for data decryption
Geolocation	Service to fetch the geographic location based on IP address
Policy Engine (OPA)	Policy Engine of IDSP

Identity Stores

This panel displays metrics of requests made to the configured identity providers during authentication (like LDAP, SCIM, AD, or INTERNAL).
It captures the following key metrics for the identity stores:

- **Request Count** - The total number of requests made to the service.
- **Latency** - The average response time (in milliseconds) for each service.

Resource Statistics

Symantec Identity Security Platform Resource Statistics - these panels display metrics related to users and groups, password activities, applications , policies etc.

The Resource Statistics dashboard provides a holistic view of resources and policies that are configured and used in the IDSP (SSP) environment, useful for admins to monitor usage patterns.

This topic includes the following panels:

- Users and Groups
- Password Activities
- Application, Certificates and Identity Providers
- Policies

Users and Groups

These are separate panels, each displaying metrics of total and newly added users and groups in IDSP.

Table 40: User and Group Panels

Panel	Description
User Count	Total number of users currently registered in the system.
New Users	Number of users newly created in the system over the selected time range.
Group Count	Total number of user groups.
New Groups	Number of new groups created in the system over the selected time range.

Password Activities

These are separate panels, each displaying metrics related to password-related actions such as resets and updates by users and admins in IDSP.

Table 41: Password Activity Panels

Panel	Description
Password Reset (By Admin)	Number of password resets performed by administrators.
Password Reset (By User/Self)	Password resets initiated by users themselves (self-service).
Password Reset Completed (By User)	Successful completion of user-initiated password resets.
Password Update (By User)	Instances where users updated their password (not necessarily due to reset).

Application, Certificates and Identity Providers

These are separate panels, each displaying the metrics related to IDSP resource usage activities, including the number of registered applications, federated identity providers, and issued certificates.

Table 42: Application and Integration Stats Panel

Panel	Description
Applications	Number of registered applications in IDSP.
Identity Providers	Number of configured identity providers (for example - LDAP, SAML, OIDC).
Certificates	Number of active certificates

Policies

These are separate panels, each displaying metrics related to the number of configured authentication, authorization, and IDP discovery policies within IDSP.

Table 43: Policy Panel

Panel	Description
Authentication Policies	Total number of policies governing user authentication rules.
Authorization Policies	Total number of policies defining access control/permissions.
IDP Discovery Policies	Policies that determine how identity providers are selected during login.

Policy Usage Statistics

Know about Symantec Identity Security Platform Policy Usage Statistics.

Policy Usage Statistics panels monitors how often authentication, IDP discovery policies, and authorization policies are matched, helping assess policy usage trends.

This topic includes the following panels:

- Matched Authentication Policies
- Matched Authentication Policies Statistics
- Matched IDP Discovery Policies
- Matched IDP Discovery Policies Statistics
- Matched Authorization Policies
- Matched Authorization Policies Statistics

Matched Authentication Policies

This panel displays metrics of how frequently different authentication policies were matched during authentication flows.

Table 44: Matched Authentication Policies Panel

Metric	Description
Policy Names	Displays the matched authentication policy names.
Value	The count of how many times a specific authentication policy was matched during the selected time range.
Percentage	The percentage share of each authentication policy match found compared to the total count of policies for that panel.

Matched Authentication Policies Statistics

This panel displays metrics on how often each policy and the policy rule is matched during authentication flows.

Table 45: Matched Authentication Policies Statistics Panel

Metric	Description
Policy Name	Displays the matched authentication policy names.
Rule Name	Displays the matched authentication policy rule name.
Count	Number of times the identified policies were matched during authentication attempt.

Matched IDP Discovery Policies

This panel displays metrics of how frequently different IDP Discovery policies were matched during authentication flows.

Table 46: Matched IDP Discovery Policies Panel

Metric	Description
Policy Names	Displays the matched IDP Discovery policy names.
Value	The count of how many times a specific IDP Discovery policy was matched during the selected time range. For example, the "Corporate IDP Policy" was matched "x" number of times.
Percentage	The percentage share of each IDP Discovery policy matches found compared to the total count of policies for that panel.

Matched IDP Discovery Policies Statistics

This panel displays a metric to help correlate IDP Discovery policies with how often each policy is matched during authentication flows.

Table 47: Matched IDP Discovery Policies Statistics Panel

Metric	Description
Policy Name	Displays the matched IDP Discovery policy names.
Rule Name	Displays the matched IDP Discovery policy rule.
Count	Number of times the identified IDP Discovery policies were matched during authentication attempt.

Matched Authorization Policies

This panel displays metrics on matched authorization policies along with their usage frequency and descriptions to help assess policy effectiveness and access patterns.

Table 48: Matched Authorization Policies Panel

Metric	Description
Policy Names	Displays the matched authorization policy names.
Value	The count of how many times a specific authorization policy was matched during the selected time range. For example, the "TenantAdminPolicy" was matched "x" number of times.
Percentage	The percentage share of each authorization policy matches found compared to the total count of policies for that panel.

Matched Authorization Policies Statistics

This panel displays metrics that helps to correlate matched authorization policies with their access pattern.

Table 49: Matched Authorization Policies Statistics Panel

Metric	Description
Policy Name	Displays the matched authorization policy names.
Rule Name	Displays the matched authorization policy rule.

Metric	Description
Count	Number of times the identified authorization policy was matched.

Services Health

Know about Symantec Identity Security Platform Services Health

The Service Health panels provide real-time insights into service and pod level resource usage and database connection pool metrics, helping monitor system performance and identify bottlenecks.

This topic includes the following panels:

- Service Status
- Service Metrics
- Service Throughput
- Pod CPU, Pod Memory, JVM Threads, DB Pool Usage

Service Status

This panel displays the metrics on the status of all the IDSP services running in the Kubernetes cluster.

Table 50: Service Status Panel

Metric	Description
Service	Displays the IDSP services running in the Kubernetes cluster.
Status	Displays the status of the services. There are many possible service status - Ready, Initializing, Terminating etc.
Replicas	Displays the number of pods or instances of the IDSP services that are running at any given time.

Service Metrics

This panel represent the metrics related to key performance indicators, such as throughput, latency, and resource usage for monitoring the health and efficiency of each IDSP service.

Table 51: Service Metrics Panel

Metric	Description
Service	Displays the IDSP services running in the Kubernetes cluster.
Request Count	Displays the total number of requests received by each of these IDSP services.
Throughput (rpm)	Indicates the rate at which API requests are served by the IDSP services, measured in request per minute (rpm).
Latency	Indicates the time taken by IDSP services to respond to requests. This is a critical metric for understanding service performance and identifying potential bottlenecks or issues.
Error Count	Indicates the number of errors or failures associated with that specific IDSP service over a given time period.

Service Throughput

This panel displays the metrics on the number of requests processed by each IDSP service, indicating overall service load and performance. This information is represented through a graph.

Graph Type: Time-series line graph with a table of service throughputs.

Y-Axis Unit: Shows throughput value

Table 52: Service Throughput Panel

Metric	Description
Max	The maximum throughput value indicates the highest API requests handled by each of the IDSP service within a specified time frame. This can be useful for identifying peak loads and capacity planning.
Average	The average throughput shows the mean throughput over a specific period, providing an overall understanding of the service's performance. It can be useful for identifying trends and comparing the service's performance over time.
Current	The current throughput reflects the real-time throughput of the IDSP service at a specific moment. It provides a snapshot of the service's current activity and can be used for monitoring and alerting based on real-time performance.

Pod CPU, Pod Memory, JVM Threads, DB Pool Usage (1m)

This panel displays metrics related to DB connection pooling, availability, performance, and resource limits.

Table 53: Pod CPU, Pod Memory, JVM Threads, DB Pool Usage Panel

Metric	Description
Pod Name	The name of the Kubernetes pod being monitored.
Node IP	The IP address of the node hosting the pod.
Request Count	Total number of requests received by the pod in the observed interval.
Throughput (rps)	The number of requests processed per second by the pod (rps = requests per second).
Latency (ms)	Average time taken to respond to requests, measured in milliseconds.
CPU Limit	The maximum CPU resource allocated to the pod.
Memory Limit	The percentage of CPU used from the allocated limit.
JVM Threads (Live)	The number of active/live Java Virtual Machine (JVM) threads running in the pod.
DB Timeouts	The count of database timeout events experienced by the pod.
DB Conn Time	The average time (in milliseconds) taken to establish a database connection. Lower values indicate better performance; high values may suggest connection delays or DB contention.
DB Pool Active	The number of currently active (in-use) database connections in the connection pool. Reflects live demand on the pool.
DB Pool Idle	The number of idle (available and ready) connections in the pool. If this number is constantly low, it may indicate the pool is under-provisioned.
DB Pool Min	The minimum number of connections maintained in the connection pool, even during low traffic. This ensures a baseline readiness.

Metric	Description
DB Pool Max	The maximum number of connections allowed in the pool. Once this limit is reached, new requests must wait for a connection to be freed. It helps in controlling DB resource usage.

Insights

Know about Symantec Identity Security Platform Insights

The Insight panels collectively provide visibility into authentication risks, geographical threat patterns, and API performance bottlenecks.

This topic includes the following panels:

- Triggered Risk Rule Vs Authentications
- Location Vs Authentication Statistics
- API with High Response Time (>100ms)

Triggered Risk Rule Vs Authentications

This panel displays metrics on different risk rules that are triggered during authentication attempts, and how those triggered risk rules affect the outcome of each authentication.

Table 54: Triggered Risk Rule Vs Authentications Panel

Metric	Description
Risk Rule	Displays the risk rule that was triggered during the authentication attempt. For example, rules could detect suspicious IP addresses, risky countries, behavior anomalies, etc.
Auth Allowed	The number of authentication attempts where the risk rule was triggered but the authentication was allowed to proceed. This means the system flagged a risk, but the user was still permitted access.
Auth Denied	The number of authentication attempts where the risk rule was triggered and the authentication was denied. This means the risk rule caused a failure in the authentication.
Auth Abandoned	The number (or rate) of authentication attempts where the risk rule was triggered but the authentication process was abandoned by the user.

Location Vs Authentication Statistics

This panel displays metrics on how authentication attempts are distributed across different geographical locations, and how those attempts succeed, fail, or get abandoned based on risky countries. It helps identify patterns of suspicious behavior linked to specific regions.

Table 55: Location Vs Authentication Panel

Metric	Description
Country	Displays the country from which the authentication attempt was made during the authentication attempt.
Auth Allowed	Number of authentications from the country that were successful.
Auth Denied	Number of authentications from the country that were rejected.
Auth Abandoned	Number of authentications that were started but not completed.

API with High Response Time (>100ms)

This panel displays metrics on the APIs that consistently take longer than 100 milliseconds to respond. It helps identify performance bottlenecks and latency issues in IDSP services.

Table 56: API with High Response Time Panel

Metric	Description
Name	Displays the list of IDSP APIs that take longer than 100 ms to respond.
Mean	The average response time of the IDSP API over the observed time range.
Last	The most recent response time recorded for the IDSP API.
Max	The maximum response time of the IDSP API observed during the time range.
Min	The minimum response time of the IDSP API observed during the time range.

Cache Health

Know about the health of Symantec Identity Security Platform Cache

The Cache Health panels gives insights into the health of Cache service (Hazelcast) in IDSP. It provides details of functional metrics (map statistics) and operational metrics (memory, heap, CPU usage) of Hazelcast cluster members.

This topic includes the following panels:

- Connection Latency
- Availability
- Status
- Member Count
- Client Count
- Member Heap Usage
- Member Memory Usage
- Member CPU Usage
- Map Statistics

Connection Latency

This panel displays metrics on latency between Hazelcast members and clients.

Availability

This panel displays the percentage availability of cache service.

Status

This panel displays the status of the Hazelcast members.

Member Count

This panel displays the number of active Hazelcast members in the cluster.

Client Count

This panel displays the number of clients connected to Hazelcast cluster.

Member Heap Usage

This panel displays the metrics on the JVM heap memory in use by each Hazelcast member.

Table 57: Member Heap Usage Panel

Metric	Description
Name	The name of the Hazelcast member (pod) in the Kubernetes cluster.
Mean	The average heap memory used by that member over the selected time range, measured in MiB (Mebibytes). This shows general memory consumption trends.
Max	The maximum heap memory consumed by that member during the selected time period. It represents the peak memory usage, helping identify memory spikes or potential overloads.

Member Memory Usage

This panel displays the metrics on the total memory used by each Hazelcast member.

Table 58: Member Memory Usage Panel

Metric	Description
Name	The name of the Hazelcast member (pod) in the Kubernetes cluster.
Mean	The average total memory (not just heap) used by the member over the selected time range, measured in MiB (Mebibytes).
Max	The maximum total memory (not just heap) consumed by that member during the selected time period.

Member CPU Usage

This panel displays metrics on the CPU usage percentage for each Hazelcast member (pod) in the Kubernetes cluster over the selected time range.

Table 59: Member CPU Usage Panel

Metric	Description
Name	The name of the Hazelcast member (pod) in the Kubernetes cluster.
Mean	The average CPU usage of the member over the selected time range, measured in percentage.
Max	The maximum CPU usage of the member over the selected time range, measured in percentage.

Map Statistics

This panel provides metrics on key operational insights about Hazelcast distributed maps within a Kubernetes cluster. Each row corresponds to a specific map held by a Hazelcast member (pod), and shows various stats related to memory, and read/write behavior.

Table 60: Member CPU Usage Panel

Metric	Description
Map Name	The name of the distributed map.
Member	The name of the Hazelcast member (pod) that holds the data for the map.
Count	The number of key-value pairs (entries) in the map on that member.
Backup Count	The number of entries held as backups on this member (in case the primary owner fails).
Memory	Approximate memory used by the map on that member.
Cache Reads	The number of times the map was read (GET operations).
Cache Updates	The number of times entries in the map were updated (PUT operations).

Database Health

Know about the health of Symantec Identity Security Platform Databases

The Database Health panels provides a detailed view of database connection activity, usage duration, timeout events, and replication latency across all the IDSP services to ensure efficient database health.

This topic includes the following panels:

- Active Connections
- Connections Usage Time
- Connection Timeouts
- Replication Latency (Populated when system setting PersistentStoreForTransactionalData=DB)

Active Connections

This panel displays metrics showing all the IDSP active database connections from various IDSP services in a selected time range.

The panel includes:

- A **time-series line graph** visualizing the active connections.
- A **table** summarizing active db connections for each IDSP services.

Graph Type: Time-series line graph

X-Axis Unit: Represents time (chronological series)

Y-Axis Unit: Represents number of active connections.

Table 61: Active Connections Panel

Metric	Description
Name	Lists the names of the IDSP services that are being tracked for active connections.
Last	The most recent active connection recorded for each IDSP services.
Mean	The average active connections that were recorded for each IDSP services during the selected time range.
Max	The highest observed active connection recorded for each IDSP services during the selected time range.

Connections Usage Time

This panel displays metrics showing how long the IDSP database connections were used during the selected time range. It helps identify potential bottlenecks or performance issues related to connection handling.

The panel includes:

- A **time-series line graph** visualizing the connection duration trends.
- A **table** summarizing usage statistics for each IDSP services

Graph Type: Time-series line graph

X-Axis Unit: Represents time (chronological series)

Y-Axis Unit: Represents connection usage time, in milliseconds (ms).

Table 62: Connections Usage Time Panel

Metric	Description
Name	Lists the names of the IDSP services.
Mean	The average duration for which the connections were used by each IDSP services during the selected time range.
Last	The most recent connection usage time recorded for each IDSP services.
Max	The highest observed connection usage time recorded for each IDSPservices.

Connection Timeouts

This panel displays metrics showing the number of connection timeouts for each Symantec Identity Security Platform service over time. This metric could indicate connectivity issues.

The panel includes:

- A **time-series line graph** visualizing the connection timeout trends.
- A **table** summarizing connection timeout for each service.

Graph Type: Time-series line graph

X-Axis Unit: Represents time (chronological series)

Y-Axis Unit: Represents number of DB connection timeouts.

Table 63: Connection Timeouts Panel

Metric	Description
Name	Lists the IDSP services that are being tracked for connection timeouts.
Mean	The average number of connection timeouts recorded for each IDSP services during the selected time range.
Last	The most recent connection timeouts recorded for each IDSP services.
Max	The highest observed connection timeouts recorded for each IDSP services.

Replication Latency (Populated when system setting PersistentStoreForTransactionalData=DB)

This panel displays metrics showing the delay in IDSP database replication when the system setting, "PersistentStoreForTransactionalData=DB" is configured.

The panel includes:

- A **time-series line graph** visualizing the replication latency trends.
- A **table** measuring average and max replication latency for each IDSP services.

Graph Type: Time-series line graph

X-Axis Unit: Represents time (chronological series)

Y-Axis Unit: Represents DB replication latency time in minutes.

Table 64: Replication Latency Panel

Metric	Description
Name The "Name" categorizes the latency metric being tracked, either "Average Latency" or "Max Latency", helping users understand what kind of latency data is being displayed in the graph.	Indicates the type of latency being measured. • Average Latency - represents the mean time delay between the moment a transaction is written to the primary database and when it is replicated to the secondary database. • Max Latency - represents the maximum delay of database replication observed during the selected time range.
Mean	The average database replication delay recorded during the selected time range. This is displayed in "µs" (microseconds).
Last	The most recent IDSP database replication delay recorded.
Max	The highest observed IDSP database replication delay recorded during the selected time range.

Policy Engine Health

Know about Symantec Identity Security PlatformPolicy Engine.

The Policy Engine Health panels show how well OPA is working, including bundle status, load/download times, and policy evaluation performance.

This topic includes the following panels:

- Policy Engine Health Metric
- OPA Policy Loading Statistics
- OPA Policy Download API Statistics
- OPA Policy Evaluation API Statistics

Policy Engine Health Panels

Table 65: Policy Engine Health Panels

Panels	Description
OPA Policy Bundle State	Shows whether the OPA policy bundle is ready (means available) for use.
OPA Policy Load Status	Indicates if the policy loading was successful.
Policy Bundle Download Latency (ms)	Time taken to download the policy bundle.
Policy Evaluation Request Latency (ms)	Time taken to evaluate policy requests.

Panels	Description
Policy Evaluation Success Rate	Percentage of successful policy evaluations.
Panels available	• Pod - refers to the pod name of the OPA service. • Last bundle request - Timestamp of the latest attempt made to request the policy bundle. • Last successful bundle request - Timestamp marking the last time the policy bundle was successfully requested and received without errors. • Last bundle download - The timestamp when the policy bundle was last fully downloaded to the OPA instance. • Last bundle activation - Indicates when the downloaded policy bundle was last activated and made available for evaluations. • Success Load Count - Displays how many times policy bundles have been successfully loaded into OPA. • Failure Load Count - Displays how many times policy bundles have failed to load into OPA.

OPA Policy Loading Statistics

This panel displays metrics showing the number of successful and failed IDSP policy loads over time.

The panel includes:

- A **time-series line graph**
- A **table** summarizing OPA policy load failure or success events.

Graph Type: Time-series line graph

X-Axis Unit: Represents time (chronological series)

Y-Axis Unit: Represents number of policy load events, success or failure.

Table 66: OPA Policy Loading Statistics Panel

Metric	Description
Name The "Name" categorizes the OPA policy loading metric being tracked, either "Policyload Failure" or "Policyload Success", helping users understand what kind of Policyload data is being displayed in the graph.	Indicates the number of policy load failure or success. • Policyload Failure - represents the number of failed policy loads. • Policyload Success - represents the number of successful policy loads.
Last	The most recent value recorded for both API Request Count and API Latency during the selected time range.
Min	The minimum value observed for each metric within the selected time range.
Mean	The average value for each metric within the selected time range.
Max	The highest observed value for each metric within the selected time range.

OPA Policy Download API Statistics

This panel tracks the number of API requests made to download OPA policies and the latency (response time) of those requests over time. It helps monitor the efficiency and responsiveness of the policy download service.

The panel includes:

- A dual-axis-time-series line **graph**
- A **table** summarizing OPA policy downloads.

Graph Type: Dual-axis-time-series line graph

X-Axis Unit: Represents time (chronological series)

Y-Axis Unit: Represents number of policy download events.

Table 67: OPA Policy Download API Statistics Panel

Metric	Description
Name The "Name" categorizes the OPA policy download API Statistics metric being tracked, either "API Request Count" or "API Latency (ms)", helping users understand what kind of API data is being displayed in the graph.	Indicates the API metric being tracked, such as API Request Count or API Latency (ms). • API Request Count - represents the number of times the policy download API was called. • API Latency (ms) - represents the time taken to respond to policy download API calls (in milliseconds).
Last	The most recent value recorded for both API Request Count and API Latency during the selected time range.
Min	The minimum value observed for each metric within the selected time range.
Mean	The average value for each metric within the selected time range.
Max	The highest observed value for each metric within the selected time range.

OPA Policy Evaluation API Statistics

This panel tracks the number of API requests made to evaluate OPA policies and the latency (response time) of those requests over time. It helps monitor the efficiency and responsiveness of the policy evaluation service.

The panel includes:

- A dual-axis-**time-series line graph**
- A **table** summarizing OPA policy evaluation stats.

Graph Type: Dual-axis-time-series line graph

X-Axis Unit: Represents time (chronological series)

Y-Axis Unit: Represents number of OPA policy evaluation events.

Table 68: OPA Policy Evaluation API Statistics Panel

Metric	Description
Name The "Name" categorizes the OPA policy download API Statistics metric with either "API Request Count" or "API Latency (ms)". This helps users understand what kind of API data is being displayed in the graph.	Indicates the API metric being tracked, such as API Request Count or API Latency (ms). • API Request Count - represents the number of times the policy evaluation API was invoked. • API Latency (ms) - represents the time taken to evaluate the policy request (in milliseconds).
Last	The most recent value recorded for both API Request Count and API Latency during the selected time range.
Min	The minimum value observed for each metric within the selected time range.

Metric	Description
Mean	The average value for each metric within the selected time range.
Max	The highest observed value for each metric within the selected time range.

Key Performance Indicator (KPI)

Know about Symantec Identity Security Platform Key Performance Indicators (KPI)

The Key Performance Indicator panels monitor IDSP API performance by tracking throughput (operations per second), latency (response time in ms), and total call count across various endpoints to identify usage trends and potential bottlenecks.

This topic includes the following panels:

- API Throughput
- API Latency
- API Total Count
- API Error Count

API Throughput

This panel monitors the IDSPAPI performance by measuring the throughput (operations per second) of various API endpoints over time.

The panel includes:

- A **time-series line graph**
- A **table** summarizing throughput statistics for each API endpoint

Graph Type: Time-series line graph

X-Axis Unit: Represents time (chronological series)

Y-Axis Unit: Represents Throughput, measured in operations per second (ops/s)

Table 69: API Throughput Panel

Metric	Description
Name	Lists the IDSP API endpoints that are being tracked.
Mean	The average throughput (ops/s) for each IDSP API during the selected time range.
Last	The most recent throughput reading of each IDSP API during the selected time range.
Max	The highest observed throughput per each IDSP API.
Min	The lowest recorded throughput per each IDSP API.

API Latency

This panel monitors and measures the response time (latency) taken by each IDSPAPI call to respond to request.

The panel includes:

- A **time-series line graph**
- A **table** summarizing latency statistics for each API endpoint

Graph Type: Time-series line graph

X-Axis Unit: Represents time (chronological series)

Y-Axis Unit: Represents Latency, measured in milliseconds

Table 70: API Latency Panel

Metric	Description
Name	Lists the IDSP API endpoints that are being tracked.
Mean	The average response time (ops/s) for each IDSP API during the selected time range.
Last	The most recent response reading of each IDSP API during the selected time range.
Max	The highest observed response time taken by each IDSP API.
Min	The lowest recorded response time taken by each IDSP API.

API Total Count

This panel displays the total number of calls made to each IDSP API endpoints over time.

The panel includes:

- A **time-series line graph**
- A **table** summarizing total API count statistics for each API endpoint

Graph Type: Time-series line graph

X-Axis Unit: Represents time (chronological series)

Y-Axis Unit: Represents Total API Call Count in the selected time range

Table 71: API Total Count Panel

Metric	Description
Name	Lists the IDSP API endpoints that are being tracked.
Mean	The average count of calls made to each IDSP API during the selected time range.
Last	The most recent count of calls made to each IDSP API during the selected time range.
Max	The highest observed count of calls made to each IDSP API.
Min	The lowest count of calls made to each IDSP API.

API Error Count

This panel tracks the number of IDSPAPI errors that occurred over a given time period.

The panel includes:

- A **time-series line graph**
- A **table** summarizing total API error count for each API endpoint

Graph Type: Time-series line graph

X-Axis Unit: Represents time (chronological series)

Y-Axis Unit: Represents the count of API errors

Table 72: API Error Count Panel

Metric	Description
Name	Lists the IDSP API endpoints that are being tracked.
Mean	The average count of errors occurred for each IDSP API during the selected time range.
Last	The most recent count of errors occurred for each IDSP API during the selected time range.
Max	The highest observed count of occurred for each IDSP API.
Min	The lowest count of occurred for each IDSP API.

Enclave Services Health

Know about Symantec Identity Security Platform Enclave Services Health

The Enclave Services Health dashboard monitors the health of all the enclave services at pod level that are supported by IDSP. The different panels in this dashboard focuses on storage and resource usage in a Kubernetes environment.

This topic includes the following panels:

- Persistent Volume Claim
- CPU and Memory Usage per pod
- Pods CPU Usage
- Pods Memory Usage

Persistent Volume Claim

This panel displays the current status and usage of Persistent Volume Claims (PVCs).

Table 73: Persistent Volume Claim Panel

Metric	Description
Persistent Volume Claim (PVC)	Lists the PVCs that are created at the pod level
Namespace	Kubernetes namespace where the PVC is defined
StorageClass	Storage class type of the PVC (here it is specified as standard-rwo)
PhysicalVolume	ID of the associated persistent volume
Capacity (GiB)	Total storage capacity allocated to each pod
Used (GiB)	Current used storage
Available (GiB)	Free space available
Status	State of the volume (example, Bound)
Used (%)	Percentage of storage used

CPU and Memory Usage per pod

This panel provides visibility into how much CPU and RAM each pod in a Kubernetes namespace is using relative to its requested and limit values.

Table 74: CPU and Memory Usage Per Pod Panel

Metric	Description
Pod	Lists the IDSP API endpoints that are being tracked.
Namespace	Kubernetes namespace to which the pod belongs
RAM Used	Actual memory currently used by the pod
RAM Requests	Memory (RAM) the pod has requested to reserve.
RAM Limits	The maximum amount of memory the pod is allowed to use.
CPU Used	Actual CPU being consumed by the pod.
CPU Requests	Minimum CPU resources reserved for the pod.
CPU Limits	Maximum CPU the pod is allowed to use.

Pods CPU Usage

This panel monitors CPU usage by different pods in cores and displays the information through a graphical representation.

The panel includes:

- A **time-series line graph**
- A **table** summarizing CPU usage by different pods.

Graph Type: Time-series line graph

X-Axis Unit: Represents time (chronological series)

Y-Axis Unit: Represents CPU cores

Table 75: Pods CPU Usage Panel

Metric	Description
Mean	Average CPU usage during the time window
Last	Latest CPU usage value reported

Pods Memory Usage

This panel displays the memory consumption by each pods.

The panel includes:

- A **time-series line graph**
- A **table** summarizing memory usage by different pods.

Graph Type: Time-series line graph

X-Axis Unit: Represents time (chronological series)

Y-Axis Unit: Represents memory usage in MiB or GiB unit

Table 76: Pods Memory Usage Panel

Metric	Description
Mean	Average memory usage during the time window
Last	Latest memory usage value

Kubernetes Cluster

Know about Symantec Identity Security Platform Kubernetes Cluster panels

The Kubernetes Cluster panels monitor the health and performance of the Kubernetes cluster.

This topic includes the following panels:

- System Time/CPU Cores/Total RAM
- CPU Usage
- Memory Usage

System Time/CPU Cores/Total RAM

These provide a snapshot of the overall resource availability and health:

Table 77: System Time/CPU Cores/Total RAM - Left Panels

Panels	Description
System Uptime	Indicates how long the system has been continuously running (for example - 2.4 weeks).
CPU Cores	Total number of CPU cores available in the cluster (for example - 24).
Total Ram	Total physical memory available across the cluster nodes (for example - 94.05 GiB).
CPU IOWait	Percentage of time CPU is waiting for I/O (input/output) operations to complete (for example - 0.35%).

CPU Usage

This panel monitors the CPU utilization over time for each node which is useful to identify CPU bottlenecks or load spikes on specific nodes.

The panel includes:

- A **time-series line graph**
- A **table** summarizing the CPU usage

Graph Type: Time-series line graph

X-Axis Unit: Represents time, showing when the CPU usage was measured.

Y-Axis Unit: Represents CPU usage percentage, how much of the CPU resources are being used.

Table 78: CPU Usage - Middle Panel

Metric	Description
Name	IP and port of the node exporter on each node (for example - 10.26.2.42:9100).
Mean	Average CPU usage percentage.
Max	Peak CPU usage recorded.

Memory Usage

This panel monitors memory usage trends over time.

The panel includes:

- A **time-series line graph**
- A **table** summarizing the Memory usage

Graph Type: Time-series line graph

X-Axis Unit: Represents time, showing when the Memory usage was measured.

Y-Axis Unit: Represents Memory usage percentage, how much of the memory resources are being used.

Table 79: Memory Usage - Right Panel

Metric	Description
Name	Shows memory consumption for each node in the cluster.
Mean	Average memory usage percentage per node.

Managing Deployment

The deployment topology governs how pods are distributed across your cluster, including regions, zones, nodes, and other user-defined topological domains. This can aid in both high availability and efficient resource utilization.

This topic includes the following sub-topics:

- Meeting Topology Requirements
- Managing Configuration Updates
- Recovering Initial Admin Credentials
- Handling DB Password Rotation
- Scheduler Job
- Populating the Internal Email Domain Column

Meeting Topology Requirements

The content in this page explains the capabilities of the Symantec Identity Security Platform helm chart to manage pods to be align with your specific topology requirements.

In Kubernetes, a Pod represents a set of containers running in a cluster. Pods can be constrained to run on specific node(s), or to prefer to run on specific node(s).

For instructions on updating the configuration of a deployed IDSP helm Chart, see Managing Configuration Changes.

This topic includes the following methods to choose from where Kubernetes schedules specific Pods:

- Node Selector matching against node labels
- Affinity and Anti-Affinity
- Tolerations
- Setting Additional Labels
- Setting Annotations
- Setting Ingress Timeouts
- AWS STS Regional Endpoints
- Helm Offline Mode
- DNS related configuration for IDSP Deployment
- Enabling Availability Metrics
- Seccomp Profile
- HTTP Proxy

Node Selector matching against node labels

The "nodeSelector" parameter is used in IDSP to instruct Kubernetes to schedule the IDSP pods only to a specific set of nodes that have a specific label.

Example:
You can use the following command to add the label "disktype=ssd" to your node:

```
kubectl label nodes <your-node-name> disktype=ssd
```

Where, the <your-node-name> is the name of the node to which you want to add the label, disktype=ssd.

Use the following helm command-line parameter to describe a pod that has a node selector, disktype=ssd.

```
--set nodeSelector.disktype=ssd
```

The same command can be added to the values yaml in this format:

```
nodeSelector:
disktype: ssd
```

Where, the IDSP pods are scheduled on node(s) with the label, disktype=ssd.

> **NOTE**
> For more information, refer to Create a pod that gets scheduled to your chosen node.

Affinity and Anti-affinity

The "affinity" parameter is the advanced version of the "nodeSelector" parameter that provides more flexibility like the ability to use the "in" operator. This parameter can be used in IDSP to instruct Kubernetes to schedule the IDSP pods only to a specific set of nodes with a specific label.

Example:
You can use the following command to add the label "disktype=ssd" to your node:

```
kubectl label nodes <your-node-name> disktype=ssd
```

Where, the <your-node-name> is the name of the node to which you want to add the label, disktype=ssd.

Use the following helm command-line parameter to schedule IDSP pods on nodes that have a label, `disktype=ssd`, using the operator value as "in".

```
--set
 affinity.nodeAffinity.requiredDuringSchedulingIgnoredDuringExecution.nodeSelectorTerms[0].matchExpressions[0].key=disk
 \
```

```
--set
 affinity.nodeAffinity.requiredDuringSchedulingIgnoredDuringExecution.nodeSelectorTerms[0].matchExpressions[0].operator
 \

--set
 affinity.nodeAffinity.requiredDuringSchedulingIgnoredDuringExecution.nodeSelectorTerms[0].matchExpressions[0].values[0
 \
```

The same command can be added to the values yaml in this format:

```
affinity:
nodeAffinity:
requiredDuringSchedulingIgnoredDuringExecution:
  nodeSelectorTerms:
  - matchExpressions:
    - key: disktype
      operator: In
      values:
      - ssd
```

Where, the IDSP pods are scheduled on node(s) that have a label, `disktype=ssd`, using the operator value as "in".

NOTE
For more information, see Schedule a pod using required node affinity.

Tolerations

The "tolerations" parameter is used in IDSP to instruct Kubernetes to allow IDSP pods to be scheduled to a specific set of "tainted" nodes. A "tainted" node rejects all pods that do not have a toleration to their taint.

Example:
Use the following command to set a node, such as node1 with a taint key1=value1:NoSchedule

```
kubectl taint nodes node1 key1=value1:NoSchedule
```

Where, none of the IDSP pods are able to schedule onto node1 unless it has a matching toleration.

You can add tolerations to IDSP using the following helm parameter in the command line:

```
--set tolerations[0].key="key1" --set tolerations[0].operator="Equal" --set tolerations[0].value="value1" --
set tolerations[0].effect="NoSchedule"
```

The same command can be added to the values yaml in this format:

```
tolerations:
- key: "key1"
operator: "Equal"
value: "value1"
effect: "NoSchedule"
```

Where, the IDSP pods are scheduled on node(s) that have the key1=value1:NoSchedule taint. The node here is node1 as mentioned in the example.

NOTE
For more information, refer to taint and tolerations.

Setting Labels

The "additionalLabels" parameter is used to add additional labels to all the IDSP (ssp) pods, Deployments, Jobs, Services, HorizontalPodAutoscaler objects, Hazelcast ConfigMaps, Secrets, and Pod Disruption Budget (PDBs).

For example, the following helm command-line parameter can be used to add the label, env=test to all the IDSP (ssp) pods:

```
--set additionalLabels.env=test
```

The same command can be added to the values yaml in this format:

Example:

```
additionalLabels:
env: test
```

Where, the label "env=test" is added to all the IDSP pods.

> **NOTE**
> The "additionalLabels" parameter does not apply to all the objects created by the IDSP (ssp) helm chart. Therefore, to apply labels to all the objects within the helm chart, use the following parameters:
>
> ```
> hazelcast-enterprise:
> labels: {}
> podLabels: {}
> service:
>     labels: {}
> global:
> additionalLabels: {}
> ```

Setting Annotations

The "additionalAnnotations" parameter is used to add additional annotations to all the IDSP (ssp) pods, Deployments, Jobs, Services, HorizontalPodAutoscaler objects, Hazelcast ConfigMaps, Secrets, and Pod Disruption Budget (PDBs).

Example: The following helm command-line parameter can be used to add the annotation, "env=test" to all the IDSP (ssp) pods:

```
--set additionalAnnotations.env=test
```

The same command can be added to the values yaml in this format:

```
additionalAnnotations:
env: test
```

Where, the annotation "env=test" is added to all the IDSP pods.

> **NOTE**
>
> The "additionalAnnotations" parameter does not apply to all the objects created by the IDSP (ssp) helm chart. Therefore, to apply labels to all the objects within the helm chart, use the following parameters:
>
> ```
> hazelcast-enterprise:
> annotations: {}
> service:
>     annotations: {}
> global:
> additionalAnnotations: {}
> ```

The following example shows the values in yaml format for setting both, ***annotations*** and Labels.

```
hazelcast-enterprise:
annotations:
 costCenter: "B05431"
labels:
 owner: "JohnD"
podLabels:
owner: "JohnD"
service:
annotations:
  costCenter: "B05431"
```

```
labels:
  owner: "JohnD"

global:
additionalAnnotations:
costCenter: "B05431"
additionalLabels:
owner: "JohnD"
```

Setting Ingress Timeouts

You can set the ingress communication timeout using the following parameters:

- For NGINX:
  - `ssp.ingress.timeoutSecs` : Defines the connection timeout for an ingress connection within the SSP (the default is 60 seconds).
- For OpenShiftRoute:
  - `ssp.ingress.openShiftRoute.timeout` :Defines the connection timeout for an OpenShift route within the SSP (the default is 60 seconds).
  - `ssp.ingress.openShiftRoute.tunnelTimeout` : Defines how long a tunnel connection in the OpenShift Ingress Controller (including websockets) remains open while idle (the default is 1 hour).

Set these parameters using an override values yaml command or using the `--set <param>=<values>` Helm command. For example in a Helm installation, use:

```
--set ssp.ingress.timeoutSecs=60
```

AWS AWS_STS_REGIONAL_ENDPOINTS

The parameter "aws_sts_regional_endpoints" allows setting the AWS AWS_STS_REGIONAL_ENDPOINTS environment variable in all the IDSP (ssp) pods.

```
ssp.global.env.aws_sts_regional_endpoints
```

If this parameter value is set, an environment variable called, AWS_STS_REGIONAL_ENDPOINTS containing that specified value is added to all the pods in the IDSP (ssp) chart.

Helm Offline Mode

The parameter "global.helmOfflineMode" allows to generate Kubernetes yaml files from ssp_helm chart using helm's --dry-run option, or helm template. This option is useful to generate a yaml manifest without actually deploying.

```
helm template <helm-repo>/<chart-name> <deployment parameters> --set global.helmOfflineMode=true
```

DNS-related configuration for IDSP Deployment

IDSP chart supports setting dnsPolicy and dnsConfig for IDSP Kubernetes pods. Update the dnsPolicy and dnsConfig settings in the IDSP values override yaml file.

```
global:

  #If dnsPolicy is not explicitly specified, then "ClusterFirst" is used.
  dnsPolicy: ""

  #When a Pod's dnsPolicy is set to "None", the dnsConfig field has to be specified
  dnsConfig: {}
```

Enabling Availability Metrics

This feature provides information on the availability and latency of the IDSP cache system. Enable the availabilityMetrics by specifying the following command-line parameter in the IDSP helm deployment command:

```
--set ssp.featureFlags.availabilityMetrics.enabled=true
```

Or use the following setting in the IDSP values override yaml file:

```
ssp:
featureFlags:
    availabilityMetrics:
        enabled: true
```

Seccomp Profile

This feature allows you to specify the "seccompProfile" value for your IDSP Kubernetes deployment. For more information, see seccomp and Kubernetes. The default value is: ***type: RuntimeDefault***.

Use the following setting in the IDSP values override yaml file:

```
global:
securityContext:
seccompProfile:
  type: RuntimeDefault
```

HTTP Proxy

This feature enables the use of an HTTP proxy for the '/token' request. This is necessary when IDSP, acting as a Service Provider, needs to access external endpoints but the cluster's direct communication with external OIDC providers is restricted. You can configure this setting during the deployment of either the IDSP chart or the Sample app chart. For IDSP, the use of "HTTP Proxy" is controlled by an IDP metadata setting called, "Use HTTP Proxy" (urn:iam:idp:useHttpProxy).

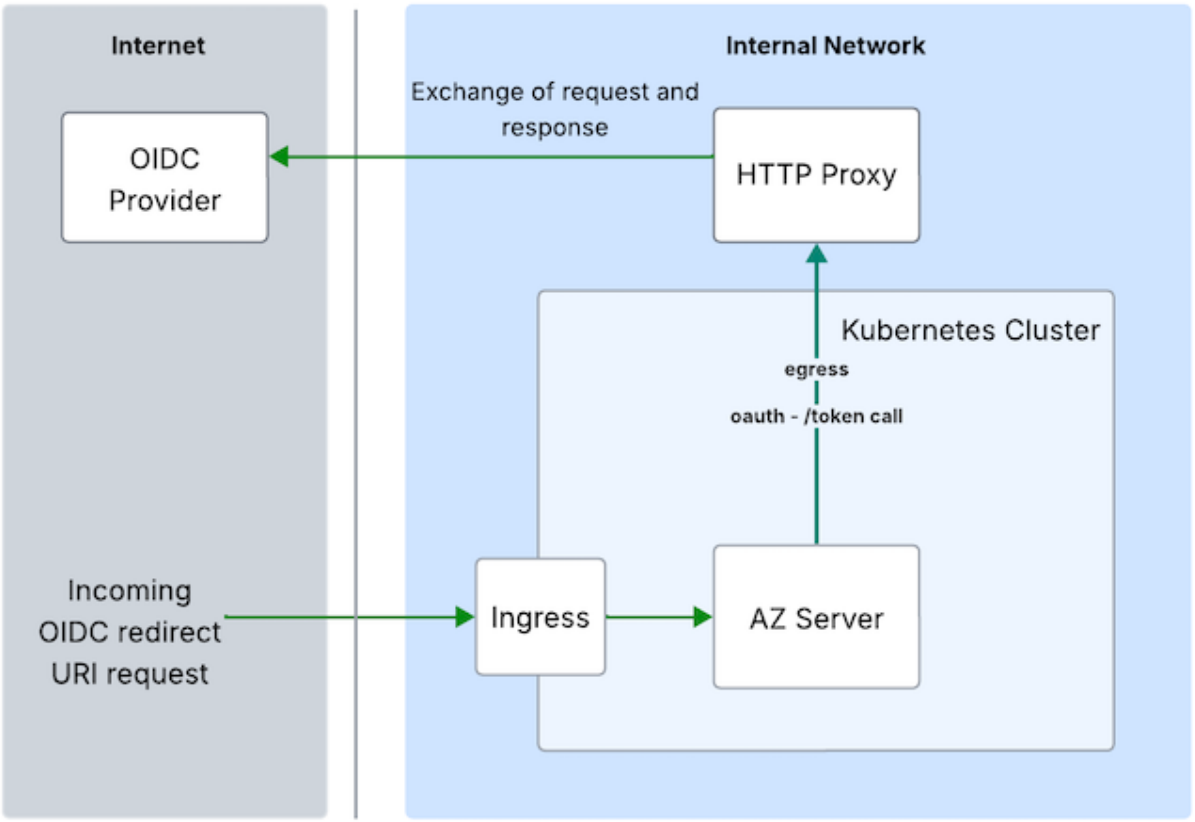
Use the following setting in the IDSP values override yaml file:

```
global:
proxy:
enabled: false
url: "https://httpproxy.example.com:443"
# if the proxy has authentication enabled, create a secret with username/password: kubectl create secret
 generic proxy-credentials --from-literal=username='<username>' --from-literal=password='<password>'
authEnabled: false
```

If your HTTP Proxy requires authentication, enable proxy authentication (`authEnabled: true`) in the previously shown values.yaml override file. Enabling proxy authentication requires to have a kubernetes secret named, "proxy-credentials" with username/password, as shown in the following command:

```
kubectl create secret generic proxy-credentials --from-literal=username='<username>' --from-
literal=password='<password>'
```

The HTTP Proxy scenario is explained with the help of the following illustration:



Steps:

1. Incoming OIDC redirect URI request with the AZ code coming to IDSP AZ server.
2. The Ingress routes the incoming request to the AZ server pod.
3. Traffic is routed to the OIDC provider's "/token" endpoint through the configured HTTP Proxy (requires IDP metadata setting called, "Use HTTP Proxy")
4. The HTTP Proxy forwards the request to the OIDC provider.
5. After receiving the token, the AZ Server completes the authentication process.

Managing Configuration Updates to the Symantec Identity Security Platform Helm Chart

Know how to make configuration updates to the deployed Symantec Identity Security Platform Helm chart by backing up current values, modifying them, and applying changes with a version-controlled upgrade.

Perform a configuration update of the IDSP helm chart

You can use the IDSP helm chart to perform deployment configuration updates. Whenever you must make a configuration change to an IDSP deployment, take a backup of the existing configuration by calling helm to get values, make the necessary config change in the values file, and run the 'helm upgrade' command.

Follow these steps:

1. Helm always uses the latest version of the IDSP chart, to guarantee we are just performing a configuration change and not an upgrade, check which version is deployed, and use it to force Helm to use this version. Save the version of the currently deployed chart by setting it as an environment variable:

```
#use the following command to get the list of all deployments in the namespace with their version.
#note that the CHART column shows the version in the format <chart-name>-<chart-version>, so, for IDSP it
 will show 'ssp-<CHART VERSION>'.

helm ls -n ${NAMESPACE}
#use this command to extract and save the current version of theIDSPchart:
export IDSP_VERSION=$(helm list --filter="${RELEASENAME}$" -n ${NAMESPACE} -o yaml |grep chart:| cut -d'-'
 -f2-)&&echo version=${IDSP_VERSION}
```

2. Save the existing chart configuration by getting the user-supplied values for the currently deployed IDSP release name and saving it into a values file:

```
helm get values ${RELEASENAME} -n ${NAMESPACE} -o yaml >exisiting_${RELEASENAME}_values.yaml
```

3. Save a copy of the resulting values file and make the desired configuration changes by updating it. Run the helm upgrade command using the updated values file:

```
helm upgrade ${RELEASENAME} -n ${NAMESPACE} ${HELM_REPO}/ssp --version=${IDSP_VERSION} --timeout=120m -f
 exisiting_${RELEASENAME}_values.yaml --set ssp.featureFlags.dataseed.enabled=false
```

   NOTE
   The configuration-update command has the "dataseed.enabled" set to "false".

4. Once you have performed the updates, save the updated value.

Reference Links

- Upgrading IDSP charts

Recovering Initial Admin Credentials

Learn about recovering the initial deployment credentials for "default-clients" and "defaultTenantadminUser" using the break-glass procedure after the 48 hours window lapses.

Before performing the Break-Glass procedure for the "default clients" and "DefaultTenantAdminUser", perform the following:

NOTE

- The commands to Break-Glass procedure use environment variables that are expected to be set in your environment. Before running those commands, ensure that these environment variables are set for your terminal session. See Configuring the Environment Variables.
- If required, such bootstrap credentials can be republished into Kubernetes secrets by re-deploying the chart with specific flags causing Kubernetes secrets to be re-created for another 48-hour period. To recreate secrets, you are required to rerun the helm chart with the CLI values as necessary to re-create the Kubernetes secrets. While doing so the dataseed needs to be executed. Therefore, ensure to set this parameter in the helm chart upgrade command - `--set ssp.featureFlags.dataseed.enabled=false`

Break-Glass procedure for the "default clients" (Infra, System, Tenant -Admin and Demo clients):

In case you missed saving the deployment Client IDs and their secrets within the 48 hours window, use the following break-glass procedure (valid for the next 48 hours):

```
helm get values ${RELEASENAME} -n ${NAMESPACE} -o yaml >exisiting_${RELEASENAME}_values.yaml
```

```
#use this command to extract and save the current version of the IDSP chart
export IDSP_VERSION=$(helm list --filter="${RELEASENAME}$" -n ${NAMESPACE} -o yaml |grep chart:| cut -d'-' -
f2-)&&echo version=${IDSP_VERSION}

helm upgrade ${RELEASENAME} -n ${NAMESPACE} ${HELM_REPO}/ssp --version=${IDSP_VERSION} --timeout=20m -f
 exisiting_${RELEASENAME}_values.yaml \
  --set ssp.featureFlags.dataseed.enabled=true \
  --set ssp.global.seedData.defaultTenant.adminClient.disclosedOnUpgrade=true \
  --set ssp.global.seedData.defaultTenant.demoClient.disclosedOnUpgrade=true \
  --set ssp.global.seedData.systemClient.disclosedOnUpgrade=true \
  --set ssp.global.seedData.infraClient.disclosedOnUpgrade=true
```

Once the Kubernetes secret is created again, use the command mentioned in the Retrieving Initial Credentials for the clients' section to retrieve the "default clients" secrets.

Break-Glass procedure for the "DefaultTenantAdminUser":

In case you missed the 48 hours window and did not create an alternate administrative identity, use the following break-glass procedure to enable the default tenant admin user, reset its password and recreate its Kubernetes secret (valid for the next 4

```
helm get values ${RELEASENAME} -n ${NAMESPACE} -o yaml >exisiting_${RELEASENAME}_values.yaml

helm upgrade ${RELEASENAME} -n ${NAMESPACE} ${HELM_REPO}/ssp --version=${IDSP_VERSION} --timeout=20m
 -f exisiting_${RELEASENAME}_values.yaml --set ssp.featureFlags.dataseed.enabled=true --set
 ssp.global.seedData.defaultTenant.adminUser.seededOnUpgrade=true
```

Once the Kubernetes secret is created again, use the command mentioned in the Retrieving Admin Users Initial Credentials section above to retrieve the "DefaultTenantAdminUser" initial password from the secret.

Handling Database Password Rotation

Learn about database password rotation.

Symantec Identity Security Platform Database (DB) password is stored in a Kubernetes Secret and mounted as a folder on the containers that require access to the DB. When mounted, Kubernetes copies the Secret's data into tmpfs (so that the confidential data is not written to durable storage), and keeps it updated with the secret data, using an eventually consistent approach. It is recommended that you create a secret containing a file called 'mysql-password' where the db password is stored, and specify its name during IDSP Database deployment using the "ssp.db.existingSecert" parameter. IDSP reads the password file from the mounted folder. The DB password is reloaded from this file when changed.

If you are using a vault to inject the DB password file into the container, you can use "ssp.db.existingVaultFolder" to indicate an alternate folder name. When this parameter is specified, IDSP will not mount the db secret and expect the folder to contain a file named 'mysql-password' with the current clear-text db password.

Scheduler Job

Learn about the **Scheduler Job that automatically does the clean-up of expired artifacts** and also the manual way of cleaning up the artifacts using the SQL commands.

Automatic Cleanup of Expired Artifacts

This document outlines the process for cleaning up expired database artifacts, primarily focusing on the automated scheduler job. The scheduler is responsible for cleaning up the following artifacts:

- **Expired Token Clean-up** -

  - **Authorization code** - An hourly process cleans up the OIDC Authorization codes that were abandoned and have never been redeemed.
  - **Device code** - An hourly process cleans up the device codes that were abandoned and have never been redeemed.
  - **Refresh token** - An hourly process cleans up the expired refresh tokens.
  - **Revoked token**- An hourly process cleans up expired revoked tokens. Revoked tokens are created to signify that a token has been cancelled, identified by its session ID (sid) and JWT ID (jti). More specifically:
    - If either the "trackAccessToken" or "trackIdentityToken" setting (at the tenant or global level) is enabled, Authentication Hub records revoked tokens by their jti. These "RevokedToken" objects are removed once the corresponding access token (AT) or identity token (IT) expires.
    - When a refresh token is revoked, a "RevokedToken" object is created for its session ID (sid) and is removed once the refresh token expires.
    - If the "ssoMode" tenant setting is disabled, revoking a session creates a "RevokedToken" object, which is deleted when the session expires.
  - **Credential Reset Token Service** - An hourly process cleans up the credential(password) reset tokens which are issued during various flows('Forgot Password'/'Account unlock'/'Account Activation' and are not redeemed and expired.
  - **Security Token** - An hourly process cleans up the credential(email/phone) verification tokens which are never redeemed and expired.

  To run the scheduler at a custom time, configure the following setting along with the IDSP installation or upgrade command:

```
--set ssp.featureFlags.scheduler.expiredTokensCleanup.fixedDelayInMilliseconds="3600000"
--set ssp.featureFlags.scheduler.expiredTokensCleanup.batchSize="5000"
```

- **FlowState** - this process is repeated every ten minutes to clean up the expired flowstate objects.

  To run the scheduler at a custom time, configure the following setting along with the IDSP installation or upgrade command:

```
--set ssp.featureFlags.scheduler.expiredFlowStateCleanup.fixedDelayInMilliseconds="600000"
--set ssp.featureFlags.scheduler.expiredFlowStateCleanup.batchSize="5000"
```

- **Kubernetes Secrets older than a certain time** (as configured in the Authentication Hub Helm chart parameter- **ssp.global.seedData.disclosureExpiryHours**) are removed from the Kubernetes cluster.
- **Purging Known IA risk tags for expired and deleted devices** - Known IA risk tags for devices that have expired or been deleted are purged daily (every 24 hours), only when risk is configured as true in the Authentication Hub Helm chart parameter- **ssp.featureFlags.iarisk.enabled**. See Known IA Risk Tags Purging Scheduler
- **Risk Active User Event Data Clean-up** - This scheduler job runs every 30 minutes to purge old risk events associated with active users. By default, events older than 730 days are removed. This retention period can be adjusted using the global setting, "riskRetentionDays", and the cleanup job itself is enabled by configuring the global setting, "isRiskCleanupEnabled" to true. (It is disabled by default). See Risk Active User Event Data Clean-Up Scheduler
- **Risk Inactive User Event Data Clean-up** - This scheduler job runs weekly, every Sunday, to purge old risk events associated with inactive users. The default retention period is 730 days, configurable through the global setting, "riskRetentionDays". This cleanup job is disabled by default and can be enabled by configuring the global setting, "isRiskInactiveUsersEventsCleanupEnabled" to true. See Risk Inactive User Event Data Clean-Up Scheduler
- **Inactive Device Purging Scheduler** - This is an automated maintenance job designed to manage device data retention in the system. This scheduler helps maintain optimal database performance by removing devices that are marked as inactive (deleted=1) and have not been accessed for a specified number of days, preventing device tables from growing indefinitely. See Inactive Device Purging Scheduler

Automatic Clean-up of IDSP objects that refers to orphan records

- **resourcesCleanupScheduler** - This scheduler job runs every 30 minutes to clean up any dangling references to the deleted resource in other operational objects.
  Example- If an AuthN policy contains an application under "apps" and that app is forcefully deleted, in this scenario, AuthN policy maintains a reference to the deleted app in the IDSP database, until scheduler job cleans up this policy to remove the dangling reference.
  To run the scheduler at a custom time, configure the following setting along with the IDSP installation or upgrade command:
  ```
  --set ssp.featureFlags.scheduler.resourcesCleanup.fixedDelayInMilliseconds="1800000"
  ```

Enabling Scheduler

This scheduler job is **enabled by default during** Symantec Identity Security Platform **deployment**. You can verify its enabled status through the following feature flag:

```
ssp:
  featureFlags:
    scheduler:
      enabled: true
```

While the scheduler handles most of the cleanup, it is important to note that if the scheduler job does not run by default for any reason, you can manually perform the clean-up using the manual commands mentioned in the next section.

Manual Cleanup of Expired Artifacts

To effectively manage your database and ensure optimal performance, it is recommended to periodically remove expired artifacts. This cleanup activity helps free up space and maintain data integrity.

To view and delete these expired entries for each artifact type, you can periodically execute the following SQL commands in the database:

- **Authorization Code (gets cleaned up every one hour)**
  View expired authorization codes:
  ```
  select * from T_AUTHORIZATION_CODE where EXPIRES_AT < sysdate();
  ```
  Delete expired authorization codes:
  ```
  delete from T_AUTHENTICATION_HOLDER where EXPIRES_AT < sysdate();
  delete from T_AUTHORIZATION_CODE where EXPIRES_AT < sysdate();
  ```
- **Device Code (gets cleaned up every one hour)**
  View expired device codes:
  ```
  select * from T_DEVICE_CODE where EXPIRES_AT < sysdate();
  ```
  Delete expired device codes:
  ```
  delete from T_DEVICE_CODE where EXPIRES_AT < sysdate();
  ```
- **Refresh Token (gets cleaned up every one hour)**
  View expired refresh tokens:
  ```
  select * from T_REFRESH_TOKEN where EXPIRES_AT < sysdate();
  ```
  Delete expired refresh tokens:
  ```
  delete from T_AUTHENTICATION_HOLDER where EXPIRES_AT < sysdate();
  delete from T_REFRESH_TOKEN where EXPIRES_AT < sysdate();
  ```
- **Revoked Token (gets cleaned up every one hour)**
  View expired revoked tokens:
  ```
  select * from T_REVOKED_TOKEN where EXPIRES_AT < sysdate();
  ```
  Delete expired revoked tokens:

```
delete from T_REVOKED_TOKEN where EXPIRES_AT < sysdate();
```

- **Flow State (gets cleaned up every ten minutes)**
  View expired flow state entries:
  ```
  select * from T_FLOW_STATE where EXPIRES_AT < sysdate();
  ```
  Delete expired flow state entries:
  ```
  delete from T_FLOW_STATE where EXPIRES_AT < sysdate()
  ```
- **Security Token (gets cleaned up every one hour)**
  View expired security token entries:
  ```
  select * from T_IDS_SECURITY_TOKEN where EXPIRATION_DATETIME < sysdate()
  ```
  Delete expired security token entries:
  ```
  delete from T_IDS_SECURITY_TOKEN where EXPIRATION_DATETIME < sysdate()
  ```
- **Credential Reset Token Service (gets cleaned up every one hour)**
  View expired Credential Reset Token entries:
  ```
  select  * from T_IDS_CREDENTIAL_RESET_TOKEN  where EXPIRATION_DATETIME < sysdate()
  ```
  Delete expired Credential Reset Token entries:
  ```
  delete from T_IDS_CREDENTIAL_RESET_TOKEN  where EXPIRATION_DATETIME < sysdate()
  ```
- **Expired Kubernetes Secrets (gets cleaned up every one hour)**
  Delete Kubernetes Secrets older than a certain time (as configured in the Authentication Hub Helm chart parameter- **ssp.global.seedData.disclosureExpiryHours**):
  ```
  kubectl delete secret <secret-name> ns <namespace>
  ```
- **Purging Known IA risk devices tags (gets cleaned up every 24 hours)**
  View tags for expired and deleted known IA risk devices:
  ```
  select * from IA_ISSUED_TAGS WHERE (sysdate() > EXPIRE_TIMESTAMP) OR DELETED = 1;
  ```
  Delete tags for expired and deleted known IA risk devices:
  ```
  DELETE FROM IA_ISSUED_TAGS WHERE (sysdate()> EXPIRE_TIMESTAMP) OR DELETED = 1;
  ```

Risk Active User Event Data Clean-up Scheduler

Learn about Risk active user event data clean-up scheduler.

The Risk Active User Event Data Clean-up Scheduler is an automated maintenance job designed to manage data retention for risk assessment events in the system. This scheduler helps maintain optimal database performance by removing outdated risk event data while preserving recent activity for security analysis.

This scheduler job runs every 30 minutes to purge old risk events associated with active users. By default, events older than 730 days are removed. The retention period can be adjusted using the global setting, "riskRetentionDays", and the cleanup job is enabled by configuring the global setting, "isRiskCleanupEnabled" to true. (Disabled by default).

NOTE

- Before running the **Risk Active User Event Data Clean-up** scheduler, note that the initial data volume may be large. It is recommended to perform a manual data clean-up beforehand to help ensure the scheduler runs smoothly and avoids longer execution times or added load on the database.
- The database scripts for cleaning up the initial data can be downloaded from the Support Portal > My Downloads (Search the Identity Security Platform in the portal, select the appropriate version number, and download the "Initial_Cleanup_db_scripts"). Ensure these scripts are first executed in the staging environment and reviewed by your DBAs before running them in production.

Database Impact

The cleanup process affects the following database tables:

- IA_EVENT
- IA_ENTITY
- IA_SUSPICIOUS_EVENTS
- IA_EVENT_CLUSTER
- IA_CASES_EVENTS
- IA_CLUSTER_DATA

Scheduler Configuration

The following table outlines the key scheduler parameter that controls when and how often the cleanup process runs:

Job Name	Value	Description
job.purge.risk.eventcleanup.fixedDelay	1800000	Execution interval in minutes (30 minutes)

Global Settings

The following settings control the behavior and scope of the risk event cleanup process:

Setting Name	Default Value	Supported Values
isRiskCleanupEnabled	false	true/false
riskRetentionDays	730	1-9999

Customizing Scheduler Settings

To run the scheduler operations at a custom time, configure the following settings along with the Symantec Identity Security Platform installation or upgrade command:

```
--set ssp.featureFlags.scheduler.riskEventCleanup.fixedDelayInMilliseconds="1800000"
--set ssp.featureFlags.scheduler.riskEventCleanup.userBatchSize="250"
--set ssp.featureFlags.scheduler.riskEventCleanup.eventBatchSize="2000"
--set ssp.featureFlags.scheduler.riskEventCleanup.deleteBatchSize="1000"
```

Risk Inactive User Event Data Clean-up Scheduler

Learn about Risk inactive user event data clean-up scheduler.

The Risk Active User Event Data Clean-up Scheduler is an automated maintenance job designed to manage data retention for risk assessment events in the system. his scheduler helps maintain optimal database performance by removing outdated risk event data while preserving recent activity for security analysis.

This scheduler job runs weekly, every Sunday, to purge old risk events associated with inactive users. The default retention period is 730 days, configurable through the global setting, "riskRetentionDays". This cleanup job is disabled by default and can be enabled by configuring the global setting, "isRiskInactiveUsersEventsCleanupEnabled" to true.

NOTE

- Before running the **Risk Inactive User Event Data Clean-up** scheduler, note that the initial data volume may be large. It is recommended to perform a manual data clean-up beforehand to help ensure the scheduler runs smoothly and avoids longer execution times or added load on the database.
- The database scripts for cleaning up the initial data can be downloaded from the Support Portal > My Downloads (Search the Identity Security Platform in the portal, select the appropriate version number, and download the "Initial_Cleanup_db_scripts"). Ensure these scripts are first executed in the staging environment and reviewed by your DBAs before running them in production.

Database Impact

The cleanup process affects the following database tables:

- IA_EVENT
- IA_ENTITY
- IA_SUSPICIOUS_EVENTS
- IA_EVENT_CLUSTER
- IA_CASES_EVENTS
- IA_CLUSTER_DATA

Scheduler Configuration

The following table outlines the key scheduler parameter that controls when and how often the cleanup process runs:

Job Name	Value	Description
job.purge.risk.inactive.usercleanup.cron	0 0 0 * * SUN	Execution interval weekly (Every Sun

Global Settings

The following settings control the behavior and scope of the risk event cleanup process:

Setting Name	Default Value	Supported Values
isRiskInactiveUsersEventsCleanupEnabled	false	true/false
riskRetentionDays	730	1-9999

Customizing Scheduler Settings

To run the scheduler operations at a custom time, configure the following settings along with the Symantec Identity Security Platform installation or upgrade command:

```
--set ssp.featureFlags.scheduler.riskInactiveUserEventsCleanup.cron="0 0 0 * * SUN"
--set ssp.featureFlags.scheduler.riskInactiveUserEventsCleanup.userBatchSize="250"
--set ssp.featureFlags.scheduler.riskInactiveUserEventsCleanup.eventBatchSize="2000"
--set ssp.featureFlags.scheduler.riskInactiveUserEventsCleanup.deleteBatchSize="1000"
```

Known IA Risk Tags Purging Scheduler

Learn about the Known IA risk tags purging scheduler for managing expired and deleted device risk tags.

The Known IA Risk Tags Purging Scheduler is an automated maintenance job designed to manage risk tag data retention in the system. This scheduler helps maintain optimal database performance by removing known IA risk tags for devices that have expired or been deleted, preventing risk tag tables from growing indefinitely.

This scheduler job runs daily (every 24 hours) to purge known IA risk tags for devices that satisfy the following criteria:

- Devices that have expired or been deleted from the system
- The purging functionality is only active when risk is configured as true in the Authentication Hub Helm chart parameter ssp.featureFlags.iarisk.enabled.

NOTE

- Before enabling the **Known IA Risk Tags Purging** Scheduler, consider the initial data volume that may need to be processed. It is recommended to review the current number of inactive devices to ensure the scheduler runs efficiently.
- Monitor the scheduler execution times and database performance during initial runs to optimize the purging schedule if needed.

Database Impact

The cleanup process affects the following database table:

- IA_ISSUED_TAGS

Scheduler Configuration

The risk tag purging process runs daily (every 24 hours). The following table outlines the scheduler configuration:

Job Name	Value	Description
job.purge.issuedtag.cron	0 0 2 * * ?	Daily execution at 2:00 AM

Customizing Scheduler Settings

To run the scheduler operations at a custom time, configure the following settings along with the Symantec Identity Security Platform installation or upgrade command:

```
--set ssp.featureFlags.scheduler.issuedTagPurge.cron="0 0 20 * * ?"
--set ssp.featureFlags.scheduler.issuedTagPurge.batchSize="5000"
```

Inactive Device Purging Scheduler

Learn about the inactive device purging scheduler for managing deleted devices.

The Inactive Device Purging Scheduler is an automated maintenance job designed to manage device data retention in the system. This scheduler helps maintain optimal database performance by removing devices that are marked as inactive (deleted=1) and have not been accessed for a specified number of days, preventing device tables from growing indefinitely.

This scheduler job runs on a configurable schedule to purge devices that satisfy the following criteria: devices not accessed in the last "N" days (where "N" is defined by global settings) and devices marked as deleted in the database. The retention period and cleanup functionality can be controlled through global settings.

NOTE

- Before enabling the **Inactive Device Purging** scheduler, consider the initial data volume that may need to be processed. It is recommended to review the current number of inactive devices to ensure the scheduler runs efficiently.
- Monitor the scheduler execution times and database performance during initial runs to optimize the purging schedule if needed.

Database Impact

The cleanup process affects the following database table:

- IA_DEVICES

Scheduler Configuration

The following table outlines the key scheduler parameter that controls when and how often the cleanup process runs.

Job Name	Value	Description
job.purge.device.cron	0 0 2 * * ?	Daily execution at 2:00 AM

Global Settings

The following settings control the behavior and scope of the inactive device cleanup process:

Setting Name	Default Value	Supported Values
isRiskDeviceCleanupEnabled	false	true/false
riskDeviceRetentionDays	730	1-9999

Customizing Scheduler Settings

To run the scheduler operations at a custom time, configure the following settings along with the Symantec Identity Security Platform installation or upgrade command:

```
--set ssp.featureFlags.scheduler.devicePurge.cron="0 0 20 * * ?"
--set ssp.featureFlags.scheduler.devicePurge.batchSize="5000"
```

Populating the Internal Email Domain Column

You can search for users by email domain by using the domain column in the `T_USER_EMAIL` table. The Identity Service SCIM API supports an indexed based search using the `T_USER_EMAIL.domain` column.

Creating or updating a user's email address automatically populates the domain column.

> **NOTE**
> For email addresses populated prior to AuthHub 3.1, the newly added domain column is empty.

To populate empty domain columns in email records, deployments can execute the following SQL statement:

```
UPDATE T_USER_EMAIL SET DOMAIN = SUBSTRING_INDEX(VALUE,'@',-1);
```

Symantec Identity Security Platform Upgrade Procedure with No Active Database Transactions

Step-by-step procedure to perform an IDSP Helm upgrade in a Kubernetes environment when there are no active transactions on the database.

Overview

This topic outlines the procedure to perform an IDSP (Identity Service Provider) Helm upgrade in a Kubernetes environment when there are no active transactions on the database. The process involves backing up autoscaler and deployment configurations, gracefully scaling all IDSP services down to zero replicas, and then executing the Helm upgrade with the preserved override values so that pods scale back to their defined counts post-upgrade.

Steps to Upgrade with No Transactions on Database

Follow the steps to perform a safe IDSP upgrade:

1. Take a Backup of Existing HorizontalPodAutoscaler (HPA) Details
   Capture the current HPA configuration for the target namespace:
   ```
   kubectl get hpa -n <namespace> > idsp_hpa_<namespace>
   ```
2. Get the IDSP Deployment Values to a Backup File
   Export the current Helm release values to an override file:
   ```
   helm get values ${RELEASENAME} -n ${NAMESPACE} > idsp-override.yaml
   ```
3. Resize the Deployments of IDSP Services to ZERO
   Scale all IDSP service deployments down to zero replicas before proceeding with the upgrade.
   There are two approaches to scale the IDSP service deployments down to zero replicas:

   - Manual Resize (Per Deployment)
   - Scripted Resize

   Manual Resize (Per Deployment)

   This is the recommended approach.

   Fetch the deployments in the IDSP namespace:

   ```
   kubectl get deployments -o name -n <namespace>
   ```

   Resize the replica count to ZERO for each deployment:

   ```
   kubectl scale deployment/<deploymentName> --replicas=0 -n <namespace>
   ```

   Scripted Resize

   To resize all deployments to zero pod count at once, use the following script as a reference. The script does the following:

   1. Fetches all deployment names into a temporary file (`/tmp/deployments`).
   2. Reads the file line by line and scales each deployment's replica count to ZERO in a loop until every deployment has been processed.

      NOTE
      Replace the `${NAMESPACE}` value with only the IDSP namespace. Providing a non-IDSP namespace scales all deployments in that namespace to zero, including those unrelated to IDSP.

   Script: ScaleIDSPDeploymentsToZero.sh

   ```
   export NAMESPACE=$1
   echo "NAMESPACE ToBe Modified is ${NAMESPACE}"

   rm -f /tmp/deployments

   kubectl get deploy -n ${NAMESPACE} -o name | cut -d'/' -f2 > /tmp/deployments

   while IFS= read -r line
   do
       echo $line
       kubectl scale deployment/$line --replicas=0 -n ${NAMESPACE}
   done < /tmp/deployments
   ```

   Run the script with the namespace as the argument:

   ```
   ScaleIDSPDeploymentsToZero.sh <namespace>
   ```

4. **Perform the Helm Upgrade**

   Run the Helm upgrade using the same build version that was previously deployed and the previously saved override file (which contains scaling details such as replicaCount, HorizontalPodAutoscaler settings, and similar configurations). After the upgrade completes, the pods scale back to the replica counts defined in the override values.

   Include the following flag to disable data seeding during the upgrade:

   ```
   --set ssp.featureFlags.dataseed.enabled=false
   ```

   To know about the IDSP Upgrade commands, see Upgrading Key definition for "pname" not found in the DITA map.

Troubleshooting

Use this section to identify and troubleshoot problems associated with Symantec Identity Security Platform.

- Using Logs to Troubleshoot Operational Errors
- General Issues
- Enclave Service Issues
- GCP Related Issues
- Database Connection Issues
- How to trace transactions between distributed services

Using Logs to Troubleshoot Operational Errors

Learn how to use logs to troubleshoot operational errors in Symantec Identity Security Platform.

By default, IDSP maintains operational and audit logs that contain data pertaining to each request processed. For example, this data can be seen in Kibana or in some other observability tools, when integrated.

Among other request-specific artifacts, each log entry contains transaction-identifying elements that can be used to observe, correlate, and troubleshoot ongoing operations. These identifiers are prefixed with the specified region when configured with `-- set ssp.deployment.region="<regionName>"` parameter in the IDSP deployment. Information about **Region Identifier** is also covered in Additional Parameters to consider adding before deploying the IDSP Helm Chart. Search for the term, **Region Identifier** in this page.

1. Use of "txnId" and "clientTxnId" in logs enables clients to correlate their logs and IDSP logs:
   - txnId - represents a unique identifier that is assigned to each incoming request. Each request that is processed is guaranteed to have a unique id that is maintained and is included in every log message throughout the processing of the request. The transaction id is included in the response returned to a client making the request in the response header X-TRANSACTION-ID.
   - clientTxnId - represents an identifier that is sent by a client making the request (via the X-CLIENT-TRANSACTION-ID header). The client would use the same client transaction Id for all the requests that should be associated together. Each message being logged by IDSP as part of these requests contain this client transaction id. For example, the Admin Console app sends the same clientTxnId for all the requests that are sent as part of the user's working session when using the admin console.
2. Use of "flowStateId" to track a user authentication ceremony across different requests. This id is associated with all the messages that are part of the authentication flow. Searching for messages with a specific flowstateId results in getting all the log messages of the end-to-end authentication flow that covers all requests from the moment authentication service is invoked until the authentication flow completes. For example, Factor Selection and OTP generation/ verification, and any other request in the same flow will have the same flowStateId.
3. Use of "clientId", "effectiveClientId", "clientIp", "appId", "appName" to track an application client making the request.
4. Use of "userGuid", "userLoginId", "userIp", "userUniversalId", and so on, to track a user on whose behalf a request is made.
5. Use of "api" to track the request being made.

General Issues

This section discusses how to troubleshoot general issues that you may encounter during the usage of the Symantec Identity Security Platform.

This topic includes the following sections:

- Slowness in IDSP Services- Check Entropy Regeneration Levels

Slowness in IDSP Services- Check Entropy Regeneration Levels

If you are experiencing slowness in your IDSP services, run this command to check the rate at which the entropy gets regenerated:

NOTE
Before running this command, ensure that the environment variable is set to your IDSP namespace.

```
kubectl exec -n ${NAMESPACE} $(kubectl get pods -n ${NAMESPACE} -l app=ssp-azserver -o name | head -1) -- time
 dd if=/dev/random of=/dev/null bs=1 count=1M
```

The expected time for generating 1mb of random data should be about 2 seconds. If you get a higher number, refer to the Entropy section.

Enclave Service Issues

This section discusses how to overcome issues with Prometheus, Elastic Search, etc.

This topic includes the following:

Unable to create an API-specific metrics map

Follow these steps to validate:

1. Validate a service generates metrics by running the following commands in the master node:
   ```
   kubectl get svc -n $(NAMESPACE)
   ```
   ```
   curl http://<cluster-ip>:<port>/actuator/prometheus -i -X GET
   ```
2. Debug Prometheus UI to check if metrics are getting scraped. Run this command in your work environment:
   ```
   kubectl port-forward -n monitoring prometheus-prometheus-operator-prometheus-0 9090
   ```
   <not sure what is meant here> you must Control-C out of it after validating next step.
3. In your work environment, open the browser and then open the "Prometheus UI". Look for http_server_... metrics.
   ```
   http://localhost:9090/graph
   ```
4. Check if monitoring dashboards reflects the current status. You can ensure this by checking the value set for the refresh interval,(default value-5secs) which should not be too long. The dashboard may take a minute or two to display the current status or the latest metrics.

Deleting Existing Index in Elastic Search

Run this command from one of the worker nodes:

```
curl -X DELETE <es-pod-ip>:9200/ssp_log
```

Where, the ip address is one of the nodes where ElasticSearch is running and ssp_log is the name of the index.

Deleting Index Pattern from Kibana

1. Run this command to find the GUID of the pattern:
   ```
   curl -XGET http://<kibana-pod-ip>:5601/api/saved_objects/index-pattern/ 165
   ```
2. Delete the index pattern by running this command:
   ```
   curl -XDELETE http://kibana-pod-ip:5601/api/saved_objects/index-pattern/<pattern-guid> 31 -H "kbn-xsrf:
    true"
   ```

Kibana Dashboard Does Not Display Any Output for Index Pattern

Take a look at the pod logs for Elastic and Kibana. It is possible that your Elastic Search or Kibana needs a restart. Delete the Elastic pod, and then the Kibana pod. The pods will auto restart.

Wait a little, then go to the kibana console to see if the logs are reappearing.

GCP Related Issues

This section discusses how to troubleshoot issues that you may encounter while setting up Symantec Identity Security Platform on Google Cloud Platform (GCP).

Issue

Error from server (Forbidden): If you are unable to run "**kubectl create clusterrolebinding cluster-admin-binding --clusterrole cluster-admin --user <USER_ACCOUNT>**" command to grant, cluster admin permission to your gcp user account, and you are getting the following error:

```
Error from server (Forbidden): clusterrolebindings.rbac.authorization.k8s.io is forbidden: User
 "john.doe@broadcom.com" cannot create resource "clusterrolebindings" in API group "rbac.authorization.k8s.io"
 at the cluster scope: Required "container.clusterRoleBindings.create" permission.
```

Solution:

1. Navigate to the *Google Cloud IAM site and click the "Go to Console" tab.*
2. Ensure your GPC user is assigned the role of "Kubernetes Engine Admin."

Database Connection Issues

This topic includes the following sections:

- DB SSL Connection Issue
- MySQL "RSA public key is not available client side (option serverRsaPublicKeyFile not set)" error
- An error occurs when connecting to a MySQL database if the password is set using a different character set

DB SSL Connection Issue

This section discusses how to overcome db ssl connection issue that you may encounter during its usage in Symantec Identity Security Platform.

1. Try connecting to the MySQL Server from a host with openssl tool and point to the db host or use localhost as shown in the following example, when running on the machine or pod of the db:
   ```
   openssl s_client -connect localhost:3306 -showcerts </dev/null
   ```
2. To validate MySQL's SSL configuration, access mysql as root from mysql client:
   - show variables like '%ssl%';
   - show status like '%ssl%';
3. To validate IDSP processes' connection to MySQL is over SSL, access mysql as root from mysql client. The IP addresses should correspond to the ip addresses of the Kubernetes pods running in IDSP micro services:
   ```
   SELECT PROCESSLIST_USER,PROCESSLIST_HOST,PROCESSLIST_INFO,CONNECTION_TYPE FROM performance_schema.threads
   where PROCESSLIST_USER="iamauth";
   ```

MySQL "RSA public key is not available client side (option serverRsaPublicKeyFile not set)" error

IDSP supports connecting to MySQL DB using a "`mysql_native_password` " user.

Error:

When connecting to a MySQL DB using unencrypted connection (`ssp.db.sslMode=DISABLED`), the "`RSA public key is not available client side (option serverRsaPublicKeyFile not set)` " error gets displayed.

Cause:

This indicates that the database user (`ssp.db.user`) is stored on the mysql database server-side using "`caching_sha2_password` " **instead of** "`mysql_native_password` ".

Solution:

Solution 1: To rectify this issue, set the "ssp.db.user" to specify a MySQL "mysql_native_password" user (see Customer Database Mode).

Solution 2: Set the parameter "ssp.db.jdbcOpts" to "allowPublicKeyRetrieval=true&useSSL=false" in the deployment yaml file.

An error occurs when connecting to a MySQL database if the password is set using a different character set.

Error:

When connecting to a MySQL DB using "mysql_native_password", you may encounter this error: "`41 more \nCaused by: java.sql.SQLInvalidAuthorizationSpecException: Could not connect to address=(host=34.118.228.175)(port=3306)(type=master) : (conn=12) Access denied for user 'root1'@'10.60.3.44' (using password: YES)\nCurrent charset is UTF-8. If password has been set using other charset, consider using option 'passwordCharacterEncoding'\n\tat org.mariadb.jdbc.internal.util.exceptions.ExceptionFactory.createException(ExceptionFactory.java \tat org.mariadb.jdbc.internal.util.e` "

Cause: You may encounter a password charset UTF issue if there are compatibility problems between the operating system and the Docker environment.

Solution:

To rectify this issue, set the following command in the IDSP deployment yaml file or pass it along with IDSP deployment command, "`--set ssp.db.jdbcOpts='useUnicode=yes&characterEncoding=UTF-8` ".

Tracing

Jaeger is an open-source tool used for tracing transactions between distributed services. It enables monitoring and troubleshooting of complex micro-services.

Symantec Identity Security Platform is developed with OpenTracing compliant tracing capabilities. Jaeger client library is used for tracing purposes. The profiling data from services can be fed to OpenTracing compliant Jaeger Agent for profiling.

Suggested Namespace	tracing
Chart Name	jaeger-operator
Chart Helm Repo	https://jaegertracing.github.io/helm-charts
Service URL	https://jaeger.<DOMAIN>
Tested Chart version	2.57.0

> **NOTE**
> The procedures discussed in this topic to deploy, enable, and configure Jaeger are applicable to Cloud Service Providers, OpenShift, and On-Premise deployments.

Deploying Jaeger for Tracing

1. Deploy Jaeger by the following these steps:
   a. Create a tracing namespace.
      ```
      kubectl create ns tracing
      ```
   b. Execute this command to apply Kubernetes Custom Resource Definitions (CRDs) for cert-manager:

```
kubectl apply -f https://github.com/cert-manager/cert-manager/releases/download/v1.13.3/cert-manager.yaml
```

c. Locate the Jaeger tracing helm chart here:

```
helm repo add jaegertracing https://jaegertracing.github.io/helm-charts
```

d. Get the latest helm chart updates by running this command:

```
helm repo update
```

2. If you want to add your own trusted certificate signed by the Certificate Authority (CA), run this command:

NOTE

- If you do not have a certificate, you can skip this as the Tracing ingress uses a self-signed certificate.
- Before running this command, ensure that the variables, ${CERTFILE} and ${KEYFILE} are set.

```
kubectl create secret tls tracing-general-tls --cert "${CERTFILE}" \
--key "${KEYFILE}" -n tracing
```

3. Deploy Jaeger.

NOTE

- Before running this command, ensure that the variable, ${DOMAIN} is set.
- If you are required to authenticate to your container-registry to pull images, do the following:
  - Create a Kubernetes secret of type docker-registry. The following command creates a secret for the Docker Hub container registry:

```
kubectl create secret docker-registry <registry-secret-name> -n tracing \
  --docker-server="https://index.docker.io/v2/" \
  --docker-username="<dockerhub-username>" \
  --docker-password="<dockerhub-password>" \
  --docker-email="<your-email-address>"
```

  - Add the following parameter to the helm installation Jaeger command:

```
--set image.imagePullSecrets[0].name="<registry-secret-name>"
```

```
helm install jaeger-operator -n tracing jaegertracing/jaeger-operator \
--set jaeger.create=true \
--set jaeger.spec.ingress.security=none \
--set rbac.clusterRole=true \
--set jaeger.spec.ingress.enabled=true \
--set jaeger.spec.ingress.ingressClassName=nginx \
--set jaeger.spec.ingress.hosts[0]=jaeger.${DOMAIN} \
--set jaeger.spec.ingress.tls[0].secretName=tracing-general-tls \
--set jaeger.spec.ingress.tls[0].hosts[0]=jaeger.${DOMAIN} \
--set jaeger.spec.storage.type=memory \
--version '2.57.0'
```

4. Verify that the pods are in Running State and Ready (1/1), by running this command:

```
kubectl get pods -n tracing
```

The following image is a sample displaying the tracing pods with the *STATUS-Running*:

```
$ kubectl get pods -n tracing
NAME                                      READY   STATUS    RESTARTS   AGE
jaeger-operator-848bcb46b-sgc9w           1/1     Running   0          34d
jaeger-operator-jaeger-695ff64774-8dwhc   1/1     Running   0          34d
```

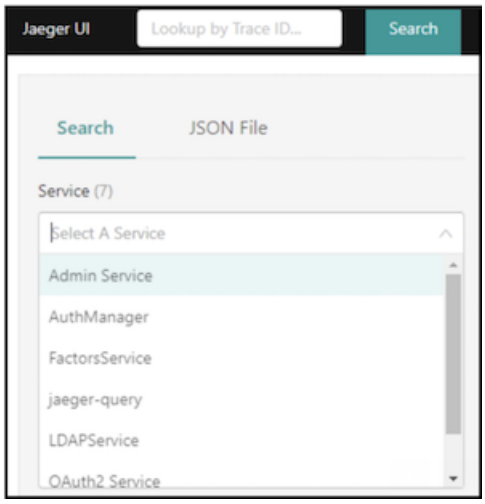
Enabling Jaeger Tracing

Jaeger Tracing is disabled by default in the solution. However, if you want to enable tracing for the services in the solution, you can either enable it during the deployment of the solution or post-deployment.

- To enable tracing globally for IDSP microservices, add the attribute, `--set ssp.global.tracing.enabled=true` to the jaeger-operator helm Install command. For example: helm install<helmRepo>/ssp --set ssp.global.tracing.enabled=true.
  This enables tracing for all the services running within the solution.

Configuring Jaeger to Trace Requests

1. Access the Jaeger service at the following location. Replace <DOMAIN > with the value that you have set in your environment during deployment, before running this command:
   ```
   http://jaeger.<DOMAIN>
   ```
2. Navigate to the Services drop-down (which can be found in the upper-left corner under Search) and select the service for which you want to view the instrumentation details.
   NOTE
   The services will be available in the drop-down only after REST API requests have been sent to the services.
   This is a sample image showing the "Service" drop-down in the Jaeger UI:



3. Click Find Traces.
   The results are displayed on the right-hand side of the application page.

Uninstalling Tracing Service

To uninstall Jaeger services from your environment, follow these steps:

1. Run this command to uninstall the Jaeger service:
   ```
   helm uninstall jaeger-operator -n tracing
   ```
2. Run this command to delete the tracing namespace:
   ```
   kubectl delete ns tracing
   ```

Understanding Resource Authorization Results using Explain

Resource Authorization results for Symantec Identity Security Platform Resource APIs (such as User, Group, applications, and so on) can often return complex outcomes. The `explain` parameter can provide detailed analysis and explanations of these outcomes.

Any IDSP Resource API that is subject to Resource Authorization supports the `explain` parameter. The `explain` parameter takes the following format:

```
{{sspHost}}/{{apiPathTenant}}/admin/v1/<ResourceType>?explain=true
```

For example:

- `{{sspHost}}/{{apiPathTenant}}/scim2/v1/Users?`**`explain=true`**
- `{{sspHost}}/{{apiPathTenant}}/scim2/v1/Groups?`**`explain=true`**

The response of a Resource API operation (POST/GET/PUT/PATCH) is a list of one or more resource elements. When `explain=true` is used, the first element in the response list is an `explain` element with the following format:

```
[
  {
     "explain": {
         // marker indicating this is the explain object (not a resource)
            "isExplainObject": "true",

         // final analysis of the constraint rules to be applied
              "adminScopeAnalysis": {},

          // the constraints the principal has
              "appliedConstraints": {},

          // which of those constraints apply to THIS request
              "constraintsApplicabilityDetermination" {},

          // the request context
              "request": {}
        },
        {
        // normal operation-specific resource elements
        }
]
```

Refer to the appropriate section of details about each element returned:

- Request Details
- Constraints Applicability Determination Details
- Applied Constraints Details
- Admin Scope Analysis Details
- Unconstrained Field Details

See also, Case-specific Exceptions to the Explain Results

Request Details

The `request` element contains the request details for the principal, the access token scopes, and the list of scoping constraints obtained from the set of Admin Roles assigned to the principal. This element provides the basis for the evaluation of the applied scope for the principal in the request.

The following sample shows an example request element:

```
"request": {
      "principal": {
  "sub_type": "USER",
      "sub": "f46d9d30-0058-4bb2-b9ed-5d12bfda0761",
      "user_loginid": "ljones"
  },
      "token": {
```

```
  "scope": "urn:iam:m.me urn:iam:t.session urn:iam:t.groups urn:iam:t.users",
      "scoping_constraints": "[
          GroupConstraint(5a74481a-f28d-4900-875c-4e02ab0384c5),
          UserConstraint(8529d589-c6d0-4262-a7cd-9b9b993702b2),
              Default Me Constraint(e51dd7ae-e8a5-4ada-a50d-cfcce23855e7)]"
  }
}
```

Constraints Applicability Determination Details

The `constraintsApplicabilityDetermination` shows the applicability of the constraints for each principal. The applicability determination is specific to the request type. For example, if the request is for an Application, a User, or a Group, the constraint would not be relevant. The `skipConstraint` field is true or false depending upon applicability. If `skipConstraint == true` a `SkipReason` field is provided.

The following example shows the constraint applicability when a User-based request has been made. The output shows that out of the three constraints that are applied to the principal, only the User-based constraint applies.

```
"constraintsApplicabilityDetermination": [
       {
                "id": "8529d589-c6d0-4262-a7cd-9b9b993702b2",
                "name": "UserConstraint",
                "resource": "urn:iam:res:user",
                "skipConstraint": false
},
    {
                "id": "5a74481a-f28d-4900-875c-4e02ab0384c5",
                "name": "GroupConstraint",
                "resource": "urn:iam:res:group",
                "skipConstraint": true,
                "skipReason": "Resource URI does not match request"
},
       {
                "id": "e51dd7ae-e8a5-4ada-a50d-cfcce23855e7",
                "name": "Default Me Constraint",
                "resource": "urn:iam:res:me",
                "skipConstraint": true,
                "skipReason": "Resource URI does not match request"
       }
]
```

Applied Constraints Details

Once it has been determined which of the constraints apply, further evaluation is made to determine which of the applicable constraint rules apply for the given resource request. The determination is shown in the `appliedConstraints` element. This element provides a summary section that shows the specific details of each applicable constraint. The applied Scope Rules section shows which of the rules are to be applied for this resource request.

The following User GET request example shows that the applied constraint has a rule that states the set of Users in scope are members of the Groups where the principal is a manager (from the instance `managedBy` rule). In this example, the principal is a manager of the *RADemo-Employees* group. This rule is the only applied scope rule for this User request.

```
"appliedConstraints": {
  "summary": {
      "constraints": "[UserConstraint(8529d589-c6d0-4262-a7cd-9b9b993702b2)]",
          "abacOps": "CURD",
          "gbacOps": "CURD",
          "disableOwner": false,
                  "instance": {
                      "managedBy": {
                                          "groups": "[RADemo-Employees]"
                      }
                   }
  },
  "appliedScopeRules": [
      {
          "constraint": "UserConstraint[8529d589-c6d0-4262-a7cd-9b9b993702b2]",
          "rule": "[ 'groups' eq 'urn:iam:adminscope:megroups' ]"
      }
  ]
}
```

Admin Scope Analysis Details

This `adminScopeAnalysis` element provides the final analysis of the rules to be applied to the request.

For resource searches (GET) the analysis contains the full set of queries to be applied to the search. In the example below, the principal (a user named *ljones*) is a manager of the *RADemo-Employees* group, so *ljones* has scope over any user who is a member of that group. Also, Resource Authorization implicitly allows access to any resource where the principal is an owner (created by the principal), so the combined query is the owner and group rule query.

```
"Admin Scope Analysis": {
  "enforcementQueries": {
      "ownerQuery": "createdBy eq ljones",
      "managedBy": {
          "groupsQuery": "groups eq RADemo-Employees"
      }
  },
  "finalSearchQuery": "ownerQuery or groupsQuery"
}
```

When the request is for an update or delete operation (POST/PUT/PATCH), the results are simplified. Rather than a query evaluation, the operation returns a determination of whether the resource is a match of the applied rule. For example, the following output is shown when a request is made to update a member of the *RADemo-Employees* group for which *ljones* is a manager:

```
"Admin Scope Analysis": {
  "groups": "match"
}
```

Unconstrained Field Details

Usually, the `"isExplainObject"` field is displayed for the `explain` object. However, there are cases where a Resource Authorization is *unconstrained*. There are multiple unconstrained conditions. If any of these conditions exist,

an `unconstrained` field is shown, along with the reason. No further explain content is provided when these conditions exist.

Condition	Field Value
`AdminScopeEnforced=false`	*Global AdminScope Enforcement is disabled*
Constraints are all inactive	*The principal doesn't have active scoping constraints*
Access Token has the scope `t.all` or `t.adminroles`	One of the following values: • *Principal has super privilege t.all* • *Principal has super privilege urn:aim:t.adminroles*
Scope is set to API scope enforcement only using the `adminScopeApi=true` setting in any of the constraints for the principal.	*The value of adminScopeApi is set as true in at least one scoping constraint*
The request is a User Self operation which is subject to administrative scope enforcement	*Self operation is allowed*

The following examples show two of the conditions and values:

```
"explain": {
      "isExplainObject": true,
  "unconstrained": "Global AdminScope Enforcement is disabled"
}

"explain": {
      "isExplainObject": true,
  "unconstrained": ""Principal has super privilege urn:iam:t.all"
}
```

Case-specific Exceptions to the Explain Results

In some use cases, the `explain` results differ slightly from the expected results.

The following examples show specific scenarios where the results of the `explain` parameter can differ from the results that are described in Understanding Resource Authorization Results using Explain:

- Delete
- Create
- Group Add/Remove Member
- ABAC/GBAC Ops (deny)
- Disable Owner

Delete

Resource DELETE provides just the status code of the operation. The operation does not provide response content or `explain` results.

Create

If attribute-based constraints are applied in create cases, the resources that are created must provide the appropriate value for these attributes.

In the following example, a User-based constraint is applied for the principal, with a rule that states *userType* = *employee*. If that value is not present in the create resource request, the operation fails. The Analysis section shows which attribute did not match the constraint.

```
"explain": {
      "isExplainObject": true,
      "Admin Scope Analysis": {
          "owner": "disabled",
          "attribute": {
              "userType": "notmatch"
          }
      },
      "appliedConstraints": {
          "summary": {
              "constraints": "[User Scope(8529d589-c6d0-4262-a7cd-9b9b993702b2),
                      HR Employee Policy(e8c80064-225b-47d5 9814-0b886de4ad0b)]",
              "abacOps": "CURD",
              "gbacOps": "URCD",
              "disableOwner": false,
              "instance": {
                  "attribute": "(userType eq employee)",
                  "managedBy": {
                      "groups": "[RADemo-Employees]"
                  }
              }
          },
          "appliedScopeRules": [
              {
                  "constraint": "HR Employee Policy[e8c80064-225b-47d5-9814-0b886de4ad0b]",
                  "rule": "[ 'userType' eq 'employee' ]"
              },
              {
                  "constraint": "User Scope[8529d589-c6d0-4262-a7cd-9b9b993702b2]",
                  "rule": "[ 'groups' eq 'urn:iam:adminscope:megroups' ]"
              }
          ]
      },
      "constraintsApplicabilityDetermination": [
          {
              "id": "8529d589-c6d0-4262-a7cd-9b9b993702b2",
              "name": "User Scope",
              "resource": "urn:iam:res:user",
              "skipConstraint": false,
              "gbacOps": "CD+RU"
          },
          {
              "id": "e8c80064-225b-47d5-9814-0b886de4ad0b",
              "name": "HR Employee Policy",
              "resource": "urn:iam:res:user",
              "skipConstraint": false
          },
          {
              "id": "5a74481a-f28d-4900-875c-4e02ab0384c5",
```

```
                "name": "Group Scope",
                "resource": "urn:iam:res:group",
                "skipConstraint": true,
                "skipReason": "Resource URI does not match request"
            },
            {
                "id": "e51dd7ae-e8a5-4ada-a50d-cfcce23855e7",
                "name": "Default Me Constraint",
                "resource": "urn:iam:res:me",
                "skipConstraint": true,
                "skipReason": "Resource URI does not match request"
            }
        ],
        "request": {
            "principal": {
                "sub_type": "USER",
                "sub": "f46d9d30-0058-4bb2-b9ed-5d12bfda0761",
                "user_loginid": "ljones"
            },
            "token": {
                "scope": "urn:iam:m.me urn:iam:t.session urn:iam:t.groups urn:iam:t.users",
                "scoping_constraints": "[Group Scope(5a74481a-f28d-4900-875c-4e02ab0384c5), User
Scope(8529d589-c6d0-4262-a7cd-9b9b993702b2), Default Me Constraint(e51dd7ae-e8a5-4ada-a50d-cfcce23855e7), HR
Employee Policy(e8c80064-225b-47d5-9814-0b886de4ad0b)]"
            }
        }
    }
```

Group Add/Remove Member

When a User is added or removed from a group, two conditions must be in place:

- The principal has to have scope over the Group (is a manager or matches a group attribute rule)
- The users to be added must be in scope for the principal. If an applicable user scope rule in not in place for the principal, then this second condition is not required.

In the following example, *ljones* is a manager of RADemo-Employees. Attempts to add the user *jholden* to the group fail because the user does not meet the applied scope rule `userType=employee` .

```
"explain": {
        "isExplainObject": true,
        "Admin Scope Analysis": {
            "managedBy": "match",
            "Analysis on Members": {
                "memberEnforcementQueries": {
                    "ownerQuery": "createdBy eq ljones",
                    "abacQuery": "userType eq employee",
                    "managedBy": {
                        "groupsQuery": "groups eq RADemo-Employees"
                    }
                },
                "memberEnforcementQueries": "notmatch"
```

```
            }

    },
    "schemas": [
        "urn:ietf:params:scim:api:messages:2.0:Error"
    ],
    "detail": "Unprivileged request to add or remove the memberships of group RADemo-Employees with users
 [jholden] not in admin's scope",
    "status": "401",
    "errorCode": "89400006"
}
```

ABAC/GBAC Ops (deny)

A Scoping Constraint can define restrictions on allowed operations by using an operation qualifier. For example, when a '-' is used on any of the Create, Read, Update, or Delete ("C", "R", "U", "D") operators, the operation is denied.

As a further example, a constraint can define the following restriction to allow read and update operations for a User, but to disallow create and delete operation for the User:

```
"abacOpts": "-CRU-D"
```

When an applied constraint has this ABAC operations restriction in place for Users, a create user request fails with the following `explain` output:

```
"explain": {
        "isExplainObject": true,
        "Admin Scope Analysis": "Operation Denied. A constraint has an explicit CREATE deny setting",
        "appliedConstraints": {
            "summary": {
                "constraints": "[User Employee Policy(d5b099f4-67a7-432b-8f9e-17c15ddf3445)]",
                "abacOps": "U-C-DR",
                "gbacOps": "CURD",
                "disableOwner": false,
                "instance": {
                    "attribute": "(userType eq employee)"
                }
            },
            "appliedScopeRules": [
                {
                    "constraint": "User Employee Policy[d5b099f4-67a7-432b-8f9e-17c15ddf3445]",
                    "rule": "[ 'userType' eq 'employee' ]"
                }
            ]
        },
```

Disable Owner

By default, Resource operations implicitly include an owner rule. Owner rules are not defined in a scoping constraint but are always included when any constraint is applied. Owner rules can be disabled by defining the `"disableOwner": true` flag in a constraint.

The following `explain` output shows this condition. The `finalSearchQuery` element excludes the typical `ownerQuery` :

```
"Admin Scope Analysis": {
        "enforcementQueries": {
            "ownerQuery": "disabled",
        "abacQuery": "userType eq employee"
    },
    "finalSearchQuery": "abacQuery"
}
```

Configuring

Describes how to configure different features in the Symantec Identity Security Platform solution.

On this page, find links to various subpages that provide detailed instructions on configuring different components and features within your IDSP environment.

Click these individual links to know more about each topic:

- Configuring the IDSP Solution
- Configuring User Life Cycle Features
- Configuring the ID Store
- Configuring the Internal ID Store
- Configuring the Zero Footprint Identity
- Configuring the User Lockout
- Configuring the User Auto-Enrollment
- Configuring Inline Enrollment
- Configuring Trusted Devices
- Configuring SoftMFA
- Advanced Configurations
  - Managing Custom Vanity Ingresses
  - Using Custom CA for Intra Cluster SSL Communications
  - Operating with Multiple Data Centers

Configuring the Solution

Contains steps to configure the Solution.

After installing the Symantec Identity Security Platform, perform these steps to configure the solution.

This topic includes the following sections:

- About retrieving the Initial Security Credentials
- Granting Admin Privileges
- Updating the Authentication Policy for Admin Console (API) Usage

Retrieving Initial Credentials for the clients'

NOTE
The commands to retrieve the initial credentials use environment variables that are expected to be set in your environment. Before running those commands, ensure that these environment variables are set for your terminal session. You can do so by running the following command:

```
echo RELEASENAME=\'${RELEASENAME}\', NAMEPSPACE=\'${NAMESPACE}\' ; if [ -z "${RELEASENAME}" ] || [ -z
 "${NAMESPACE}" ]; then echo "***** ERROR: RELEASENAME or NAMESPACE environment variables are not set
 *****" ;fi
```

The following initial credentials can be retrieved within 48 hours from the time of deployment by using the following commands:

Client	Role (AZ Policy)	Tenant Name	Steps to acquire Client ID
InfraClient	Infra Admin	System	kubectl get secret ${RELEASENAME}-ssp-secre jsonpath="{.data.clientId}" | base64 --decode; ecl kubectl get secret ${RELEASENAME}-ssp-secre jsonpath="{.data.clientSecret}" | base64 --decode
SystemClient	System Admin	System	kubectl get secret ${RELEASENAME}-ssp-secre jsonpath="{.data.clientId}" | base64 --decode; ecl kubectl get secret ${RELEASENAME}-ssp-secre jsonpath="{.data.clientSecret}" | base64 --decode
DefaultTenantClient	Tenant Admin	Default	kubectl get secret ${RELEASENAME}-ssp-secre jsonpath="{.data.clientId}" | base64 --decode; ecl kubectl get secret ${RELEASENAME}-ssp-secre jsonpath="{.data.clientSecret}" | base64 --decode
DefaultTenantAdminUser You can use this user to login to the admin console and configure the default tenant. The validity of this admin user is limited to 48 hours by default, starting from the deployment time.	Tenant Admin User	Default	echo TENANT_ADMIN_USER=$(kubectl get sec defaulttenantadminuser -n ${NAMESPACE} -o js echo TENANT_ADMIN_USER_PASSWORD=$(secret-defaulttenantadminuser -n ${NAMESPACE decode)

NOTE
To know more about these bootstrap clients, see Administrative Model.

Invoke Token Endpoint

1. Invoke the Token Endpoint to get the Access Token.

```
POST https://{{IDSPHost}}/{{apiPathTenant}}/oauth2/v1/token
```

Example of Granting Admin Privileges

Perform this step as an administrator to grant admin role to a group or users in your ID store that will act as tenant administrators. To grant the admin role to a group or user, perform a "GET" of ".../admin/v1/AdminRolesDelegator" API to retrieve all the authorization policies in the solution, this helps you to find the policy ID of the Tenant Admin Authorization policy (TenantAdminPolicy) and perform a POST operation on it.

1. Perform a GET operation of the Authorization Policy using the following API:

```
GET https://{host}}/{{tenantName}}/admin/v1/AdminRolesDelegator
```

   The GET call response retrieves all the seeded IDSP's authorization policies. Find the "TenantAdminPolicy" in the list and note its corresponding ID. The following codeblock showcases the response specifically for the "TenantAdminPolicy."

```
{
        "id": "42a1faba-654a-4774-95af-5ee0331cd53f",
        "name": "TenantAdminPolicy",
        "displayName": "Tenant Administrator",
        "description": "Manage everything in a tenant",
        "principal": {
            "clientApp": {
                "operator": "in",
                "value": [
                    "baff7ce2-5dc9-4eec-b8f9-13a82b5ed93b"
```

```
                ]
            },
            "user": {
                "operator": "in",
                "value": [
                    "internal/DefaultTenantAdminUser"
                ]
            }
        },
        "isGrantableClientOnly": false
}
```

2. Use the POST operation to grant admin access to a new "*group*" principal condition in the TenantAdminPolicy. Replace the "<REPLACE-BY-POLICY-ID>" with the id of the TenantAdminPolicy id and update the ["<Group-Value>"]:

```
POST https://${SSP_FQDN}/{{tenantName}}/admin/v1/AdminRolesDelegator
```

NOTE

- To know the value of ${SSP_FQDN} environment variable, see Configuring IDSP Environment Variables.
- The default value for `<tenantName>` is "default".
- Replace the text {{text}} including {{}} characters with appropriate values, in all the endpoints shown in the above table.
  For example:
  `https://{{host}}/{{tenantName}}/admin/v1/AdminRolesDelegator`
  should look similar to:
  `https://example.com/default/admin/v1/AdminRolesDelegator`
- To know more about the scopes that are required to secure these APIs, refer to the Rest APIs and Associated Privileges section.

Request:

```
{
  "id": "<REPLACE-BY-POLICY-ID>",
  "principal": {
    "group": {
      "operator": "in",
      "value": ["<GROUP-VALUE>"]
    }
  }
}
```

Sample Request:

```
{
  "id": "42a1faba-654a-4774-95af-5ee0331cd53f",
  "principal": {
    "group": {
      "operator": "in",
      "value": ["admin"]
    }
  }
}
```

Response:

```
{
            "id": "42a1faba-654a-4774-95af-5ee0331cd53f",
            "name": "TenantAdminPolicy",
            "displayName": "Tenant Administrator",
```

```
        "description": "Manage everything in a tenant",
        "principal": {
            "group": {
                "operator": "in",
                "value": [
                    "Admin"
                ]
            },
            "clientApp": {
                "operator": "in",
                "value": [
                    "baff7ce2-5dc9-4eec-b8f9-13a82b5ed93b"
                ]
            },
            "user": {
                "operator": "in",
                "value": [
                    "internal/DefaultTenantAdminUser"
                ]
            }
        },
        "isGrantableClientOnly": false
    }
```

Example of Updating the Authentication Policy (AdminLoginPolicy) for Admin Console Usage

If you plan to use the Admin Console, you can perform any one of the following options:

- ***Using the default tenant*** - The initial deployment of IDSP creates a tenant named "default." This is primarily to facilitate the setup of the initial tenant. Within the default tenant creation process, a "defaulttenantclient" (assigned the tenant admin role) and a "DefaultTenantAdminUser" (part of the internal ID Store) with complete administrative privileges are provisioned by the seeded "TenantAdminPolicy" of Authorization policy (mentioned in the previouse step) and the user will be given authentication rights provisioned by the seeded "AdminLoginPolicy" Authentication Policy. You can use these credentials to access the admin console and configure the default tenant. For more details on the initial credentials seeded by IDSP deployment, see Initial Security Credentials.
  Example of the "AdminLoginPolicy" Authentication Policy where the "DefaultTenantAdminUser" is already provisioned:

```
{
    "policyId": "2067529c-f71e-44e5-b562-66f769e7fd80",
    "policyName": "AdminLoginPolicy",
    "description": "Default policy for Tenant Admin Console",
    "status": "active",
    "matchAnyApp": false,
    "apps": [
        {
            "name": "DefaultTenantClient",
            "id": "baff7ce2-5dc9-4eec-b8f9-13a82b5ed93b"
        },
        {
            "name": "AdminConsole",
            "id": "$TENANT_ADMINCONSOLE"
        }
    ],
    "rules": [
```

```
        {
            "id": "b59789db-bfe8-4fa9-add2-d18aac87f6c3",
            "conditions": {
                "principal": {
                    "user": {
                        "operator": "in",
                        "value": [
                            "internal/DefaultTenantAdminUser"
                        ]
                    }
                },
            "result": {
                "effect": "allow",
                "reAuthenticate": "false",
                "obligations": [
                    "PASSWORD:1"
                ],
                "msg": "This policy is for admin login"
            }
        }
    ]
```

- ***Creating your own tenant*** - If you opt for creating your own tenant, you need to configure the seeded "AdminLoginPolicy" Authentication policy with suitable rule conditions or create your own policy with appropriate rule conditions. See Managing Tenants .

Next Steps

After you complete performing the above steps, you can now use the DEMO environment to test the functionalities of the solution or use the REST APIs to perform the authentication flows.

Configuring the User Lifecycle Features

Know about User Life Cycle Management (LCM) and ID LCM WebHooks.

The User Lifecycle Management (Identity LCM) in Symantec Identity Security Platform allows notifications to be sent to an authoritative component regarding the state of an identity. This can be done through ***ID Store updates*** or ***ID LCM WebHooks***.

ID Store Updates

Configuration parameters, such as `isAuthoritativeForIDLCM` and `isAuthoritativeForUserCredsLCM` , control whether these updates are made in the Identity Store. These parameters are defined in the ID Store configuration.

- ***isAuthoritativeForIDLCM*** - If set to true, this parameter ensures that the user's lockout state in the IDSP is also updated in the Identity Store after a user lock.
- ***isAuthoritativeForUserCredsLCM*** - If set to true, this parameter ensures that the user credential registered in the IDSP during inline enrollment is also updated in the Identity Store.

Notifications include for the following User Credential LCM:

- User's lockout state
- Inline enrollment of user credentials (including email and phone number)

ID LCM WebHooks

SCIM-compliant webhooks can be set up to deliver these notifications to other authoritative systems.

The IDSP enables you to define a SCIM-compliant webhook indicating the events to be hooked and the SCIMconfigs resource to use as the target.

To configure the ID LCM WebHook, use the following API:

```
PATCH https://${SSP_FQDN}/{{apiPathTenant}}/admin/v1/Configs
```

NOTE

- To know the value of ${SSP_FQDN} environment variable, see Configuring IDSP Environment Variables.
- The default value for `<tenantName>` is "default".
- Replace the text {{text}} including {{}} characters with appropriate values, in all the endpoints shown in the above table.
  For example:
  `https://{{host}}/{{tenantName}}/admin/v1/Configs`
  should look similar to:
  `https://example.com/default/admin/v1/Configs`
- To know more about the scopes that are required to secure these APIs, refer to the Rest APIs and Associated Privileges section.

The ID LCM Web Hook is one of the properties under Service Configuration, called "idEventHookConfig".
Update the Global/Tenant parameter, "idEventHookConfig":

```
{
"name": "idEventHookConfig",
"value": "<SCIMconfigs-id-or-name>, event1, event2,..."
}
```

Where the "idEventHookConfig" parameter value contains:

- A value that starts with "#" implies a commented out / disabled configuration.
- A SCIMconfigs resource id or name, followed by one or more of the supported events:

  NOTE
  To know more about these auditing events, see Auditing in IDSP.

  The following events result in a SCIM request sent to the endpoint indicated by the SCIMconfig object:
  - ***factor.me.auth.lock.success*** - (Fires when a user gets locked out during authentication or password change due to exceeding max strike count) - sends a SCIM user update operation to lock the user (set user's "active" state to "false")
  - ***factor.me.auth.unlock.success*** - [Fires when a user gets unlocked from IDStore in authentication flow (requires IDStore, "isAuthoritativeForIDLCM=true" and "userAutoUnlockPeriodMinutes" defined)] - sends a SCIM user update operation to unlock the user (set user's "active" state to "true")
  - ***admin.me.user.lock.success*** - [Fires when a internal user (stored in IDSP internal ID Store) gets locked out during authentication or password change due to exceeding max strike count] - sends a SCIM user update operation to lock the user (set user's "active" state to "true")
  - ***admin.me.user.unlock.success*** - (Fires when a user gets unlocked during self-service password reset) - sends a SCIM user update operation to unlock the user (set user's "active" state to "true")
  - ***factor.me.register.complete.success*** - sends a SCIM user PATCH request whenever a new credential is created for a user (email or phone number).
  - ***internal.user.sync.initiate*** - sends a SCIM user PATCH request whenever a user in the internal ID store is created or updated. For more information, see Configuring User Change Event Hook.
- The following events result in a CAEP event sent to the endpoint indicated by the SCIMconfig object:

- ***session.revoke.success*** - sends a Continuous Access Evaluation Protocol (CAEP) message indicating that the user session is revoked, and includes a list of applications to be notified. For more information, see IDSP as CAEP Transmitter.
- ***identity.scim.user.account.disable.success*** - when an admin disables a user in the internal ID store when initiated using SCIM API.
- ***identity.scim.user.account.enable.success*** - when an admin enables a user in the internal ID store when initiated using SCIM API.
- ***identity.scim.user.account.lock.success*** - when an admin locks a user in the internal ID store when initiated using SCIM API.
- ***identity.scim.user.account.unlock.success*** - when an admin unlocks a user in the internal ID store when initiated using SCIM API.
- ***internal.cred.sync.initiate*** - when the passwords get updated for a user in the internal ID store when initiated using SCIM API.

NOTE
While the SCIMconfig resource is used as the identity store defining what ID LCM operations should be executed against the identity store, the same configuration is used to define a SCIM endpoint to deliver supported notifications. For example, in the case of the ZFP App where no ID Store is present, ID LCM notifications can be delivered using the ID LCM WebHook feature.

The appropriate ID LCM configuration depends on the deployment requirements and the authoritative identity source, which could be the ID Store or another system initiating necessary provisioning actions in response to updates initiated by IDSP.

The following table shows supported ID LCM options:

***"Yes" implies execute this Operation* Configuration Resource**	**Current ID Store**	
	LDAP	**SCIM**
ID Store LCM Operations • isAuthoritativeForIDLCM (true/false) • isAuthoritativeForUserCredsLCM (true/false)	Yes if the ID Store is authoritative for operation.	Yes if the ID Store is authoritative for operation.
ID WebHook Operations • factor.me.auth.lock.success • factor.me.auth.unlock.success • admin.me.user.unlock.success • factor.me.register.complete.success • internal.user.sync.initiate	Yes - if the webhook is configured	• Yes - if the webhook is configured. • No - – If ID Store is NOT authoritative – If the ID store is authoritative and is the same as the one configured in the ID webhook.

User Change Event Hook

Learn about the user change even hook.

The User Sync webhook triggers when an internal user is created or updated due to various actions.

The actions could include the following:

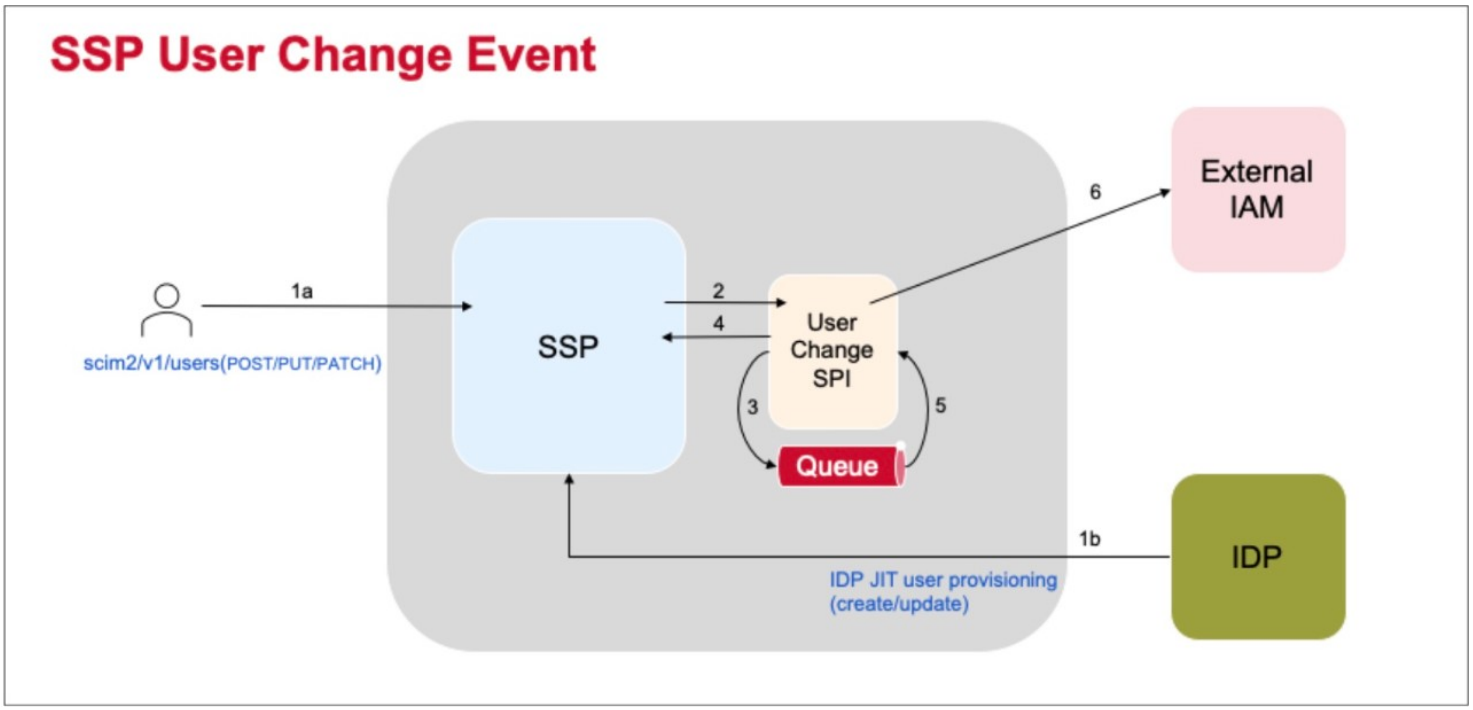
- federating to an external Identity Provider (IDP) configured for Just-In-Time (JIT) User Provisioning
- performing SCIM operations (POST, PUT, PATCH) on scim2/v1/Users/<userId-or-unique-loginid>

This webhook is represented by a SCIM Identity Store that is modeled in the Symantec Identity Security Platform, and mapped to the "internal.user.sync.initiate" event through an EventHook.

Upon firing, the webhook should process requests promptly by stashing them for asynchronous handling and returning a status code 204 without any response.

The SCIM Identity Store provides options for configuring connection and timeout settings, SSL validation settings, and client authentication security settings.

User profile attributes correspond to both native and custom logical user attributes, as shown on the Internal Identity Store configuration panel.



- Change events are triggered by either direct user changes through SCIM user API (1a) or JIT user provisioning during user authentication by the IDP (1b).
- Whenever a user change event occurs, the IDSP (Single Sign-On Platform) invokes the registered user change event hook Service Provider Interface (SPI) via webhook, sending a REST request containing a SCIM patch payload (2).
- The SPI must handle the request asynchronously, saving the information to a queue and responding with an HTTP 203 status code to acknowledge receipt. At this point, IDSP continues processing its request, reporting successful hook event delivery.
- The queue requests processor handles queue requests by creating or updating users in the external Identity and Access Management (IAM) system.

For simplicity, an in-memory queue can be used, with a separate thread managing the provisioning of users in the external IAM system.

Configuring Event Hook in IDSP

To configure the IDSP to invoke the User-Change SPI, follow these steps:

1. Create an ID Store object of type SCIM representing the "/user" SPI endpoint.
   a. Indicate the SCIM base (service hostname and base path) as scimURL.
   b. Configure proper authentication to the service.
   c. Configure SSL settings.
   d. Configure the attributeMappings property with the attributes that you must communicate to the external IAM system on each user change event.

e. The following example shows a sample of configuring a SCIM ID store:

```
{
    "configName": "SCIM Test",
    "configDescription": "",
    "securityMethod": "basic",
    "clientId": "test",
    "clientSecretAlias": "SCIM Test ID Store Password",
    "oauthResourceInAzRequest": "none",
    "scimURL": "https://example.com",
    "ignoreSslValidation": true,
    "sslMode": "verify_ca",
    "userLoginIdAttributeMappingName": "user_loginid",
    "groupNameAttributeMappingName": "name",
    "attributeMapping":
"user_loginid=userName,family_name=name.familyName,given_name=name.givenName,phone_number=phoneNumbers[primary]
    "groupAttributeMapping": "name=displayName,members=members.display",
    "isAuthoritativeForIDLCM": false,
    "isAuthoritativeForUserCredsLCM": false,
    "isAuthoritativeForDetectingLockedState": false,
    "statusEncoding": "scim",
    "accountRegisterURL": null,
    "privacyPolicyURL": null,
    "accountUnlockURL": null,
    "lookupQuery": "userName Eq \"${loginid}\"",
    "useUserLoginIdAsScimId": false,
    "useGroupNameAsScimId": false,
    "endpointSuffixOverride": {},
    "requestCtxBase64":
"W3sia2V5Ijoic2tpcHJlc3BvbnNlIiwidmFsdWUiOiJ0cnVlIiwidHlwZSI6Imh0dHAtaGVhZGVyIn1d",
    "readTimeoutMillis": "5000",
    "connectTimeoutMillis": "5000",
    "oauthTokenIgnoreSslValidation": true,
    "oauthTokenSslMode": "verify_ca",
    "oauthTokenReadTimeoutMillis": "10000",
    "oauthTokenConnectTimeoutMillis": "10000",
    "testConnectionURL": "https://example.com",
    "skewTimeSecs": "0",
    "idStoreMappingStrategy": "",
    "isPasswordAuthenticatorCapable": false,
    "createdDateTime": "2024-03-11 10:54 PM UTC",
    "updatedDateTime": "2024-03-12 06:42 AM UTC",
    "createdBy": {
        "principalType": "USER",
        "principalId": "4ed30eec-3c1f-4eeb-b4e8-cdb52c2ee01f",
        "principalName": "admin"
    },
    "updatedBy": {
        "principalType": "USER",
        "principalId": "4ed30eec-3c1f-4eeb-b4e8-cdb52c2ee01f",
        "principalName": "admin"
    },
    "scimConfigId": "97b89fa5-b674-4fa0-8133-57c2b7ba7ca2"
```

```
    }
```

2. Update Tenant Settings, ***idEventHookConfig*** to indicate the ID Store ID or the ID store name followed by a comma-separated list of events that should trigger a call to this ID Store. The user change event is "internal.user.sync.initiate". For example: Use the following API to update the configuration setting:

```
POST https://${SSP_FQDN}/{{apiPathTenant}}/admin/v1/Configs
```

NOTE

- To know the value of ${SSP_FQDN} environment variable, see Configuring IDSP Environment Variables.
- The default value for `<tenantName>` is "default".
- Replace the text {{text}} including {{}} characters with appropriate values, in all the endpoints shown in the above table.
  For example:
  `https://{{host}}/{{tenantName}}/admin/v1/Configs`
  should look similar to:
  `https://example.com/default/admin/v1/Configs`
- To know more about the scopes that are required to secure these APIs, refer to the Rest APIs and Associated Privileges section.

API Request:

```
{
"name": "idEventHookConfig",
"value": "97b89fa5-b674-4fa0-8133-57c2b7ba7ca2, internal.user.sync.initiate"
            }
```

This results in sending a scim patch call to this specified IDStore on every user update.

For more information about the various ID Store options, see Configuring the ID Store.

The following is an example of such an event-triggered scim patch call:

```
PATCH https://example.com/Users/2a5f7092-fb27-49d4-ad58-4384f424cf7d

{
    "schemas": [
        "urn:ietf:params:scim:api:messages:2.0:PatchOp"
    ],
    "Operations": [
        {
            "op": "replace",
            "path": "emails[primary eq true].value",
            "value": "malbail@gmail.com"
        },
        {
            "op": "add",
            "path": "name.familyName"
        },
        {
            "op": "add",
            "path": "name.givenName"
        },
        {
            "op": "add",
            "path": "idp_first_name",
            "value": "Rohit"
        },
        {
```

```
            "op": "add",
            "path": "idp_last_name",
            "value": "Soni"
        },
        {
            "op": "add",
            "path": "is_federated_user",
            "value": "true"
        },
        {
            "op": "add",
            "path": "active",
            "value": false
        },
        {
            "op": "remove",
            "path": "phoneNumbers[primary eq true].value"
        },
        {
            "op": "add",
            "path": "userName",
            "value": "malbail@gmail.com"
        }
    ]
}
```

Configuring the ID Store

Contains information on ID Store overview, topology diagram, ID store attributes, and ID store APIs.

This topic includes the following sub-topics:

- ID Store Overview
- ID Store Capabilities
- ID Store Reserved User Attributes
- ID Store Reserved Group Attributes
- ID Store Other Attributes
- Configuring Tenant Settings
- ID Store Mapping in Password Authentication
- ID Store APIs
- ID Store Updates

ID Store Overview

The Identity Store represents an authoritative source of Identity for sourcing identity data that is used by the Symantec Identity Security Platform to manage authentication for non-Zero-Identity-Footprint applications. Access to such applications requires an identity to have an account in the Identity Store containing information that is used by IDSP to perform a user disambiguation, obtain, and update user's credentials such as email, phone number, validate user/group memberships, obtain/update disabled status.

IDSP supports any number of identity stores that can be accessed using LDAP or SCIM protocols.
Support for multiple identity stores introduces a number of concepts:

Identity Source: It represents an identity namespace such as LDAP or SCIM user directory, Federated Identity Provider, or a custom identity namespace used in ZFP-based token interactions.

- A ***User ID*** representing a user who undergoes the authentication flow in IDSP belongs to an identity namespace identified by the Id Store or Identity Provider ID. This results in a combination of identity namespace id and user login id, when taken together must be unique. Such uniqueness is enforced by IDSP's data schema constraints on the user account table in the database.
- The ***ID of the Identity Store and Identity Provider resources*** represents the identity source identifier. This identifier is used in ***policy bindings***, ***Id Store search order*** (tenant and application properties), and ***other use cases*** where the source of the identity must be maintained deterministically.

Tenant-level setting: This tenant-level setting helps maintain the uniqueness of user accounts and ensures that the correct identity is always used for operations. This is necessary to prevent users with the same login id across multiple identity stores from inadvertently being linked to the incorrect account in the IDSP account store.

- The "***identitySourceIdRequired***" tenant setting ensures tight compliance with the unique user requirement. There are few IDSP APIs that currently do not require use of the identity source id when invoking the API. However, this tenant setting mandates the use of such APIs to comply with the requirement to have a unique identity source id when invoking those APIs.
  - ***"identitySourceIdRequired"="false"(default)*** - implies user login ids are unique across identity namespaces. Therefore, use of a user login id without the identity source id is sufficient to locate the user account in the IDSP database. With multiple identity stores in action, user authentication may fail for a user with a login id that is not unique across identity stores, even if such login id is unique within a single identity store.
  - ***"identitySourceIdRequired"="true"*** implies user login ids are not unique across identity namespaces.
- "***principalConditionRequiredInPolicy***" tenant/global setting has been introduced as part of this feature to control whether an empty ***principal*** condition can be allowed in a policy.
  - ***"principalConditionRequiredInPolicy"="false"***- The existing policies and new policies without the principal condition continues to exist as-is.

    NOTE
    When "***principalConditionRequiredInPolicy***"="***false***", it is essential to have a principal condition ***ONLY*** if "***Admin Console***" is listed as one of the applications in the "apps" section within the authentication policy.
  - ***"principalConditionRequiredInPolicy"="true"(default for new deployments)*** - The POST and PUT calls of Authentication Policy API ("...admin/v1/AuthPolicies/{{policyId}}") should have the principal condition (user or group) specified in the new policies. See Settings and see Principal conditions to check for the "user" and "group" values supported.

    NOTE

    - The ***"principalConditionRequiredInPolicy"*** is set to "***false"*** for ***upgrade*** to allow existing policies that are created without principal conditions to exist as is, and allows editing the policies without specifying a principal condition. However, it is recommended to add principal conditions, as policies without the principal condition may not be fully operational when working with multiple identity stores.
    - When "***principalConditionRequiredInPolicy***" is set to"***false***", it is essential to have a principal condition ***ONLY*** if "***Admin Console***" is listed as one of the applications in the "apps" section within the authentication policy.

NOTE
"***idStoreToUse***" application setting should be set to ***"true"***. The "idStoreToUse" application setting accepts a comma-separated list of identity store IDs, whose order is significant. This enables the use of multiple identity stores that are implemented by LDAP or SCIM user directories. If this property is not configured, the system defaults to the "idStoreToBeUsed" setting in the tenant configuration.

ID Store Capabilities

The following table describes capabilities for each of the id store types supported.

Capability	LDAP ID Store	SCIM ID Store
Configuration Resource	`/LDAPconfigs` Only one resource can be configured per tenant representing the active identity store	`/SCIMconfigs` Only one resource can be configured per tenant representing the active identity store
Validate User Password	Yes	Yes, using a custom endpoint that is exposed by a SCIM service
Search User using a filter (during a user disambiguation)	Yes	Yes
Get/Update User Attributes	Yes	Yes
Get User Group Memberships	Yes	Yes
Update User Group Memberships	No	No
Lock/Unlock User Account (get & set a user locked status)	Yes	Yes
Get & Set User Credentials (phone number, email address)	Yes	Yes
Get Groups	Yes	Yes
Connection - Authentication	Bind DN & Password	Access Token via OAuth2 client id/secret Access Token via OAuth2 client assertion Basic Auth
Connection - SSL	Yes	Yes

ID Store - Reserved User Attributes

When working with the ID Store, the IDSP uses logical attributes that are mapped to physical id store schema attributes. The full set of attribute mappings is composed of mandatory attributes that are required to operate the solution, and optional attributes the solution must be aware of to support certain use cases.

The following is the list of reserved logical attributes that are used to operate the solution. Each of these logical attributes must be mapped to a physical schema attribute.

Reserved Attributes (Logical Attribute name)	Description	LDAP Attribute-Mapping value Example (AD/CA Dir)	SCIM Attribute Mapping value Example
user_loginid This logical attribute name is defined by the value of "userLoginIdAttributeMappingName". The mapping of the above logical attribute to the physical attribute is defined in the "attributeMapping" field.	This attribute represents the unique identifier of the user in the ID store. This unique identifier is used to associate the user with the IDSP account. This account stores additional information about the user, such as user credentials, device information. The physical attribute used for storing the user's user_loginid must be unique across the ID store and immutable (its value should never change). If you intend to allow the user login name (the username used on the login screen) to change, that can be achieved by using a disambiguation search query that uses a different physical attribute (not the one that is mapped to `user_loginid`). This disambiguation search query must be unique across the ID store, but it does not need to be immutable.	AD: sAMAccountName/ userPrincipalName CA Dir: cn	userName
name	End-User's full name in displayable form including all name parts, possibly including titles and suffixes, ordered according to the End-User's locale and preferences.	displayName	displayName
family_name	Surnames or last names of the End-User.	sn	name.familyName
given_name	Given names or first names of the End-User.	givenName	name.givenName
email	Preferred e-mail address for an OTP delivery. See the OTP section for more information.	mail	emails[primary]
phone_number	Preferred telephone number for an OTP delivery.	telephoneNumber	phoneNumbers.[mobile]
user_universalid	This attribute represents the Universal Id concept as used by SiteMinder.	<custom>	<custom>
status	Define the name of the attribute in the ID Store that contains the "Disabled Flag" value that is used by SiteMinder. See SiteMinder Documentation. This mapping is needed only when the statusEncoding is set to "siteminder" to indicate the same semantics for setting & discovering disabled status should be used.	<custom>	<custom>
memberof	This attribute is used to determine if 'memberOf' is enabled in the ID Store or not. • If the value is **True**, then the list of groups of the user is read from the user's attribute that is mapped to the "memberof" attribute. • If the value is **False**, then the group membership is determined by querying for the groups where the user's DN is listed in the group attribute that is defined by the **"groupUserMappingAttribute"** LDAPconfig/ SCIMconfig attribute.	memberOf	groups.display

ID Store - Reserved Group Attributes

The following is the list of reserved logical attributes that are used to operate the solution. Each of these logical attributes must be mapped to a physical schema attribute.

Reserved Attributes (Logical Attribute name)	Description	LDAP Attribute-Mapping value Example (AD/CA Dir)	SCIM Attribute-Mapping value Example
name This logical attribute name is defined by the value of "groupNameAttributeMappingName".	This attribute represents the unique identifier of the group in the ID store.	cn	displayName
members	This attribute represents the list of groups' members.	member	members.display

ID Store - Other Attributes Table

Using ID Store attributes in the context of OpenID Connect requires clients requesting identity data via "/UserInfo" request to have the necessary privilege. The following table describes the mapping between the client's OpenID Connect privileges as configured by the "allowedOpenIDScopes" property and OpenID Connect's attributes represented by logical attributes. Each of these logical attributes must be mapped to a physical schema attribute. Refer to Standard OpenID Connect spec for more details.

OAuth Scope	AH Logical Attributes
me	family_name, given_name, middle_name, zoneinfo, local
profile	name, family_name, given_name, middle_name, nickname, preferred_username, profile, picture, website, gender, birthdate, zoneinfo, locale, and updated_at.
email	email, email_verified
phone	phone_number, phone_number_verified
address	address
groups	groups

ID Store to be Used

There are two kinds of identity stores supported - LDAP-based and SCIM-based. Each tenant may have only one active Identity Store at a time. Each identity store is described by a configuration object, to configure this you need to set the idStoreToBeUsed tenant setting that controls whether a tenant uses the GUID of an LDAP configuration or the GUID of an SCIM configuration. For information, see Global/Tenant Settings. The default value is GUID of the configured ID store.

Use the ***PATCH https://${SSP_FQDN}/{{apiPathTenant}}/admin/v1/Configs*** API to update the ID store in IDSP. The following is an example of the tenant setting:

```
[
    {
        "name": "idStoreToBeUsed",
        "value": "cfbfe9d2-0749-487b-a5c0-c471d4f9516f"
    }
]
```

ID Store Mapping in Password Authentication

The ID Store property, "***idStoreMappingStrategy***" is required when the ID store where the user was disambiguated is different from the ID store where the user password authentication is carried out. This property should be configured on the ID Store where the user password authentication is performed.

The following table shows examples of the ID Store Strategy mapping value:

Format of the "idStoreMappingStrategy" value	Examples of a "idStoreMappingStrategy" value	Description
"userdn"	userdn	*"userdn"* is a keyword that indicates that the users in both ID stores have the same DN (find by dn).
"universalid"	universalid	*"universalid"* is a keyword that indicates that the users in both the ID stores have the same UniversalID value (find by the UniversalID field)
<disambiguated user value>	${idprofile.user_loginid} See Dynamic Environment Variable Substitution	Find the user using the lookup query (disambiguation query) that is configured in the target user store (using the value that is specified as the login id string)
=<disambiguated user value>	=${idprofile.user_loginId}	Search in the authentication ID store using the query, <user loginId attribute name>=<specified value> (find by user_loginid)
<local logical attr>=<disambiguated user value>	• email=${idProfile.email} • phone_number= ${idprofile.phone_number	Search for the user using the provided filter

ID Store APIs

The following table displays the list of ID Store APIs that can be used by an administrator to perform CRUD operations in the solution:

Operation Description	Operation Type	Endpoint URLs
Search for a user by using the user login id This operation performs disambiguation by applying ID store search order to locate the user by lookup filter configured on the id store.	GET	https://${SSP_FQDN}/{{tenantName}}/idstore/v1/Users/{{userLoginName}}?appid=<appid>&groups=<groups> • appId: <appid> • configid: <idstore-config-id> • groups: <true> or <false>
Search a user by filter This operation performs disambiguation by applying ID store search order to locate the user by the given filter.	GET	https://${SSP_FQDN}/{{tenantName}}/idstore/v1/Users?predicate=user_loginid&op=eq&value=admin&groups=true • appId: <appid> • configid: <idstore-config-id> • groups: <true> or <false> • predicate: user_loginid (any user logical attribute from id store attribute mapping) • op: eq (value = exact match), dis (apply search order to disambiguate using id store lookup query), dn (value = specific DN) • value: value to search for

Update a specific user detail in the ID Store	PATCH	https://${SSP_FQDN}/{{tenantName}}/idstore/v1/Users/{{userLoginName}}
		• configid: <idstore-config-id>
		• groups: <true> or <false>
		{
		"operations" : [
		
		{
		"action" : "REPLACE",
		"attrName": "email",
		"attrValues": ["example@gmail.com"]
		},
		
		{
		"action" : "REPLACE",
		"attrName": "phone_number",
		"attrValues": ["123-456-7980"]
		}
		
		]
		}

Update a specific user detail in the ID Store by using the filter	PATCH	https://${SSP_FQDN}/{{tenantName}}/idstore/v1/Users?predicate=user_loginid&op=eq&value=admin&groups=true • configid: <idstore-config-id> • groups: <true> or <false> • predicate: user_loginid (any user logical attribute from id store attribute mapping) • op: eq (value = exact match), dis (apply a search order to disambiguate using id store lookup query), dn (value = specific DN) • value: value to search for

Update a user's locked state by specifying the user login id	POST	https://${SSP_FQDN}/{{tenantName}}/idstore/v1/UserLocker/{{userLoginName}}
		• configid: <idstore-config-id>
		{
		"locked": true
		}

Retrieve a user's locked state by specifying the user login name	GET	https://${SSP_FQDN}/{{tenantName}}/idstore/v1/UserLocker/{{userLoginName}} • configid: <idstore-config-id>
Retrieve all ID Store groups	GET	https://${SSP_FQDN}/{{tenantName}}/idstore/v1/Groups • configid: <idstore-config-id> • members: <true> or <false>
Search a group by specifying the group name	GET	https://${SSP_FQDN}/{{tenantName}}/idstore/v1/Groups/{{groupName}} • configid: <idstore-config-id> • members: <true> or <false>

Search a group by using filter	GET	https://${SSP_FQDN}/{{tenantName}}/idstore/v1/Groups?predicate=<predicate>&op=<op>&value=<value> • configid: <idstore-config-id> • members: <true> or <false> • predicate: name (any group logical attribute) • op: eq (return one) or meq (return many) or dn (value=group DN) • value: * or x* or *x or x*y

Update a group by specifying the group name	PATCH	https://${SSP_FQDN}/{{tenantName}}/idstore/v1/Groups/{{groupName}}
		• configid: <idstore-config-id>
		• members: <true> or <false>
		{
		"operations" : [
		{
		"action" : "ADD",
		"attrName": "members",
		"attrValues": ["cn=nbruce,ou=Employees,o=democorp,c=us"]
		},
		{
		"action" : "REMOVE",
		"attrName": "members",
		"attrValues": ["cn=edunn,ou=HR,o=democorp,c=us"]
		}
		]
		}

Update a specific group by using filter	PATCH	https://${SSP_FQDN}/{{tenantName}}/idstore/v1/Groups/{{groupName}} • configid: <idstore-config-id> • members: <true> or <false> • predicate: name (any group logical attribute) • op: eq (return one) or dn (value=group DN) • value: * or x* or *x or x*y

NOTE

- To know the value of ${SSP_FQDN} environment variable, see Configuring IDSP Environment Variables.
- The default value for `<tenantName>` is "default".
- Replace the text {{text}} including {{}} characters with appropriate values, in all the endpoints shown in the above table.
  For example:
  `https://{{host}}/{{tenantName}}/idstore/v1/Groups`
  should look similar to:
  `https://example.com/default/idstore/v1/Groups`
- To know more about the scopes that are required to secure these APIs, refer to the "Scopes" section here.

ID Store Updates

The Identity Store, when in non-ZFP mode, is always authoritative for determining the user's initial lockout state and, if so configured, the user's initial credentials to be enrolled. In some cases, the Identity Store must be updated when such state

changes in the IDSP. Such behavior can be configured in IDSP by specifying appropriate feature flags on the Identity Store configuration resource:

- ***isAuthoritativeForIDLCM*** - If set to true, this parameter ensures that the user's lockout state in the IDSP is also updated in the Identity Store after a user lock.
- ***isAuthoritativeForUserCredsLCM*** - If set to true, this parameter ensures that the user credential registered in the IDSP during inline enrollment is also updated in the Identity Store.

Links to LDAP and SCIM Configurations:

- To know more about LDAP Configuration, see LDAP Configuration
- To know more about SCIM Configuration, see SCIM Configuration

Link to ID Store Search:

- To know more about ID Store Search, see ID Store Search

Configuring the Internal ID Store

For non-Zero-Identity-Footprint applications, in addition to support for LDAP or SCIM ID Stores, Symantec Identity Security Platform supports an Internal ID Store.

The Internal ID Store is part of the IDSP ID Store architecture. The Internal ID Store supports all the same concepts and capabilities as the current LDAP or SCIM user directories in addition to the Identity Service capabilities described. The internal ID store is automatically deployed and ready for use in IDSP.

The IDSP Admin Console > Identity Stores page lists the internal ID Store by default.

> **NOTE**
> For more information, see Configuring an Identity Store using the Admin Console in the Internal Identity Store topic.

You can configure the internal ID store through the Admin Console or through the Identity Store APIs. To configure the internal ID store through the Admin Console, see Internal Identity Store Configuration.

Internal ID Store Configuration Properties

The Internal ID store configuration properties appear in the following table.

Property Name	Description	Property Value
`accountActivationRequired`	When creating SCIM users, the account must be activated. If set to false, the account is automatically activated at creation.	false – an account is automatically activated at creation true - the account must be activated (default)
`accountActivationTokenExpiryDays`	The number of days within which the account must be activated before the token that is created by the activation request expires.	
`accountRegisterUrl`	An optional value that, when defined, provides a **Register Account** link on the **Sign-in App** login page.	This value is empty by default.

accountRegisterUrl	An optional value that, when defined, provides a **Register Account** link on the **Sign-in App** login page.	This value is empty by default.
activationNotificationDestinations	Identifies which credentials (Email or phoneNumber) are returned by the Verified Credentials API for the user, which is then used to deliver the activation token (see Identity Self-Service Operations API.). **Writer:** Change xref to new self service account activation topic. This flag is used to determine where the activation token is delivered.	Comma-separated list of email addresses or SMS-enabled phone numbers. The value is "email, sms" by default.
adminCanGeneratePassword	This setting determines if an Administrator can change a user password.	true/false. The default is false. If you change the value, you must issue new access tokens to reflect the permission change.
allowAdminSelfModifyOperation	By default, administrators cannot modify their own profile information. If set to true, administrators can modify their own profile information	false – do not allow administrators to modify their own profile information (default) true - allow administrators to modify their own profile information
allowSelfServiceAccountActivation	Allow a user to activate an account the first time that the user authenticates to the account. See Self Service Account Activation in the Identity Service	false – do not allow self-service account activation (default) true - allow self-service activation
allowStartIndexSearchIndex	Start Index is used in the SCIM pagination model to indicate the next page set to retrieve. With large query results, specifying a high start Index value (for example, page number 10k out of a 20K user query) can have a significant performance effect. Start index is turned off by default, both as a precaution and to bring awareness of the impact of its use.	true/false. The default is false
allowLocalPasswordForFederatedUsers	Allows federated users to have a local password.	true/false. The default is false.
disambiguationQuery	The query is used to disambiguate the user. **Note**: Make sure to consider minimal latency when defining this query.	`user_loginid eq ${loginid} or email eq ${loginid}`
displayNameTemplate	Defines how the user display name is generated from the user attribute values.	`"${idprofile.given_name} ${idprofile.family_name}"`

emailDomainForSimulatedAuthenticationFailure	When idle authentication failure is true and a user requests to reset a password, the Forgot Password flow presents a randomly generated and obfuscated email address or phone number to the user. Use this property to define the email domains that appear on this page for the user. Set whether the **Forgot Password** page presents an email address or phone number in the selfServiceAccountActivationStrategy property.	Comma-separated list of email domains. The default value is **null**.
emailsMustBeUnique	Determines if user email values must be unique across the tenant.	true/false. The default is true.
idStoreMappingStrategy	This property is used to determine how to look up the user for Password Authentication.	user_loginid=${idprofile.user_loginid}
loginIdRegexEnabled	This regular expression formats the user login ID to match the corresponding attribute value in the identity store.	true/false. The default is false.
loginIdRegexFrom	A regular expression to be applied to the user login ID.	
loginIdRegexTo	A regular expression that is used to format the user login ID to match the corresponding attribute value in the identity store.	***Example***: The "**loginIdRegexFrom**" and "**loginIdRegexTo**" parameter has been explained through the following example. In this example, when the following values are considered, • loginIdRegexFrom = ^(.*)\s(.*)$ • loginIdRegexTo = 0{2} • Input value = +32 495551320 The regular expression transforms the input value +32 495551320 into 0495551320 (result) by capturing the part after the space and adding 0 in front of it.
passwordHashAlgo	The Admin Console password is encrypted using the SHA-256 encryption algorithm. Select how to apply the SHA-256 algorithm.	• **SHA256**: the password is encrypted using one iteration with the SHA256 algorithm. • **SHA256_600**: the password is encrypted using 600,000 iterations with the SHA256 algorithm. The SHA256-600 option provides an additional level of security. The higher iteration count significantly increases the time that is required to compute the hash, making it more difficult for brute-force attacks to succeed.
privacyPolicyUrl	An optional value that, when defined, provides a **View Privacy Policy** link on the **Sign-in App** login page.	This value is empty by default.

scimBulkMaxOperations	The maximum number of SCIM operations that can be handled by the SCIM bulk API.	Default: 1000
scimBulkMaxPayloadSize	The maximum size of the payload request for the SCIM bulk API.	Default: 1 MB
scimSearchLimit	The search limit for SCIM User and Group search requests.	Default: 500
searchTimeoutSecs	The number of seconds after which the search fails if no values are returned.	Default: 0 Maximum: 1000
selfServiceAccountRecoveryCredentialStrategy	Identifies which credentials (Email or phoneNumber) are returned by the Verified Credentials API for the user (see User Self Service API and Identity Self-Service Operations API.). These credentials can be used in subsequent API calls to deliver the token for Password Reset or Account Unlock operations.	Comma-separated list of email addresses or SMS-enabled phone numbers. The value is "email, sms" by default
skipEmailValidation	When creating users, email addresses are validated for correctness. If set to false email addresses are not validated.	**false** – do not validate email addresses during user creation **true** - validate email addresses during user creation (default)
skipPhoneValidation	When creating users, phone numbers are validated for correctness. If set to false phone numbers are not validated.	false – do not validate phone numbers during user creation true - validate phone numbers during user creation (default)
strictValidationEnabled	Controls whether to adhere to Strict SCIM protocol in SCIM calls.	false – do not adhere to Strict SCIM protocol (default) true - adhere to Strict SCIM protocol
unlockAccountAfterPasswordReset	Support for Self-Service Account unlock. When initiating Account unlock a Password Reset flow is invoked, which, upon completion unlocks the user account.	false – Self-service account unlock is disabled (default) true – Self-service unlock using Password Reset is enabled
useMaskedCredentialValues	When a user profile email or phone number is used as a credential, a value of true for `displayName` indicates that the email or phone number contains a masked value and that value should be used when displaying the credential.	False – let the service provide the masked email and phone value to be displayed. True – assumes the persisted email/phone.displayName field on the user profile contains the masked value to be displayed

usePriorityToDetermineUserEmail	Some User multi-value user attributes support the designation of a primary value (for example, email.primary). In the absence of a primary designation, you can use a priority value on the attribute. The lowest priority value is deemed primary.	false – do not use priority for designating a primary (default) true - use priority for designating a primary
userNameGenerationRule	The rule that determines the structure of system-generated usernames. The username generation rule can be formed with the combination of one or more string-literals, place-holder-for-number-of-digits, and variables which can be separated by '+' character. See Username Generation Rules	"${idprofile.given_name} + '.' + ${idprofile.family_name}".
validatePolicyPrincipals	When saving an authorization or authentication policy, we validate the existence of the principal of the policy.	false – do not validate that the principal exists when saving an authentication or authorization policy (default) true - validate that the principal exists when saving an authentication or authorization policy
customUserAttributes	Defines the set of User custom attribute definitions.	See the following User Schema section for details.

Internal ID Store Configuration APIs

The following table displays the list of Internal ID Store Configuration APIs that an administrator can use to get the configuration properties for the store.

Operation Description	Operation Type	Endpoint URLs
Retrieve the current configuration	GET	https://${SSP_FQDN}/{{tenantName}}/admin/v1/InternalIdStoreConfig

Update the current configuration	PUT	https://${SSP_FQDN}/{{tenantName}}/admin/v1/InternalIdStoreConfig
		
		{
		"idStoreMappingStrategy": "user_loginid=${idprofile.user_loginid}",
		"disambiguationQuery": "user_loginid eq ${loginid} or email eq ${loginid}",
		"unlockAccountAfterPasswordReset": false,
		"useMaskedCredentialValues": false,
		"passwordResetInitiatorUrl": null,
		"passwordResetChangerUrl": null,
		"accountUnlockInitiatorUrl": null,
		"customUserAttributes": null
		}

NOTE

- To know the value of ${SSP_FQDN} environment variable, see Configuring the Environment Variables.
- The default value for `<tenantName>` is "default".
- Replace the text {{text}} including {{}} characters with appropriate values in all the endpoints that are shown in the preceding table.
  For example:
  `https://{{host}}/{{tenantName}}/admin/v1/InternalIdStoreConfig`
  should look similar to:
  `https://example.com/default/admin/v1/InternalIdStoreConfig`
- To know more about the scopes that are required to secure these APIs, refer to the Rest APIs and Associated Privileges section.

Configuring the Zero Footprint Identity

Learn about configuring Zero Footprint (ZFP) in Symantec Identity Security Platform.

This topic includes the following sections:

- About Zero Footprint (ZFP)
- Use Case: Using ZFP with IDSP and SiteMinder
- ID Token Hint Details
- ZFP Configuration in IDSP
  - Configuring Application Entity
  - Settings Configuration
- Display Name Generation in ZFP

About Zero Footprint (ZFP)

In some scenarios, it may be necessary to use ZFP instead of relying on direct communication routes to identity stores. For example, a deployment where the IDSP (solution) does not have direct access to a user store or where such a user store requires an expensive process of buildout or provisioning, the ZFP approach provides the solution with a simple way to extend its services.

Following are the benefits of ZFP, when applicable:

- Simplifies integration by not requiring ID Store connection between IDSP and user directories
- Minimizes dependency on having multiple external identity stores
- Maximizes resiliency by not requiring a physical connection

Zero Footprint (ZFP) - Best Practices

Table 80: ZFP Best Practices Table

ZFP Benefits (When to use ZFP)	ID Store Benefits (When not to use ZFP)
This approach becomes the only viable option when there is no connection to the ID Store.	When the user has a substantial number of groups and profile attributes that are essential for Authentication and Access policies requiring clients to issue Identity Token with that information, causing tokens to exceed header size limits supported by infrastructure.
ZFP provides greater resilience in situations where the connection to the ID Store is unreliable, offering more fault tolerance.	In cases where specific applications require app-specific tokens, authentication, or access policies that rely on real-time access to user profile attributes and group memberships.
By eliminating at least one trip to the ID Store, it improves performance, particularly in SiteMinder Web Flows that delegate authentication to IDSP.	ID store does not rely on the requesting client or a third-party Identity Provider to provide user profile and group membership data.
ZFP reduces dependency on the ID Store when not essential, making the system more robust.	When multiple clients are requesting IDSP services, and these clients do not share a common view of the user identity, this approach can be used.

Use Case: Using ZFP with IDSP and SiteMinder

ZFP enables SiteMinder to propagate the primary authentication context (for example- establish through Username and Password) to IDSP, which in turn evaluates MFA policy for additional step-up requirements.

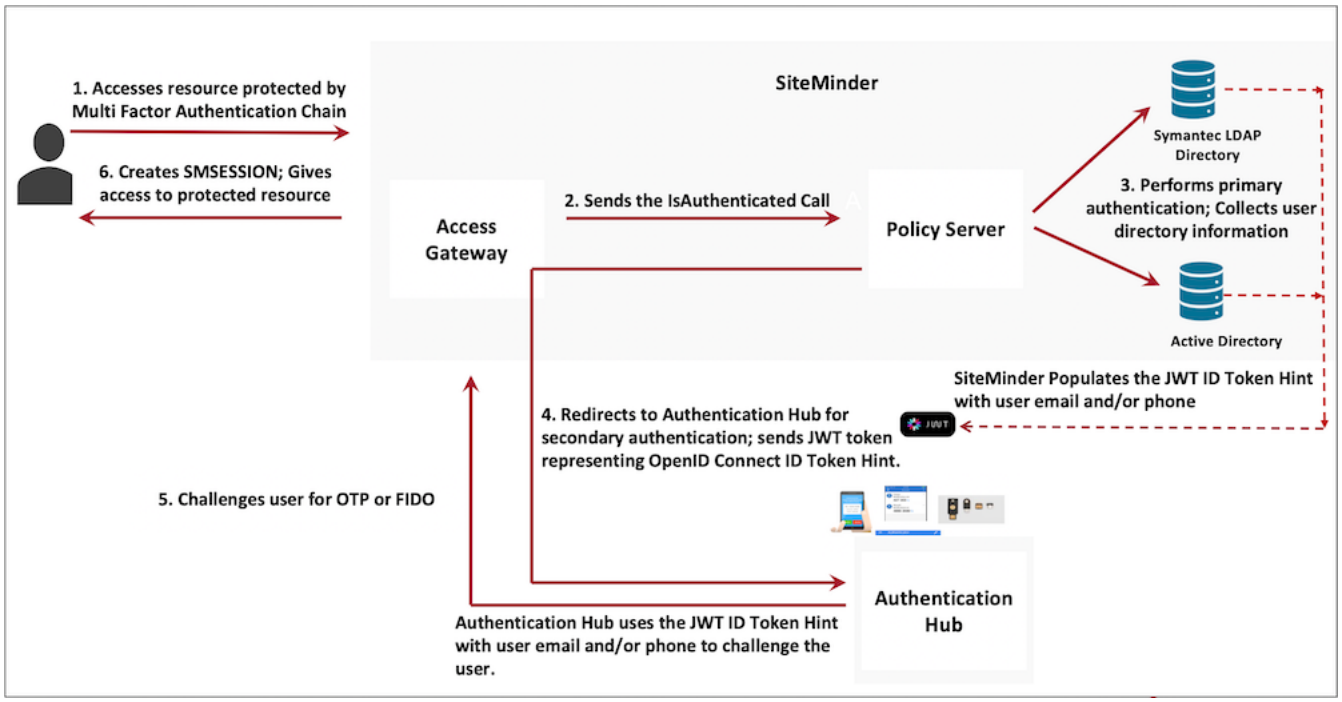
The SiteMinder integration with IDSP supports various use cases to support identity propagation. For the complete list, see the Supported Use Cases section in Identity Propagation in SiteMinder.

The following use case describes how IDSP uses an authentication context from SiteMinder when a user accesses a resource and IDSP is required to perform additional authentication depending on the user identity namespace represented by the SiteMinder User Directory.

Assumptions:

- SiteMinder has the following two user directories configured:
  - User Directory 1 - Symantec LDAP Directory
  - User Directory 2 - Active Directory
- SiteMinder has two user directories that are configured, Dir1-(CA Directory), and Dir2-(Active Directory)
- A Multi-Factor Authentication Chain authentication scheme is configured in SiteMinder with the primary authentication through the HTML Form authentication scheme, and secondary authentication being delegated to IDSP.
- In IDSP, an authentication policy defines the use of PWD + OTP for Symantec Directory users and PWD + FIDO for Active Directory users.

The following high-level diagram describes the process flow when the use case is executed:



The following process describes the execution flow of the use case:

- A user without an existing session accesses a resource that is protected by the Multi-Factor Authentication Chain authentication scheme.
- Access Gateway intercepts the request and forwards it to Policy Server.
- Policy Server authenticates the user using HTML Form authentication and creates ID Token Hint with a user ID and user directory name.
- Policy Server redirects the user to IDSP through Access Gateway for secondary authentication.
- IDSP performs the following steps:
  - Evaluates the ID Token Hint to determine how the user must be further challenged.
  - The user is not challenged PWD as SiteMinder has already authenticated the user for PWD.
  - IDSP evaluates the claim in the received Identity Token Hint to decide if the specified user email or phone number that is conveyed by the token should be auto-enrolled as authentication credentials for MFA purposes.
  - If the user belongs to Symantec LDAP Directory, IDSP challenges the user for OTP. If the user belongs to Active Directory, IDSP challenges the user for FIDO.
  - IDSP returns ID Token with its user authentication information to SiteMinder.
- SiteMinder creates an SMSESSION cookie for the user and grants the user access to the requested protected resource.

ID Token Hint Details

When SiteMinder (requesting client) integrates with IDSP and enables the "zeroFootPrint" property to true, (example-"zeroFootPrint": true) then the solution does not validate the user identity against the local LDAP directory, rather uses the ID Token Hint submitted by the requesting client through the (/auth/v1/authenticate) REST API or OpenID Connect "login_hint" request parameter (/oauth/v1/authorize). The client is assumed to have the authority to issue such hint to represent the user first factor, and must be declared as "Trusted" in VIP IDSP.

The ID Token Hint passed by the requesting client through the REST API (/authenticate) or OpenID Connect /Authorize grant, must include the following mandatory claims representing the Identity:

- email: The email ID configured in the requesting client end.
- phone_number: The phone number of the user who is configured in the client.
- user_universalID: The login ID of the requesting client.
- auto_inline_enrollment:
  - When this claim is set to true, the solution auto enrolls the credentials based on the value in the ID Token Hint
  - When this claim is set to false, the solution ignores the credentials that are sent in the ID Token Hint

NOTE

- If the ID Token Hint (JWT token) did not include the email and phone number of the requesting client, then inline enrollment of the client phone and email is allowed without challenging for a step-up. However, for inline enrollment to work, the JWT should contain "auto-enrolment" in ID Token Hint.
- If the ID Token Hint did include the email and phone number of the client, and auto-enrolment" in ID Token Hint is set to 'true', then client credentials are enrolled automatically in the solution.

The following table shows the ID Token Hint Claims as expected by IDSP and the attributes that are passed in the ID Token Hint:

Attribute	Description
Regular JWT Attributes as per IT spec	
user_loginId	User loginId used to identify the user. This value must uniquely identify the user and must be immutable.
aud	Client ID of Requesting Client (for example:SiteMinder) application in AuthenticationHub
auth_time	Time when the user was authenticated by the Requesting Client (SiteMinder)
iss	Issuer by which Requesting Client (SiteMinder) is identified
exp	Expiry time of the Identity Token Hint
nonce	nonce
iat	Time when the Identity Token Hint was issued
jti	Unique *identifier* for the JWT
nbf	Time when the user was authenticated by the Requesting Client (SiteMinder)
Required for user lookup	
email	Based on Requesting Client's (SiteMinder) User Directory (UD) attribute
phone_number	Based on Requesting Client's (SiteMinder) Authentication Scheme config. Leave the value empty, if it is not mapped to the UD attribute
user_universalID	Based on Requesting Client's (SiteMinder) UD attribute config
auto_inline_enrollment	Indicates if the credentials sent in the ID Token should be automatically enrolled (Based on Requesting Client's (SiteMinder) config. When this field is set to false then IDSP, ignores the creds that are sent in IT When this field is set to true then IDSP automatically enrolls the creds in the solution based on the values in the ID Token Hint.
Required for policy eval	

idp_name	A logical name representing the user identity namespace Note: In case of SiteMinder integrating with IDSP using ZFP,`idp_name` is the name of the User Directory where the user identity exists. SiteMinder's "IDSP" Auth Scheme sets this claim automatically.
Required for identity propagation	
amr	Based on the list of AMRs supported by IDSP. Note: In case of SiteMinder integrating with IDSP using ZFP,`amr` is the AMR value that is associated with the authentication method that is applied by SiteMinder during user authentication prior to requesting MFA from IDSP. SiteMinder's "IDSP" Auth Scheme sets this claim automatically.

ID Token Hint Sample

The following sample illustrates an ID Token Hint sent by the requesting client:

```
{
"sub": "nbruce",
"auto_inline_enrollment": true,
"idp_name": "Employees",
"user_universalid": "nbruce",
"amr": [
"PWD"
],
"user_loginid": "nbruce",
"iss": "https://security.com/iam/example",
"nonce": "382443df-9734f4d9-21553cf7-08425087-941d212a-cc",
"aud": "e4df1123-5579-474e-bbae-a23518d2e3a3",
"nbf": 1612428071,
"auth_time": 1612428071,
"phone_number": "+9190012530000",
"exp": 1612428371,
"iat": 1612428071,
"email": "nbruce@example.com",
"jti": "382443df-9734f4d9-21553cf7-08425087-941d212a-cc"
}
```

ZFP Configuration in IDSP

Staying with the SiteMinder example, upon successfully authenticating an identity using username/ pwd, SiteMinder sends the ID Token Hint with user ID, name of the user directory and other details to IDSP for secondary authentication. The ID token Hint contains the attribute "amr" that represents a factor that has already been applied by SiteMinder. Therefore, IDSP evaluates the Identity token hint to determine the next obligations that the user should be challenged with. However, the obligation that is conveyed in 'amr' is skipped, since this factor has already been used to authenticate the user in SiteMinder. Thus, the user is challenged with the remaining factors.

To know about configuring "IDSP" Authentication Scheme in SiteMinder, refer to SiteMinder-IDSP integration doc.

Configuring Application Entity

In IDSP, the Zero Footprint property is added to the "Application" configuration as a boolean value (default is set to "false"). To make use of this property, set `"zeroFootPrint": true` . The sample code shows the "zeroFootPrint" property configuration in the "Application" API:

```
{
   "status": "active",
```

```
    "name": "democlient",
    "description": "Demo client to perform tenant level operations for demo purpose.",
    "clientType": "TRUSTED",
    "allowedOpenIDScopes": [
        "openid",
        "profile",
        "email"
    ],
    "redirectURIs": [
        "https://testapp.vlsampleapp.bm.com/oauth2/callback"
    ],
    "allowedGrantTypes": [
        "client_credentials",
        "authorization_code",
        "urn:ietf:params:oauth:grant-type:jwt-bearer"
    ],
    "userInfoEndpointResponseFormat": "PLAIN_JSON",
    "skipIssuerAudienceForIT": false,
    "skipEmailForIT": false,
    "zeroFootPrint": false,
    "allowedOperations": [
        "introspect"
    ],
    "enableTrustedDevice": false,
    "appId": "df11af0f-e872-44c1-bafe-1fc310734e96",
    "updatedBy": {
        "principalType": "CLIENT",
        "principalId": "7073a00c-cbad-4fa3-a58e-a3f02dc00793",
        "principalName": "defaulttenantclient"
    },
    "createdDateTime": "2020-10-27 23:27 PM UTC",
    "updatedDateTime": "2020-11-10 23:08 PM UTC",
    "secret": "0524011e-4172-4e96-abaa-2a30e4521792",
    "clientId": "3cb1361e-2f22-4d0e-b679-693db7e3c1ae"
}
```

See Managing Applications

Settings Configuration

(Optional) To use the User Auto-Enrollment feature, enable the "isAutoEnrollmentAllowed" setting in IDSP. The settings description is detailed in Settings. To know about User Auto-Enrollment, see here.

Configuring Authentication Policy

The IDSP Authentication Policy includes "idpName" condition for "zeroFootPrint". This condition indicates the name of the logical identity namespace in a policy condition. Optionally, add this condition to the policy by using a POST/PATCH operation.

For example: With SiteMinder using ZFP to integrate with IDSP, the identity namespace is represented by the name of the SiteMinder User Directory containing the user.

```
{
     "policyName": "Feature Policy Demo - siteminder integration",
     "description": "Feature Policy Demo - siteminder integration",
     "status": "active",
```

```
    "matchAnyApp": false,
    "apps": [
        {
            "name": "siteminder",
            "id": "7f27b5cd-5e22-43b7-a7a5-942472581ffe"
        }
    ],
    "rules": [
        {
            "conditions": {
                    "idpName": {
                           "operator": "in",
                           "value": ["Employees"]
                       },
                "acr": {
                    "operator": "in",
                    "value": [
                        "test"
                    ]
                }
            },
            "result": {
                "effect": "allow",
                "reAuthenticate": "false",
                "obligations": [
                    "PASSWORD:1"
                ],
                "msg": "Rule1: Password auth for users in 3rd party directory"
            }
        },
        {
            "conditions": {
                "idpName": {
                    "operator": "in",
                    "value": ["Consumers"]
                },
                "acr": {
                    "operator": "in",
                    "value": ["test"]
                }
            },
            "result": {
                "effect": "allow",
                "reAuthenticate": "false",
                "obligations": [
                    "PASSWORD:1", "OTP:2", "MOBILEOTP:2"
                ],
                "msg": "Rule1: Password auth for users in LDAP store"
            }
        }
    ]
}
```

Display Name Generation in ZFP

When a ZFP account is created, Symantec Identity Security Platform ensures that the display name of the account is always set. Symantec Identity Security Platform generates the `displayName` value from one of the following sources (in order):

1. metadata of the identity provider; or,
2. metadata of the application; or,
3. `displayNameTemplate` configured in the internal identity store configuration (see Internal Identity Store Configuration); or,
4. `givenName` and `familyName` ; or,
5. user `loginId` .

Configuring the User Lockout

A setting that locks a user after the maximum number of failed login attempts has been reached.

This topic includes the following sections:

- User Account Lockout Behavior
- Updating the ID Store Config Request
- Using the User Locker APIs
- Resetting the Locked User Account
- User Lock Behavior Scenarios and Error Messages Table
- Lock User On Next Auth Failure Warning in the authentication API response

User Account Lockout Behavior

When a user attempts to log into a protected resource several times without success, the individual may be suspected of being fraudulent or malicious, resulting in a security vulnerability. As a result, a feature known as User Locker has been added to the solution. This feature prevents a user from performing unsuccessful logins beyond a certain number of attempts and locks the user in the authoritative source. There are a few tenant-level settings added to customize this option in the solution. These settings control the number of times a user can try unsuccessfully to log in before being locked out by the administrator for a predetermined length of time. The admin can manually choose to unlock the user by invoking the UserLocker API.

The required settings to be configured for user account lockout are explained in the following section.

Configuring the settings

The following table lists the tenant-level settings that should be configured in the solution:

Property Name	Property Scope	Property Description	Default Value
userMaxStrikeCount	Tenant	This property allows administrators to specify how many failed authentication attempts are allowed before the user is locked out. • If this value is set to '0', then this property will not be updated and the user will not be locked out. • If this value is set to more than '0', then the user will get locked in the authoritative source after this value is reached. The authoritative source is defined by the attribute "isAuthoritativeForIDLCM" in the ID Store configuration.	0

userAutoUnlockPeriodMinutes	Tenant	This property allows administrators to specify the number of minutes a locked-out account should remain locked before it is automatically unlocked. The locked user will be unlocked after this time period expires. • The default value configured for this setting is "0" minutes, which implies that autoUnlock functionality is disabled. Any positive value for this setting indicates that when the specified number of minutes have elapsed, autoUnlock will be enabled. • If the ID Store attribute,"isAuthoritativeForIDLCM" is set to "true", the "userAutoUnlockPeriodMinutes" property unlocks the user in the ID Store as well.	0
trackLastLogin	Tenant	This property allows administrators to track whether the last authentication was successful or unsuccessful.	false

These configuration settings are also covered in Global/Tenant Settings.

Updating the ID Store Config Request

The following attributes should be configured in the ID Store configuration request payload for UserLocker behavior:

- ***statusEncoding*** - This attribute checks the ID Store type being used. It helps to understand how the status attribute is encoded.
  If this value is not specified, then the ID Store service falls back to the backward compatibility mode where the status field is used with AD semantics.
- ***isAuthoritativeForIDLCM*** - This attribute checks if the ID Store that is being configured, is also the authoritative source for user locking. This is a boolean string with a value of true/false. If this value is set to "false", then Symantec Identity Security Platform becomes the authoritative locking source and the ID Store that has been configured will not be the locking source. The user locking is done when the user strike count reaches the maximum allowed value. If this value is set to "true", the user lock is done in the user store.

The descriptions for these attributes have also been covered in the LDAP ID Store Attributes table and SCIM ID Store Configs table.

Using the User Locker APIs

The UserLocker API allows an administrator to check and change the status of a user from unlock to lock and vise versa. To determine how to handle the user status for a certain directory, this API uses an ID Store config called "statusEncoding." The API also checks if the ID Store defined in the solution is the authoritative source for locking the user using an ID Store config called "isAuthoritativeForIDLCM". These ID Store attributes have been explained above.

Users who use the **ZFP flow** are not looked up in the ID Store User Directory; hence, they cannot be locked in ID Store but can be locked in the IDSP database. The locked-out user will be automatically unlocked later based on the tenant setting, "userAutoUnlockPeriodMinutes."

The administrator can use the following ID Store APIs to update the users status and also to retrieve the current status of the user from the ID Store directories:

Operation Description	Operation Type	Endpoint URLs
This API is used to update the user's account status as "Locked" or "Unlocked" in the ID Store by sending the request parameter called, "locked". When "locked" = "true", the user gets locked, and when "locked" = "false", the user gets unlocked.	POST	https://${SSP_FQDN}/{{tenantName}}/idstore/v1/UserLocker/{{userLoginid}}
This API is used to check the user's "Status". The API response contains information on whether the user is locked. The user's status is returned as "locked" = "true/false" in the payload.	GET	https://${SSP_FQDN}/{{tenantName}}/idstore/v1/UserLocker/{{userLoginid}}

NOTE

- To know the value of ${SSP_FQDN} environment variable, see Configuring IDSP Environment Variables.
- The default value for `<tenantName>` is "default".
- Replace the text {{text}} including {{}} characters with appropriate values, in all the endpoints shown in the above table.
  For example:
  `https://{{host}}/{{tenantName}}/idstore/v1/UserLocker/{{userLoginid}}`
  should look similar to:
  `https://example.com/default/idstore/v1/UserLocker/{{userLoginid}}`
- To know more about the scopes that are required to secure these APIs, refer to the Rest APIs and Associated Privileges section.

Example of the POST UserLocker API

```
POST /idstore/v1/UserLocker/{UserLoginId}

200 OK
{
"locked": false
}

400 BAD REQUEST
{
    "errorCode": "1003022",
    "errorMessage": "Unable to update user's lockout state: Missing status encoding value in ID Store
 definition"
}

400 BAD REQUEST
{
    "errorCode": "1003019",
    "errorMessage": "Unable to update user's lockout state"
}
```

Example of the GET UserLocker API:

```
GET /idstore/v1/UserLocker/{UserLoginId}
```

```
200 OK
{
"locked": false
}

400 BAD REQUEST
{
    "errorCode": "1003022",
    "errorMessage": "Unable to detect user's lockout state: Missing status encoding value in ID Store
 definition"
}
```

Resetting the Locked User Account

The locked user account can be reset in two ways:

- An administrator can manually reset a user's account by invoking the "/UserLocker" API with the request, "locked" = "false/true". If set to true, the user account is locked and vice versa.
- A locked user account that uses the ZFP flow gets automatically unlocked after the timeframe specified in the attribute "userAutoUnlockPeriodMinutes" ends. See Global/Tenant Settings for more details.

User Lock Behavior Scenarios and Error Messages Table

The following table describes the user lock behavior based on the configuration of the following two settings:

- hideAuthenticationFailureReason
- skipHideAuthenticationFailureReasonForLockedUser

Scenario	**Pattern A** • hideAuthenticationFailureReason = false • skipHideAuthenticationFailureReasonForLockedUser = false	**Pattern B** • hideAuthenticationFailureReason = true • skipHideAuthenticationFailureReasonForLockedUser = false	**Pattern C** • hideAuthenticationFailureReason = true • skipHideAuthenticationFailureReasonForLockedUser = true
When the user is not found	"errorMessage": "User disambiguation failed. [USER_NOT_FOUND] []	The user is displayed with the password authentication screen a set number of times as determined by the configuration of the "maxStrikeCount" property. Once this threshold is reached, the user receives an "AUTH_DENIED" response.	The user is displayed with the password authentication screen a set number of times as determined by the configuration of the "maxStrikeCount" property. Once this threshold is reached, the user receives an "AUTH_DENIED" response.
When the user is locked	"errorMessage": "The user in the request is not active. [8800041] [SmDisabledReason=2,SmAuthReason=7,Encoding is missing]	The user is displayed with the password authentication screen a set number of times as determined by the configuration of the "maxStrikeCount" property. Once this threshold is reached, the user receives an "AUTH_DENIED" response.	"errorMessage": "The user in the request is not active. [8800041] [SmDisabledReason=2,SmAuthReason=7,Encoding

When the user is disabled by the admin	"errorMessage": "The user in the request is not active. [8800041] [SmDisabledReason=1,SmAuthReason=7,Encoding=is as def"	The user is displayed with the password authentication screen a number of times as determined by the configuration of the "maxStrikeCount" property. Once this threshold is reached, the user receives an "AUTH_DENIED" response.	"errorMessage": "The user in the request is not active. [8800041] [SmDisabledReason=1,SmAuthReason=7,Encodin
When the user is disabled due to inactivity	"errorMessage": "The user in the request is not active. [8800041] [SmDisabledReason=4,SmAuthReason=25,Encoding=is as def"	The user is displayed with the password authentication screen a number of times as determined by the configuration of the "maxStrikeCount" property. Once this threshold is reached, the user receives an "AUTH_DENIED" response.	"errorMessage": "The user in the request is not active. [8800041] [SmDisabledReason=4,SmAuthReason=25,Encodi

Lock User On Next Auth Failure Warning in the Authentication Response

The "lockUserOnNextAuthFailure" parameter is a warning message that is returned in the authentication response of any obligation (for example- Password, SMS OTP), when there is only one user strike left before the system locks the user's account. Therefore, if the user strike count left in the authentication flow is more than one, this parameter is not returned.

The following example shows the "userLockOnNextAuthFailure"="true" warning in the password obligation authentication response:

```
{
    "flowState":
 "SkFhcUhSQUQram1NbjBtL1hhSHE0eERTUHBtekxKNmszMUdXN0Uzb1VIS3N1WkovampBa1VYaWRBakFuejdybXU2M1VFS3dpanJxMmFjaWJjVCtGenJUN
    "nextaction": "PASSWORD_AUTH",
    "currentFactors": [
        "PASSWORD"
    ],
    "data": {
        "errorMessage": "Incorrect credentials",
        "errorCode": "3001033"
    },
    "userLockOnNextAuthFailure": "true",
    "additional": {
        "idpName": "TestConfig2",
        "idpGuid": "01f6dac1-08ce-4f4b-b777-b7f474ac0620",
        "idpType": "ldap",
        "currentFactorLevel": 1,
        "predicatesForCurrentFactors": [
            {
                "factor": "PASSWORD",
                "predicate": "TestConfig2",
                "providerAmr": "PWD"
            }
        ],
```

This parameter (lockUserOnNextAuthFailure) is also dependent on two tenant setting configurations:

- ***hideAuthenticationFailureReason*** -

  - If "hideAuthenticationFailureReason"="false", the authentication response returns the "lockUserOnNextAuthFailure" warning.
  - If hideAuthenticationFailureReason=false, and the next action is 'AUTH_DENIED', then the following error message is displayed in the response:

```
"data":
        {
            "errorCode": "00000125",
            "errorMessage": "There are no registed credentials and inline enrollment is disabled"
        }
```

  If "hideAuthenticationFailureReason"="true", the "lockUserOnNextAuthFailure"="true" warning is not returned in the authentication response of an obligation.
- ***skipHideAuthenticationFailureReasonForLockedUser*** - This parameter is dependent on the "hideAuthenticationFailureReason" parameter. Therefore, consider the following use cases:
  - When "hideAuthenticationFailureReason"="true" and "skipHideAuthenticationFailureReasonForLockedUser"="true", the authentication response of an obligation returns the "lockUserOnNextAuthFailure"="true" warning. This is because the "skipHideAuthenticationFailureReasonForLockedUse" parameter setting takes precedence over the "hideAuthenticationFailureReason" setting.
  - When "hideAuthenticationFailureReason"="true" and "skipHideAuthenticationFailureReasonForLockedUser"="false", the authentication response of an obligation does not return the "lockUserOnNextAuthFailure"="true" warning.
  - When "hideAuthenticationFailureReason"="false" and "skipHideAuthenticationFailureReasonForLockedUser"="false", the warning "lockUserOnNextAuthFailure"="true" is returned in the authentication response of an obligation.

These tenant settings, "hideAuthenticationFailureReason", and "skipHideAuthenticationFailureReasonForLockedUser" are coved in Global/Tenant Settings.

Configuring the User Auto Enrollment and Credential Synchronization

This topic includes the following sections:

- Auto Enrollment and Credential Synchronization
- Multiple Credential Synchronization Flows
- Table Showing Credential Synchronization Scenarios

Auto Enrollment and Credential Synchronization

The Auto enrollment functionality allows automatic synchronization of user credentials from an ID Store to the Symantec Identity Security Platform database when the "isAutoEnrollmentAllowed" tenant setting is set to **true**. This setting ensures that the IDSP's user credentials always reflect the latest state of the ID Store as the synchronization happens between user data in the ID Store and its credentials in IDSP.

The solution supports multiple credentials of a given type for a user during the auto enrollment or credential synchronization process. For example, multiple phone numbers or email IDs of a user can be enrolled. Apart from synchronizing user credentials from ID Store, it also synchronizes users' credentials that come from external systems acting as a primary authenticator, such as SiteMinder, during Zero Footprint or OIDC flow.

The solution maintains the origin and origin type of the auto enrolled credentials in the following ways:

Source of the credentials	ORIGIN	ORIGIN TYPE
Using the ID Store (LDAP/SCIM/Internal/SiteMinder)	<guid> of the id store	IDSTORE
Using an ID Token	<token-issuer>	IDTOKEN

Using the self-service flow	USER	USER
Using the import tool	IMPORT	IMPORT

User Credential Synchronization

The synchronization of the credentials from the source to the IDSP's database can be done by following the steps that are mentioned in this section. However, there are two points to consider before synchronizing the user credentials:

- The validation of user credentials coming from ID store or ID Token Hint will depend on the status of the "***isAuthoritativeForUserCredsLCM***" ID Store configuration setting. If it is set to true, IDSP will not validate user credentials from the ID Store or ID Token Hint assuming that these credentials are coming from a reliable source. If it is set to false, then IDSP verifies the status of the "skipValidationInAutoEnrollment" tenant setting.
- If the "***skipValidationInAutoEnrollment***" tenant setting is set to true, then IDSP skips the validation of user credentials during auto enrollment and credential synchronization. However, if set to false, then IDSP continues to validate the user credentials from ID Store or ID Token Hint.

Additional Notes on User Credential Synchronization Scenarios

- The user credentials are updated in the IDSP database when the credentials in the database differ from that in the ID Store.
- The user credentials are created in the IDSP database if the credentials do not exist. The creation of user credentials depends on whether the SMS and Email Id are added correctly in the ID Store. For example, if the phone number or the email id is specified in the wrong format, then the sync fails.
- In ZFP flow, ensure to enable the "auto_inline_enrollment" setting in SiteMinder along with "isAutoEnrollmentAllowed" setting in IDSP for the auto enrollment or credential synchronization to work correctly. See ZFP.
- Make sure that the Identity Store Config from which the credentials should be synced has logical attributes defined for "email" and "phone_number" mapping it to the physical id store attributes. The physical attribute representing the phone number is expected to comply with the international format (+1 ...).
- In addition to email and phone number, a credential of type TOTP can be auto enrolled by syncing it from the id store using the logical attribute, "credentials:devices:totp". For example, credentials:device:totp=carLicense. This logical attribute maps to a physical attribute containing TOTP seeded in one of the following formats -
  a. ***Symmetric Encryption using a {<Secret's alias>}*** - prefix indicating the alias of the secret containing the encryption key.
     AES-based data encryption using customer-supplied secret pointed by <secrets-alias> (Key must be a multiplier of 16, IV must be equal to the first 16 characters of the key, with offset 0)
  b. ***PKI (RSA) Encryption using a {<Key's alias>}*** - prefix indicating the alias of an RSA Key containing the private key to be used for decryption.
  c. ***PKI encryption using {x5c} prefix*** - similar to the previous PKI encryption, but using the tenant signing key indicating that the PKI encryption was done using the tenant's signing cert (using the public key of the tenant signing key which can be retrieved from the jwks endpoint)
  d. ***Plain text*** - No prefix. TOTP information is considered sensitive, hence it is not recommended to store it in plain text.
- Supports only SMSOTP, EmailOTP, IVROTP, and TOTP credentials.

To auto enroll the user credentials, perform the following steps:

1. Invoke the following API to update the tent/global settings:

```
PATCH https://${SSP_FQDN}/{{tenantName}}/admin/v1/Configs
```

NOTE

- To know the value of ${SSP_FQDN} environment variable, see Configuring IDSP Environment Variables.
- The default value for `<tenantName>` is "default".
- Replace the text {{text}} including {{}} characters with appropriate values, in all the endpoints shown in the above table.

For example:
`https://{{host}}/{{tenantName}}/admin/v1/Configs`
should look similar to:
`https://example.com/default/admin/v1/Configs`

- To know more about the scopes that are required to secure these APIs, refer to the Rest APIs and Associated Privileges section.

2. Configure the following tenant/global settings:

NOTE

- The following configuration settings are also covered in Global/Tenant Settings.
- The tenant administrator can override the global settings using tenant settings.

a. **isAutoEnrollmentAllowed**
Auto enrollment of IDSP credentials happen only if this property is set to true. For ZFP flow, along with this property, auto enrollment should be enabled in the ID token.

NOTE

- If **isAutoEnrollmentAllowed** and **isInlineEnrollmentAllowed** are set to **false**, a user whose credentials are not registered in IDSP is denied further authentication.
- If **isAutoEnrollmentAllowed** is set to **false** and **isInlineEnrollmentAllowed** is set to **true**, a user whose credentials are not registered in IDSP is prompted for registration.

Default value: true
Possible values: true or false

b. **preserveOriginInAutoEnrollment**
This property ignores or considers the origin and origin type in the Credential Synchronization flow depending on the following values:

- If **preserveOriginInAutoEnrollment** is set to **false**: Ignores the origin and origin type in the Credential Synchronization flow and replaces an existing credential with a new credential from the authoritative source. **For example**: If there is an existing credential in the IDSP database with the cred type SMS OTP and the Origin and Origin Type as User (registered via the self-service portal) and the "preserveOriginInAutoEnrollment" setting is set to false, the existing credential is replaced with a new credential when that new credential comes from another authoritative source, such as the ID store (Origin). Note that the replacement takes place only when the cred type is the same but the cred value is different.
- If **preserveOriginInAutoEnrollment** is set to **true**: Considers the Origin and Origin Type in a Credential Synchronization flow and replaces an existing credential with the new credential from the authoritative source only when the origin and credential type match (ignores case). Note that the existing credential is replaced only when the credential value is changed.

Default value: false
Possible values: true or false

c. **autoEnrollCredentialSyncPolicy**
This property controls how the credentials coming from an endpoint are synced into the IDSP database.

NOTE
For this property to work, the "**preserveOriginInAutoEnrollment**" setting should be set to **true**.

Default value: REPLACE
Possible values: REPLACE or MERGE
REPLACE and MERGE have the same behavior in replacing the existing credentials of a user in the following scenarios:

- **When the credentials from a specific origin and origin type are already stored in the IDSP database, and an authentication flow contains new credentials that are from the same origin and origin type**: In this case, the existing credentials are replaced with the new credentials in the database.

Example: Assume that an email ID with the IDSTORE origin and origin type is already stored in the database. If the new credential is an email ID with the same origin and origin type in the authentication flow, the existing email ID is replaced with the new email ID.

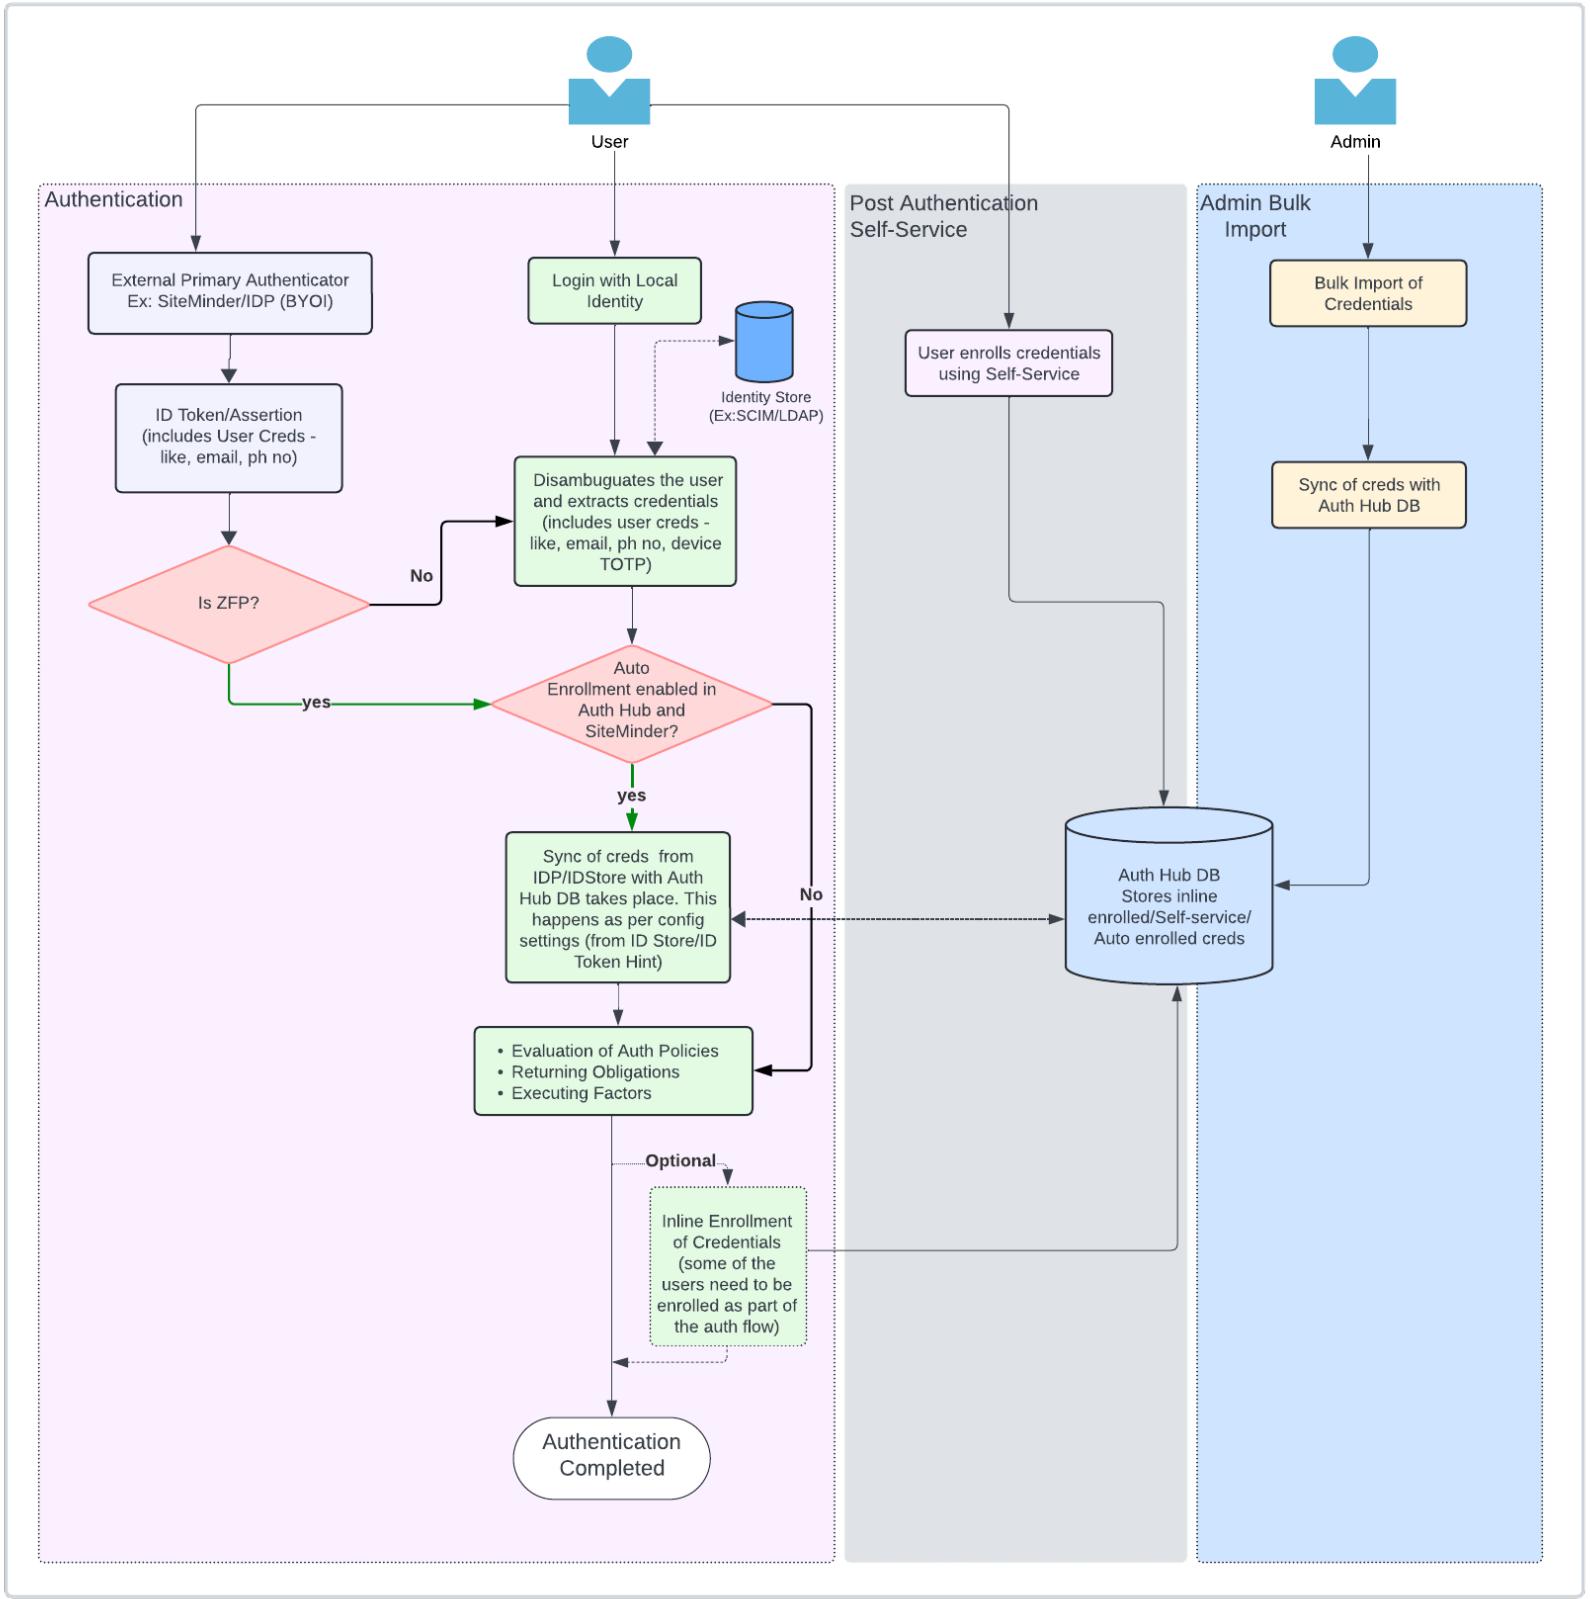
- **When an authentication flow contains new credentials that are not available in the IDSP database**: In this case, the new credentials and its origin and origin type are stored in the database.
  Example: Assume that an email ID with the USER origin and origin type is already stored in the database. If the authentication flow contains a mobile number with the IDSTORE origin and origin type, the mobile number with the IDSTORE origin is stored in the database. There is no change to the existing email ID with the USER origin and origin type.

However, REPLACE and MERGE differ in replacing the existing credentials of a user in the following scenario:

- **When the credentials with a specific origin and origin type are already stored in the IDSP database, and the authentication flow contains the same credentials but from a different origin**: If REPLACE is selected, the origin and origin type of the existing credential is replaced with the origin and origin type of the new credential in the authentication flow. If MERGE is selected, the existing origin and origin type is *not* replaced.
  Example: Assume that an email ID with the USER origin and origin type is already stored in the database. If an authentication flow contains the same email ID but from the IDSTORE origin and origin type, the behavior of the setting is as follows:
  - If REPLACE is selected, the existing origin and origin type is replaced with IDSTORE.
  - If MERGE is selected, the existing origin and origin type is not replaced and it remains USER.

Multiple Credential Synchronization Flows

The following diagram shows the different ways in which the multi credentials can sync with the IDSP database:



User
Admin
Authentication
Post Authentication Self-Service
Admin Bulk Import
External Primary Authenticator Ex: SiteMinder/IDP (BYOI)
Login with Local Identity
Identity Store (Ex:SCIM/LDAP)
User enrolls credentials using Self-Service
Bulk Import of Credentials
ID Token/Assertion (includes User Creds - like, email, ph no)
Disambuguates the user and extracts credentials (includes user creds - like, email, ph no, device TOTP)
Sync of creds with Auth Hub DB
Is ZFP?
No
yes
Auto Enrollment enabled in Auth Hub and SiteMinder?
yes
Sync of creds from IDP/IDStore with Auth Hub DB takes place. This happens as per config settings (from ID Store/ID Token Hint)
No
Auth Hub DB Stores inline enrolled/Self-service/ Auto enrolled creds
• Evaluation of Auth Policies
• Returning Obligations
• Executing Factors
Optional
Inline Enrollment of Credentials (some of the users need to be enrolled as part of the auth flow)
Authentication Completed

External Primary Authentication Flow

Flow Description:

1. The user initiates authentication into IDSP using an external system acting as a Primary Authenticator, such as SiteMinder, or using BYOI from a SAML IDP/OpenID Provider. The primary authenticator generates an ID Token or a SAML assertion and returns it to the IDSP server during the authentication flow. The ID Token (sent as id_token_hint) or the SAML assertion (sent as part of SAML authentication response) may contain information about the user credentials such as Email or Phone number. To enable auto enrollment during the authentication flow in IDSP, the "**auto_inline_enrollment**" property must be configured as **true** in the ID Token/ID Token Hint or SAML Assertion.
   - When the "**auto_inline_enrollment**" property is set to **false**: the email and phone number details that are available with the external authenticator are ignored.
   - When the "**auto_inline_enrollment**" property is set to **true**: the email and phone number details that are available with the external authenticator are considered for auto enrollment.
2. Depending on the ZFP configuration controlled by the application configuration or the IDP configuration in IDSP, the user may or may not be required to exist in the IDSP identity store.
3. In a ***non-ZFP (Zero FootPrint Identity) mode***, the user must be found (disambiguated) in the designated ID store, which is a source for additional user credentials such as email, phone no, and device (totp) information. ***For ZFP mode this step can be skipped***.
4. In IDSP, the "**isAutoEnrollmentAllowed**" tenant setting must be set to **true**, to enable auto enrollment during the authentication flow. When this setting is configured as true, the user credential information is taken from the ID Token/ SAML assertion, and/or ID Store and synchronized with the existing credentials that are already registered in the IDSP DB according to the "**autoEnrollCredentialSyncPolicy**" setting.
5. The IDSP server checks the status of the "**autoEnrollCredentialSyncPolicy**" tenant property as follows:
   - If "**autoEnrollCredentialSyncPolicy**" is set to **REPLACE**: IDSP replaces all the existing credentials of a user that matches the origin of the ID Token's issuer, with the credentials in the ID Token Hint. If a duplicate credential with an origin that differs from the ID Token's issuer already exists in the IDSP database, the origin of the existing credential is replaced with the origin of the ID Token's issuer.
   - If "**autoEnrollCredentialSyncPolicy**" is set to **MERGE**: IDSP replaces all the existing credentials of a user that match the origin of the ID Token's issuer, with the credentials in the ID Token Hint. If a duplicate credential with an origin that differs from the ID Token's issuer already exists in the IDSP database, the origin of the existing credential is not replaced.

     NOTE
     If the tenant property, "**preserveOriginInAutoEnrollment**" is set to **false**, the credentials' origin is ignored during the sync operation. This setting is also covered in Managing Settings.
6. If "**auto_inline_enrollment**" property is not set in the ID Token or the tenant property "**isAutoEnrollmentAllowed**" is set to **false** in IDSP, then the IDSP server skips auto enrollment or credential synchronization of the existing IDSP credentials with the credentials that are coming from the ID Token/IDToken Hint/SAML Assertion.
7. The Authentication Policies are evaluated and obligations are returned. The user executes the authentication factors to get authenticated.
8. (Optional)-In case, inline enrollment is required for any of the credentials, the user is prompted to enroll their credentials inline.

ID Store Flow

In this flow, the user initiates the login using the Identity store (LDAP/SCIM).

Flow Description:

1. The user initiates authentication into IDSP using the ID Store flow.
2. In this flow, the user credentials are also fetched from the ID Store like LDAP or SCIM during user disambiguation.
3. If the "**isAutoEnrollmentAllowed**" tenant property is set to **true** in IDSP, then the IDSP server checks the status of the "**autoEnrollCredentialSyncPolicy**" tenant property.

- If "**autoEnrollCredentialSyncPolicy**" is set to **REPLACE**: IDSP replaces all the existing credentials of a user that have the origin as IDSTORE, with the user credentials from the ID Store. If a duplicate credential with an origin other than IDSTORE already exists in the IDSP database, the origin of the existing credential is replaced with IDSTORE.
- If "**autoEnrollCredentialSyncPolicy**" is set to **MERGE**: IDSP replaces all the existing credentials of a user that have the origin as IDSTORE, with the user credentials from the ID Store. If a duplicate credential with an origin other than IDSTORE already exists in the IDSP database, the origin of the existing credential is not replaced.

4. If the tenant property "**isAutoEnrollmentAllowed**" is set as **false** in IDSP, then the IDSP server skips auto enrollment or credential sync of the existing IDSP credentials with the credentials that are coming from the ID Store.
5. The Authentication Policies are evaluated and obligations are returned. The user executes the authentication factors to get authenticated.
6. (Optional)-In case, inline enrollment is required for any of the credentials, the user is prompted to enroll their credentials inline.

Self-Service Flow

Flow Description:

1. The user initiates authentication into IDSP using the Self-Service flow to enroll their credentials.
2. The user registers their phone number or email id in the IDSP.
3. The enrolled credentials are automatically created in the IDSP database.

Import Flow

Flow Description:

1. Tenant Admin invokes the Bulk API. For more information, see Bulk Import Credentials and Bulk API.
2. The credentials get auto synced with the IDSP database.
   The credential auto-sync may include POST, PUT, and DELETE operations.

Table Showing Credential Synchronization Scenarios

The following table displays the various scenarios of syncing multiple credentials of users with the IDSP database:

- Scenarios of synchronizing multiple credentials in IDSP database

Configuring Inline Enrollment

The Inline Enrollment feature enables users to swiftly enroll their unregistered credentials within the authentication process at any stage, without interrupting the authentication flow.

When user credentials are not registered in the user directory prior to authentication, the Inline Enrollment feature allows users to enroll their credentials on the fly during the Sign In flow. If users are entitled to Multi-factor Authentication (MFA), they are prompted to select factors for the inline enrollment at all authentication levels. When the inline enrollment process completes, user credentials are updated in the user directory. The next time users log in, they will be presented with the authentication factors for which they have enrolled their credentials.

This topic includes the following sections:

- Configuration Settings Governing Inline Enrollment
- Authentication Flow for Inline Enrollment
- Sample Scenarios

Configuring Tenant Settings Governing Inline Enrollment

The following settings govern the inline enrollment of user credentials in the Symantec Identity Security Platform authentication flow.

- **inlineEnrollmentAllowed (AuthN Policy Property)**: This **authentication policy property** controls whether inline enrollment for new authentication factors is explicitly permitted or prevented. It allows you to tailor enrollment based on the security context, for instance, enabling it for on-network access and disabling it for off-network access to prevent unauthorized additions. When this policy property is explicitly set to true or false, it overrides and effectively **ignores the tenant-level isInlineEnrollmentAllowed** setting. For more information, see AuthN Policy Property.
  Therefore, it is important to check whether the inlineEnrollmentAllowed authN policy property is configured, if yes then inlineEnrollmentAllowed tenant setting will be disregarded.
- **isInlineEnrollmentAllowed**: Inline registration of user credentials is allowed only when this configuration setting is set to **true.**
- **inlineEnrollmentFactorsRequired**: Specifies comma-separated mandatory authentication factors with or without the corresponding authentication levels at which these factors should be executed before enrolling the user credentials inline. Users can proceed with the inline registration process only after completing the mandatory authentication factors specified in this setting. The default authentication factor set for this setting is PASSWORD.
  - The mandatory authentication factor configured as part of the **InlineEnrollmentFactorsRequired** setting is considered only during the inline registration of the **FIRST** unregistered factor, irrespective of the authentication levels. In the subsequent registration flow, users proceed with the inline enrollment of unregistered credentials only after authenticating themselves with an already registered credential at the same authentication level. If a registered credential does not exist at the same authentication level, then the user is allowed to proceed with the registration of an unregistered credential.
  - If a user is not registered for any of the mandatory factors that are specified in the "inlineEnrollmentFactorsRequired" setting, except for "Password," the authentication process results in AUTH_DENIED. For example, if SMSOTP is the configured as the mandatory inline factor, but the factor is not already registered then the user is denied to proceed with the inline enrollment flow. Upon denied authentication, the appropriate error message is displayed to the user only when the setting, ***"hideAuthenticationFailureReason"*** is configured as "***false***." To know more about this setting, see here.
  - You can add multiple mandatory factors and can determine their respective authentication levels in the "inlineEnrollmentFactorsRequired" setting. The sequence of authenticating these factors depend upon the levels specified in the setting's value. For instance, in the following example the user has to complete the "PASSWORD:1 or SMSOTP:1 as these factors are specified as level (1) before moving to the second level or authentication specified as (2), that is FIDO:2".

    ```
    {
      "name": "inlineEnrollmentFactorsRequired",
      "value": "PASSWORD:1,SMSOTP:1,FIDO:2",
      "origin": "tenant"
    }
    ```

  - In case the authentication levels for the mandatory factors are not specified within the "inlineEnrollmentFactorsRequired" setting, all these factors are at assumed to be at level (1) one. For instance, if you define the factors in the following manner, both PASSWORD OR SMSOTP factors are automatically considered to be at level one.

    ```
    {
     "name": "inlineEnrollmentFactorsRequired",
     "value": "PASSWORD,SMSOTP",
     "origin": "tenant"
    }
    ```

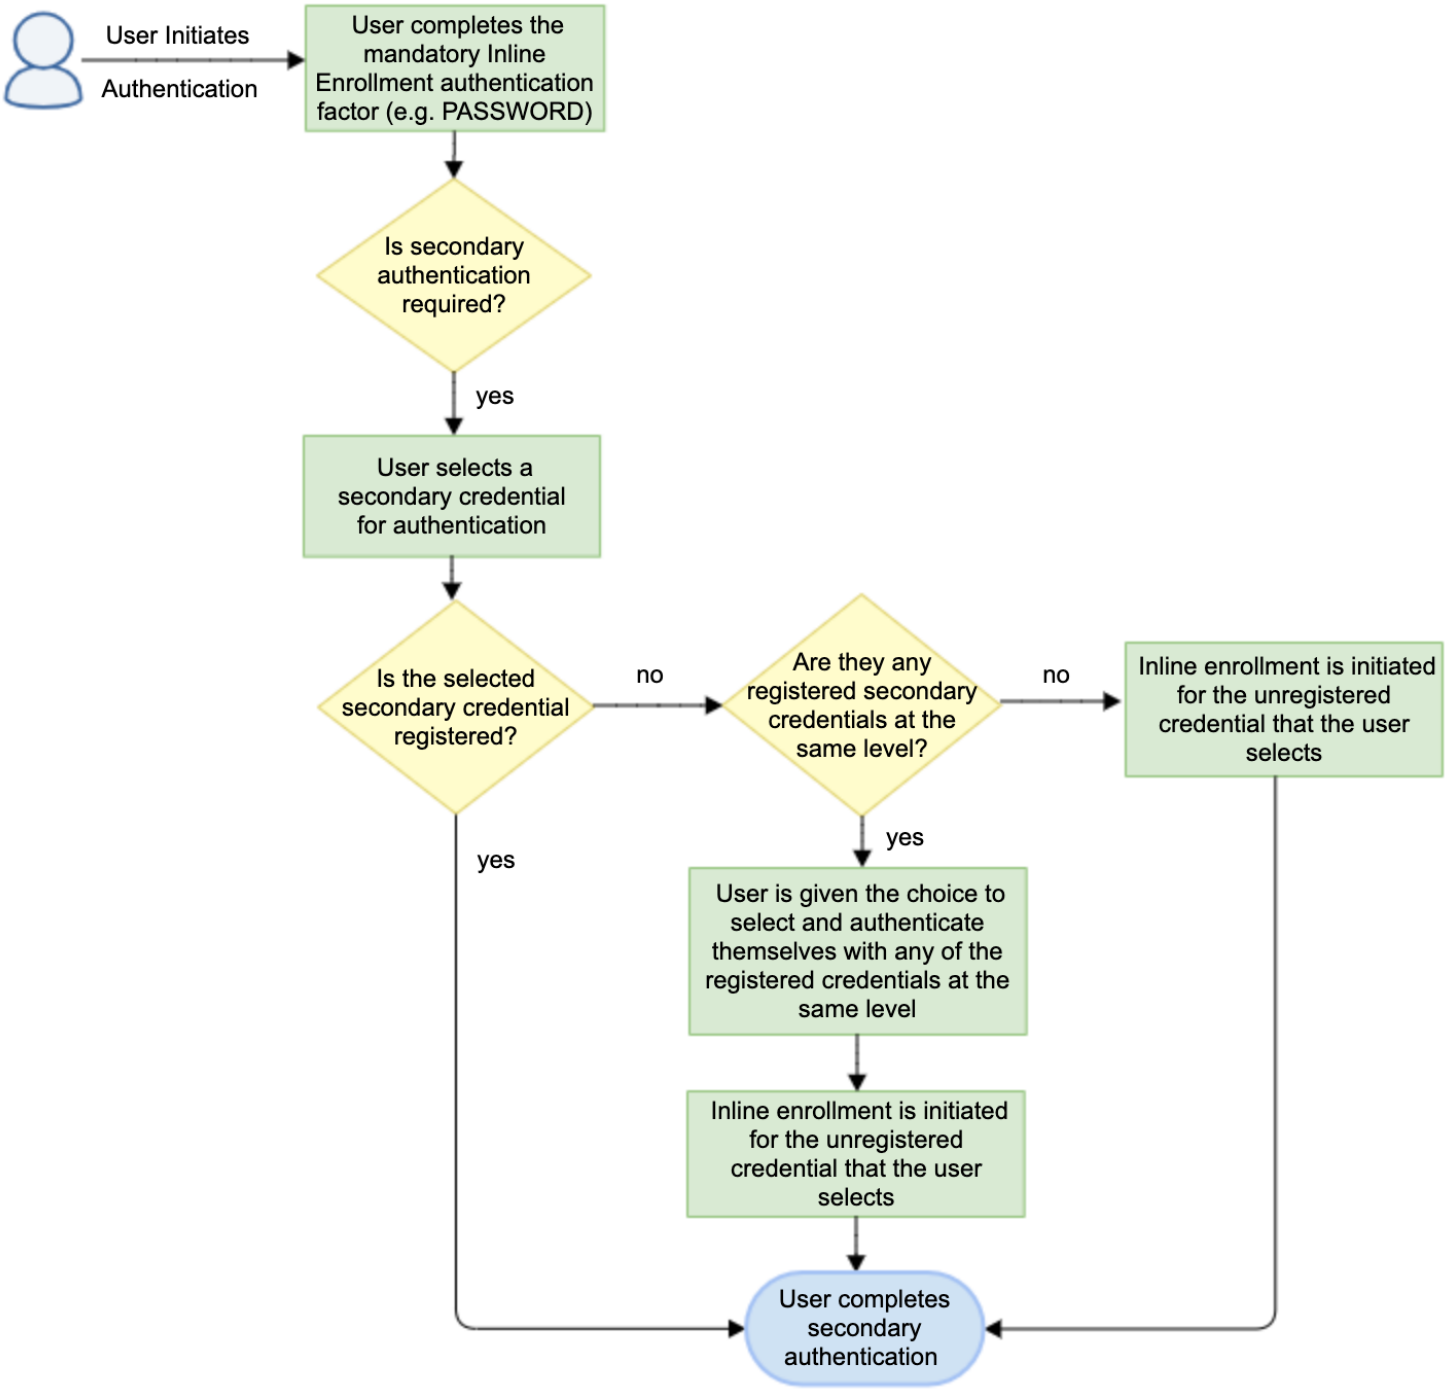
- **isInlineOTPEnrollmentToBePersisted:** User credentials that are enrolled using inline enrollment persist in the database when this property is set to **true**. When this configuration setting is set to **false**, all the user credentials that were enrolled using inline enrollment gets deleted.

These tenant configurations are also covered in Managing Settings topic.

Authentication Flow for Inline Enrollment

The following diagram is a pictorial representation of how the inline enrollment of user credentials works in an authentication flow.

Figure 8: Inline Enrollment - Authentication Flow



Sample Scenarios

Given are a few sample scenarios to help you understand how the authentication flow for inline enrollment works.

Scenario 1:

Assumption: Nina Bruce is obligated to sign into an application by satisfying the authentication factors - PASSWORD:1, SMSOTP:2, EMAILOTP: 2. She has not registered her phone number and email ID with the user directory prior to authentication. Assume that an administrator has configured "PASSWORD" as the mandatory factor for Inline Enrollment.

User Flow: Nina Bruce completes primary and mandatory authentication by providing PASSWORD in the SignIn screen. On successful authentication, she is given the choice to select the secondary factor as either SMSOTP or EMAILOTP. Assume that she selects SMSOTP as the secondary factor. Since SMSOTP is not registered, she is prompted to register or enroll her phone with the user directory. Once registered, she can use SMSOTP as the factor for the subsequent authentications.

Scenario 2:

Assumption: Emily Russell is obligated to sign into an application by satisfying the authentication factors - PASSWORD:1, MOBILEOTP: 2, EMAILOTP:2, SMSOTP:2 She has registered EMAILOTP and SMSOTP with the user directory prior to authentication. Assume that an administrator has configured "PASSWORD" as the mandatory factor for Inline Enrollment.

User Flow: Emily Russell completes primary and mandatory authentication by providing PASSWORD in the SignIn screen. On successful authentication, she is given the choice to select the secondary factor as either MOBILEOTP, EMAILOTP, or SMSOTP. Assume that she selects MOBILEOTP as the secondary factor. Since MOBILEOTP is not registered, she is forced to authenticate herself for the registered credential at the same level before allowing inline enrollment of the unregistered credential. In this case, she is prompted to select from one of the existing registered factors (EMAILOTP, SMSOTP). After successfully completing authentication for the registered credential at the same level, she is prompted to register or enroll her MOBILEOTP with the user directory. Once registered, she can use MOBILEOTP as the factor for the subsequent authentications.

Scenario 3:

Assumption: Brenda Steer is obligated to sign into an application by satisfying the authentication factors - MOBILEOTP:1, PASSWORD:2, SMSOTP:2, EMAILOTP:2, FIDO:2. She has registered MOBILEOTP, EMAILOTP, and FIDO with the user directory prior to authentication. Assume that an administrator has configured "PASSWORD" as the mandatory factor for Inline Enrollment.

User Flow: In the first level of authentication, Brenda Steer authenticates herself with MOBILEOTP. After completing the first level of authentication, she is given the choice to select the secondary factor as either PASSWORD, SMSOTP, EMAILOTP, or FIDO. Assume that she selects SMSOTP as the secondary factor. Since SMSOTP is not registered, she is prompted to authenticate with PASSWORD as it is the mandatory factor for Inline Enrollment. Next, she is prompted to register or enroll SMSOTP with the user directory.

Scenario 4:

Assumption: Enid Dunn is required to sign into an application using FIDO:1 authentication. However, she has not enrolled her credentials for FIDO yet. She intends to carry out inline registration for her FIDO credentials. Before proceeding with the authentication, she has already enrolled SMSOTP and EMAILOTP in the user directory. It is important to note that an administrator has established PASSWORD:1, SMSOTP:2, EMAILOTP:3 as the mandatory factors for Inline Enrollment.

User Flow: In the first level of authentication, Enid Dunn verifies herself using PASSWORD:1. Once this step is completed, she proceeds to authenticate using SMSOTP:2, and subsequently EMAILOTP:3. Upon successfully completing all three mandatory authentication levels, she is prompted to enroll for FIDO (biometrics). After successfully enrolling, she can use FIDO as the factor for the subsequent authentications.

Scenario 5:

Assumption: Dean Roth must access an application using FIDO:1 authentication. However, she has not enrolled her credentials for FIDO yet. She intends to carry out inline registration for her FIDO credentials. Additionally, Dean has not added her phone number to the user directory to receive SMSOTP. Note that the administrator has configured PASSWORD:1 and SMSOTP:2 as the required factors for Inline Enrollment.

User Flow: In the first level of authentication, Dean Roth verifies herself using PASSWORD:1. Once this step is completed, she is denied authentication (AUTH_DENIED) since she did not register her phone number to receive SMSOTP.

Scenario 6:

Assumption: Christopher Moran is required to sign into an application using FIDO:1 authentication. However, he has not enrolled her credentials for FIDO yet. He intends to carry out inline registration for his FIDO credentials. Before proceeding with the authentication, he has already registered his phone number in the user directory to receive SMSOTP. It is important to note that an administrator has established PASSWORD, SMSOTP as the mandatory factors for Inline Enrollment.

User Flow: In this use case, the factors are specified without the levels at which these should be authenticated. Therefore, both these factors (PASSWORD or SMSOTP) are assumed to be at level one. During the inline enrollment, Christopher is prompted to select either PASSWORD or SMSOTP as the authentication factor. He verifies using PASSWORD and upon successfully completing password authentication, he is prompted to enroll for FIDO (biometrics). After successfully enrolling the FIDO credentials, Christopher can use FIDO for the subsequent authentications.

Configuring Trusted Devices

Learn how to reduce the frequency of multi-factor authentication prompts for recognized devices when accessing a secured resource by setting up your device as a trusted device.

As a tenant admin, when you perform activities that deal with sensitive information such as editing user PII data or performing banking transactions, you are required to perform multi-factor authentications to ensure that this sensitive information is only accessed by you, and is secured. Most often, to perform these activities, you use the same set of devices like your personal mobile phone, tablet, or home computer. Therefore, you can use the trusted devices functionality to designate the most commonly used device or a handful of devices as trusted, which will allow you to log in to the protected resource by performing only the first factor of authentication and skipping other factors in all subsequent logins.

NOTE

- Trusted Device functionality is supported in SignIn UI, Sample app, and Mobile (Hedmoral -Android & iOS) applications.
- To skip complete authentication on known secure endpoints, configure the "**urn:iam:app:skipAuthenticationForTrustedDevice**" metadata attribute (see Application Metadata).
- "TrustedDevices" only applies to Multi-Factor Authentication scenarios. You are advised not to use trusted devices for sensitive applications.
- If there are multiple policies that are assigned to an application that has both “mfaFrequency”: “OnceForTrustedDevice” and “mfaFrequency”: “EveryTime” configured, then the latter takes precedence over the former and the user is obliged to authenticate all the factors.
- The "Remember This Device" option gets cleared off from the UI and the login device is treated as a new device and not a trusted device,
  when:

  - the device has not been used for the period that has been configured in the "trustedDeviceExpiryDays" parameter.
  - you clear the device-tag cookie from the browser that you have used to authenticate.

  In both these cases, you must select the "Remember This Device" checkbox in the UI once again.
- If multiple authentication factors are configured for your authentication flow, then the "Remember This Device" option is displayed only before authenticating the last factor. For example, if you have factors in this order, Password>SMSOTP, then the "Remember This Device" checkbox gets displayed only before the SMSOTP authentication.
- When risk is enabled for a trusted device, it is essential that the device recognition risk rule is also active. See Device Recognition risk rule.

Trusted Device Flows

There are two scenarios to explain regarding the trusted device functionality:

- ***Login from a New Device***: In this scenario, we will walk through the steps to set up your new device as a trusted one for future operations.
- ***Login from a Trusted Device***: In this scenario, your device is already established as a trusted device, which streamlines the multi-factor authentication process and grants you access to secured resources immediately after fulfilling the first authentication factor.

These scenarios have been explained in the following sections.

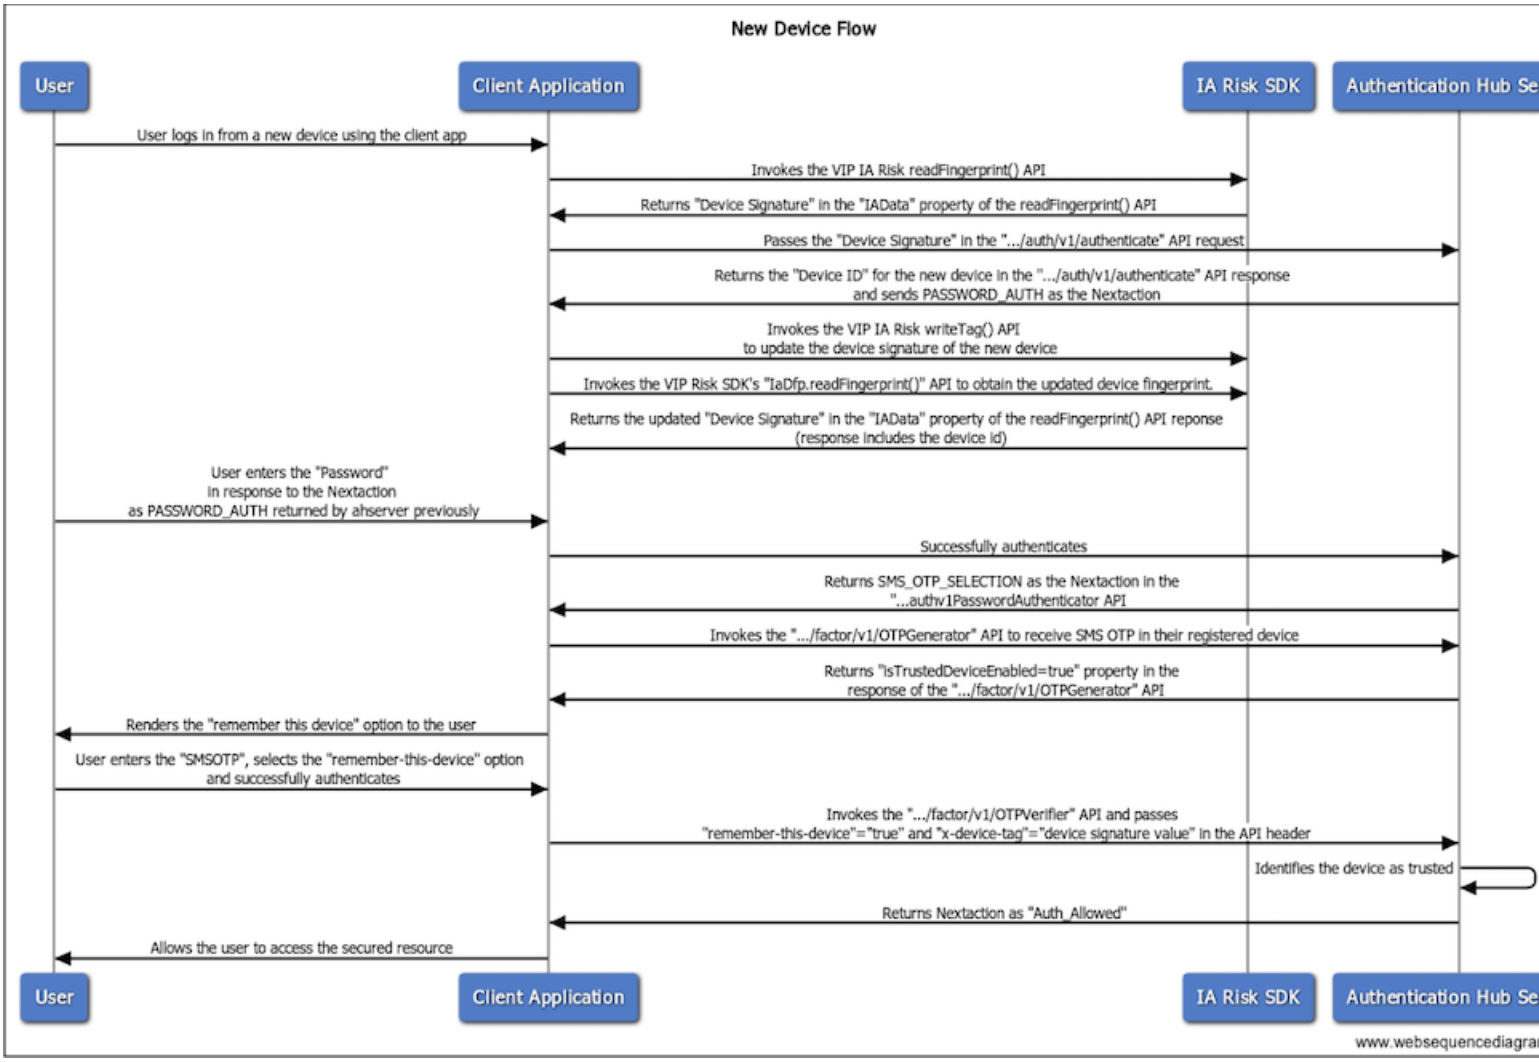
New Device Flow

In this scenario, we will walk through the steps required to set up your new device as a trusted one for future authentications.

List of participants and what they represent:

- ***User*** : One who initiates the authentication flow to configure a new device as a trusted device in Symantec Identity Security Platform.
- ***Client Application (Mobile/Web App)***: Represents the application that calls the IDSP REST APIs and VIP IA Risk SDK to obtain the device fingerprint to complete the authentication flow.
- ***IA SDK***: VIP IA RISK SDK that is called by the client application to get and update the device fingerprint.
- ***IDSP Server***: Server that is used to evaluate and authenticate the trusted device flow.

The following sequence diagram outlines the authentication flow that occurs when a user logs in from a new device and sets it up as a trusted device.



Assumption: In this flow we have assumed that the primary authentication factor is "***Password"***, while the secondary authentication factor is "***SMSOTP"***.

User experience when you login from a new device:

1. The user logs in to IDSP using a new device from the client app.
2. The client app invokes the VIP Risk SDK's "`IaDfp.readFingerprint()` " API to retrieve the device fingerprint value.
3. The VIP Risk SDK's "`IaDfp.readFingerprint()` " API returns the device fingerprint as part of the "iadata" property in the response.
4. The client app invokes the IDSP's "**/auth/v1/authenticate"** API and passes the device fingerprint value in the API request.
5. The IDSP server returns the "DeviceID" of the new device in the "**/auth/v1/authenticate"** API response and also sends "PASSWORD_AUTH" as the Nextaction to the client app.
6. The client app invokes the VIP Risk SDK's "writeTag()" API to update the device fingerprint for the new device.
7. The client app invokes the VIP Risk SDK's "`IaDfp.readFingerprint()` " API once again to obtain the updated device fingerprint.
8. The VIP Risk SDK's "`IaDfp.readFingerprint()` " API returns the updated device fingerprint along with the device id as part of the "iadata" property in the response.

9. User enters the "Password" in response to the Nextaction as PASSWORD_AUTH returned by the IDSP server previously (in step 5) and authenticates successfully.
10. IDSP server returns SMS_OTP_SELECTION as the Nextaction in the "**...\auth\v1\PasswordAuthenticator**" API.
11. The client app invokes the "**.../factor/v1/OTPGenerator**" API to receive OTP in their registered device.
12. Assuming that ***SMSOTP*** is the ***last authentication factor***, IDSP server returns the ***"isTrustedDeviceEnabled=true"*** property in the ***".../factor/v1/OTPGenerator"*** API to the client app.

    NOTE

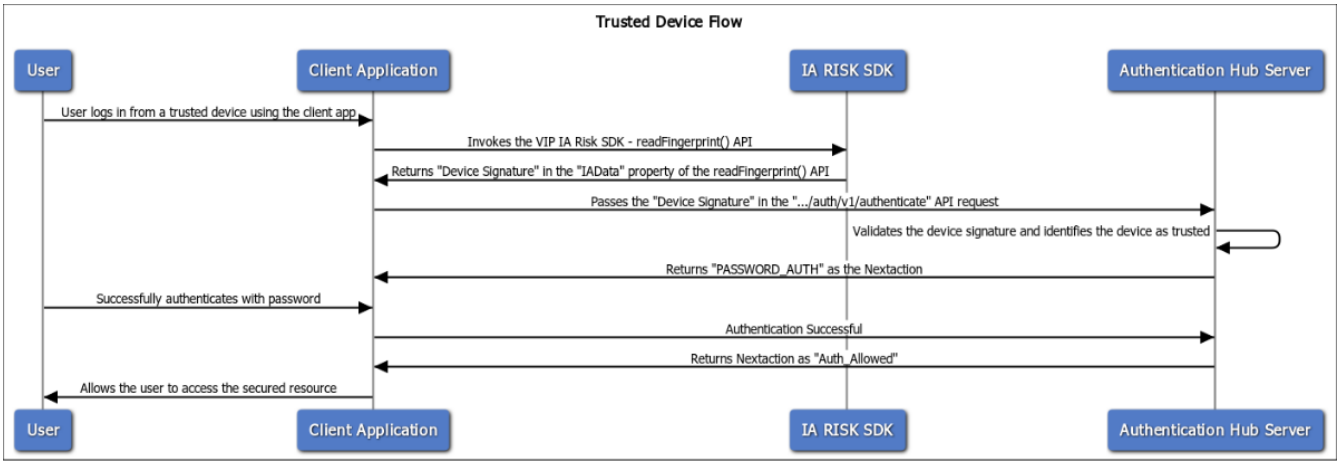
    If multiple authentication factors are configured for your authentication flow, then the "Remember This Device" option is displayed only before authenticating the last factor. For example, if you have factors in this order, Password>SMSOTP, then the "Remember This Device" checkbox gets displayed only before the SMSOTP authentication.
13. The client app renders the ***"Remember This Device"*** checkbox to the user.
14. The user receives OTP on email or phone and then enters the "OTP" in response to the Nextaction as SMSOTP returned by IDSP server previously (in step 10), and selects the ***"Remember This Device"*** checkbox.
15. Upon successful authentication by the user, the client app invokes the ***".../factor/v1/OTPVerifier"*** API and passes ***"remember-this-device"="true"*** and ***"x-device-tag"="device signature value"*** in the API header.
16. The IDSP server identifies the new device as a trusted device, returns nextaction as "Auth_Allowed" and allows the user to access the secured resource.

Trusted Device Flow

In this scenario, your device is already established as a trusted device, which streamlines the multi-factor authentication process and grants you access to secured resources immediately after fulfilling the first authentication factor.

List of participants and what they represent:

- ***User*** : One who initiates the authentication flow with a trusted device in IDSP.
- ***Client Application (Mobile/Web App)***: Represents the application that calls the VIP IA RISK SDK to obtain the device fingerprint to complete the authentication flow.
- ***IA SDK***: VIP IA RISK SDK that is called by the client application to update and get the device fingerprint.
- ***IDSP Server***: Server that is used to evaluate and authenticate the trusted device flow.



Assumption: In this flow we have assumed that the primary authentication factor is "***Password"***, while the secondary authentication factor is "***SMSOTP"***.

User Experience when you login from a Trusted Device

1. The user logs in to IDSP using a trusted device from the client app.

2. The client app invokes the VIP Risk SDK's "`IaDfp.readFingerprint()` " API to return the device fingerprint value in the response.
3. The VIP Risk SDK's "`IaDfp.readFingerprint()` " API returns the device fingerprint as part of the "iadata" property in the response.
4. The client app invokes the IDSP's ".../**auth/v1/authenticate"** API and passes the device fingerprint value in the API request.
5. IDSP server validates the device fingerprint and identifies it as a trusted device and returns "PASSWORD_AUTH" as the Nextaction in the ".../**auth/v1/authenticate"** API to the client app.
6. Using the client app, the user successfully authenticates with password.
7. IDSP server returns Nextaction as "Auth_Allowed" and allows the user to access the secured resource without prompting any other multi-factor-authentication.

> **NOTE**
> IDSP supports the transmission of "Device Signature" and "X-Device-Tag" values in an encrypted format. To learn how to encrypt these device signature and x-device-tag values, see Device Signature Encryption .

Steps to enable "TrustedDevices"

To enable "TrustedDevices", you must update configurations in the Tenant Config, update the Authentication Policy, and Invoking the Initiate Authenticate Call.

Updating Tenant Configuration

1. Use the following PATCH call to enable "TrustedDevices":
   `https://${SSP_FQDN}/{{tenantName}}/admin/v1/Configs`
2. Enable the following parameters in the PATCH request:
   - ***isTrustedDeviceEnabled***- This is a boolean value and the default is false.
   - ***maxTrustedDevicesPerUser***- This is an integer and the default value is 10. Possible values - 1 to 50.
   - ***trustedDeviceExpiryDays***- This is an integer and the default value is 365 days. Possible values - Valid values range from 0.0 upward with no restrictions on upper limits.

   The following is a patch request sample:

```
[
    {
     "name": "isTrustedDeviceEnabled",
     "value": "true"
    },
    {
      "name": "maxTrustedDevicesPerUser",
      "value": "10"
    },
   {
     "name": "trustedDeviceExpiryDays",
     "value": "365"
   }
]
```

   The parameter gets updated in the Tenant Configs.

These tenant configurations are also covered in Managing Tenant Settings.

Updating Authentication Policy

1. Use the following PUT/PATCH call to enable "TrustedDevices":
   `https://${SSP_FQDN}/{{tenantName}}/admin/v1/AuthPolicies/{{policyId}}`
2. Update the following parameter in the policy ***results***:

– ***mfaFrequency:OnceForTrustedDevice***

This enables the "**Remember This Device**" checkbox in the UI.

To know how to patch a policy, click here and, to know about the Authentication policy, click here.

Invoking the Initiate Authenticate Call

As discussed earlier in the notes section of this topic, if multiple authentication factors are configured for your authentication flow, then the "Remember This Device" option is displayed only before authenticating the last factor.

For example, if you have factors in this order, **Password > SMSOTP**, then the "Remember This Device" checkbox gets displayed only before the SMSOTP authentication.

Taking the same example into account, the steps that you must follow once you authenticate your last factor (SMSOTP) have been explained here.

Steps to update "**Remember This Device**":

1. Invoke the following OTPGenerator call:

   ```
   https://${SSP_FQDN}/{{tenantName}}/factor/v1/OTPGenerator
   ```

   The response fetches **"isTrustedDeviceEnabled": true** under the "**additional**" section as shown in the following sample:

   ```
   {
       "flowState": "eyJya....",
       "nextaction": "EMAIL_OTP_AUTH",
       "currentFactors": [
           "EMAILOTP"
       ],
       "data": {
           "credId": "206ed729-b9a2-4c91-a40a-81f2f6bbe782",
           "message": "030844"
       },
       "additional": {
           "currentFactorLevel": 2,
           "isTrustedDeviceEnabled": true
       }
   }
   ```

2. Use the following OTPVerifier call, and add the **"remember-this-device"** and **"x-device-tag"** parameters in the API header:

   ```
   https://${SSP_FQDN}/{{tenantName}}/factor/v1/OTPVerifier
   ```

   The response generates the "nextaction: AUTH_ALLOWED" as shown in the following sample:

   ```
   {
       "flowState": "eyJya....",
       "nextaction": "AUTH_ALLOWED",
       "data": {
           "status": "OK",
           "message": "One-Time Password (OTP) is verified successfully"
       },
       "id_token": "eyJ4......",
       "additional": {
           "authLevelsData": {
               "0988e396-089f-4c70-936f-d0ba27467a7b+craiglink+2": "SMSOTP",
               "0988e396-089f-4c70-936f-d0ba27467a7b+craiglink+1": "PASSWORD"
           },
           "currentFactorLevel": 2
   ```

```
        }
    }
```

To know more about Initiate Authenticate call, click here.

APIs to Manage Trusted Devices

Trusted Devices can be managed by Admins and Users.

Admin APIs to Manage Trusted Devices

The following table displays the list of Trusted Device APIs that an admin can invoke to manage user devices. For sample requests and response payloads of all these URLs, refer to the reference link provided at the end of the page for Trusted Devices API Swagger documentation.

Operation Description	Operation Type	Endpoint URLs
Retrieve all trusted devices of a user	GET	https://${SSP_FQDN}/{{tenantName}}/admin/v1/TrustedDevices/{userId}
Retrieve the user's trusted device details	GET	https://${SSP_FQDN}/{{tenantName}}/admin/v1/TrustedDevices/{userId}/{deviceId}
Delete trusted devices of a user	DELETE	https://${SSP_FQDN}/{{tenantName}}/admin/v1/TrustedDevices/{userId}/{{deviceId}}

User APIs to Manage Trusted Devices

The following table displays the list of Trusted Device APIs that a user can invoke to manage their own devices.

Operation Description	Operation Type	Endpoint URLs
Retrieve all my trusted devices	GET	https://${SSP_FQDN}/{{tenantName}}/auth/v1/MeTrustedDevices
Retrieve my trusted device details	GET	https://${SSP_FQDN}/{{tenantName}}/auth/v1/MeTrustedDevices/{deviceId}
Delete my trusted device	DELETE	https://${SSP_FQDN}/{{tenantName}}/auth/v1/MeTrustedDevices/{deviceId}

NOTE

- To know the value of ${SSP_FQDN} environment variable, see Configuring IDSP Environment Variables.
- The default value for `<tenantName>` is "default".
- Replace the text {{text}} including {{}} characters with appropriate values, in all the endpoints shown in the above table.
  For example:
  `https://{{host}}/{{tenantName}}/admin/v1/MeTrustedDevices`
  should look similar to:
  `https://example.com/default/admin/v1/MeTrustedDevices`
- To know more about the scopes that are required to secure these APIs, refer to the Rest APIs and Associated Privileges section.

Examples

Getting Trusted Devices of a user

This section explains how to fetch all trusted devices for a specific user using their User ID.

Invoke this API to get all known devices for a user:

Request

```
GET https://${SSP_FQDN}/{{tenantName}}/auth/v1/MeTrustedDevices
```

Response

```
[
    {
        "userTrustDeviceId": "4641e562-93dd-4527-b6fb-a3fc541aacfd",
        "name": "Device:Mac, Browser:Chrome 144.0.0.0, OS:macOS 10.15.7",
        "status": "Active",
        "createdDatetime": "2026-02-20 06:45 AM UTC",
        "lastUsed": "2026-02-20 06:45 AM UTC",
        "userAgent": "Mozilla/5.0 (Macintosh; Intel Mac OS X 10_15_7) AppleWebKit/537.36 (KHTML, like Gecko)
 Chrome/144.0.0.0 Safari/537.36"
    }
]
```

- Swagger Documentation for Trusted Devices and Branded Settings.
- About SignIn User Interface

Encrypting the Device Signature

In the Symantec Identity Security Platform, Device Signature can be encrypted. The steps to encrypt the device signature are discussed in the following section.

Device signature encryption involves the utilization of a distinctive cryptographic signature, derived from device-specific characteristics, to safeguard customer device signatures during transmission, ensuring their confidentiality between the customer's mobile application or browser and the IT system where signature verification takes place. Encryption of Device Signature is implemented in IDSP as part of the ***Trusted Devices*** functionality.

To secure the device signature with encryption during the authentication flow, perform the following steps:

1. Configure the "***fieldsToBeEncryptedInAuthFlow***" branding settings value in the IDSP by invoking the following API:
   `hhttps://${SSP_FQDN}/<tenantName>/admin/v1/Configs`

   NOTE

   - To know the value of ${SSP_FQDN} environment variable, see Configuring IDSP Environment Variables.
   - The default value for `<tenantName>` is "default".
   - Replace the text {{text}} including {{}} characters with appropriate values, in all the endpoints shown in the above table.
     For example:
     `https://{{host}}/{{tenantName}}/admin/v1/Configs`
     should look similar to:

```
https://example.com/default/admin/v1/Configs
```

- To know more about the scopes that are required to secure these APIs, refer to the Rest APIs and Associated Privileges section.

NOTE

1. The relevant configuration settings are covered in Global/Tenant Settings.
2. The tenant administrator can override the global settings using tenant settings.

Property Name	Property Scope	Property Description	Default Value	Comments
fieldsToBeEncryptedInAuthFlow	Global/Tenant/Branding Settings	• This property lists the fields that must be encrypted in the authentication flow. • As part of the branding setting, it helps the SignIn UI to decide if the device signature must be encrypted.	None	Possible values: devicesignature

2. Launch the application and generate the client Access Token.

   NOTE

   If you use the JavaScript (Web) SDK, Android SDK, and iOS SDK, which is provided out-of-the-box by the solution, then the SDK performs steps 3, and 4 automatically. If you do not use the SDK, then follow steps 3, and 4 as explained below.

3. Invoke the POST `https://${SSP_FQDN}/<tenantName>/auth/v1/NonceGenerator` API to get the server nonce by passing the encrypted client_nonce as input:

   NOTE

   If you have downloaded the JavaScript SDK, Android SDK, or iOS SDK, in step 1, then the SDK generates a client_nonce and stores it in the client app (browser or mobile) for the session duration. The client_nonce is encrypted using the IDSP public key. See SDK for more details.

```
Authorization: <client Access Token>

Payload:
{
    "clientNonce": "<client_nonce encrypted with AH public key>"
}
```

   The API response generates a server_nonce and server_nonce_id and stores them in the cache. server_nonce is encrypted (AES256) with client_nonce as shown here:

```
{
    "serverNonceId": "<server_nonce>"
    "serverNonce": "<server_nonce encrypted with client_nonce>"
}
```

4. ***Initiate the Authentication Flow***

   a. Initiate the `https://${SSP_FQDN}/<tenantName>/auth/v1/authenticate` API by passing the userLogin and authContext information:

   - userLogin
   - userContext (Device Signature)

```
POST /auth/v1/authenticate
Headers
    Authorization: <client Access Token>
```

```
Payload:
{
    "subject": "<userLoginid>",
    "channel": "web",
    "ipAddress": "10.10.123.124",
    "action":"authenticate",
    "rememberMe" : true,
    "device": {
        "signature": {
            "iaAuthData": "<Encrypted device signature>"
        }
    },
    "authContext": [
        {
            "key" : "nonceId",
            "value" : "<serverNonceId>"
        }
    ]
}
```

b. Internally, the authentication process is initiated and a flow state is generated for the authentication flow. The server_nonce is stored as part of the flow state and is used for validating the encrypted device signature that is sent by the client. The Flow State Id returns the authentication obligations to the client app (browser or mobile app).

5. Invoke the "***encryptWithSymmetricKey***" API from the IDSP SDK (iOS/Android/Web) to encrypt the ***x-device tag*** value with the symmetric key. However, this API is used to encrypt any sensitive data using symmetric encryption based upon server nonce

Configuring SoftMFA

SoftMFA is a setting available on an application resource that makes the multi-factor authentication (MFA) process more flexible. SoftMFA allows users without complete MFA registrations to still authenticate successfully. It skips unregistered factors instead of failing the login attempt.

When the **SoftMFAEnabled** setting is set to true, the authentication flow skips any required authentication factor if the user does not have that factor registered with the Symantec Identity Security Platform.

If the user successfully completes the available registered factors at each authentication level, the system returns an AUTH_SUCCESS response, even if some unregistered factors were originally required.

Additionally, when SoftMFA is enabled, the application's **isInlineEnrollmentEnabled** setting is ignored — meaning users are not prompted to enroll missing authentication methods during login.

> **NOTE**
> It applies across all authentication levels.

See Managing Applications for application configurations and Settings for global and tenant-level setting descriptions.

Examples of SoftMFA scenarios

Example 1: Skipping first-factor authentication

- The Authentication policy returned the following obligations:`FIDO:1, SMSOTP:1, EMAILOTP:2` where,

- FIDO (Biometric) - Level 1
- SMSOTP (SMS One-Time Password) - Level 1
- EMAILOTP (Email One-Time Password) - Level 2

User's situation:
The user has Biometric registration but has no phone or email registered for OTP.
With **SoftMFAEnabled** set to **true**: The user completes the FIDO authentication. Since they do not have registered SMSOTP and EMAILOTP methods, the second level is skipped. The authentication flow returns AUTH_SUCCESS after the FIDO authentication.

Example 2: Skipping second-factor authentication

- The Authentication policy returned the following obligations:`PWD:1, SMSOTP:2, EMAILOTP:2`
  where,
  - PWD (Password) - Level 1
  - SMSOTP (SMS One-Time Password) - Level 2
  - EMAILOTP (Email One-Time Password) - Level 2

  User's situation:
  The user has a password but has no phone or email registered for OTP.
  With **SoftMFAEnabled** set to **true**: The user completes the password (PWD) authentication. Since they do not have registered SMSOTP and EMAILOTP methods, the second level is skipped. The authentication flow returns AUTH_SUCCESS after the password authentication.

Table shows the SoftMFA Use Cases

The following table shows how enabling SoftMFA in the solution influence the Authentication Flow:

NOTE
In the following table,

- **Complete Delegation** refers to a scenario where all obligations are carried out in IDSP.
- **Partial Delegation** refers to a scenario where the first obligation is carried out in Siteminder, while the other obligations are carried out in the IDSP.
- **"Yes" or "No"** in the table columns indicates that the **"Final Obligation"** and "**Behavior"** remain unchanged, regardless of the selection.

	Delegation of Authentication in IDSP	Obligations returned by Policy	SoftMFA Enabled	Second Factor Registered	Trusted Device Enabled	Auth initiated from a Trusted Device	Final Obligations	Behavior
1	Complete Delegation	PWD:1, SMSOTP: 2	Yes	Yes	Yes	Yes	PWD	SMSOTP is ignored because the authentication has been initiated from a trusted device.
2	Complete Delegation	PWD:1, SMSOTP:2	Yes	Yes	Yes/No	No	PWD, SMSOTP	As the authentication request is initiated from a non trusted device, all factors returned by the policy will be considered for authentication.

	Delegation of Authentication in IDSP	Obligations returned by Policy	SoftMFA Enabled	Second Factor Registered	Trusted Device Enabled	Auth initiated from a Trusted Device	Final Obligations	Behavior
3	Complete Delegation	PWD:1, SMSOTP:2	Yes	No	Yes/No	Yes/No	PWD	SMSOTP:2 is ignored because it is not registered in the solution
4	Complete Delegation	PWD:1, SMSOTP:2	No	Yes/No	Yes	No	PWD, SMSOTP	When SoftMFA is disabled and the authentication request is initiated from a non trusted device, all factors returned by the policy will be considered for authentication.
5	Complete Delegation	PWD:1, SMSOTP:2	No	Yes/No	Yes	Yes	PWD	SMSOTP is ignored because the authentication has been initiated from a trusted device.
6	Complete Delegation	PWD:1, SMSOTP:2	No	Yes/No	No	NA	PWD, SMSOTP	When SoftMFA is disabled, all factors returned by the policy will be considered for authentication.
7	Partial Delegation	SMSOTP:2	Yes	Yes	Yes	Yes	NONE	AUTH_SUCCESS is returned by IDSP without any authentication as the authentication has been initiated from a trusted device.
8	Partial Delegation	SMSOTP:2	Yes	Yes	Yes/No	No	SMSOTP	SMSOTP is performed as the authentication has not been initiated from a trusted device.
9	Partial Delegation	SMSOTP:2	Yes	No	Yes/No	Yes/No	NONE	AUTH_SUCCESS is returned by IDSP without any authentication as SoftMFA is enabled and the user does not have any second factor registered
10	Partial Delegation	SMSOTP:2	No	Yes/No	Yes	No	SMSOTP	When SoftMFA is disabled and auth request is from a non trusted device, all factors returned by the policy will be considered for authentication.

	Delegation of Authentication in IDSP	Obligations returned by Policy	SoftMFA Enabled	Second Factor Registered	Trusted Device Enabled	Auth initiated from a Trusted Device	Final Obligations	Behavior
11	Partial Delegation	SMSOTP:2	No	Yes/No	Yes	Yes	NONE	AUTH_SUCCESS is returned by IDSP without any authentication as the authentication has been initiated from a trusted device.
12	Partial Delegation	SMSOTP:2	No	Yes/No	No	NA	SMSOTP	When SoftMFA is disabled, all factors returned by the policy will be considered for authentication when the Trusted device is disabled.
13	Complete Delegation	SMSOTP:1, PUSH:2	Yes	Both SMSOTP and PUSH are not registered for the user	Yes/No	Yes/No	-	AUTH_DENIED is returned by IDSP as there are no registered factors and softMFA is enabled.
14	Partial Delegation	SMSOTP:1, PUSH:2	Yes	Both SMSOTP and PUSH are not registered for the user	Yes/No	Yes/No	-	AUTH_SUCCESS is returned by IDSP without any authentication as primary was done at SSO and softMFA is enabled.
15	Complete Delegation	PWD:1, SMSOTP:2, PUSH:3	Yes	SMSOTP cred is not registered. PUSH cred may or may not exist.	Yes/No	Yes/No	PWD:1	SMSOTP:2 is ignored because it is not registered in the solution. Only PWD is performed.
16	Partial Delegation	SMSOTP:2	No	Yes/No	Yes/No	Yes/No	-	SMSOTP:2 → if SMSOTP is registered. AUTH_DENIED is returned by IDSP if SMSOTP is not registered.
17	Complete/Partial Delegation	PWD:1, SMSOTP:2, MOBILEOTP:3, PUSH:4	Yes	-	Yes/No	No	-	PWD:1 → if SMSOTP is not registered PWD:1, SMSOTP:2 → if MOBILEOTP is not registered PWD:1, SMSOTP:2, MOBILEOTP:3 → if PUSH is not register

Advanced Configurations

This topic includes the following advanced configurations that can be applied in Symantec Identity Security Platform:

- Managing Custom Vanity Ingresses
- Using Custom CA for Intra Cluster SSL Communications
- Operating with Multiple Data Centers
- Dynamic Environment Variable Substitution

Creating Vanity URLs

Vanity URLs are fully qualified domain names (FQDN) that are uniquely associated with an Symantec Identity Security Platform tenant. Learn how to configure vanity URLs and assign them to tenants.

A tenant can be configured to have one or more vanity URLs. To support vanity host names, you must update the IDSP ingress routing rules. The IDSP (ssp) chart manages the list of vanity hosts to ensure the ingress definition properly routes traffic.

Prerequisites

- You have deployed the solution in your Kubernetes cluster and exposed the main FQDN and System FQDN through an ingress controller.
- You have access to a system admin client to invoke the `.../system/admin/v1/Tenants` API.
- The vanity host cannot be a subdomain of the main FQDN specified during deployment. For example, if the FQDN is `authub.example.com` , the vanity host cannot be `api.authub.example.com` .

Types of Vanity Hosts

IDSP shows two types of vanity hosts that can be created:

Profile	Description	Default Hostname	Example Vanity
Full (main)	Exposes all IDSP paths, including admin, end-user, and API and routes them to the corresponding services.	`ssp.example.com`	`iam.acme.com`
End-User Vanity	Restricts access to end-user login portals only (sign-in, self-service, OIDC). Keeps admin APIs inaccessible.	*(none by default)*	`login.acme.com`

Tenant Configuration

The following step assumes that you have deployed IDSP (ssp) in your Kubernetes cluster and exposed the IDSP (ssp) FQDN and the IDSP (ssp) System FQDN through an ingress controller.

> **NOTE**
> The vanity hostname cannot be a subdomain of the IDSP FQDN that was specified during deployment. For example, if the FQDN of IDSP is "authub.example.com", the vanity host cannot be "api.authub.example.com".

To enable a vanity URL, you must register the vanity hostname with the tenant using the System Admin API so that the system can recognize and route requests for that hostname.

> **NOTE**
> If you omit this step, the router rejects requests arriving on the vanity hostname because the hostname is not associated with an active tenant.

Note that you must also configure the Helm chart to provision the underlying infrastructure (covered in the Helm Chart Configuration section).

For Versions 4.0 and 4.0.1

Using a system admin client, invoke the `.../system/admin/v1/Tenants` API to create or patch a tenant to add a vanity FQDN in the `vanityHosts` attribute.

When creating a new tenant (4.0 and 4.0.1): Include `vanityHosts` in the POST request:

```
curl -X POST "https://<MGMT_HOST>/system/admin/v1/Tenants" \
  -H "Authorization: Bearer <SYSTEM_ADMIN_TOKEN>" \
  -H "Content-Type: application/json" \
  -d '{
    "tenantName": "<name>",
    "masterKey": "<encryption-key>",
    "demoSetup": false,
    "defaultUserSetup": true,
    "defaultClientSetup": true,
    "vanityHosts": [
        "login.example.com",
        "iam.example.com"
    ]
}'
```

When updating an existing tenant (4.0 and 4.0.1): Use a PATCH request to add vanity hosts:

```
curl -X PATCH "https://<MGMT_HOST>/system/admin/v1/Tenants/<TENANT_ID>" \
  -H "Authorization: Bearer <SYSTEM_ADMIN_TOKEN>" \
  -H "Content-Type: application/json" \
  -d '{
    "vanityHosts": [
        "login.example.com",
        "iam.example.com"
    ]
}'
```

For Version 4.0.2

For 4.0.2, use the `vanityHostsInfo` array instead of `vanityHosts` . You must provide the host FQDN and its type (`ENDUSER` or `FULL`) within the `vanityHostsInfo` attribute.

When creating a new tenant (4.0.2): Include `vanityHostsInfo` in the POST request:

```
curl -X POST "https://<MGMT_HOST>/system/admin/v1/Tenants" \
  -H "Authorization: Bearer <SYSTEM_ADMIN_TOKEN>" \
  -H "Content-Type: application/json" \
  -d '{
    "tenantName": "<name>",
    "masterKey": "<encryption-key>",
    "demoSetup": false,
    "defaultUserSetup": true,
    "defaultClientSetup": true,
    "vanityHostsInfo": [
        {
            "hostFqdn": "login.acme.com",
            "type": "ENDUSER"
        }
```

```
    ]
}'
```

When updating an existing tenant (4.0.2): Use a PATCH request to add vanity hosts:

```
curl -X PATCH "https://<MGMT_HOST>/system/admin/v1/Tenants/<TENANT_ID>" \
  -H "Authorization: Bearer <SYSTEM_ADMIN_TOKEN>" \
  -H "Content-Type: application/json" \
  -d '{
    "vanityHostsInfo": [
        {
            "hostFqdn": "login.acme.com",
            "type": "ENDUSER",
            "allowScim": true
        },
        {
            "hostFqdn": "iam.acme.com",
            "type": "FULL"
        }
    ]
}'
```

The `type` field corresponds to the chart configuration: `ENDUSER` maps to end-user vanity hosts, and `FULL` maps to full vanity hosts.

Helm Chart Configuration

> **NOTE**
> **TLS Certificate Requirements:** Each vanity host requires a valid TLS certificate. You can configure TLS using one of the following methods:
>
> - **Per-host certificate:** Specify the `tlsSecretName` for each vanity host entry.
> - **Shared wildcard certificate:** Use a single wildcard certificate if multiple vanity hosts share a common domain (e.g., `*.acme.com`).
> - **Main certificate:** Set `tlsSecretName: null` to reuse the main ingress TLS certificate, provided it covers the vanity domain via Subject Alternative Name (SAN).

To configure vanity hosts, update the corresponding settings in your `values.yaml` (or `ssp-override.yaml`) file and upgrade your Helm release.

For Versions 4.0 and 4.0.1

Follow these steps to create routing rules for the vanity ingress:

1. Add the new vanity FQDN to the deployment ingress configuration. Get your current `values.yaml` by running the following command:

   ```
   helm get values ${RELEASENAME} -n ${NAMESPACE} >ssp-override.yaml
   ```

   > **NOTE**
   > Ensure to set the `RELEASENAME` and `NAMESPACE` environment variables prior to running this command. To get those values, use: `helm ls --all-namespaces`

2. Edit the `ssp-override.yaml` file, and modify the `ssp.ingress` section to add `fullVanity` and/or `endUsersVanity` URLs as shown in this example:

   ```
   ssp:
     ingress:
       fullVanity:
         enabled: true
         hosts:
   ```

```
    - host: iam.democorp.com
      tlsSecretName: iam-cert
    - host: iam.acme.com
      tlsSecretName: null
  endUsersVanity:
    enabled: true
    ingressClassName:
    additionalLabels: {}
    additionalAnnotations: {}
    allowScim: false
    hosts:
    - host: abc.example.com
      tlsSecretName: abc-cert
    - host: login.example.com
      tlsSecretName: null
```

In this example:

- Two full vanity FQDNs are created: `iam.democorp.com` uses its own TLS certificate from the Kubernetes secret `iam-cert` , and `iam.acme.com` sets `tlsSecretName: null` to reuse the main ingress TLS certificate (provided it covers the vanity domain via SAN). If you omit `tlsSecretName` , the chart uses the `ssp.ingress.tls.secretName` TLS secret.
- Two end-user vanity FQDNs are created: `abc.example.com` uses its own TLS certificate from the Kubernetes secret `abc-cert` , and `login.example.com` reuses the main ingress TLS certificate.
- `additionalLabels` and `additionalAnnotations` allow you to attach metadata to the end-user vanity ingress objects. `allowScim` controls whether SCIM provisioning paths are exposed on end-user vanity hosts.
- If you do not specify the `ingressClassName` , the chart uses the default `ssp.ingress.ingressClassName` value.
- If you use OpenShift Routes as the ingress type, depending on your ingress controller configuration, you may need to use labels to distinguish between different ingress controllers. See Using Additional Labels.

For OpenShift Routes, you can also specify `additionalLabels` under the ingress sections to target specific internal or external routers.

3. To upgrade the helm chart after adding the new vanity FQDN, run this command:

```
helm upgrade ${RELEASENAME} ssp_helm_charts/ssp -n ${NAMESPACE}  -f ssp-override.yaml \
--set ssp.featureFlags.dataseed.enabled=false \
--version=<current-ssp-version>
```

For Version 4.0.2 (Gateway API Support)

Follow these steps to create routing rules for the vanity ingress:

1. Add the new vanity FQDN to the deployment ingress configuration. Get your current `values.yaml` by running the following command:

```
helm get values ${RELEASENAME} -n ${NAMESPACE} >ssp-override.yaml
```

NOTE
Ensure to set the `RELEASENAME` and `NAMESPACE` environment variables prior to running this command. To get those values, use: `helm ls --all-namespaces`

2. Edit the `ssp-override.yaml` file, and modify the `ssp.ingress` section to add `fullVanity` and/or `endUsersVanity` URLs as shown in this example:

```
ssp:
  ingress:
    type: gatewayapi
    # Top-level Gateway API configuration (shared defaults for all endpoints)
    gatewayApi:
```

```
  gatewayType: auto                    # auto, envoy, gke-l7, azure-agc, aws-alb, avi, custom
  createGateway: true

What the Chart Creates:

Based on your `values.yaml` settings, the chart provisions the following resources:

Configuration	Gateway	HTTPRoute	Listeners
`endUsersVanity.enabled` + `createGateway: false` + no `existingGateway`	Uses main Gateway	Separate HTTPRoute (`*-router-enduser`)	Adds listeners to main Gateway
`endUsersVanity.enabled` + `createGateway: false` + `existingGateway: xyz`	Uses `xyz` Gateway	Separate HTTPRoute	Adds listeners to `xyz` Gateway
`endUsersVanity.enabled` + `createGateway: true`	Creates `*-gateway-enduser`	Separate HTTPRoute	Own listeners on separate LB
`mgmt.enabled` + `createGateway: false` + no `existingGateway`	Uses main Gateway	Separate HTTPRoute (`*-router-mgmt`)	Adds listener to main Gateway
`mgmt.enabled` + `createGateway: false` + `existingGateway: xyz`	Uses `xyz` Gateway	Separate HTTPRoute	Adds listeners to `xyz` Gateway
`mgmt.enabled` + `createGateway: true`	Creates `*-gateway-mgmt`	Separate HTTPRoute	Own listeners on separate LB
`fullVanity.enabled`	Uses main Gateway	Uses main HTTPRoute (`*-router-full`)	Adds listeners to main Gateway

Summary of Configuration Differences Between Versions 4.0/4.0.1 and 4.0.2:

- Version 4.0.2 introduces `gatewayapi` as new values for `ssp.ingress.type`, alongside the existing `nginx` and `openshiftroute` types.
- A new top-level `ssp.ingress.gatewayApi` section defines shared Gateway API configuration, including gateway type detection (`gatewayType`), Gateway resource creation (`createGateway`), `gatewayClassName`, backend TLS policies (`createBackendTLSPolicy`), backend references (`backendRef`), and controller-specific settings for Envoy (`connectionBufferLimitBytes`, `maxRequestBodySize`) and AVI (`sslProfile`).
- `endUsersVanity` gains a `gatewayApi` sub-section that supports network isolation through separate Gateways (`createGateway`), pre-existing Gateways (`existingGateway`, `existingGatewayNamespace`), traffic policies (`createTrafficPolicies`), static addressing (`addresses`), and HTTPRoute annotations

(`httpRouteAnnotations`). The `additionalAnnotations` parameter at the `endUsersVanity` level is removed in 4.0.2.

- `mgmt` gains the same `gatewayApi` sub-section as `endUsersVanity` , and a new `tls.generateSelfSignedCert` parameter.

Validating the Vanity Ingress Routing Rules

To verify the vanity ingress configuration, access the OpenID configuration discovery endpoint. A successful response confirms that the ingress is routing traffic correctly.

Sample Request

```
GET https://my.vanity.fqdn/common/.well-known/openid-configuration
{
    "issuer": "https://my.vanity.fqdn/common/",
    "authorization_endpoint": "https://my.vanity.fqdn/common/oauth2/v1/authorize",

```

Using Custom CA for Intra Cluster SSL Communications

Use of Internal Signing Key (ISK) for Internal Cluster Communications

All internal cluster communications are authenticated using an Access Token signed by the Internal Signing Key (ISK). The ISK is also used for intra-cluster SSL communication.

Symantec Identity Security Platform automatically generates an ISK during its deployment. If you want to use your own certificate as the ISK, follow these steps to create a secret and pass it in the IDSP deployment:

Before creating a secret, ensure that;

Your certificate has the Subject Alternative Name (SAN) that looks like the following:

```
*.<k8s-namespace>.svc.
```

For example, assuming that the Kubernetes namespace = 'dev', the SAN should look like the following:

```
X509v3 Subject Alternative Name: critical
    DNS:*.dev.svc
```

NOTE

- The SAN in the certificate should match the proxy-ssl-name specified in the IDSP Ingress objects annotations:

  ```
  "http://nginx.ingress.kubernetes.io/proxy-ssl-name">nginx.ingress.kubernetes.io/proxy-ssl-name:
   any.{{ .Release.Namespace }}.svc
  ```

- The wildcarded SAN in the certificate is expected to match the "proxy-ssl-name" used by the IDSP Ingress:

  ```
  nginx.ingress.kubernetes.io/proxy-ssl-name: any.dev.svc
  ```

- Creating a secret requires the server certificate (tls.crt), server key (tls.key), and CA certificate (CA.crt).

1. Create a secret using the following command (this command assumes that the file names are: ca certificate is caroot.pem, isk certificate is isk-certificate.pem, and isk certificate key is isk-key.pem):

   ```
   kubectl create secret generic -n <namespace>  <isk-secretname> \
     --from-file=ca.crt=caroot.pem \
     --from-file=tls.crt=isk-certificate.pem \
     --from-file=tls.key=isk-key.pem
   ```

   NOTE

   - The isk-certificate.pem file may contain multiple intermediate certificates in PEM. It must have the server certificate first followed by intermediate certificates.
   - The isk-key.pem file must be in PKCS8 PEM format (starts with "-----BEGIN PRIVATE KEY-----" and ends with "-----END PRIVATE KEY-----")

2. Pass the secret that was created in the previous step when installing the IDSP helm chart deployment by adding the following syntax in the deployment command:

```
--set ssp.keys.isk.existingSecret=<k8s-tls-secret-name>
```

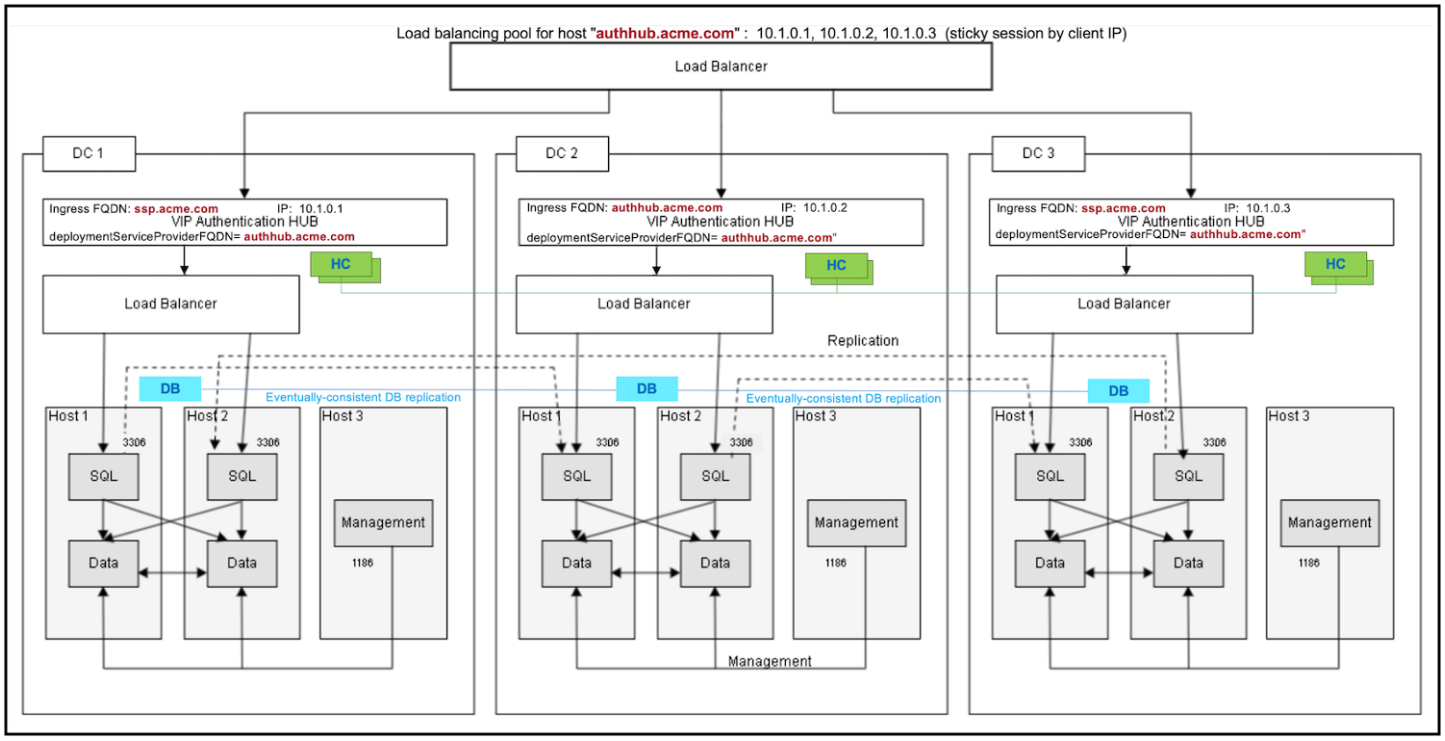
Operating with Multiple Data Centers

Advanced settings covering transactional artifacts

The following diagram illustrates the use of the Symantec Identity Security Platform with three data centers operating in Active/Active mode. Each data center has its own IDSP deployed with a dedicated MySQL cluster with InnoDB Storage Engine, integrated through eventually-consistent data replication.

Figure 9: Multi Data Center Image



NOTE
In this diagram, **HC** refers to Hazelcast Cache.

While operating with multiple data centers, the following advanced global settings have been added to IDSP to support configurable retries when reading transactional artifacts (such as Flow State, Az Code, Device Code, and User Code) that persist in eventually-consistent storage.

The following settings have to be used in the Multi Data Center mode:

- ***persistentStoreForTransactionalData*** - Note that this setting must be set to "db" for IDSP to be operational with multiple data centers. The default is "***cache***".
- ***transactionalDataReadsRetryCount***
- ***transactionalDataReadsRetryWaitPeriodMillis***

These configuration settings are covered in Global/Tenant Settings.

Dynamic Substitutions

This topic provides information on the supported dynamic environment variables in Symantec Identity Security Platform.

IDSP supports dynamic environment variables in various places. These environment variables are substituted with the appropriate value coming from different contexts.

This topic includes the following sections:

- Supported Dynamic Substitution Notations
- Supported Dynamic Variable Namespaces
- Supported Dynamic Substitution Functions
  - stringUtils Table
  - arrayUtils Table
- Usage of Dynamic Environment Substitutions

Supported Dynamic Substitution Notations

The dynamic substitution uses the following three types of notations:

- ${<namespace>.<param>} notation returns a single string, in case of multi-value attribute, it returns a csv string
- $(<namespace>.<param>) notation returns a single string, containing a csv wrapped with [] where every value in the csv is wrapped with double quotes (""), and a double quote inside the value is escaped by a backslash ("\").
- $[<namespace>.<param>] notation returns a list of strings.

NOTE

When a value is expected to return a list, you can choose the format in which the list is represented using either curly braces, square brackets, or parenthesis:
- $[...] returns a native list
- ${...} returns a CSV in a single element
- $(...) returns a CSV in a single element, wrapped with [ ] where:
  - every value in the csv is wrapped with double quotes (" ")
  - a double quote is escaped by a backslash ("\")

Examples: SAML Assertion:

Using $[...]

```
<saml2:Attribute Name="$[idProfile.email]" NameFormat="urn:oasis:names:tc:SAML:2.0:attrname-
format:basic">
<saml2:AttributeValue xmlns:xsi=http://www.w3.org/2001/XMLSchema-instance
xsi:type="xsd:string">malbail17222@example.com</saml2:AttributeValue>
<saml2:AttributeValue xmlns:xsi=http://www.w3.org/2001/XMLSchema-instance
xsi:type="xsd:string">malbail17222@example.com</saml2:AttributeValue>
</saml2:Attribute>
```

Using ${...}

```
<saml2:Attribute Name="${idProfile.email}" NameFormat="urn:oasis:names:tc:SAML:2.0:attrname-
format:basic">
<saml2:AttributeValue xmlns:xsi=http://www.w3.org/2001/XMLSchema-instance
xsi:type="xsd:string">malbail17222@example.com,malbail17222@example.com</saml2:AttributeValue>
</saml2:Attribute>
```

Using $(...)

```
<saml2:Attribute Name="$(idProfile.email)" NameFormat="urn:oasis:names:tc:SAML:2.0:attrname-
format:basic">
```

```
<saml2:AttributeValue xmlns:xsi=http://www.w3.org/2001/XMLSchema-instance xsi:type="xsd:string">
["malbail17222@example.com","malbail17222@example.com"]</saml2:AttributeValue>
</saml2:Attribute>
```

Examples: JWT:

Using $[...]

```
"$[idProfile.email]": [
"malbail17222@example.com",
"malbail17222@example.com"
],
```

Using ${...}

```
"${idProfile.email}": "malbail17222@example.com,malbail17222@example.com",
```

Using $(...)

```
"$(idProfile.email)": "[\"malbail17222@example.com\",\"malbail17222@example.com\"]",
```

Supported Dynamic Variable Namespaces

The following table lists the supported variable namespaces that will be substituted with their corresponding values:

Namespace Identifier	Description	E
system.<*propertyName*>	Available property names: • issuerUrl - returns the issuer Url of the current request. • host - returns the host header variable of the current request. • newUuid - returns newly generated UUID. • thisResourceId - returns the ID of the subject-object of the request.	$ $
idProfile.<*logical-attribute*>	Returns the user profile attribute that is mapped with the indicated user profile logical attribute. If the attribute is not present in the ID Store or ZFP ID Token, the keyword is replaced with NODATA. If ZFP flow is used, the attribute is presumed to have been provided in the incoming ID Token.	$
rawAssertion.<*claim-name*> (Available from IDSP version-3.3)	Returns the value of a named claim from the Identity Assertion Token returned by the Identity Provider in a BYOI. If the ID Token is present in the flow but the claim is not present in the ID Token, the keyword is replaced with NODATA.	$
idToken.<*claim-name*>	Returns the value of a named claim from the original ID Token, if present in the flow. Otherwise, the key-value pair is skipped. If the ID Token is present in the flow but the claim is not present in the ID Token, the keyword is replaced with NODATA.	{
appMetadata.<*property-name*>	Returns the metadata property of the application for the specified property name. If the metadata property is not present, the keyword is replaced with NODATA.	$ v
idpMetadata.<*property-name*>	Returns the metadata property of the identityProvider for the specified property name. If the metadata property is not present, the keyword is replaced with NODATA.	$ v

clientContext.*<propertyName>*

Returns the clientContext value for the specified property name. If the client context property is not present, then the keyword is replaced with NODATA.

The `clientContext` can be provided through various methods:

- **Request Payload in Authenticate API**: The clientContext property can be passed into the ".../auth/v1/authenticate" call in the request payload. For example -

```
{
"subject": "nbruce",
"channel": "web",
"action": "authenticate",
"rememberMe": true,
"urn:iam:authn:clientContext": [
{
 "key": "email",
 "value": "user@example.com"
}
]

}
```

- **As a claim in the "id_token_hint" Parameter**: The clientContext property can be passed as a query parameter to ".../oauth2/v1/authorize" or can be passed into ".../auth/v1/authenticate" API call through the "existingIDToken" or "id_token_hint" payload parameters. The following example represents the decoded id_token_hint with clientContext claim:

```
{
"sub": "dd433ba1-b9ed-46bf-9d3e-15759d6bf89b",
"idp_name": "aa_idp",
"user_dn": "cn=user1,ou=Employees,o=democorp,c=us",

"72316d69-9749-4ef7-a9bb-d92e433efe28"
],
```

${requestParams.xxx}	This placeholder would be replaced with the value of a request parameter named xxx.	$
userGroups.all_groups	It returns the entire list of groups that the user is a member of. Returns a list or a csv depending on how it is invoked: ${userGroups.all_groups} returns a csv $[userGroups.all_groups] returns a list $(xxx.yyy) returns a csv wrapped with [] where: • every value in the csv is wrapped with double quotes ("") • a double quote is escaped by a backslash ("\")	$
userGroups.regex_groups	It is replaced by a filtered list of user's groups by applying a regex expression specified in application metadata. For OIDC (JWT): urn:iam:app:jwtGroupApplicabilityRegex For SAML: urn:iam:app:samlGroupApplicabilityRegex	$
userGroups.<*group_name*>	returns a boolean indicating if the user is a member of the specified group ${userGroups.<*groupname*>} returns true or false depending on whether the user is a member of the specified group.	$
• evaluateIsTrue.< expression *resulting in "true" / "false"*> • evaluateIsNotTrue.< expression *resulting in "true" / "false"*>	used to convert a string value to a boolean value "false" or "true" depending on the string value. A string value of "true", ignoring the case, causes "true" to be returned, otherwise "false" is returned.	"

Supported Dynamic Substitution Functions

The following table lists the supported functions (stringUtils and arrayUtils) that can be used with the substituted values mentioned in the previous table:

stringUtils Table

NOTE
String compares are case insensitive.

Functions	Description	Exa
${stringUtils.empty("string")	returns "true" if "string" is null or empty, otherwise returns "false"	${st
${stringUtils.notEmpty("string")}	returns "true" if "string" is not null and not empty, otherwise returns "false"	${st
${stringUtils.contains("string", "substring")	returns "true" if "string" contains "substring", otherwise returns "false"	${st
${stringUtils.notContains("string", "substring")}	returns "true" if "string" does not contain "substring", otherwise returns "false"	${st
${stringUtils.startsWith("string", "prefix-string")}	returns "true" if "string" starts with "prefix-string", otherwise returns "false"	${st
${stringUtils.notStartsWith("string", "prefix-string")}	returns "true" if "string" does not start with "prefix-string", otherwise returns "false"	${st
${stringUtils.endsWith("string", "suffix-string")}	returns "true" if "string" ends with "suffix-string", otherwise returns "false"	${st
${stringUtils.notEndsWith("string", "suffix-string")}	returns "true" if "string" does not end with "suffix-string", otherwise returns "false"	${st
${stringUtils.compare("string1", "string2")}	returns "true"/"false" if "string1" equals "string2"	${st

${stringUtils.if(“boolean-string”, “string-true”, “string-false”	returns “string-true” if “boolean-string” is “true”, otherwise returns “string-false”	${st “Er
${stringUtils.prefix(“string”, “substring”)}	returns the part of “string” that is before “substring” (not including “substring”)	${st
${stringUtils.suffix(“string”, “substring”)}	returns the part of “string” that is after “substring” (not including “substring”)	${st
${stringUtils.lower(“string”)}	returns “string” in lower case	${st
${stringUtils.upper(“string”)}	returns “string” in the upper case	${st
${stringUtils.toList(“csv-string”)}	parses a comma-separated value (CSV) string into a list of strings	
The following stringUtils functions are supported from IDSP v3.3.1 only.		
${stringUtils.maskEmail(“string”)}	returns masked email id	${st
${stringUtils.maskPhoneNumber(“string”)}	returns a masked phone number	${st
${stringUtils.maskString(“string”)}	returns masked string	${st
${stringUtils.guid("string")}	returns "true" if "string" is a valid UUID/GUID, otherwise returns "false"	${st
${stringUtils.notGuid("string")}	returns "true" if "string" is not a valid UUID/GUID, otherwise returns "false"	${st
${stringUtils.greaterThan("stringINT1", "stringINT2")}	returns "true" if the integer value of "stringINT1" > "stringINT2", otherwise "false"	${st
${stringUtils.lessThan("stringINT1", "stringINT2")}	returns "true" if the integer value of "stringINT1" < "stringINT2", otherwise "false"	${st
${stringUtils.or("bool1", "bool2")}	returns "true" if at least one of "bool1" or "bool2" is "true", otherwise "false"	${st ${st
${stringUtils.and("bool1", "bool2")}	returns "true" if both "bool1" and "bool2" are "true", otherwise "false"	${st ${st
${stringUtils.substring("string", startPos, endPos)}	returns substring from startPos (0-based, inclusive) to endPos (exclusive). Use negative startPos to count from end. Use endPos=-1 for rest of string. If endPos > length, returns to end.	${st
${stringUtils.quote("string")}	wraps string in quotes and escapes internal quotes. If already quoted, returns as-is.	${st
${stringUtils.unquote("string")}	removes surrounding quotes and unescapes. If not quoted, returns as-is.	${st

arrayUtils Table

NOTE
String compares are case insensitive.

Functions	Description
$(arrayUtils.filterStartsWith(“string-array”, “string”))	returns a csv with entries that do start with “string”
$(arrayUtils.filterNotStartsWith(“string-array”, “string”))	returns a csv with entries that do not start with “string”
$(arrayUtils.filterEndsWith(“string-array”, “string”))	returns a csv with entries that end with “string”
$(arrayUtils.filterNotEndsWith(“string-array”, “string”))	returns a csv with entries that do not end with “string”
$(arrayUtils.filterContainsSubString(“string-array”, “string”))	returns a csv with entries that contain the “string” as a substring of the

$(arrayUtils.filterNotContainsSubString(“string-array”, “string”))	returns a csv with entries that do not contain “string” as a substring of
${arrayUtils.at(“string-array”, <index>)}	returns the value in location <index> in the array (index=0 for first item range return “”
${arrayUtils.size(“string-array”)}	returns the number of elements in the array as a string
$(arrayUtils.filterByRegEx(“string-array”, “regex”))	returns a csv with entries that contain only the strings that match the r
$[arrayUtils.rewriteByRegEx(“string-array”, “regex”, "template")]	For each string in the array, apply the regex and rewrite the string usir In the template string, use $1 and $2 to indicate the regex group id to $(arrayUtils.rewriteByRegEx($[IdProfile.groups], "ad-(\w+)-(\d+)", "arn $2:role/$1"))"; or $(arrayUtils.rewriteByRegEx($[IdProfile.groups], "group_aws_(\d+)_(\ "arn:aws:iam::$1:role/$2"))
${arrayUtils.empty("string-array")}	returns "true" if array is null, empty, or "[]", otherwise "false"
${arrayUtils.notEmpty("string-array")}	returns "true" if array has at least one element, otherwise "false"
${arrayUtils.contains("string-array", "string")}	returns "true" if array contains exact match of "string" (case insensitive "false"
${arrayUtils.notContains("string-array", "string")}	returns "true" if array does not contain "string" (case insensitive), othe
${arrayUtils.filterByRegEx("string-array", "regex")}	returns csv of entries where the entire string matches the regex (case Java Pattern.matches().
$[arrayUtils.rewriteByRegEx("string-array", "regex", "replacement")]	applies String.replaceAll(regex, replacement) to each element. Suppo backreferences ($1, $2, etc).

NOTE

- filterByRegEx requires the entire string to match the pattern (anchored)
- rewriteByRegEx replaces all occurrences of the pattern in each string
- Use $[...] syntax for functions returning arrays (MVA), ${...} for scalar values

Where can Dynamic Environment Substitution be used?

Functional Area	Description
LDAPconfig	ldapQueryStart, ldapQueryEnd
SCIMconfig	lookupQuery
	requestCtxBase64, oauthTokenRequestCtxBase64 (the *value* field of requestCtxBase64 (or oauthTokenRequestCtxBase64) entries of *http-header*)
Both LDAPconfig and SCIMconfig	IdStoreMappingStrategy <value> will be "disambiguated" against the authentication id store (using idstore lo start/end search query) or <authn-id-store-attr>=<value> query against authentication idStore (on both the ids and the value)

provider config (Custom SPI)	providerHeaders and providerProperties
App	FlowURL This URL can use variables of the namespaces appMetadata, and idToken.
	errorUrl
	logoutUrl
	Application custom claim See Custom Token Claims.
Tenant Settings	InternalIdStoreDisambiguationQuery
Identity Provider	IDP Configuration

	IDP claim mapping Dynamic substitution using standard namespaces (and expressions as covered by Substitution Functions) is applicable to IDP's Subject Claim and Claim Mapping configuration.

Identity Service

Contains information about Managing Identities in the Internal Id Store using the Identity Service.

The section contains information on the Identity Service, the service capabilities, schemas, and the Identity Service API.

> **NOTE**
> Before you can manage identities, you must configure the Identity Service. For more information, see Internal Identity Store Configuration.

The Identity Service is a Business Service running in the Security Services Platform that manages identities and related capabilities. The Identity Service exposes REST APIs, including a SCIM interface that conforms to the SCIM v2 standard, for User and Group Management. The service operates on User and Groups maintained in the Internal ID Store. The service includes the following capabilities:

- Internal ID Store Configuration
- Full lifecycle management of Users and Groups
- Extensible User Schema
- Self Service Password Recovery
- Self Service Account Unlock
- User State Management
- Password Management including Password Policy support

User and Group Schemas

Describes the User and Group Schemas supported by Symantec Identity Security Platform.

The Identity Service supports the SCIM v2 User and Group core schema, the User Enterprise schema extension, the SSP-based Symantec Identity Security Platform User schema extension, and User custom schema extension that can be defined by deployments. You can also use the `UserSchemaHelper` parameter that supports filtering by schema fields.

The following table lists the defined schemas.

SCIM schema URN	Attribute Name	>Description	Value
`urn:ietf:params:scim:schemas:core:2.0:User`	active	Indicates the locked state of the user account	**True** – account is unlocked **False** – account is locked

	`addresses {`
	`country`
	`formatted`
	`locality`
	`postalCode`
	`primary`
	`region`
	`streetAddress`
	`type`
	`verified`
	`}`
		One or more address sets comprised of a composition of single value attributes representing the various address parts.
		country – users country
		formatted – The full mailing address, formatted for display or use with a mailing label.
		locality – users city/town
		postalCode – the postal code
		primary - a boolean indicating the primary address. Only one address can be marked as primary
		region – state or province
		streetAddress -= physical address
		type -a user-defined type (e.g. work or home)
		verified - a boolean SSP extension that is used to indicate the address has been verified	

	`emails {`
	`display`
	`primary`
	`priority`
	`type`
	`value`
	`verified`
	`}`
		One or more email sets comprised of a composition of single value attributes representing the various email parts.
		display – Value to use when displaying the email.
		primary – a Boolean indicating the primary email. Only one email can be marked as primary
		priority – an optional value indicating the priority. Used when the primary designation is not defined. The lowest priority value indicates primary.
		type – a user-defined type (e.g. work or home)
		value – the email value
		verified – a boolean SSP extension that is used to indicate the email has been verified
		Note: Only verified emails can be used as an Email Credential.	

SCIM schema URN	Attribute Name	>Description	Value
	displayName	The displayName of the user.	This value is also used in the list of Group members On a create User request, the Identity Service generates the `displayName` value from the `displayNameTemplate` configured in the internal identity store configuration (see Internal Identity Store Configuration). By default, the Display Name Template is set to `givenName` and `familyName` . If some or all of the values for the specified attributes are present, the display name is generated from the available values. If none of the values are present, the display name is generated from the user `Login` value.
	id	The unique SCIM resource id for the User	id is an immutable value that is generated by the Identity Service when a user is created (POST User) and which is returned in the POST response. Optionally, you can pass a unique value for the id into the Create User request. The value must be a unique GUID.
	groups	The list of groups the user is a member of	
	locale	Used to indicate the default location of the user for purposes of localizing such items as currency, date time format, or numerical representations.	

	`name {`
	`formatted`
	`familyName`
	`givenName`
	`middleName`
	`honorificPrefix`
	`honorificSuffix`
	`}`
		Name a composition of single value attributes representing the various name parts
		formatted - The full name, including all middle names, titles, and suffixes as appropriate, formatted for display
		familyName – family name or last name
		givenName – given name or first name
		middleName – middle name
		honorificPrefix- prefix or title
		honorificSufffix- suffix	

	nickName	The nickname of the user	

SCIM schema URN	Attribute Name	>Description	Value
	password	The password of the user	The request containing the user password can be clear text or in an in-transit encrypted format. See the section Password Management section for details.

	phoneNumbers {
	capabilityType
	display
	primary
	priority
	type
	value
	verified
	
	}
		One or more phoneNumber sets comprised of a composition of single value attributes representing the various phoneNumber parts.
		capabilityType– an SSP extension used to describe the capabilities that the phone has when used as a phone Credential.
		display – Value to use when displaying the phone.
		primary – a Boolean indicating the primary phone. Only one phone can be marked as primary
		priority – an optional value indicating the priority. Used when the primary designation is not defined. The lowest priority value indicates primary.
		type – a user-defined type (e.g. work or home)
		value – the phone number
		verified – a boolean SSP extension that is used to indicate the phone has been verified
		Note: Only verified phones can be used as a Phone Credential.
			capabilityType supported values: “sms” and “ivr”

	preferredLanguage	Indicates the preferred written or spoken languages of the user and is used for selecting a localized user interface.	
	profileUrl	The profile URL of the user	A URI that is a uniform resource locator (as defined in Section 1.1.3 of [RFC3986]) and that points to a location representing the online profile of the user (e.g., a web page).
	timezone	The time zone of the user, in IANA Time Zone database format	
	title	The title of the user	
	userName	The name of the user. Used for user login	The user name must be unique

SCIM schema URN	Attribute Name	>Description	Value
	userType	The user type. Typical values used might be "Contractor", "Employee", ”Partner” but any value may be used.	
urn:ietf:params:scim:schemas:extension:enterprise:2.0:User			
	costCenter	a value representing the cost center of the user	
	department	the department of the user	
	division	the division of the user	
	employeeNumber	the employeeNumber of the user	
	organization	the organization of the user	

	manager {
	value
	$ref
	displayName
	}
		the manager of the user
		A user cannot set himself or herself as their own manager. Additionally, a client must have scoping privileges on a manager.
		value – the id of the SCIM user representing the manager of the user
		$ref - The URI of the SCIM resource representing the manager of the user
		displayName – the display name of the manager of the user	

urn:ietf:params:scim:schemas:extension:iam:ssp:1.0:User			
	birthdate	The birthdate of the user	The format is in ISO 8601 Date time format
	disabled	The disabled state of the user	false – the user is not disabled true – the user is disabled
	gender	The gender of the user	
	passwordMustChange	A Boolean flag indicating if the user must change their password during the next authentication	false – password is not required to change true – password must be changed after authentication succeeds
	updateable	A flag indicating whether the user is updateable.	Typically set to true for Internal ID Store users. For users created using IDP JIT this flag could be set to false.
	birthdate	The birthdate of the user	The format is in ISO 8601 Date time format
urn:ietf:params:scim:schemas:extension:iam:ssp:1.0:User:credentials			

SCIM schema URN	Attribute Name	>Description	Value
	Credentials	Credentials are the set of user credentials based on verified user	
`urn:ietf:params:scim:schemas:extension:iam:ssp:1.0:User:custom`			
	The attributes within this URN are deployment-specific. See the User Schema extensions section for details.		
`urn:ietf:params:scim:schemas:core:2.0:Group`			
	displayName	The unique name of the group	
	id	The unique SCIM resource id for the Group	id is an immutable value that is generated by the Identity Service when a Group is created (POST Group) and is returned in the POST response
	members	A list of members of the Group.	

User Schema Extensions for the Identity Service

The Identity Service supports extending the User schema for deployment-specific needs.

You can define custom attributes using the Additional User Attributes section on either the Internal ID Store Configuration page, or the Internal ID Store API. The following additional attribute definitions are supported:

Property	Description	Value
name	A unique name for the attribute. The name must be unique across all of the SCIM attribute URNs defined in the Internal Identity Store Configuration.	
type	The data type of the attribute: • STRING • INTEGER • BOOLEAN • DATE	one of the supported types
searchable	An indicator if the attribute can be used in a search operation. **Note:** This enforcement is only honored using the ID Store API, SCIM protocol does not define searchable.	**false** – attribute cannot be used in a search expression **true** - attribute cannot be used in a search expression
enabled	Defines the enabled state. Attributes whose enabled state = false cannot be used in requests, searches, and are not returned in responses.	**false** – the attribute is disabled and cannot be used in user operations **true** - the attribute is enabled and can be used in user operations
multivalued	Sets whether attributes can have more than one value. Applies only to attributes of type string, integer, or date. Once set to multivalue, an attribute cannot be changed to single value.	**false** – the attribute can have only one value **true** - the attribute can have multiple values. If this property is not set, the attribute supports only a single value.

Defining Additional User Attributes for the Identity Service

The Symantec Identity Security Platform Admin Console supports managing ID Stores through the ID Store Management section.

When selecting the Internal ID Store, the main page provides an Additional User Attributes control where you can add/remove user attributes using the properties that are described in the User Schema Extensions for the Identity Service topic.

Also, the Internal ID Store Configuration API supports the **customUserAttributes** property. The following example shows the definition of five additional user attributes:

```
"customUserAttributes": [
     {
         "name": "officeLocation",
         "type": "STRING",
         "searchable": true,
         "enabled": true
         "multivalued": true
     },
     {
         "name": "jobCode",
         "type": "INTEGER",
         "searchable": true,
         "enabled": true
         "multivalued": false
     },
     {
         "name": "isUsCitizen",
         "type": "BOOLEAN",
         "searchable": true,
         "enabled": true
         "multivalued": false
     },
     {
         "name": "hireDate",
         "type": "DATE",
         "searchable": true,
         "enabled": true
         "multivalued": false
     },
     {
         "name": "adminType",
         "type": "STRING",
         "searchable": true,
         "enabled": true
         "multivalued": false
     }
 ]
```

Manage Users and Groups in the Identity Service

User and Group management is provided via a standard SCIM v2 interface, along with schema extensions that you can use as required by the business service. The Identity Service and the supported SCIM v2 interface operate on Users and Groups in the Internal Id Store. You can create Users and Groups using the SCIM interface, or optionally created via from an Identity Provider configured to support Just-In-Time (JIT) provisioning. For more information, see Identity Provider Discovery - Just-In-Time (JIT) User Provisioning.

This section provides an overview of the User and Group management capabilities and considerations. The Management APIs are fully documented in the Identity User API and Identity Group API topics of the Identity REST APIs section.

Manage Users in the Identity Service

User Management is provided through a standard SCIM v2 interface along with User schema extensions that you can use as required by the business service.

The Identity Service and the supported SCIM v2 interface operate on Users in the Internal Id Store. You can create Users with either the SCIM interface, or optionally from an Identity Provider that is configured to support Just-In-Time (JIT) provisioning.

For more information, see Identity Provider Discovery - Just-In-Time (JIT) User Provisioning.

This section provides an overview of the User Management capabilities and considerations. The User Management APIs are fully documented in the Identity User and Identity Group sections of the REST APIs.

Learn how to manage users with the Identity Service with the following capabilities:

- Creating Users
- Deleting Users
- Retrieving Users
- Updating Users
- User Self Service

Creating Users

You create users through the Identity Service SCIM2 Users API (`{tenantName}/scim2/v1/Users`) using a POST operation. Consider the following factors during User creation.

Identity Uniqueness

Identities must be unique. The **id** and **username** attributes are used to guarantee uniqueness. The **id** attribute (also known as a resource Id) identifies the unique SCIM User resource. The **id** attribute is automatically generated by the Identity Service on a create user request. Optionally, on a create user request, a client can pass in a unique GUID value for the **id**.

The **userName** must also be unique. **UserName** is an attribute that is typically used for user disambiguation as part of an Authentication Flow. You must provide the **userName** attribute as part of the create User request and the service checks for uniqueness. The request fails if the provided **userName** is not unique.

Emails and Phone Numbers

Emails and phone numbers are typical profile attributes that have a unique characteristic in Symantec Identity Security Platform, in that they *can be used* as a Credential for authentication.

To support using email and phone numbers for authentication, an extension to the standard SCIM User Emails/Phone Numbers adds a `verified` attribute: If the Email/Phone Number has a `verified=true` value, these entities populate as email and SMS credentials. Phone numbers support a `capabilityType` attribute, with a value of either `sms` or `ivr` . The IDSP Credential APIs returns these verified emails and phone numbers in the list of User credentials.

Subsequent updates to emails and phone numbers update the appropriate credential value. Changing the verified value of an email or phone number to false removes the associated credential.

The following table describes these attributes:

Attribute	Verified	Capability Type	Populated as a Credential
emails	true/false		When `verified = true`
phoneNumbers	true/false	values: `sms` , `ivr`	When`verified = true` The credential type matches the capability type

Verified emails and phone numbers are also used as authentication factors for Self Service Password Recovery and Self Service Account Unlock. See the Self Service sections for details.

Password Attribute

The password is an optional attribute that can be set on the user depending upon the business solution requirements. Composed passwords must conform to the associated Password Policy rules. AuthHub supports one more applicable Password Policies. A submitted password in a User request that does not conform to the applicable password policy fails the request.

> **NOTE**
> Administrators may or may not be allowed to set the User password. For more information, see the Administrative Password Management section of the Password Management in the Identity Service topic.

In-transit Password Encryption

The User APIs support the ability to encrypt the password in transit. A client of the API can first encrypt the password before making a User request containing the password. This ability is also true for the Password Authenticator. For example: `{tenantName}/scim2/v1/PasswordAuthenticator`

Create User Post-Processing

When a Create User request completes and that request did not have the User password that is defined in the request, the post-processing handler performs the following actions:

- Retrieves the primary email address for the user. If the created user has no defined primary email address, the process aborts.
- Initiates a `PasswordResetInitiator` request.
- Sends a welcome email to the primary email for the user containing a link allowing the user to set their password.

Applications willing to own the Create User Post-processing notifications can turn off the default behavior of sending welcome emails. To do so, set the query parameter `dontSendActivationNotice` to **true** to the create User API. For more information, see User API.

Retrieving Users

The SCIM v2 interface supports retrieving users by resource Id, with a GET operation or searching for users through filters using GET or POST.

These operations appear as follows:

```
GET {tenantName}/scim2/v1/Users/<user_id>
```

```
GET {tenantName}/scim2/v1/Users/?filter={attribute}{op}
{value}&sortBy={attributeName}&sortOrder={ascending|descending}
```

```
POST {tenantName}/scim2/v1/Users/.search
```

```
 {
    "schemas": [
        "urn:ietf:params:scim:api:messages:2.0:SearchRequest"
```

```
    ],
    "filter": "(userType eq Employee) and (jobCode eq 10)"
}
```

Supported Attribute Operators

Attribute Operators	Description
eq	equals
ne	not equals
co	contains
sw	starts with
ew	ends with
pr	present (has a value)
gt	greater than
ge	greater than or equal
lt	less than
le	less than or equal

Examples:

```
?filter=title contains manager
```

```
?filter=department contains operations
```

```
?filter=addresses.country eq usa
```

Supported Logical Operators

You can combine attribute operators with the following logical operators:

Operators	Description
and	logical AND of attribute operators
or	logical OR of attribute operators
not	logical OR of attribute operators

Examples:

```
?filter=userType eq employee and addresses.country eq usa
```

```
?filter=(userType eq employee or userType eq contractor) and addresses.country eq usa
```

Paging Support

Paging is supported for /Users and /Group queries.

Operators	Description
count	Specifies the number of entries to return in each page.
startIndex	The index from the result is set to use for the next page.

Examples:

Returns the first 50 users from the query:

`?`**`count=50&startIndex=1`**`&filter=userType eq employee and addresses.country eq usa`

Returns the next 50 users from the query:

`?`**`count=50&startIndex=51`**`&filter=userType eq employee and addresses.country eq usa`

Attributes to Retrieve

SCIM supports the ability to specify the set of attributes to retrieve with the attributes parameter. The set of attributes that are persisted with the user are returned by default in a user request response. SCIM supports two attribute parameters to control this default behavior, as shown in the following table:

Parameter	Description
attributes	Defines the set of attributes to be returned in a User response.
excludedAttributes	Defines attributes that should not be returned in User response.

NOTE
The **User.groups** attribute is dynamically calculated. Like other attributes, it can be excluded if desired.

Updating Users

You can update Users with either a PATCH or PUT operation. PATCH replaces just the attributes that are specified in the request. PUT replaces the entire user object with the specified attributes in the request, except for attributes that are not writeable using SCIM. See the Internal Id Store Configuration page in the Admin Console for the list of attributes that are not SCIM writeable.

Deleting Users

You can delete users with the DELETE operation. The DELETE operation takes the user ID (mandatory) and ReplaceManager (optional) as input. User deletion is permanent; you can only restore deleted users from the Internal ID Store database backups.

Use the ReplaceManager parameter when deleting a manager to assign the provided managerID to all accounts previously assigned to the deleted manager.

User Self Service

Per SCIM standard in addition to the `/Users` endpoint a `/Me` endpoint (***`{tenantName}/scim2/v1/Me`***) is supported by the Identity Service.

The following additional self service operations are supported using the Identity Service:

- Initiate My Email Verification
- Verify My Email
- Initiate My Phone Number Verification
- Verify My Phone Number
- Get My Verified Credentials

See the complete details in the Identity Self Service section of the Using the REST APIs sections.

To access the Self Service endpoints, you require a User Access token as generated from an authentication flow (`/auth/v1/authenticate`) and a successful authentication that is based on the configured authentication flow.

Simple Attribute Names in API Parameters

Typically, attributes are uniquely identified by prefixing the attribute name with its schema URN separated by a colon (:). For example, the `birthDate` attribute is identified as `attributes=urn:ietf:params:scim:schemas:extension:iam:ssp:1.0:User.birthdate` .

When listing attributes for use with `filter` , `sort` , `attributes` , and `excludedAttributes` when managing users, it is not necessary to specify the complete attribute name (including URN); the simple attribute name is sufficient. For example: `filter=birthDate` .

Manage Groups in the Identity Service

This section provides an overview of the Group Management capabilities and considerations.

Group Management is provided using a standard SCIM v2 interface. The Identity Service and the supported SCIM v2 interface operate on Groups in the Internal Id Store. You can also fully manage Groups using the SCIM interface.

The Group Management APIs are fully documented in the Identity UserUser API and Identity GroupGroup API management sections of the Identity REST APIs sections.

Learn how to manage groups with the Identity Service with the following capabilities:

- Creating Groups with the Identity Service
- Adding and Removing Members with the Identity Service
- Retrieving Groups with the Identity Service

Creating Groups with the Identity Service

You create groups using the Identity Service SCIM2 Group API (***{tenantName}/scim2/v1/Groups***) using a POST operation. Consider the following factors during Group creation.

- ***Group Uniqueness***: Groups must be unique. The **id** and **displayName** attributes are used to guarantee uniqueness. The **id** attribute (also known as the resource Id) identifies the unique SCIM Group resource. The Identity Service automatically generates the **id** attribute on a create group request.
- The **displayName** must also be unique. You must provide the **displayName** attribute as part of the create Group request, and the service checks for uniqueness. The request fails if the provided **displayName** is not unique.

Making a Group Read Only

You set whether groups are read-only using the Identity Service GroupOperator API (`https://${SSP_FQDN}/{{tenantName}}/admin/v1/GroupOperator/{{groupID}}`) using a **readOnly** operational attribute in a POST operation. When the **readOnly** attribute is set to **true** for the group, the principal can read the group details but cannot perform any update or delete operations on the group, including updating group memberships. If set to `false`, principals with the appropriate permissions can read the details of the group and can perform update or delete operations on the group.

You can use the Identity Service GroupOperator API as a GET operation to view the read-only status of a group.

Adding and Removing Members with the Identity Service

The SCIM Group interface includes support for adding Users as members of a given group using the PATCH operation.

> **NOTE**
> Currently the Identity Service limits the maximum number of members to 5,000. Attempts to add members beyond this count cause the Add member operation to fail.

The following example shows add and remove member operations:

```
PATCH /scim2/v1/Groups/<group_id>
{
"schemas": [
    "urn:ietf:params:scim:api:messages:2.0:PatchOp"
],
"Operations": [
    {
        "op": "add",
        "path": "members",
        "value": [
            {
                "value": "89ac5e06-208e-4799-8c06-0ab981aa9848"
            }
        ]
    }
]
}

{
"schemas": [
    "urn:ietf:params:scim:api:messages:2.0:PatchOp"
],
"Operations": [
    {
        "op": "remove",
        "path": "members",
        "value": [
            {
                "value": "86ac5e06-208e-4799-8c06-0ab981aa2212"
            }
        ]
    }
]
}
```

Retrieving Groups with the Identity Service

The SCIM v2 interface supports retrieving groups either by resource Id with a GET operation, or searching for groups with filters using GET or POST.

The following examples show these operations:

```
GET {tenantName}/scim2/v1/Groups/<user_id>
GET {tenantName}/scim2/v1/Groups/?filter={attribute}{op}{value}&sortBy={attributeName}&sortOrder={ascending|
descending}
POST {tenantName}/scim2/v1/Groups/.search
{
"schemas": [
    "urn:ietf:params:scim:api:messages:2.0:SearchRequest"
],
"filter": "displayName eq EmployeeGroup"
}
```

Attributes to Retrieve

SCIM supports the ability to specify the set of attributes to retrieve with the attributes parameter. The set of attributes that are persisted with the group are returned by default in a group request response. SCIM supports two attribute parameters to control this default behavior, as shown in the following table:

Parameter	Description
attributes	defines the set of attributes to be returned in a User response
excludedAttributes	defines attributes that should not be returned in User response

NOTE
`Group.members` is NOT returned by default. This functionality is by design, due to the large number of values that can be returned for groups with many members. Adding the parameter `?attributes=members` returns the members set.

Constraining User and Group Administration by Origin ID

User and Group Administration can be constrained by the Identity Provider (IDP) from which these resources originated.

In Federated Authentication scenarios using Just In Time (JIT) provisioning, authenticated users and their associated groups can be provisioned into the Symantec Identity Security Platform internal identity store. When this JIT provisioning occurs, the originating IDP Identifier is maintained in the originId field of the JITprovisioned resources. Similarly, Users and Groups can be created using the IDSP SCIM API where the originId is specified in the request.

The SCIM User and Group APIs include an option to restrict administration of these users and groups based on a matching origin ID in the access token of the authenticated principal.

Enabling Origin Id in the access token

To enable the presence of the origin ID in the access token, you must configure the client application to invoke the /SCIM2/v1 User or Group API to contain the following metadata property:

Application Metadata Property	Value
urn:iam:app:assertIdpOriginIdOnScimOperations	`<idpID>`

This metadata property can be set using the Application API:

```
https://{{sspHost}}/{{apiPathTenant}}/admin/v1/Apps
```

The following example shows a sample JSON output which includes the required metadata property:

```
metadata": [
      {
          "name": "urn:iam:app:assertIdpOriginIdOnScimOperations",
          "value": "e5f61dec-93e2-4a57-bf6e-0fa27e4592d0"
          // Note: value could be the IDP Name (e.g. “bankingIDP”)
      }
]
```

When this property is set on the client application that is used to obtain an access token for the SCIM API request, the access token contains the following field matching the metadata property value for the application:

```
"idp_origin_id": ["e5f61dec-93e2-4a57-bf6e-0fa27e4592d0"]
```

SCIM Enforcement of origin ID

If the access token associated with the SCIM User or Group request contains the origin ID field as shown in the example above, the SCIM API relies on the value to operate on the matching User and Group resources.

The following table shows the User and Group origin Id attributes:

Resource	Origin ID Attribute
User	idpOriginId
Group	originId

SCIM Operational Semantics when access token has an origin ID field

The following table shows the operational enforcement semantics when the access token that is presented to a SCIM request contains an origin ID field:

Resource	SCIM Operation	Origin ID in Request	Result
User/Group	POST (create)	No	A User or Group is created where <originId> is set to `AT.idp_origin_id`.
		Yes	If <originId> = `AT.idp_origin_id`, a user or group is created containing this <originId> value. Otherwise, returns a not authorized error.
	GET (by ID)	N/A	If User/Group <originId>= `AT.idp_origin_id`, the User or Group is returned. Otherwise, returns a not authorized error.
	GET (search with filters)	No	User/Group <originId> = `AT.idp_origin_id` is added as a default filter.
		Yes	If User/Group <originId> = `AT.idp_origin_id` results are returned. Otherwise, no results are returned.
	PUT/PATCH (update)	No	If User/Group <originId> = `AT.idp_origin_id`, allows the operation. Otherwise, returns a not authorized error.
		Yes	If User/Group <originId> = `AT.idp_origin_id`, allows the operation. Otherwise, returns a not authorized error.

Resource	SCIM Operation	Origin ID in Request	Result
	DELETE	N/A	If User/Group <originId>= `AT.idp_origin_id` the User or Group is deleted. Otherwise, returns a not authorized error.
Group (members)	PUT/PATCH (with members)		For each member to be added or removed, the User.<originId> must match the `AT.idp_origin_id` and the `Group.<originId>`.

Managing the Identity State

There is a set of attributes for the User that control the operational state. These Boolean attributes and their values and operational semantics appear in the following table.

Attribute	Description	Operational Semantics	Default value if not designated in the create request
active	Determines the locked state	true: user is unlocked false: user is locked	false
disabled	Designates the enabled/ disabled state	true: user is disabled false: user is enabled	false
passwordMustChange	Determines if the user must change the password post-authentication	true: user must change password after login false: not required to change password after login	false
updateable	determines if the user can be modified	true: allow user changes false: prevent user changes	true

Password Management in the Identity Service

Identity Service provides Password Management for Users in the Internal ID Store.

The Password Management Operations described in this section only pertain to the Internal ID Store Users.

Learn how to manage passwords with the Identity Service with the following capabilities:

- Defining Password Policies
- The Default Password Policy
- Administrative Password Management
- Modifying Credentials or Profile Attributes for Another Administrator
- Administrative Password Reset and Email Templates
- Setting the Password Must Change Condition for a User
- Sign-in Application Force Change Password
- Federated User Lifecycle Management
- Managing the Federated Lifecycle Using a Privileged Application
- Authentication APIs
- Privileged Application Security Tokens Generation for Password-based Account Activation and Credential Verification

Defining Password Policies

Identity Service lets you define one or more Password Policies. Password policies define the following items:

- Composition rules
- History rule (number of previous passwords to maintain)
- Password age rules
- Optional dictionary of disallowed words in passwords
- Applicable user criteria (a directory search filter of ALL or the set of Groups where members apply)
- A priority value if more than one policy matches a user.
- Options to re-evaluate policies during Authentication
  - Evaluate Composition Rules On Authentication = true. (false by default)
    - Handles cases where a password composition rule has changed and during authentication of a password you want the new rules to take effect immediately. This policy forces the validation of the current password against the updated composition rules. If the current password does not meet the new rules, the user is forced to update their password.
  - Evaluate Expiration Rules On Authentication = true. (false by default)
    - Handles cases where a password expiration rule has changed and during authentication of a password you want the new rules to take effect immediately. This policy requires the validation of the current password age against the updated password expiration rule. If the current password is older than the updated expiration rule, the user is forced to update their password.

The Default Password Policy

A default Password Policy deploys when the Identity Service first deploys in Symantec Identity Security Platform. This password policy is named **DefaultPasswordPolicy.** *This policy cannot be disabled or deleted; it can only be updated.*

Password Policies are consulted in the following operations:

- All Password updates (administrative or self-changes)
- Explicit Invocation of the password validation API (/identity/v1/UserPasswordValidator)
- Invocation of the Generate Temporary Password API (/identity/v1/UserPasswordGenerator)

You can update the default password policy in the Admin Console (see Setting a Password Policy) or the Password Management API (see Password Management API).

Administrative Password Management

An Administrator performs password management on Users either through SCIM or dedicated Password Changer APIs.

Administrative Password Management is a privileged operation that is governed by the following items:

- The **Administrators Can Generate Password** setting (true/false) determines if Administrators can set a user password, and as a result, proves that the administrator has knowledge of that password. For more information, see Configuring the Internal ID Store.
- The Administrator having been granted the User Password Administrator Role that provides the `urn:iam:t.userpasswordadmin` privilege in an Access Token (AT).

The following table describes the Administrator Password semantics based on the setting, and an Administrator granted the User Password Administrator Role.

Setting	Value	`t.userpasswordadmin` privilege	Password Change Behavior
AdministratorCanGeneratePassword	false	Not present in AT	APIs containing a password are not allowed. Requests fail with 403
AdministratorCanGeneratePassword	true	Present in AT	APIs containing a password are allowed

An Administrator performs password management on Users either through SCIM or a dedicated Password Changer API, as shown in the following examples:

`PATCH scim2/v1/User/<userId>`

```
{
    "schemas": [
        "urn:ietf:params:scim:api:messages:2.0:PatchOp"
    ],
    "Operations": [
        {
            "op": "replace",
            "path": "password",
            "value": "Sample@1234"
        }
    ]
}
```

`/identity/v1/UserPasswordChanger`

```
{
    "subject": "defaulttenantadminuser",
    "password": "Sample@1234"
}
```

Modifying Credentials or Profile Attributes for Another Administrator

An AuthHub Administrative User is a user that is granted any administrative privilege using an Auth Hub Administrative Role. Modifying the credentials or profile attributes of another or deleting an Admin User is restricted to a set of highly privileged Administrators.

A subject (authenticated principal) is limited to what changes they can make to an Administrative User target. Unless the following conditions are true for the subject, such subjects require new privileges to modify the credentials of an Administrative User, modify profile attributes, or delete an Administrative User.

1. The subject admin is the target admin (self-modify only, not deletion)
   - **Access Token conditions enforced**:
     `AT.user_guid eq target user_guid`
2. The subject is the Tenant Admin and for the email/phone/password changes the Internal Identity Store Configuration property `adminCanGeneratePassword` is set to true.
   - **Access Token conditions enforced**:
     `AT.scope co (urn:iam:t.all and urn:iam:t.userpasswordadmin)`
3. The subject admin is "System Admin", has been granted either the `urn:iam:t.adminroles` or `urn:iam:t.all` privilege, and for the email/phone/password changes the Internal Identity Store Configuration property `adminCanGeneratePassword` is set to true.

- **Access Token conditions enforced**:

```
AT.tenant eq "system" and AT.scope co (urn:iam:t.adminroles or urn:iam:t.all) and AT.scope co
 urn:iam:t.userpasswordadmin
```

Administrative Password Reset and Email Templates

An Identity Service administrator can set a password for a new user, and initiate a password recovery for a user. The Password Recovery feature relies on either a verified email or a verified phone number to authenticate and deliver a Password Reset Token. This Password Reset Token allows the user to reset their password using a Password Reset Changer Endpoint. Like the token, the Password Reset Changer endpoint message is sent to the primary or selected verified email or verified phone number of the user during the Password Recovery Process.

Administrative Password Recovery Process

The following procedure describes the Administrative Password Recovery Process. The client can be either a deployment-specific client or the Sign-in Application.

1. The Client invokes the API for the User, and returns one or more verified email or phone numbers.
   - **Endpoint URL**: `/identity/v1/VerifiedCredentials`
   - **Operation**: `GET`

   When invoked with the `primaryOnly=true` parameter, the API returns only the verified email or phone number that is set as a primary.
   - **Endpoint URL**: `/identity/v1/VerifiedCredentials?primaryOnly=true`
   - **Operation**: `GET`
2. The user selects a verified email or phone to use to deliver a Password Reset link
3. The client invokes the Password Reset Initiator API that provides the verified email or phone.
   - **Endpoint URL**: `/identity/v1/PasswordResetInitiator`
   - **Operation**: `POST`

   A Password Reset Token is generated. An email or SMS message delivers the password reset link. See the following sub-procedure: “Email and Phone Message Templates for Administrative Password Reset and Create New User”.

   Invoking the `PasswordResetInitiator` with the `newUser=true` parameter delivers a welcome message by email or SMS to the end user that contains the link to reset the password. See the following Message Templates `NEW_USER_WELCOME` actions for more information.
   - **Endpoint URL**: `/identity/v1/PasswordResetInitiator?newUser=true`
   - **Operation**: `POST`

   To activate a new user or reset a password using a vanity URL include the `passwordResetVanityURL` parameter:
   - For new user activation: `/identity/v1/PasswordResetInitiator?newUser=true&passwordResetVanityURL=<vanityIssuerUrl>`
   - For password reset: `/identity/v1/PasswordResetInitiator?passwordResetVanityURL=<vanityIssuerUrl>`
4. The users receive the email or SMS, and then the user selects the link to invoke the Password Reset Changer API with the Password Reset Token.
5. The client invokes the Password Reset Changer API.
   - **Endpoint URL**: `/identity/v1/PasswordResetChanger?token=<reset-token>`
   - **Operation**: `POST`
6. The API verifies the token and, if verified, allows the user to reset their password.

Email and Phone Message Templates for Administrative Password Reset and Create New User

The Administrative password reset email and SMS messages that are delivered are based on the following template actions and message types. The email message requires separate templates for the email subject and the email body.

Message template for SMS messages:

- **Message Action**: `ADMIN_PASSWORD_RESET`
- **Message Type**: `ADMIN.PASSWORD.RESET.SMS`

Message template for email subjects:

- **Message Action**: `ADMIN_PASSWORD_RESET`
- **Message Type**: `PASSWORD.RESET.EMAIL.SUBJECT`

Message template for the email body:

- **Message Action**: `ADMIN_PASSWORD_RESET`
- **Message Type**: `PASSWORD.RESET.EMAIL.BODY`

The welcome messages delivered to a newly created user by the Administrator are based on the following message template actions and message types.

Message template for SMS messages:

- **Message Action**: `NEW_USER_WELCOME`
- **Message Type**: `NEW.USER.WELCOME.SMS`

Message template for email subjects:

- **Message Action**: `NEW_USER_WELCOME`
- **Message Type**: `NEW.USER.WELCOME.EMAIL.SUBJECT`

Message template for the email body:

- **Message Action**: `NEW_USER_WELCOME`
- **Message Type**: `NEW.USER.WELCOME.EMAIL.BODY`

The `Get Messages` API lists the messages in the system.

- **Endpoint URL**: `/admin/v1/Messages`
- **Operation**: `GET`

The `Update Messages` API supports updating the message content.

- **Endpoint URL**: `/admin/v1/Messages`
- **Operation**: `PUT`

Setting the *Password Must Change* Condition for a User

Administrators can force users to change their password the next time that they log in if the `passwordCannotBeChanged` attribute for the user is **false**. An Administrator can do this change by setting the User attribute `passwordMustChange` to **true**. The default is **false**.

Sign-in Application Force Change Password

When authenticating through the Sign-In Application, after the user has completed authentication (which typically includes password as a factor), the user is then redirected to a **Password Must Change** page, if the `passwordCannotBeChanged` attribute for the user is **false**.

Federated User Lifecycle Management

Users can be created in two ways:

- Locally, typically using the SCIM Service API.
- Externally when a user accesses your system from an external identity provider (IdP) and **Just In Time Provisioning** is enabled.

The first time that a user authenticates from an external location, the user is added as a new account. The federated attribute for a user account that is created with Just in Time Provisioning is automatically set as true.

The following topics describe how to create and manage federated users with the SCIM Service API. Users which are service accounts cannot be federated.

NOTE
Federated users have a password only when the `allowLocalPasswordForFederatedUser` flag is set to **true** in the internalIdStoreConfig settings. See Internal ID Store Configuration API.

Creating a federated user

By default, the `federated` flag set to **false** for a user created locally using the SCIM Service API. However, you can manually create a federated user:

1. Use a POST operation to create a user and set them as federated.
2. Set the user attributes as required. Specifically, set the `federated` flag to **true** and provide a valid external IdP or external identity source for the `idpOriginId` flag.

For example:

```
{
    "schemas": [
      "urn:ietf:params: scim:schemas: core:2.0:User",
            "urn:ietf:params: scim:schemas: extension: iam:ssp:1.0:User",
            "urn:ietf: params: scim:schemas: extension:iam:ssp:1.0:User: custom"
    ],
    "userName":
    "displayName":
    "active": true,
    "name": {
            "formatted": "<value>",
            "familyName": "<value>",
            "givenName": "<value>"
    },
    "title": "HR Manager",
    "userType": "Employee",
    ...
    ...
    "urn:ietf: params: scim:schemas: extension: iam:ssp:1.0:User": {
            "gender": "male",
            "birthDate": "1990-01-01T00:00Z",
            "disabled": false,
            "federated": true
    },
    "urn:ietf: params: scim:schemas: extension: iam:ssp:1.0:User:custom": {
            "string1": "value",
            "integer1": "5",
            "boolean1": "true
}
```

Changing a local user to a federated user

To change a user from local to federated:

1. Use a PATCH operation to add `federated` to the schema.
2. Set the `federated` flag to **true** and provide a valid external IdP or external identity source for the `idpOriginId` flag.

3. Optionally, use the `forceReset` flag to require the user to reset the account.

For example:

```
{
   "schemas": [
      "urn:ietf:params:scim:api:messages:2.0:PatchOp"
   ],
   "Operations": [
      {
         "op": "replace",
         "path": "urn:ietf:params:scim:schemas:extension:iam:ssp:1.0:User:federated",
         "value": "true"
      }
   ]
}
```

Changing a federated user to a local user

To change a user from federated to local:

1. Use a PATCH operation to add `local` to the schema. For example:
2. Set the `federated` flag to **false** and, optionally, set the `idpOriginId` flag to **internal**.

For example:

```
{
   "schemas": [
      "urn:ietf:params:scim:api:messages:2.0:PatchOp"
   ],
   "Operations": [
      {
         "op": "replace",
         "path": "urn:ietf:params:scim:schemas:extension:iam:ssp:1.0:User:federated",
         "value": "false"
      }
   ]
}
```

The account is set to an inactive state, and the `passwordMustChange` flag is set to **true**. The user receives a security token in an email or SMS message (depending upon your Managing Message Provider Configuration). The user must reset the password and the account by following the instructions in the email or SMS message.

Using bulk operations to modify the federated flag

The procedures for using a bulk API operation to change a group of users from local to federated, or from federated to local, are nearly the same as when performing the action for single users. However, note the following differences:

- You cannot mix conversion types. That is, you cannot change some users to federated and some to local in the same operation. Use a separate operation for each type of change.
- Bulk conversions can only be performed on users.
- When converting from local to federated, all users in the bulk request must belong to the same idpOriginId.

For more information about bulk API operations, see Bulk API.

User Attribute Status based on token usage and operation

Attribute status per function illustrates the status of User attributes when a token is generated and after it is redeemed, as a result of the following operations:

NOTE
Only one token of any type can exist at one time. Each time a token is generated, the new token overwrites any existing token of that type.

- Resetting a password
- Activating a new user
- Changing a user from federated to local
- Changing a user from local to federated.

Table 81: Attribute status per function

Function	API	
Password Reset	Privileged Client: `/identity/v1/PasswordResetInitiator?target=api`	CRED_RES (Token is ge

New User Activation	Privileged Client:
	`/identity/v1/PasswordResetInitiator?target=api&newUser=true`
	SCIM:
	POST
	`/scim2/v1/Users`
		CRED_RES
		(Token is ge

Federated to Local	Privileged Client: `/identity/v1/PasswordResetInitiator?target=api&federated=false` SCIM: • PATCH `/scim2/v1/Users/` (patching federated as false) • PATCH (Bulk) `/scim2/v1/Bulk`	CRED_RES (Token is ge

Local to Federated	Privileged Client:
	`/identity/v1/PasswordResetInitiator?target=api&federated=true&idpOriginId=`
	SCIM PATCH:
	`/scim2/v1/Users/&?idpOriginId= (patching federated as true) PATCH (Bulk) /scim2/v1/Bulk/?idpOriginId=`
		No token ge

Managing the Federated Lifecycle Using a Privileged Application

The procedures for using a privileged application to change a user from local to federated, or from federated to local, are nearly the same as when using the SCIM Service API. However, note the following differences:

- You must send the following flags:
  - Set `federated` to **true** when converting a local account to federated, or to **false** when converting a federated account to local.
  - Set `idpOriginId` to a valid external IdP or external identity source when converting a local account to federated. Optionally, set `idpOriginId` to **internal** when converting a federated account to local.
- You may optionally set `forceReset` to **true** to require the user to reset the account (the default is **false**).
- You may optionally set the `newUser` to **true** (the default is **false**).

  - If sent, the response acts as a new user accountActivation token. The user must activate the account and reset the password.
  - If not sent, the response includes a password reset URL.
- If the user is changed from local to federated, no security token is generated. If the user is changed from federated to local, a new security token is generated and returned in the API response. The privileged application must provide this security token to the user to reset the account and password.

For more information about privileged applications, see Privileged Application Security Tokens Generation for Password-based Account Activation and Credential Verification.

Authentication APIs

When using the Authentication APIs, after successful authentication the **nextAction** is set to **CHANGE_PASSWORD**. The following code shows examples:

```
/auth/v1/authenticate
{
    "channel": "web",
    "subject": "lawrence_haley",
    "ipAddress": "10.10.123.124",
    "action":"authenticate",
    "acrValues": [],
    "authContext": [
        {
            "key": "useTenantKeyForITEncryption",
            "value": "false"
        }
    ]
}
```

Response (partial):

```
{
    "flowState":
 "NWsvSVZPQUN1Zko5enlWT0JCYUxnUHlxSXlCVVZHK1J0M1l5VnpRR25PeUcyenkrekx1SmJPOUVPUkV6U0czN0tiVDFlSFU3K1RKb3pUQ3R4R2s0OWg3e
    "userName": "lawrence_haley",
    "userId": "89ac5e06-208e-4799-8c06-0ab981aa9848",
    "nextaction": "PASSWORD_AUTH",
    "currentFactors": [
        "PASSWORD"
    ],

}
 /factor/v1/PasswordAuthenticator
{"password":"Sample@1234"}
```

Response (partial):

```
{
    "flowState":
 "NWsvSVZPQUN1Zko5enlWT0JCYUxnUHlxSXlCVVZHK1J0M1l5VnpRR25PeUcyenkrekx1SmJPOUVPUkV6U0czN0tiVDFlSFU3K1RKb3pUQ3R4R2s0OWg3e
    "userName": "lawrence_haley",
    "userId": "89ac5e06-208e-4799-8c06-0ab981aa9848",
    "nextaction": "CHANGE_PASSWORD",
    "currentFactors": [
```

```
        "CHANGEPASSWORD"
    ],
    "data": {
        "errorCode": "1003033",
        "message": "Password authentication success, however password must be changed",
        "passwordResetURL": "https://xxxx/default/ui/v1/signin/initiatePasswordReset?x-flow-
state=NWsvSVZPQUN1Zko5enlWT0JCYUxnUHlxSXlCVVZHK1J0M1l5VnpRR25PeUcyenkrekx1SmJPOUVPUkV6U0czN0tiVDFlSFU3K1RKb3pUQ3R4R2s0C
}
```

Privileged Application Security Tokens Generation for Password-based Account Activation and Credential Verification

Application teams handling their own user onboarding can generate one-time, expiring security tokens to use when notifying users of account activation (password reset), email verification, and phone verification.

Application teams intending to send their own notification can access appropriate APIs like `/identity/v1/PasswordResetInitiator` , `/identity/v1/EmailVerificationInitiator` , and `/identity/v1/PhoneVerificationInitiator` to request security tokens.

Access to these initiator APIs is protected by the `SecurityTokenAdminPolicy` Authorization policy in the `system` tenancy. Clients requiring such capability must request a privileged application in the `system` tenancy and must be granted access to the `SecurityTokenAdminPolicy` Authorization policy.

Applications use the registered ClientId and Client Secret of the privileged application to get an access token by invoking the `/oauth2/v1/token` API using the OAuth2 Client Confidential grant with the `X-Client-Tenant-Name=system` header to assert the tenancy.

Applications would then access the APIs with the query param `target=api` in the Admin mode using the previously generated access token.

```
https://${SSP_FQDN}/{{apiPathTenant}}/identity/v1/PasswordResetInitiator?target=api
https://${SSP_FQDN}/{{apiPathTenant}}/identity/v1/EmailVerificationInitiator?target=api
https://${SSP_FQDN}/{{apiPathTenant}}/identity/v1/PhoneVerificationInitiator?target=api
```

The requesting applications can also send the following optional flags:

Flag	Description
`federated`	Send `federated` to identify the user as accessing your system from an external IdP or external identity source. You must also send the `idpOriginId` flag with this flag. Do not send this flag if you are sending the `local` flag.
`local`	Send `local` to identify that the user is stored in your internal identity store. You must also send the `idpOriginId` flag with this flag. Do not send this flag if you are sending the `federated` flag.
`redirectUri`	Enter the URL where the user is redirected after the user performs an action through the requesting application. The `redirectUri` that is saved against the generated security token, which is then returned during the token redemption. If the `redirectUri` is not provided, then the Application HomeUrl from the AccessToken is saved against the security token.
`idpOriginId`	Send the `idpOriginId` flag to identify the identity source for the user: • Enter a valid external IdP or external identity source when the `federated` flag is sent. • Enter **internal** when the `local` flag is sent.

Flag	Description
`forceReset`	Send the `forceReset` flag to require the user to activate the account and reset the password: • If sent with the `federated` flag, the response includes an activation URL. • If sent with the `local` flag, the response acts as an accountActivation token.

Request Payload

```
{
   "subject": "<sampleUserId>",
   "redirect_uri": "<application-specific-redirect-uri>"
}
```

Example

```
{
   "subject": "ff4eb70e-9c99-4d7d-bacb-b01707b94a1e",
   "redirect_uri": "https://www.example.com"
}
```

Response

```
{
  "activationUrl": "<passwordResetUrl/EmailVerifier/PhoneVerifier>?token=<security-token>"
  "token": "<security-token>"
}
```

Example

```
{
"activationUrl":https://localhost/default/identity/v1/EmailVerifier?token=dpPfHolEoymH6k05HzUayBDRZDK"
  "token": "dpPfHolEoymH6k05HzUayBDRZDK"
}
```

Redeeming the Security token using the activationUrl returns the response, the saved redirectUri if present.

Response

```
{
   "redirect_uri": "<application-specific-redirect-uri>"
}
```

Example

```
{
   "redirect_uri": "https://www.example.com"
}
```

Self Service Account Activation in the Identity Service

The Identity Service provides an option for Users to activate their Account the first time that the user authenticates to the account.

During the User disambiguation phase of authentication the User's activation is checked. If the User account is not activated, they cannot proceed to the authentication phase. In the Sign-in Application, if the identified

user account is disabled and inactive, **accountActivated** is false, **passwordMustChange** is true, and **allowSelfServiceAccountActivation** is set to true, the User is prompted to activate their account. After the user successfully activates their account, they can proceed to the authentication phase.

Enabling Self Service Account Activation

Getting and setting the **allowSelfServiceAccountActivation** property.

The **Get Internal Identity Store Configuration** API is used to retrieve the value.

```
Endpoint URL: /admin/v1/InternalIdStoreConfig
Operation: GET
{
    "idStoreMappingStrategy": "user_loginid=${idprofile.user_loginid}",
    "disambiguationQuery": "user_loginid eq ${loginid} or email eq ${loginid}",
    "unlockAccountAfterPasswordReset": false,
    "useMaskedCredentialValues": false,
    "passwordResetInitiatorUrl": "${system.issuerUrl}/ui/v1/signin/initiatePasswordReset",
    "passwordResetChangerUrl": "${system.issuerUrl}/ui/v1/signin/passwordReset",
    "accountUnlockInitiatorUrl": "${system.issuerUrl}/ui/v1/signin/initiateAccountUnlock",
    "usePriorityToDeterminePrimary": false,
    "allowSelfServiceAccountActivation" : false,
    "customUserAttributes": []
}
```

The **Set Internal Identity Store Configuration** API is used to set all the values including the **allowSelfServiceAccountActivation** property.

```
Endpoint URL: /admin/v1/InternalIdStoreConfig
Operation: PUT
{
    "idStoreMappingStrategy": "user_loginid=${idprofile.user_loginid}",
    "disambiguationQuery": "user_loginid eq ${loginid} or email eq ${loginid}",
    "unlockAccountAfterPasswordReset": true,
    "useMaskedCredentialValues": false,
    "passwordResetInitiatorUrl": "${system.issuerUrl}/ui/v1/signin/initiatePasswordReset",
    "passwordResetChangerUrl": "${system.issuerUrl}/ui/v1/signin/passwordReset",
    "accountUnlockInitiatorUrl": "${system.issuerUrl}/ui/v1/signin/initiateAccountUnlock",
    "usePriorityToDeterminePrimary": false,
    "allowSelfServiceAccountActivation" : true,
    "customUserAttributes": []
}
```

Configuring the Activation Token Delivery

Self service account activation supports only SMS and Email for where the account activation token is delivered. You may set this configuration to SMS, email, or both using the `"accountNotificationStrategyOrder": "email, sms"` property.

```
Endpoint URL: /admin/v1/InternalIdStoreConfig
Operation: GET
{
    "idStoreMappingStrategy": "user_loginid=${idprofile.user_loginid}",
    "disambiguationQuery": "user_loginid eq ${loginid} or email eq ${loginid}",
```

```
    "unlockAccountAfterPasswordReset": false,
    "useMaskedCredentialValues": false,
    "passwordResetInitiatorUrl": "${system.issuerUrl}/ui/v1/signin/initiatePasswordReset",
    "passwordResetChangerUrl": "${system.issuerUrl}/ui/v1/signin/passwordReset",
    "accountUnlockInitiatorUrl": "${system.issuerUrl}/ui/v1/signin/initiateAccountUnlock",
    "allowLocalPasswordForFederatedUser": false,
    "usePriorityToDeterminePrimary": false,
    "accountNotificationStrategyOrder": "email, sms",
    "customUserAttributes": []
}
```

Self Service Password Recovery in the Identity Service

The Identity Service supports the ability for a user to recover their password (aka forgot my password use case). The Password Recovery feature relies on a verified email or verified phone as the means of authentication and delivery of a Password Reset token. This Password Reset Token allows the User to reset their password via a Password Reset Changer Endpoint. The delivery of the token and the Password Changer endpoint is via a message sent to the User selected verified email or verified phone number during the Password Recovery Process.

Learn about passwords recovery with the Identity Service with the following capabilities:

- Password Recovery Process
- Password Recovery via the Sign-in Application
- Email and Phone Password Reset Message Templates
- Email and Phone Number Verification

Password Recovery Process

The Password Recovery Process is shown below. The client can be a deployment specific client or the Sign-in Application.

- The client invokes the API for the User (returns one or more verified email or phone numbers)
  - Endpoint URL: /identity/v1/VerifiedCredentials
  - Operation: GET
- The user selects a verified email or phone to be used to deliver a Password Reset link using the Password Token
- The client invokes the **Initiate Password Recovery** API providing the verified email or phone
  - Endpoint URL: /identity/v1/PasswordResetInitiator
  - Operation: POST
  - A password reset token is generated
  - An email or SMS message is delivered with the password reset token and link (see Password Reset Message Templates, below)

    NOTE
    Only one active password recovery token can exist at a time. Each time the User invokes the **Initiate Password Recovery** API, the operation overwrites any existing password reset token with a new token.
- Users receive the email or SMS and invokes the Password Reset Changer Endpoint with the password reset token
- The client invokes the **Password Reset Changer API**
  - Endpoint URL: /identity/v1/PasswordResetChanger?token=<reset-token>
  - The API Verifies the token and if verified allows the user to reset their password

Password Recovery via the Sign-in Application

When using the Sign-in Application to authenticate to an Application, if a Password Factor is configured for authentication flow when presented with the enter a password screen, a “Forgot Password?” The link appears to initiate the Password Recovery Process.

If the user does not have a verified email or phone number, a **No verified credentials** message appears, and the process halts. Otherwise, a list of verified email and phone numbers appears to the user to use to deliver the password reset token.

If the user's attribute `passwordCannotBeChanged` is set as **true**, then the request is forbidden. If not set to **true**, a confirmation page then appears, instructing the user to check their email or phone for a link to return to sign-in after recovering the password. To complete the password recovery process, the user selects the link in the delivered email or SMS message to display a page where they can then reset their password.

Email and Phone Password Reset Message Templates

The Password Reset email and SMS message delivered are based on the following template actions and message types.

Message Action: PASSWORD_RESETMessage

Type: PASSWORD.RESET.SMS

OR

Message Type: PASSWORD.RESET.EMAIL.BODY

The **Get Messages** API lists the messages in the system.

Endpoint URL: /admin/v1/Messages

Operation: GET

The **Update Messages** API supports updating the message content.

Endpoint URL: /admin/v1/Messages

Operation: PUT

Email and Phone Number Verification

Administrators typically mark User emails and phone numbers form trusted sources as verified when creating or updating users in the Internal Id Store. The following example shows a verified email change:

```
Endpoint URL: /scim2/v1/Users/<user_id>
Operation: PATCH
{
    "schemas": [
        "urn:ietf:params:scim:api:messages:2.0:PatchOp"
    ],
    "Operations": [
        {
            "op": "replace",
            "path": "emails",
            "value": [
                {
                    "value": "some-user@acme.com",
                    "display": "***user@**me.com",
                    "type": "work",
                    "primary": true,
```

```
                    "verified": true
                }
            ]
        }
    ]
}
```

In cases where users do not have a verified email or phone to use in the Password Recovery process, the Identity Service provides Self Service APIs for users to verify their email or phone numbers.

This process appears as follows:

- The User authenticates and generates a User Access Token
  - **Endpoint URL**: oauth2/v1/token
  - **Operation**: POST
- The User invokes the **Initiate My Email Verification** or **Initiate My Phone Number Verification** API with the User Access Token
  - **Endpoint URL**: /identity/v1/MeEmailVerificationInitiator
  - **Operation**: POST
    OR
  - **Endpoint URL**: /identity/v1/MePhoneVerificationInitiator
  - **Operation**: POST
- An email or SMS message is delivered with a verification token (see Verification Message Templates, below)

  NOTE
  Only one type of identity verification token can exist at a time; either an active email verification token or an active phone verification token. Each time the User invokes the **Initiate My Email Verification** or **Initiate My Phone Number Verification API** API, the operation overwrites any existing verification token with a new token of the requested type.
- The user invokes the **Verify My Email** or **Verify My Phone Number** API using the verification token
  - **Endpoint URL**: /identity/v1/MeEmailVerifier?token=<verification token>
  - **Operation**: POST OR
  - **Endpoint URL**: /identity/v1/MePhoneVerifier?token=<verification token>
  - **Operation**: POST
- The user can then confirm the process was successful using the **Get My Verified Credentials** API
  - **Endpoint URL**: /identity/v1/MeVerifiedCredentials
  - **Operation**: GET

Email and Phone Verification Message Templates

The Verification email and SMS message delivered are based on the following template actions and message types.

Message Action: VERIFY_PHONE

Message Type: VERIFY.PHONE.SMS

Message Action: VERIFY_EMAIL

Message Type: VERIFY.EMAIL.BODY

The **Get Messages** API lists the messages in the system.

Endpoint URL: /admin/v1/Messages

Operation: GET

The **Update Messages** API supports updating the message content.

Endpoint URL: /admin/v1/Messages

Operation: PUT

Self Service Account Unlock in the Identity Service

The Identity Service provides an option for Users to unlock their Account. An Account can be locked for a number of reasons including reaching the configured strike limit during authentication. The **User.active** attribute indicates the lock status. A value of false indicates the account is locked.

During the User disambiguation phase of authentication the User's lock state is checked. If the User is locked, they cannot proceed to the authentication phase. In the Sign-in Application if the identified user is locked and Self Service Account Unlock is enabled, an option is provided to allow the User to unlock their account. After the user successfully unlocks their account, they can proceed to the authentication phase.

The Identity Service relies on the Internal Identity Store Configuration's **unlockAccountAfterPasswordReset** property to determine if the self-service account unlock feature can be used. Self Service Account unlock is disabled by default. The Self Service Account Unlock Flow is implemented via an invocation of a successful Password Recovery (Reset) Process.

When **unlockAccountAfterPasswordReset=true**, the user's account unlocks when the Password Reset process completes.

Enabling Self Service Account Unlock

Getting and setting the **unlockAccountAfterPasswordReset** property.

The **Get Internal Identity Store Configuration** API is used to retrieve the value.

```
Endpoint URL: /admin/v1/InternalIdStoreConfig
Operation: GET
{
    "idStoreMappingStrategy": "user_loginid=${idprofile.user_loginid}",
    "disambiguationQuery": "user_loginid eq ${loginid} or email eq ${loginid}",
    "unlockAccountAfterPasswordReset": false,
    "useMaskedCredentialValues": false,
    "passwordResetInitiatorUrl": "${system.issuerUrl}/ui/v1/signin/initiatePasswordReset",
    "passwordResetChangerUrl": "${system.issuerUrl}/ui/v1/signin/passwordReset",
    "accountUnlockInitiatorUrl": "${system.issuerUrl}/ui/v1/signin/initiateAccountUnlock",
    "usePriorityToDeterminePrimary": false,
    "customUserAttributes": []
}
```

The **Set Internal Identity Store Configuration** API is used to set all the values including the **unlockAccountAfterPasswordReset** property.

```
Endpoint URL: /admin/v1/InternalIdStoreConfig
Operation: PUT
{
    "idStoreMappingStrategy": "user_loginid=${idprofile.user_loginid}",
    "disambiguationQuery": "user_loginid eq ${loginid} or email eq ${loginid}",
    "unlockAccountAfterPasswordReset": true,
    "useMaskedCredentialValues": false,
    "passwordResetInitiatorUrl": "${system.issuerUrl}/ui/v1/signin/initiatePasswordReset",
```

```
    "passwordResetChangerUrl": "${system.issuerUrl}/ui/v1/signin/passwordReset",
    "accountUnlockInitiatorUrl": "${system.issuerUrl}/ui/v1/signin/initiateAccountUnlock",
    "usePriorityToDeterminePrimary": false,
    "customUserAttributes": []
}
```

Self Service Password Reset for a Federated User

The Identity Service provides an option for Federated users to reset their Account Password. In the Sign-in Application, if the identified user forgets their password, an option allows the user to reset their account password. After the user successfully resets their account password, they can authenticate.

The Identity Service relies on the Internal Identity Store Configuration's `allowLocalPasswordForFederatedUser` property to determine if federated users can use the self-service account password reset feature. The self service account password reset is disabled by default. Setting `allowLocalPasswordForFederatedUser=true` allows the user's account password reset during the Sign-In flow.

Enabling Self Service Account Password Reset for Federated Users

Use the following code to get and setting the `allowLocalPasswordForFederatedUser` property.

The **Get Internal Identity Store Configuration API** is used to retrieve the value.

```
Endpoint URL: /admin/v1/InternalIdStoreConfig
Operation: GET
{
    "idStoreMappingStrategy": "user_loginid=${idprofile.user_loginid}",
    "disambiguationQuery": "user_loginid eq ${loginid} or email eq ${loginid}",
    "unlockAccountAfterPasswordReset": false,
    "useMaskedCredentialValues": false,
    "passwordResetInitiatorUrl": "${system.issuerUrl}/ui/v1/signin/initiatePasswordReset",
    "passwordResetChangerUrl": "${system.issuerUrl}/ui/v1/signin/passwordReset",
    "accountUnlockInitiatorUrl": "${system.issuerUrl}/ui/v1/signin/initiateAccountUnlock",
    "allowLocalPasswordForFederatedUser": false,
    "usePriorityToDeterminePrimary": false,
    "customUserAttributes": []
}
```

The **Set Internal Identity Store Configuration API** is used to set all the values, including the `allowLocalPasswordForFederatedUser` property.

```
Endpoint URL: /admin/v1/InternalIdStoreConfig
Operation: PUT
{
    "idStoreMappingStrategy": "user_loginid=${idprofile.user_loginid}",
    "disambiguationQuery": "user_loginid eq ${loginid} or email eq ${loginid}",
    "unlockAccountAfterPasswordReset": false,
    "useMaskedCredentialValues": false,
    "passwordResetInitiatorUrl": "${system.issuerUrl}/ui/v1/signin/initiatePasswordReset",
    "passwordResetChangerUrl": "${system.issuerUrl}/ui/v1/signin/passwordReset",
    "accountUnlockInitiatorUrl": "${system.issuerUrl}/ui/v1/signin/initiateAccountUnlock",
    "allowLocalPasswordForFederatedUser": true,
    "usePriorityToDeterminePrimary": false,
    "customUserAttributes": []
}
```

NOTE
An Identity Administrator can always reset a federated User password without any dependency with the `allowLocalPasswordForFederatedUser` Internal Store Configuration property.

Self Service Password Recovery and Account Unlock API

The Identity Service supports APIs allowing users to recover their password (aka forgotten password). The APIs rely on a User's verified email or verified phone as supported credentials to allow recovery.

The Account Unlock is a configurable capability. If enabled (using the **unlockAccountAfterPasswordReset** property on the Internal ID Store), when the **PasswordResetChanger** completes, the account unlocks.

Operation Description	Operation Types	Endpoint URLs
Self Service Password Recovery		
Get Verified Credentials	POST	`https://${SSP_FQDN}/{{tenantName}}/identity/v1/VerifiedCredentials`
Password Reset Initiator	POST	`https://${SSP_FQDN}/{{tenantName}}/identity/v1/PasswordResetInitiator`
Password Reset Validator	POST	`https://${SSP_FQDN}/{{tenantName}}/identity/v1/PasswordResetValidator`
Password Reset Changer	POST	`https://${SSP_FQDN}/{{tenantName}}/identity/v1/PasswordResetChanger`
Self Service Account Unlock		**Note**: If Self Service Account unlock is enabled, Account Unlock is executed once the Password Reset API sequence completes.
Verified Credentials return only primary, verified credentials	GET	`/identity/v1/VerifiedCredentials?primaryOnly=true/false`

NOTE

- To know the value of ${SSP_FQDN} environment variable, see Configuring IDSP Environment Variables.
- The default value for `<tenantName>` is "default".
- Replace the text {{text}} including {{}} characters with appropriate values, in all the endpoints shown in the above table.
  For example:
  `https://{{host}}/{{tenantName}}/identity/v1/PasswordResetChanger`
  should look similar to:
  `https://example.com/default/identity/v1/PasswordResetChanger`
- To know more about the scopes that are required to secure these APIs, refer to the Rest APIs and Associated Privileges section.

Sample Get Verified Credentials Request:

```
{
    "subject": "lhaley",
    "type": "email,sms"
}
```

Sample Get Verified Credentials Response:

```
[
```

```
    {
        "displayValue": "la*******@example.com",
        "deliveryType": "email",
        "credId": "5d69daad-ee81-4504-9daf-20228226f600"
      },
    {
        "displayValue": "xxxxxx5555",
        "deliveryType": "sms",
        "credId": "e8db1ce9-0a2a-4e1b-b617-1be09968d95f
    }
]
```

Sample Password Reset Initiator:

```
{
    "subject": "lhaley",
    "deliveryType": "email",
    "credId" : "e8db1ce9-0a2a-4e1b-b617-1be09968d95f",
    "language": "en_US"
}
```

Sample Password Reset Response:

```
{
    "token": "7cjbMij1IRcTcFD8hkq9lkVQzssrlgVJ"
}
```

NOTE
A token is normally not returned in the response. This sample response shown was returned when the cluster is deployed in test mode. The token is normally delivered to the verified email or phone only.

Sample Password Reset Changer request:

```
POST https://${SSP_FQDN}/{{apiPathTenant}}/identity/v1/PasswordResetChanger?
token=7cjbMij1IRcTcFD8hkq9lkVQzssrlgVJ
```

Configuring the Token Delivery for Password Reset and Account Unlock

Password Reset and Account Unlock token delivery support only SMS and Email. You may set this configuration to SMS, email, or both using the `"selfServiceAccountNotificationStrategy": "email, sms"` property.

```
Endpoint URL: /admin/v1/InternalIdStoreConfig
Operation: GET
{
    "idStoreMappingStrategy": "user_loginid=${idprofile.user_loginid}",
    "disambiguationQuery": "user_loginid eq ${loginid} or email eq ${loginid}",
    "unlockAccountAfterPasswordReset": false,
    "useMaskedCredentialValues": false,
    "passwordResetInitiatorUrl": "${system.issuerUrl}/ui/v1/signin/initiatePasswordReset",
    "passwordResetChangerUrl": "${system.issuerUrl}/ui/v1/signin/passwordReset",
    "accountUnlockInitiatorUrl": "${system.issuerUrl}/ui/v1/signin/initiateAccountUnlock",
    "allowLocalPasswordForFederatedUser": false,
    "usePriorityToDeterminePrimary": false,
    "selfServiceAccountNotificationStrategy": "email, sms",
    "customUserAttributes": []
}
```

Setting-Up the Demo Environment

Learn how to set up and run the Symantec Identity Security Platform demo environment.

This section outlines the sample demo environments that are offered by the solution, and the steps to deploy and configure these environments for testing.

Prior to deploying and configuring the demo environment for multi-factor authentication, it is crucial to familiarize yourself with key concepts. This includes understanding the embedded sample directory within the environment, reviewing sample policies, and understanding the various use cases available. You can find detailed information regarding these aspects in the following links:

- IDSP Concepts (includes use of Internal Identity Store, and Sample policy)
- Understanding the Demo Use Cases
- Deploying Demo Web Application
- Deploying Demo Mobile Application (Android and iOS)

Sample Applications

IDSP provides sample Web and Mobile applications to try out the authentication features.

Web Application

The Sample Web demo application discusses how to set up a demo environment and test the various multi-factor authentications flows offered by the solution. The demo environment can be set up by deploying the Sample application. To set up your web demo environment, see Deploying Demo Web Application.

Mobile Application

The Sample Mobile application aims to demonstrate an easy and complete framework for testing multi-factor authentication flows by using a mobile app. The Sample Mobile application is called "*Hedmoral"* application and is available in both, Android and iOS platform. See Deploying the Demo Mobile Application for more details.

Out of the Box - DemoClient

The IDSP provides a DemoClient app that is seeded with a client id and secret out of the box. This app performs the following tasks for you and immediately prepares the Sample application for use.

1. Creates an application
2. Creates a policy and associates it to the application
3. Updates the Authorization (AuthZ) policy with the required privileges

The DemoClient credentials are stored as a secret in the IDSP cluster. We have incorporated the step to retrieve the DemoClient client id and secrets from Kubernetes, in the web and mobile application topics respectively. In web app, see Deploying Sample App in IDSP Namespace, and under Deploying the Sample Application and in Mobile app, see section, Obtaining Client Id and Secret.

Symantec Identity Security Platform Concepts

Learn about Symantec Identity Security Platform concepts, Sample DIT, and Sample Policy.

This topic includes the following:

- IDSP Concept
- Internal Identity Store
- Sample Policy Used for Demo

IDSP Concepts

Before trying out the use cases in the demo environment, we recommend you to go through these concepts:

- Risk
- Policy
- Factors
- Step-Up functionality

Use of Internal Identity Store in the Demo Environment

The demo environment comes with an embedded Internal Identity store. Users and Groups along with demo-client app gets created in this environment. You can make use of these sample users to test the solution's multi-factor authentication capabilities. To know more about the sample users, see Demo Users.

Sample Policy Used for Demo

The sample policy comprises of a set of ***conditions*** defined in ***rules*** that govern the workflows that users must comply with, to access a protected resource. This sample policy is provided to users who are interested in implementing the use cases that are mentioned here.

```
{

        "policyId": "ead57040-d5bc-42be-ac41-91d7a5e8f50f",

        "policyName": "Feature Policy for Demo client",

        "description": "Feature Policy Demo client",

        "status": "active",

        "matchAnyApp": false,

        "apps": [

            {

                "name": "DemoClient",

                "id": "52caabed-c3ea-4e6a-bb0f-afda7029dded"

            }

        ],

        "rules": [

            {

                "id": "5e83badc-1e0e-45f8-ab80-0da55a050a6a",

                "conditions": {

                    "principal": {
```

```
            "group": {
                "operator": "in",
                "value": [
                    "Human Resources"
                ]
            }
        },
        "action": {
            "operator": "in",
            "value": [
                "authenticate"
            ]
        },
        "channel": {
            "operator": "in",
            "value": [
                "web",
                "mobile"
            ]
        }
    },
    "result": {
        "effect": "allow",
        "reAuthenticate": "false",
        "obligations": [
            "PASSWORD:1",
```

```
                        "EMAILOTP:2",
                        "SMSOTP:2",
                        "FIDO:2",
                        "SECURITYKEY:2"
                    ],
                    "msg": "This condition is for the Human Resources Group with PW+OTP or PW+FIDO or PW
+SECURITYKEY on the Web and Mobile Channels. Login with edunn for autoenrol and erussell for inline enrol."
                }
            },
            {
                "id": "a8eca05b-2e0b-4165-ad2a-e9985160dbf4",

                            "web"
                        ]
                    }
                },
                "result": {
                    "effect": "allow",
                    "reAuthenticate": "false",
                    "obligations": [
                        "PASSWORD:1"
                    ],
                    "msg": "This condition is for the Employees Group with Password Only - Login with nbruce. Also for the Security Administrators Group when using OAuth/OIDC Postman flows - Login with mhunter, rchase, or vhickey."
                }
            },
            {
                "id": "faac6d75-a045-49a3-938a-aa5bd626e8bc",
                "conditions": {
                    "principal": {
                        "group": {
                            "operator": "in",
                            "value": [
                                "Employees"
                            ]
                        }
```

```
                    },
                    "action": {
                        "operator": "in",
                        "value": [
                            "commercial"
                        ]
                    },
                    "channel": {
                        "operator": "in",
                        "value": [
                            "web",
                            "mobile"
                        ]
                    }
                },
                "result": {

Understanding the Demo Use Cases

This section outlines the different multi-factor authentication use cases that are supported by Symantec Identity Security Platform Sample Web Application.

> **NOTE**
> Sample Web application is used to perform these use cases. To know more about it, see Deploying Sample Web application.

This page includes the following topics:

Common Terminologies

This section helps you understand certain terminologies that have been used in the use cases.

1. Multi-factor authentication (MFA)

Multi-factor authentication is an authentication method where a user is given access to a protected resource only after two or more factors have been authenticated. The authentication mechanism is categorized into the following three factors:

Authentication Mechanism	Description	Examples
Something you KNOW (Knowledge)	Things that you know	Password, Pin
Something you HAVE (Possession)	Things that you have. Security Key based authentication	Yubikey, OTP
Something you ARE (Inherence)	Some form of a physical characteristic of you (Biometrics)	Fingerprint

2. Two-factor authentication (2FA)

This is a way of validating the claimed identities of the users by combining two different factors. These factors may include a combination of any two types of the following authentication:

1) something they know, 2) something they have, or 3) something they are.

3. User Profile

When users attempt to log into a secured application having access to sensitive applications, belonging to groups such as HR that perform sensitive tasks, untrusted IP's, or have higher risk scores based on the risk factor evaluation, all such users are identified with varying levels of risks and therefore, classified into three different categories:

- High-Risk User Profile- A user profile with a higher risk score is considered a high-risk user profile. This type of user profile leads to higher challenges and most definitely requires multi-factor authentication.
- Medium Risk User Profile - A user profile with a medium risk score is considered a medium-risk user profile. This type of user profile is needed to undergo a two-factor authentication.
- Low-Risk User Profile- A user profile with a low-risk score is considered a low-risk user profile. This type of user profile is mostly requested for single-factor authentication.

4. Auto Enrolment

Auto Enrolment is a process wherein users are automatically enrolled in the IDSP when their Personally Identifiable Information (PII), such as phone number and/or email ID, is updated in the User Directory prior to performing any form of authentication. Only the OTP factor can be auto-enrolled.

5. Inline Enrolment

This is a process whereby users can immediately register their credentials in IDSP, if they have not done so before performing any form of authentication. Users can complete this process by following the prompts in their mobile or web application, whichever device is used to authenticate. If the users are entitled to multiple authentication factors, then they are prompted to select which factor they would like to enrol. When the inline enrolment process completes, user credentials are updated in the solution. The next time users log in, they will be presented with the authentication factors for which they have enrolled their credentials. For more information, see Configuring Inline Enrolment.

Demo Users

The following table details the demo users, and the demo use cases that can be executed for testing the environment.

Full Name	Username	Groups	Notes	Authentica
Nina Bruce	nbruce ("vburn", "swise" These are alternate users in the Employee group.)	Employees	Web Channel, Low risk	password
			Mobile Channel	Password uses FIDO
			Untrusted IP address and thereby has been identified as a high-risk user profile	Two-factor • Passwo by • SMS or
Enid Dunn	edunn	Human Resources	Medium risk	Two-factor • Passwo by • Email C
Emily Russell	erussell	Human Resources	Medium risk Both Web and Mobile Channels	Two-factor • Passwo • OTP or
Brenda Steer	bsteer	Finance	High risk	Two-factor • Passwo • Biomet
Christopher Moran	cmoran ("rrex"- This is an alternate user in the Development group)	Development	Frictionless Authentication	Password- scanner or
Dean Roth	droth	Customers	Migrate to using password-less authentication	• Passwo • Biomet • Securit • Push A

Web Use Cases

Business Owners with Low-Risk User Profiles require a Low Level of Assurance to access Application

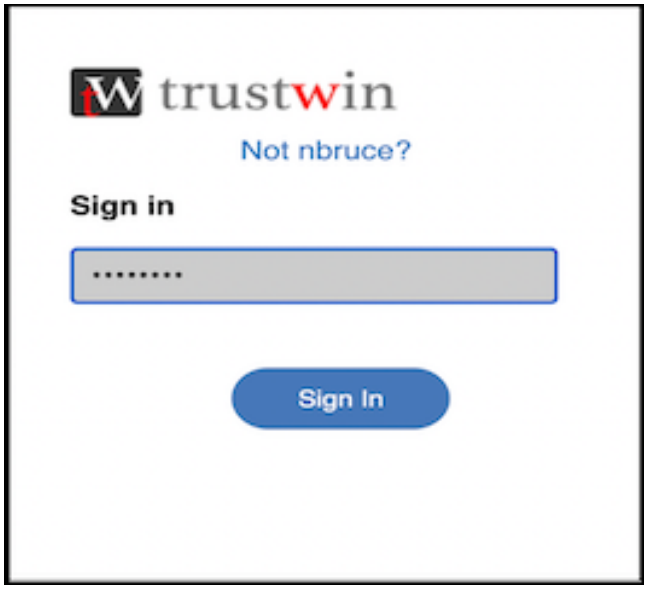
Assumption:

Nina Bruce (nbruce) is identified as a low-risk user by the IDSP. Therefore, she is asked to authenticate with minimum factor, 'Password' to access the Sample application. Her email Id and phone number are updated in the user directory prior to the authentication.

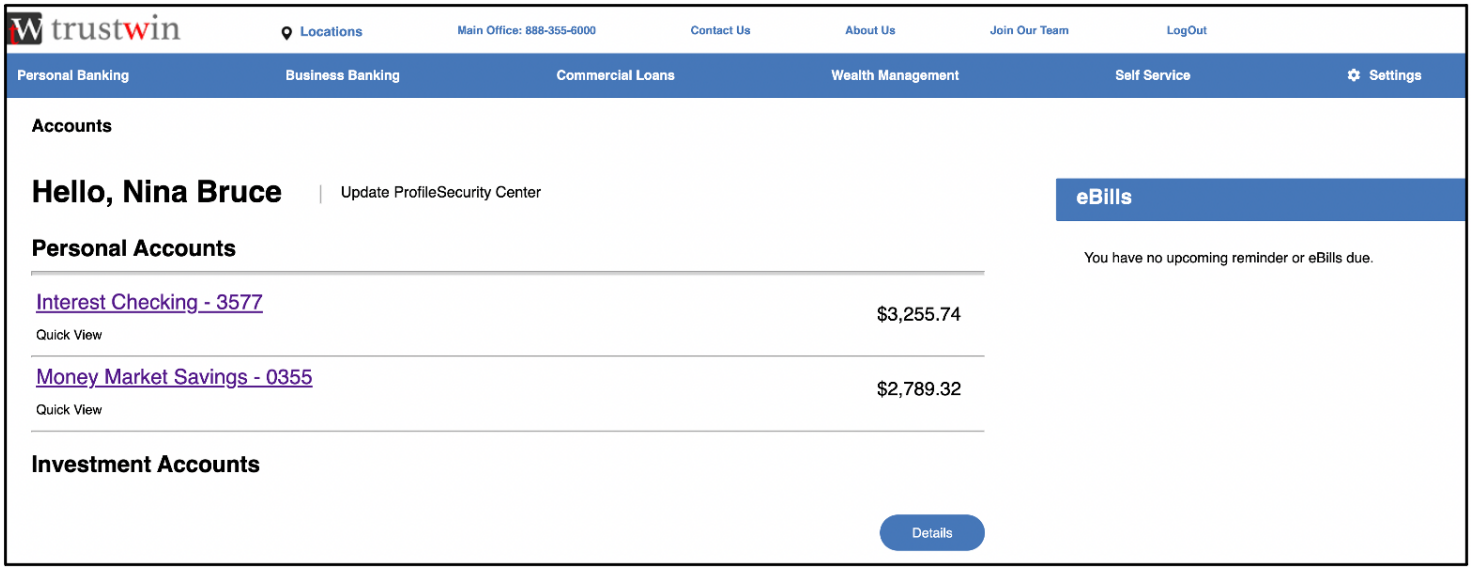
User Flow:

Nina Bruce logs into the Sample application with ‘Password’ (Something she knows) and gets access. She is not prompted to any other form of authentication. The following figure shows the Sign In page where she enters her username.

She enters her password to authenticate.



Nina gets access to the login page after successfully authenticating with her password.



Security Admins want to protect access to Personally Identifiable Information (PII) and therefore requires users to undergo Two-Factor Authentication

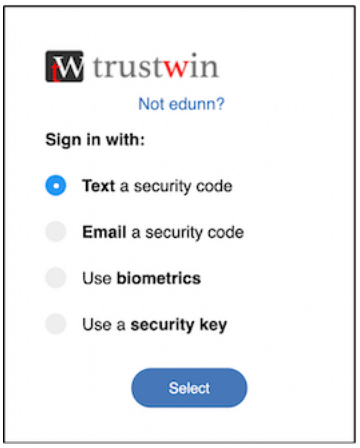
Assumption:

Enid Dunn (edunn) is a member of the HR Team and has access to Personally Identifiable Information (PII) information of customers. Therefore, she has been requested to undergo two-factor authentication, performing Password authentication as the first factor, followed by Email OTP or FIDO as the second factor. She has registered her phone number in the user directory prior to the authentication, which was used by the solution to create her SMS OTP credential. She goes ahead with SMSOTP as the second factor.

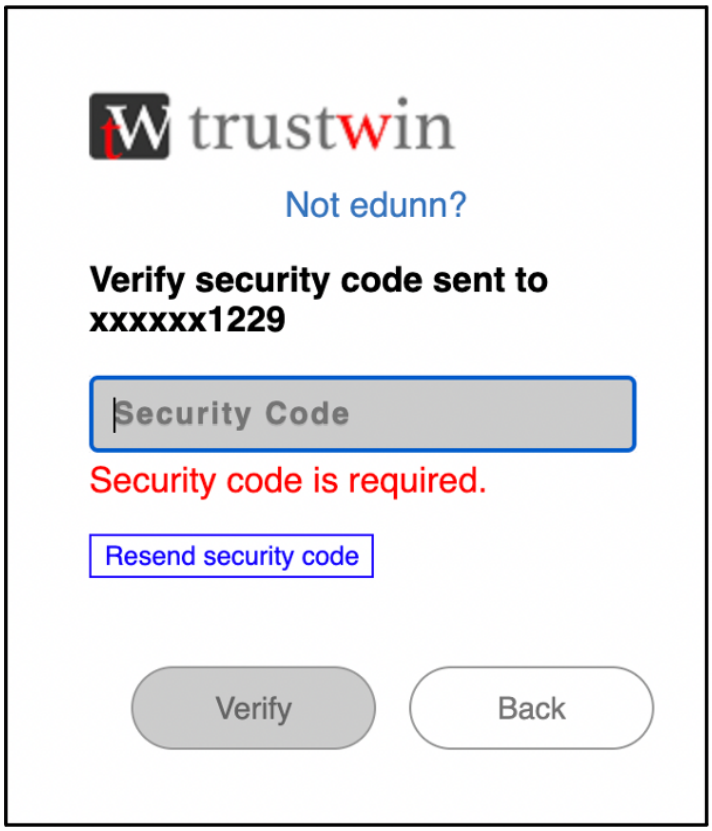
User Flow:

Enid Dunn logs into the sample application using a password (something she knows). Upon successfully authenticating with the password, she is presented with the following screen, where she is required to select a second factor. She opts for SMSOTP authentication (something she has).

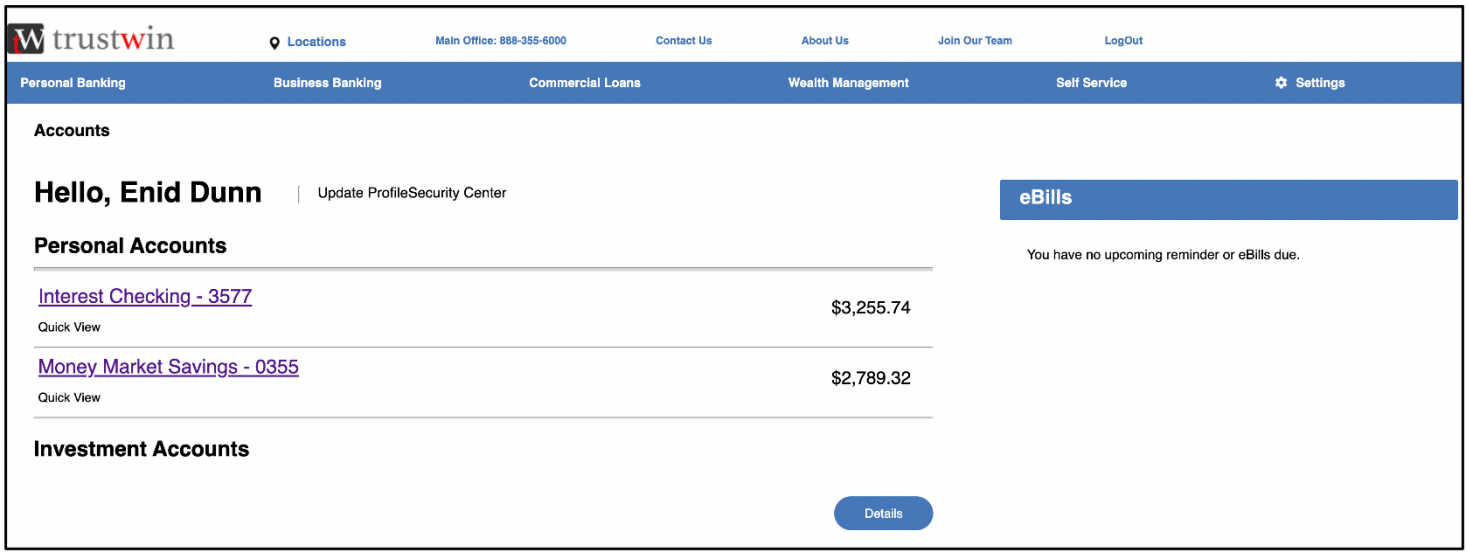
In the following figure, Enid selects email as the credential type where she gets the OTP delivered



Here, she selects "Text a security code" as the credential type and the OTP gets delivered to her registered number.



She enters the code, successfully authenticates the second factor, and gains access to the Sample application. The following figure shows the Sample app page to which Enid Dunn gets access after authenticating with SMSOTP.



Business Owners want to provide the option of inline enrolment to the users who have been requested with Two-Factor Authentication

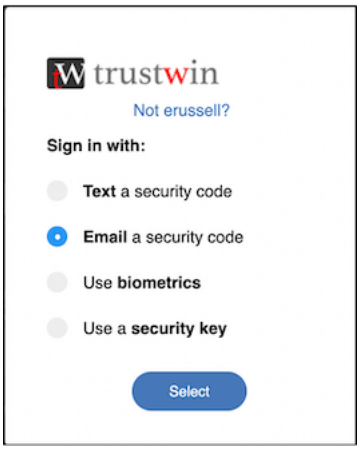
Assumption:

Emily Russell (erussell) is a member of the HR team and has access to Personally Identifiable Information (PII) of customers. Therefore, she has been requested to undergo two-factor authentication, performing Password authentication,

followed by OTP or FIDO. Her OTP credentials, such as phone number or email ID have not been registered in the user directory so she is prompted to perform an inline enrolment.

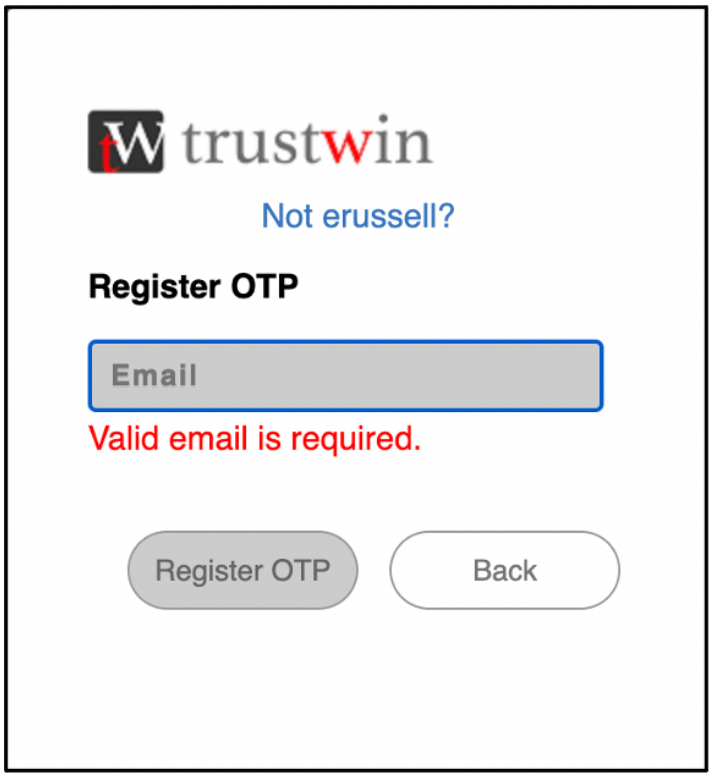
User Flow:

Emily Russell logs into the Sample application using a password (something she knows). Upon successfully authenticating with the password, she is presented with the following screen, where she is required to select a second factor.



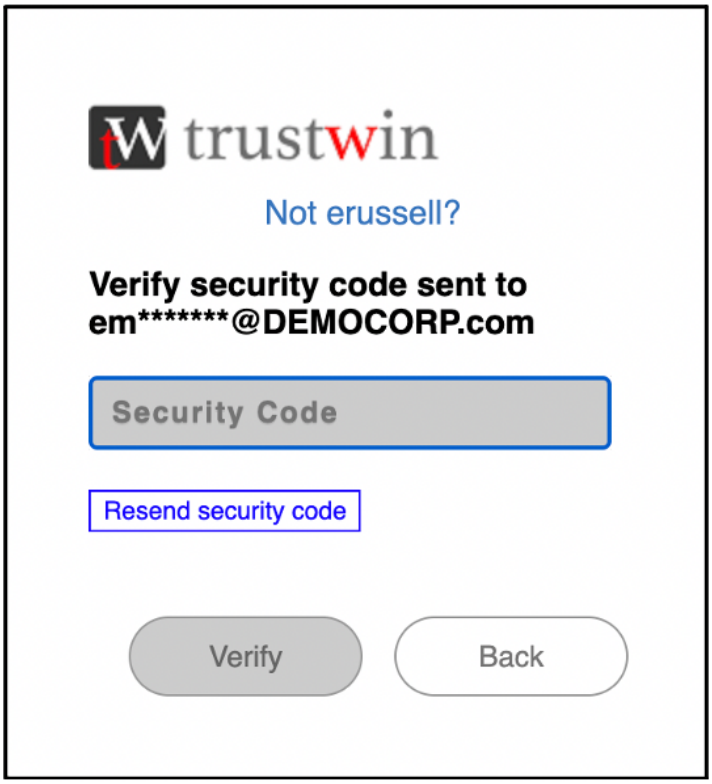
She opts for Email OTP authentication (something she has), therefore, she is prompted to register her Email OTP credentials through inline enrolment.

The following figure shows the inline enrolment page presented to Emily Russell where she must register her EMAIL to get the OTP delivered.

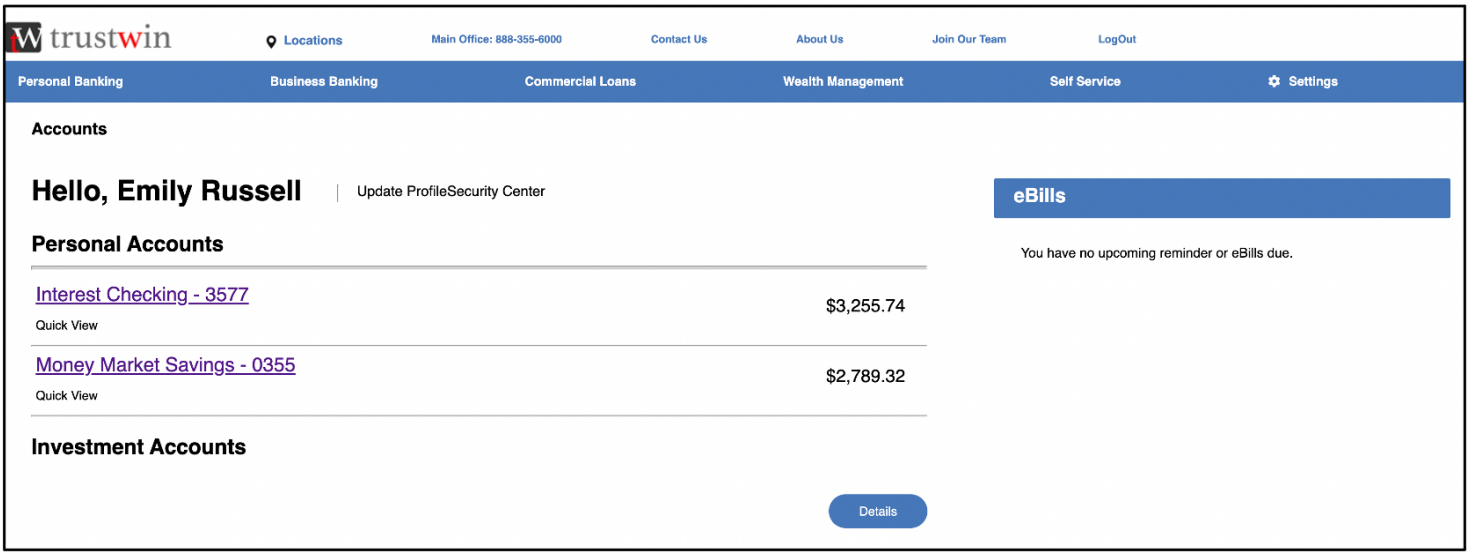


She registers her email Id where the OTP gets delivered.

In the following figure she by entering the email OTP that she received in her email.



The following figure shows the Sample app page to which Emily Russell gets access after authenticating with Email OTP.



Security Admins require Multi-Factor Authentication for High-Risk Users

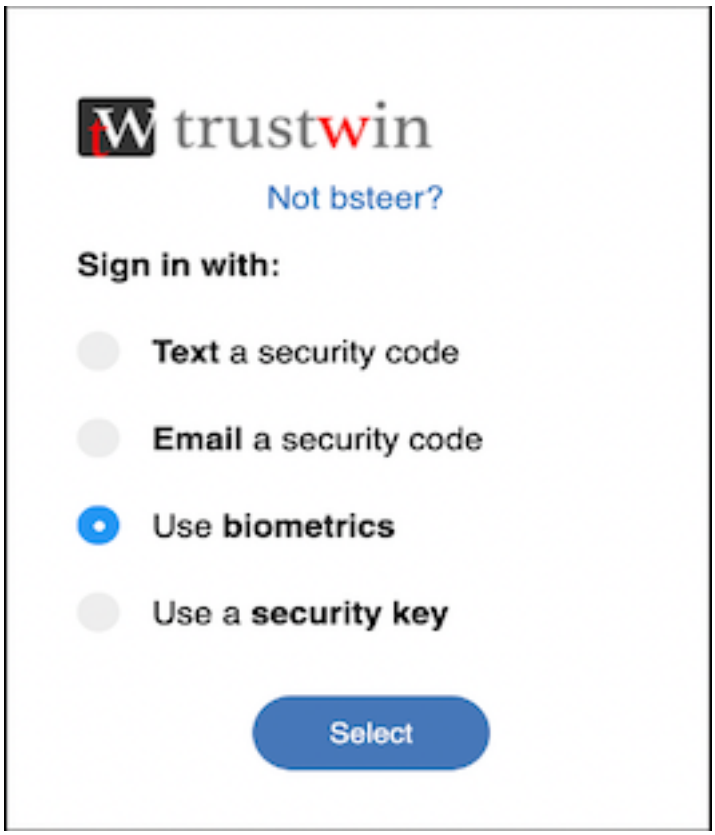
Assumption:

Brenda Steer (bsteer) is a member of the Finance Team and she has been identified as a high-risk user. She has been requested to undergo two-factor authentication, performing Password authentication, followed by

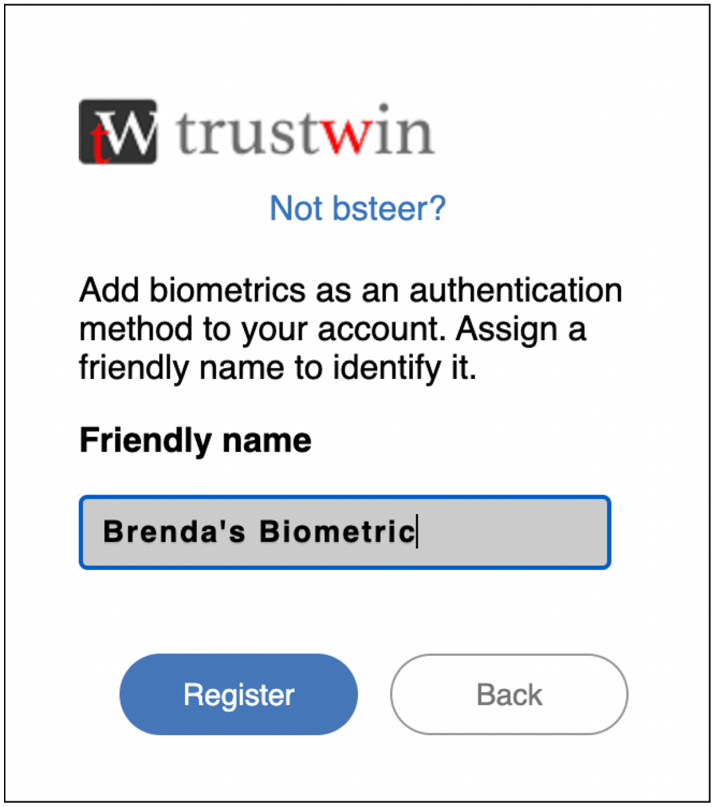
Biometrics authentication using her fingerprint. She is a new user and has not registered her Biometric credential in IDSP, so she is prompted to enroll inline.

User Flow:

Brenda Steer logs into the application using her password. Upon successfully authenticating with her password, she is prompted to select a second factor to register inline. In the following figure, she opts to register her Biometrics.



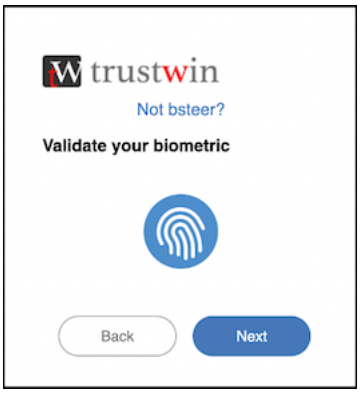
In the following figure, Brenda performs inline enrolment to register her biometrics.



She is displayed with the following screen to validate her fingerprint.

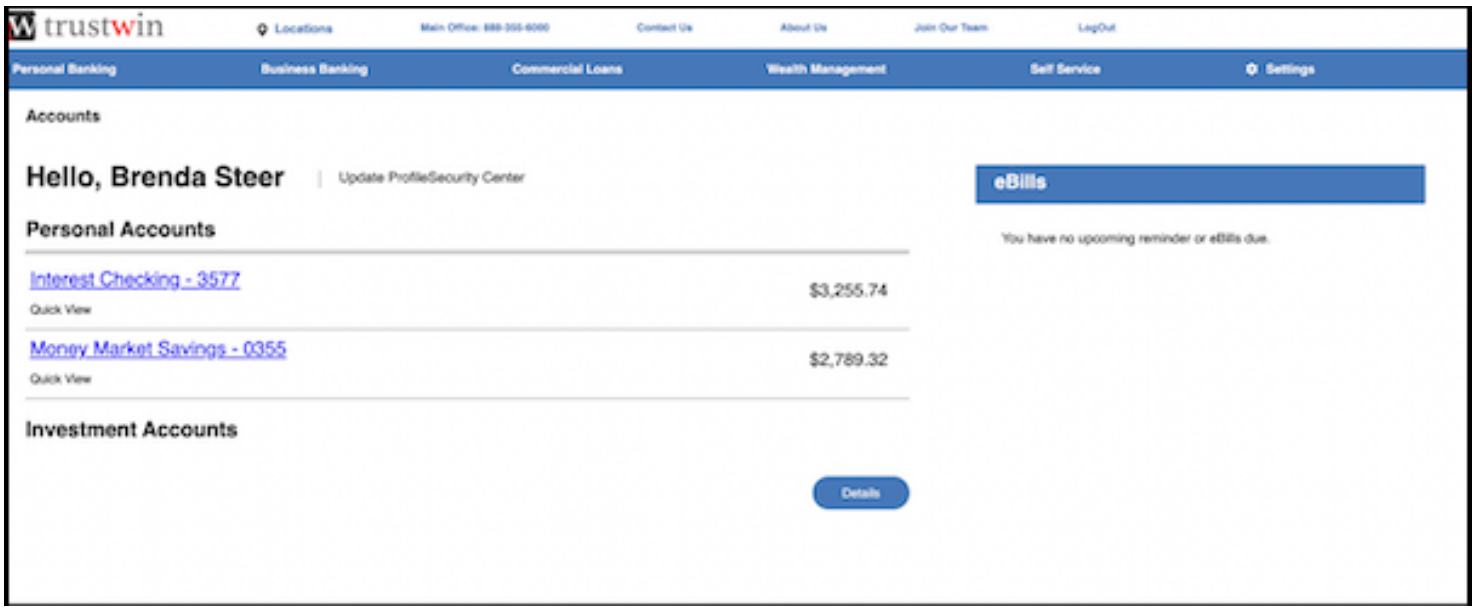
She validates her fingerprint by tapping on the fingerprint scanner that is embedded in her laptop. At this point, her biometric registration is complete.

In the following screen, Brenda clicks Next.



She is displayed with the following validation screen again, but this time it is for second-factor authentication.

Upon successfully authenticating with her fingerprint, she gains access to the protected application.



The next time that she attempts to log in, she will be prompted to enter her password and authenticate with her biometric.

Business Owners require Frictionless Authentication reducing the burden on customers while maintaining strong security

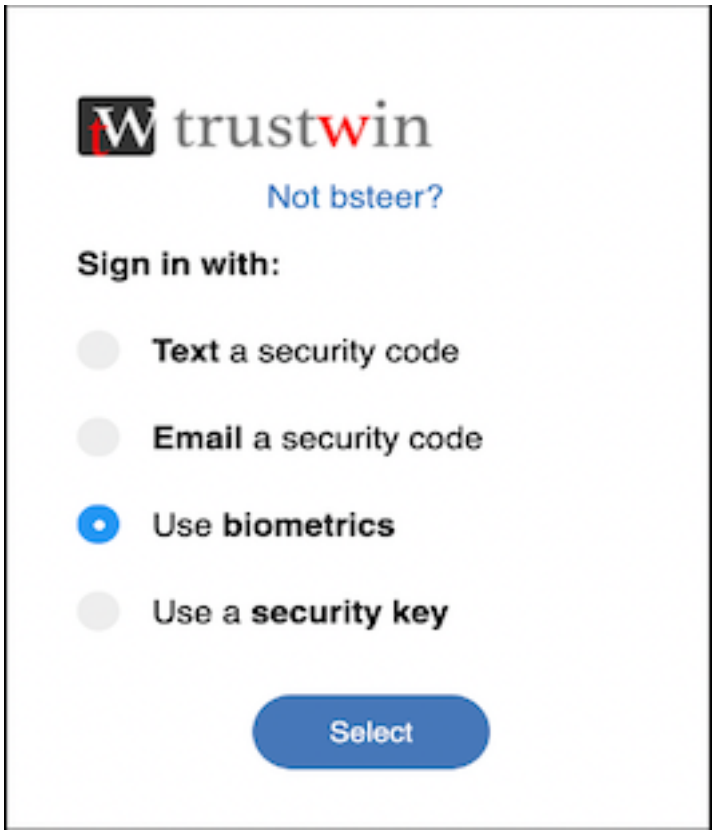
Assumption:

Christopher Moran (cmoran) is a member of the Development Team. He wants to be able to use password-less authentication by using a fingerprint scanner on his Mac computer (FIDO protocol). He is a new user and has not registered his biometric credentials in IDSP prior to the authentication, so he is prompted to enroll inline.

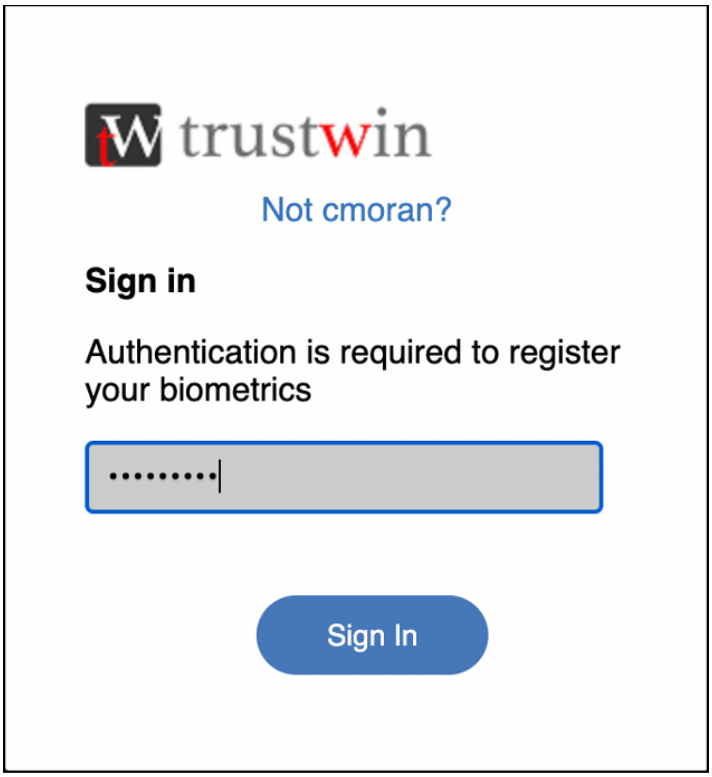
User Flow:

Christopher Moran logs into the Sample application by entering his username and password. After authenticating with the password, he is prompted to select one of the two factors to continue the authentication flow.

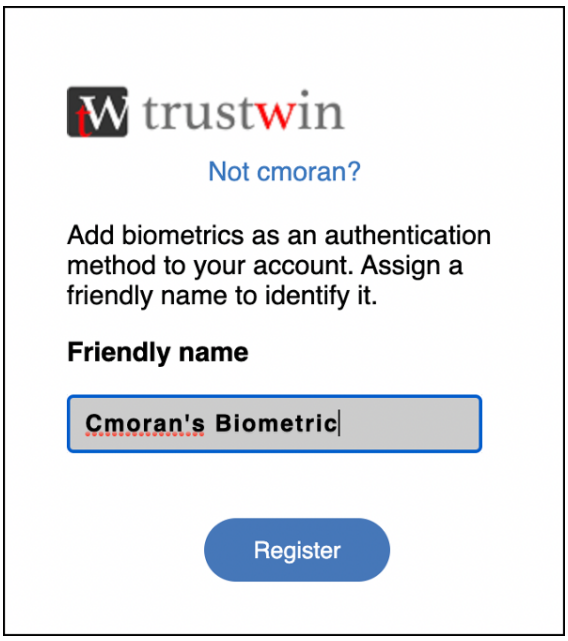
In the following figure, Christopher selects the biometric authentication factor.



Since Christopher has not registered for biometrics, he is required to carry out the mandatory Password authentication as part of the biometrics inline enrolment. The following figure shows the mandatory Password screen where Christopher authenticates using his password, before moving on to biometrics registration.

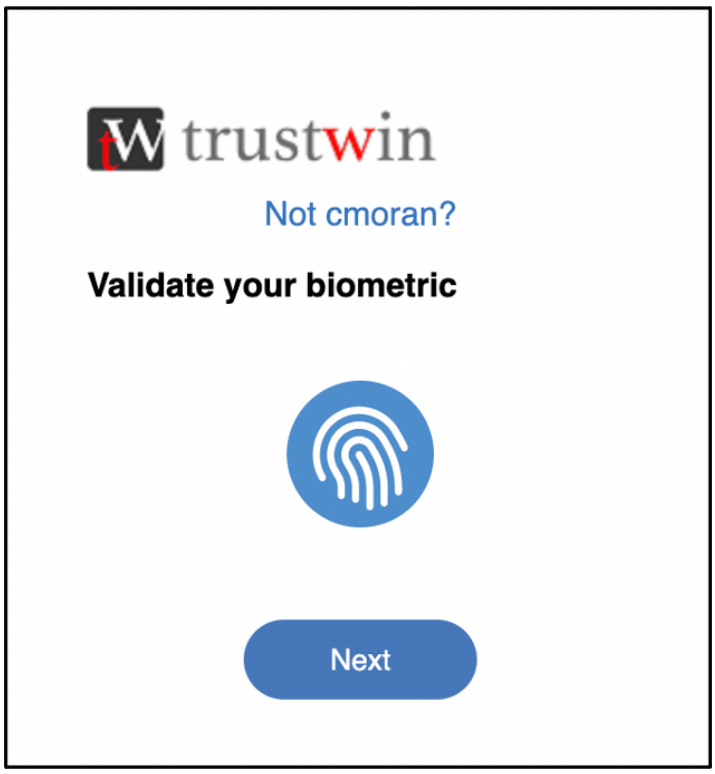


In the following figure, Christopher registers his biometrics with a friendly name to uniquely identify the factor.



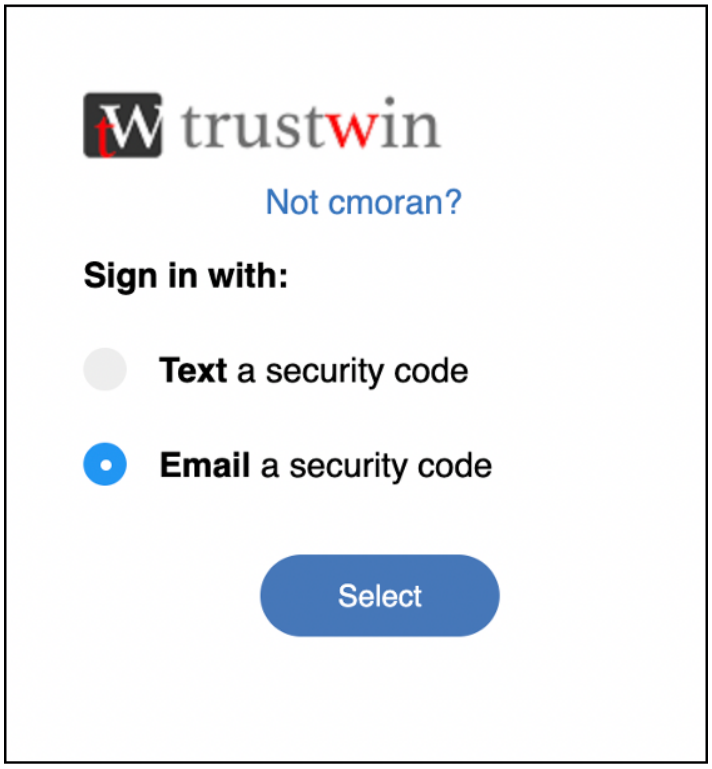
After registering his device for biometrics, he is displayed with the validation screen.

He authenticates by tapping the fingerprint sensor on his Mac computer. At this point, the security key registration is complete. In the following screen, Christopher clicks Next.

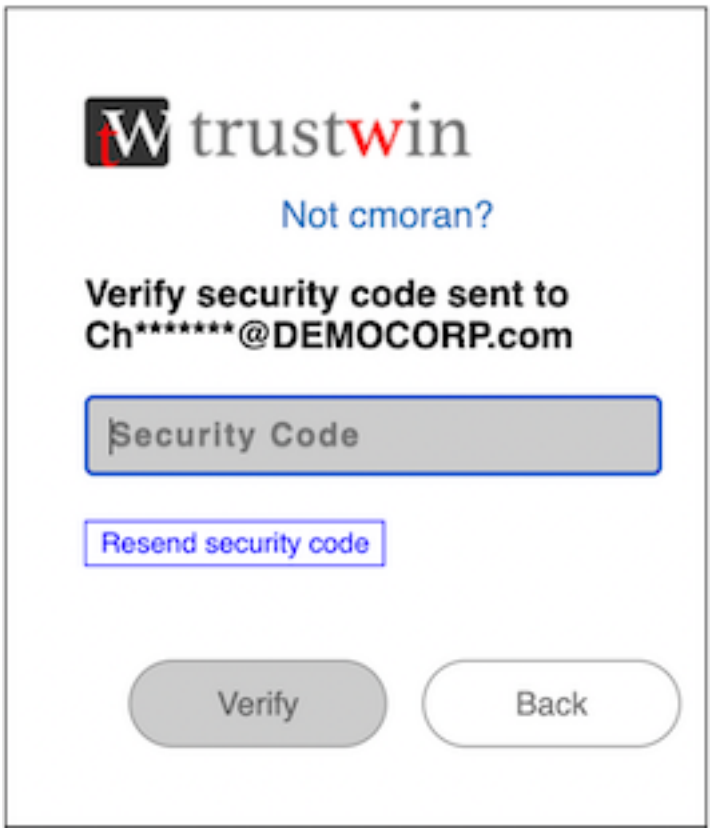


Christopher is displayed with the following validation screen again, but this time it is for second-factor authentication.

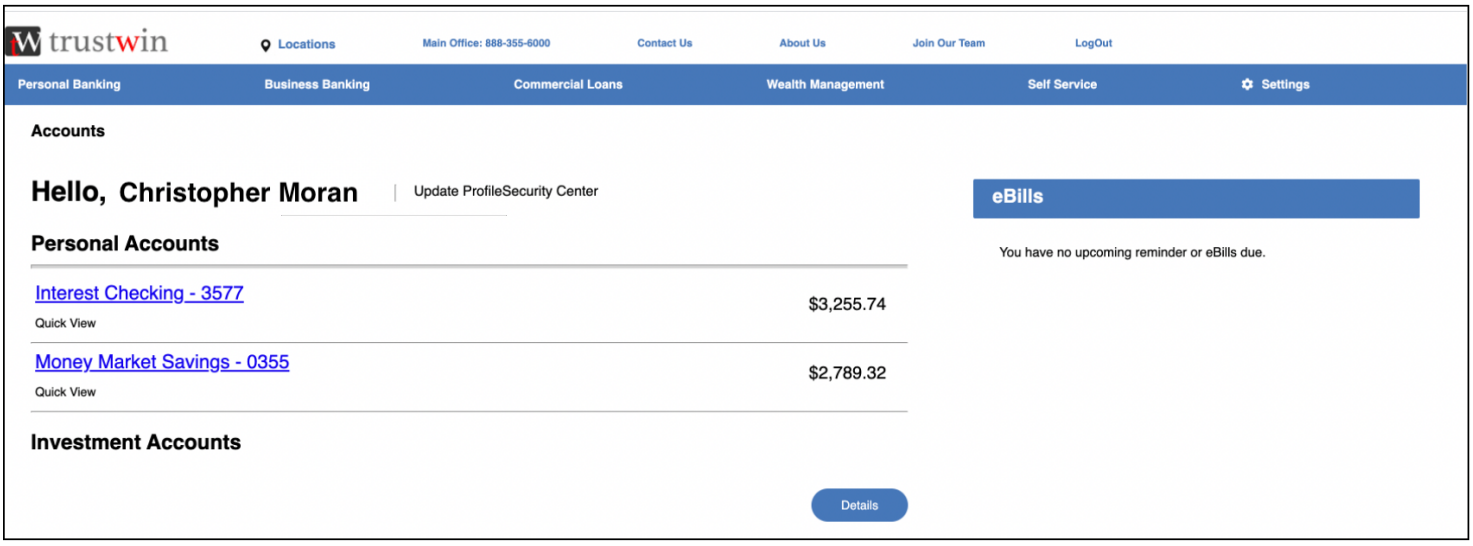
Now, as part of the IDSP risk evaluation process, since Christopher is accessing the Sample app for the first time from this device, he is also asked to authenticate using another factor. He chooses Email OTP as his second factor.



The following figure displays the screen where Christopher has to enter the Email OTP that has been delivered to his email. In the following figure, he enters the OTP received through his email and gains access to the Sample application.



The following figure shows the Sample app page to which Christopher Moran gets access after authenticating with Email OTP.



The next time Christopher attempts to log in, he is prompted to authenticate with his fingerprint alone and not prompted to any other form of authentication.

Step-Up Use Case

Security Admins want to provide increased security for users accessing sensitive assets within an application by initiating a step-up authentication.

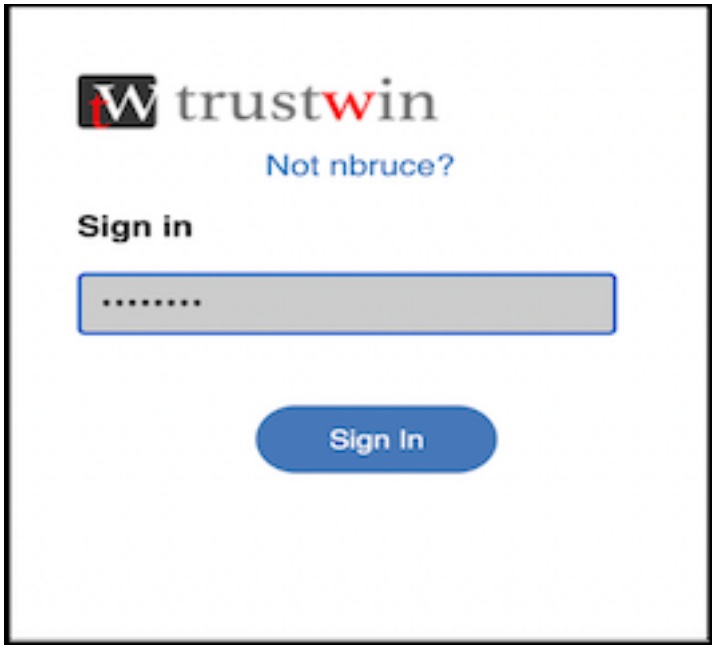
Assumption:

Nina Bruce (nbruce) is identified as a low-risk user by the IDSP. Therefore, she is asked to authenticate with the minimum factor, 'Password' when she initially signs in to the Sample application. However, when she accesses sensitive information on the application, IDSP prompts her for additional authentication. She uses the VIP Access app to authenticate further, which she downloads from the play store.

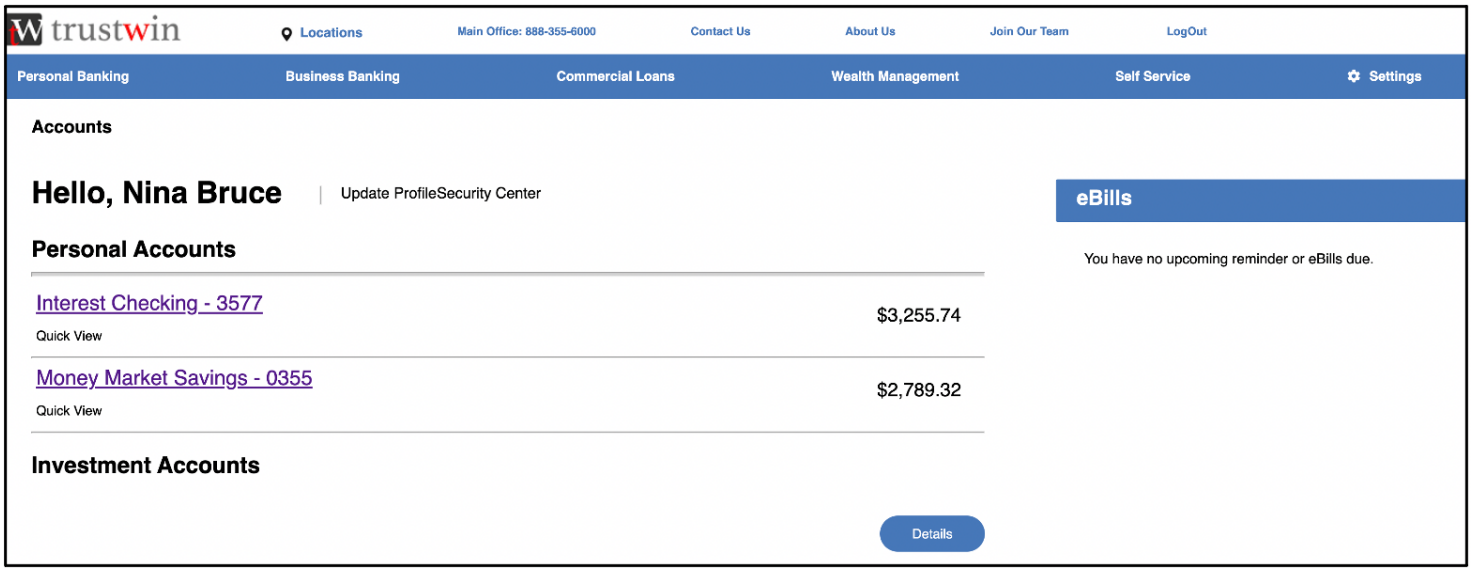
User Flow:

Nina Bruce logs in to the Sample application with only ‘Password’ (Something she knows) and gets access to perform simple tasks. The following figure shows the Sign In page where she enters her username.

She enters her password to authenticate.

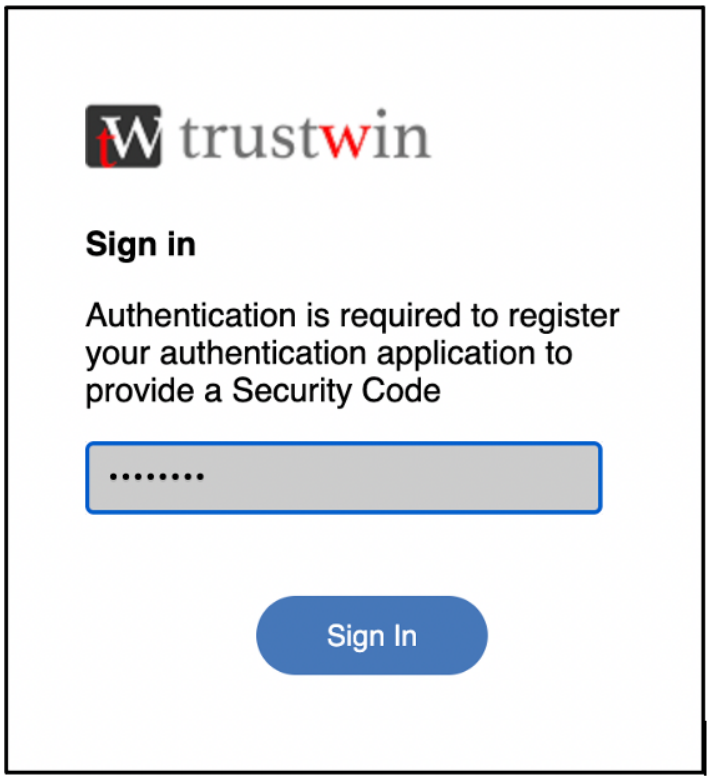


The following figure shows the Sample app page to which Nina Bruce gets access after authenticating with Password.



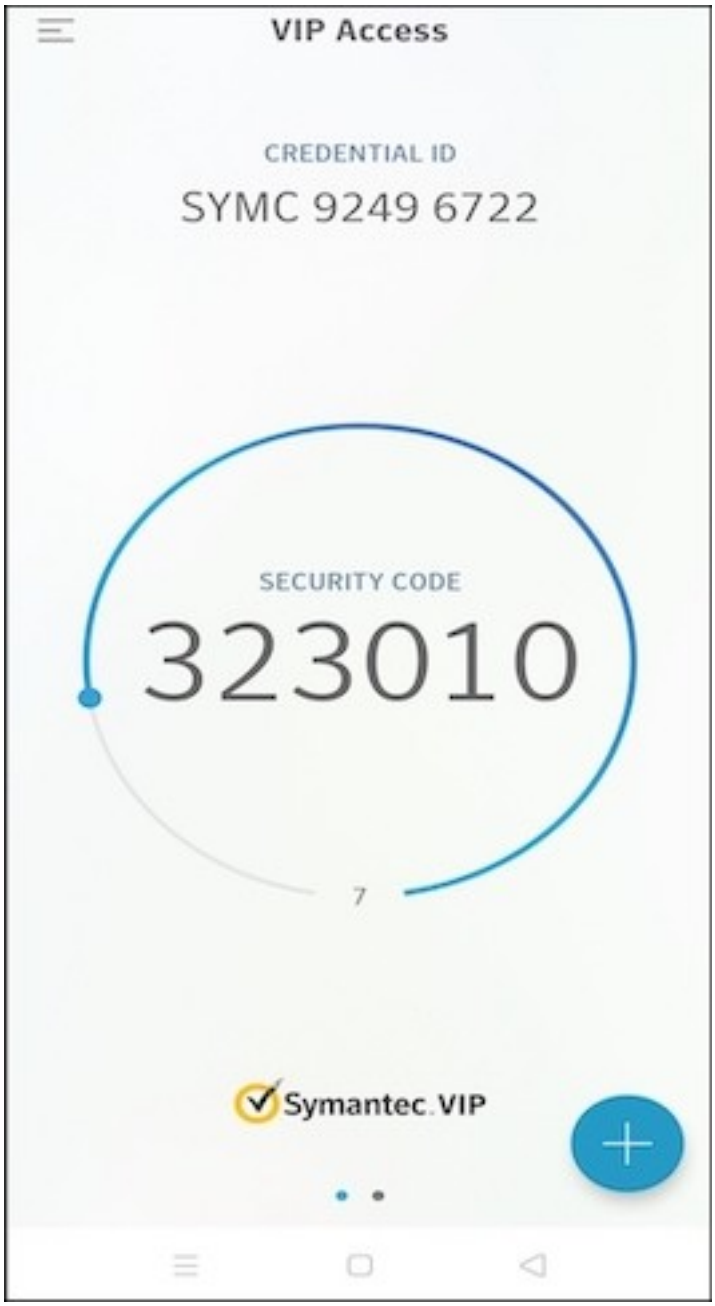
Later, Nina accesses the Wealth Management feature of the Sample application. IDSP recognizes the increased security requirements of her access to sensitive data and prompts her to register inline with MOTP and perform a step-up. However, before performing the step-up, she is asked to perform password authentication as a mandatory step.

The following figure shows the mandatory password screen where Nina authenticates using her password before she moves on to the step-up authentication. But before she does that, she must download the VIP Access app to perform mobile OTP authentication with IDSP.



Screen From VIP Access Mobile App

Nina downloads the Symantec VIP Access App from the play store. Upon installation, the app creates a credential ID for that particular installation and generates the otp. The following is the UI screen of the VIP Access App which generates the credential ID and OTP.

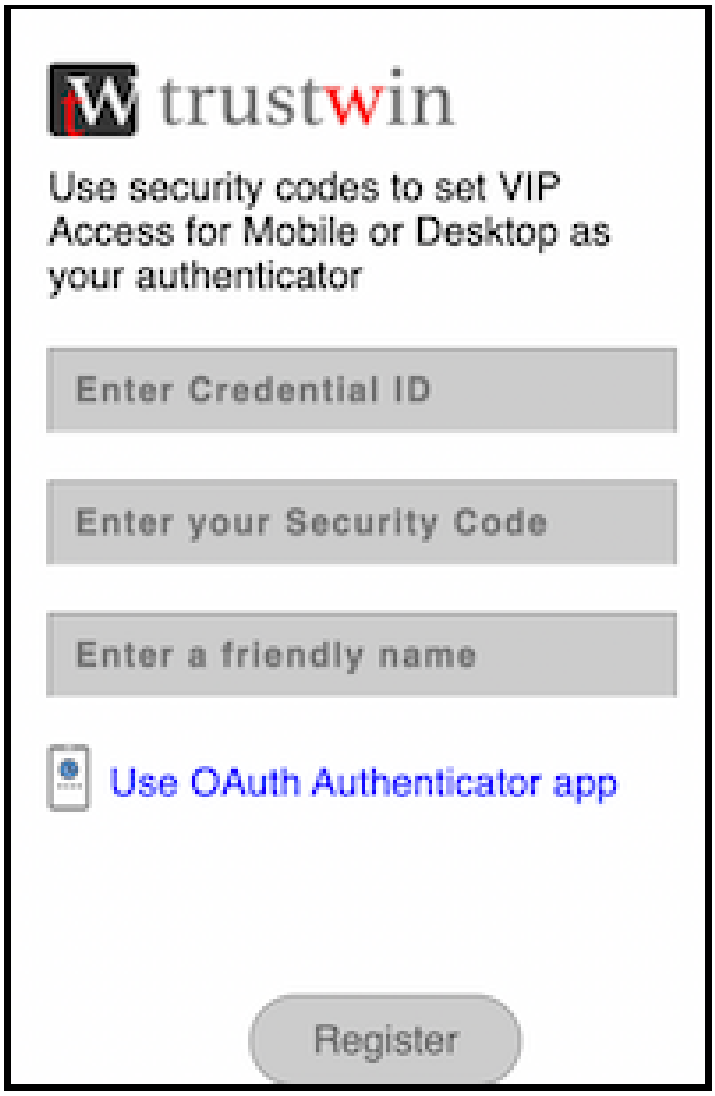


4

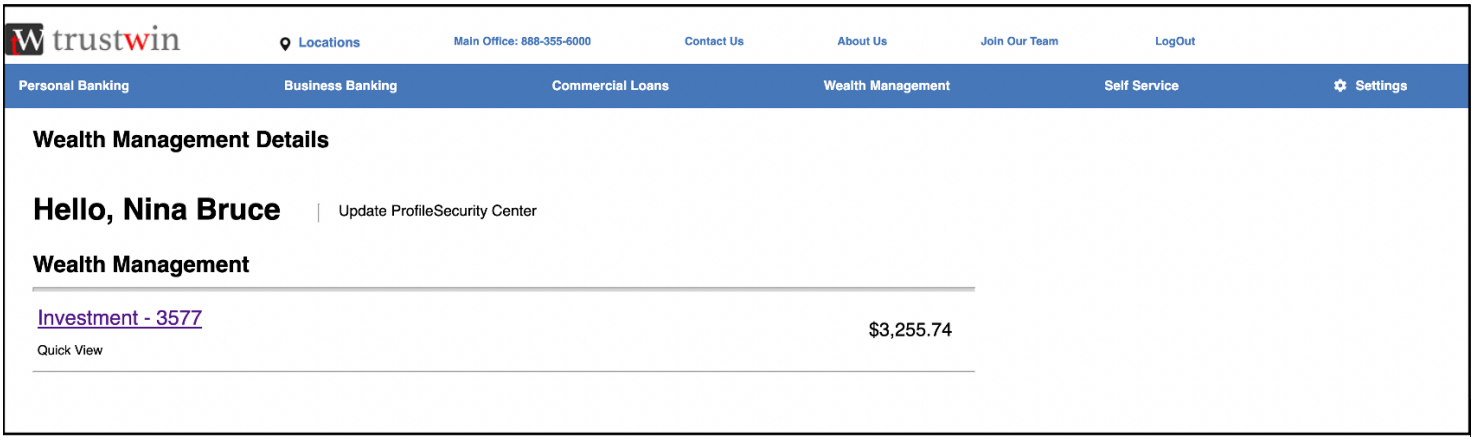
Now coming back to the demo use case, Nina is displayed with the Mobile OTP registration screen where she must enter the following details:

- VIP Credential ID
- Security Code
- Friendly Name

In this figure, Nina enters the details that she obtained from the VIP Access App.



The VIP Access App authenticates the details that are entered by Nina and gives her access to Wealth Management.



Using OAuth Authenticator App (Google Authenticator)

Nina can also use any other OAuth Authenticator app which uses QR code to generate otp and authenticate a request. For example, She can download Google Authenticator to scan the QR code using her mobile.

The following figure shows the QR code screen from the Google Authenticator app. Nina scans the QR code, enters the otp that is received after scanning the QR code, and provides a name to uniquely identify the mobile device. The app verifies the details that are entered by Nina. Upon successful verification, she is allowed to access the Wealth Management page in the Sample app.

Mobile Use Cases

Business Owners require Two-Factor Authentication when using Mobile Applications

Assumption:

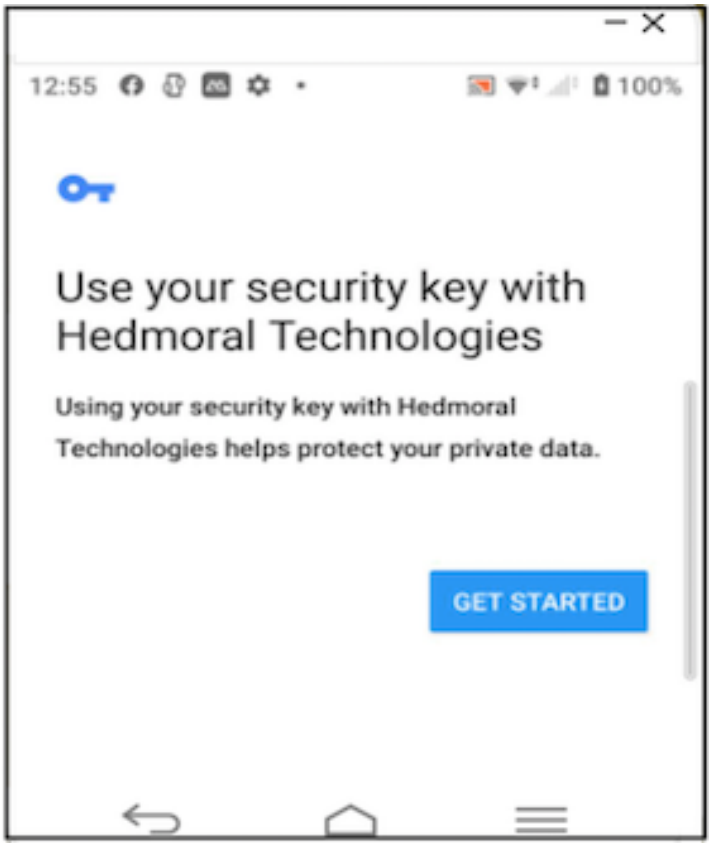
Nina Bruce (nbruce) logs in to the Sample application using her mobile device. She is requested to perform a (step-up) two-factor authentication, password followed by Security Key authentication (which uses FIDO standards). Earlier when she logged in to the Sample application through the web channel, she was only asked to perform a password authentication. Her security key credentials are not registered with the IDSP, so she is prompted to enroll inline.

User Flow:

Nina Bruce logs in to the application using a password, (something she knows). Upon successfully authenticating with a password, she is prompted to inline register her security device for second factor Security Key authentication (something she has).

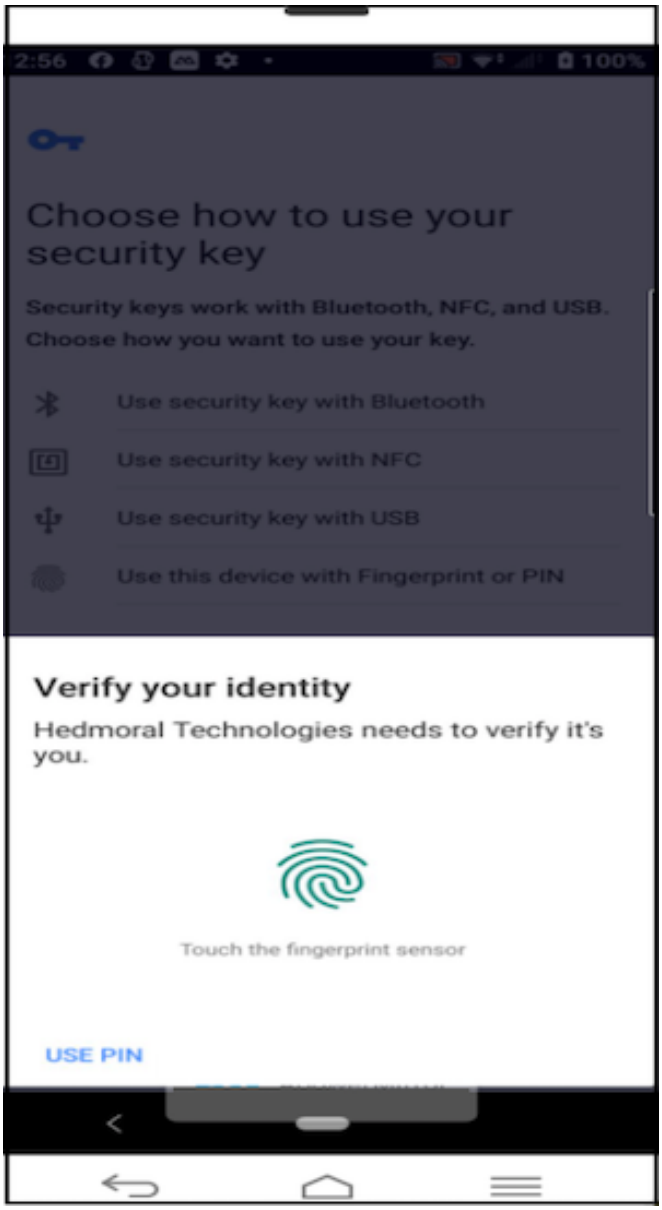
In this image, Nina is registering her security device:

After submitting her device name, she is prompted to provide her security key to complete the registration process. The following screen is displayed in front of her:

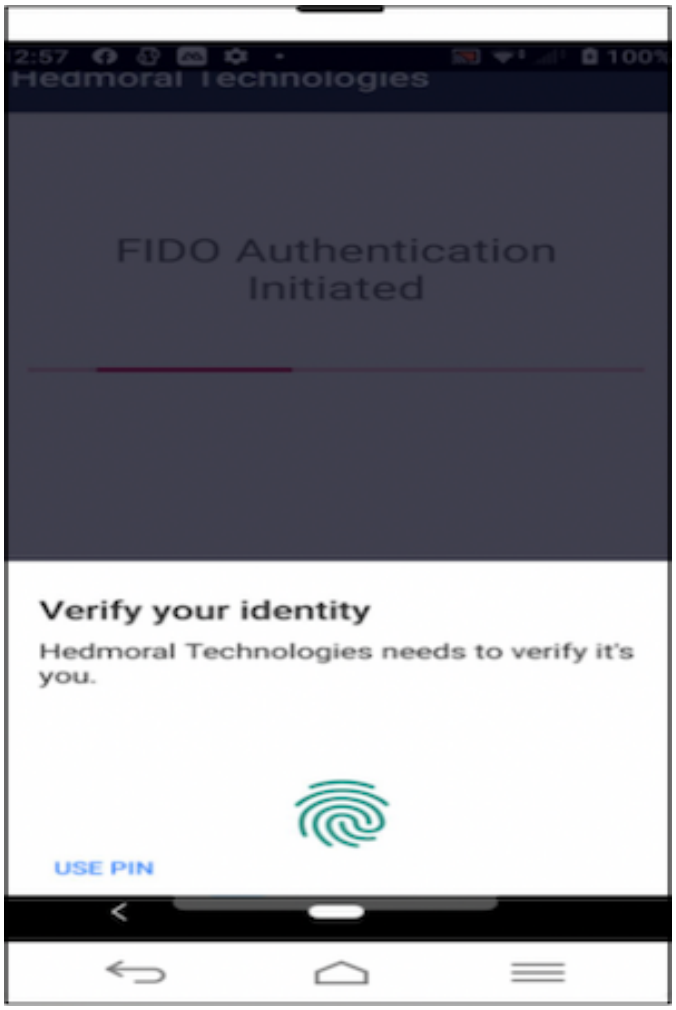


Another screen is displayed to her, where she must select a way in which she uses the security key:

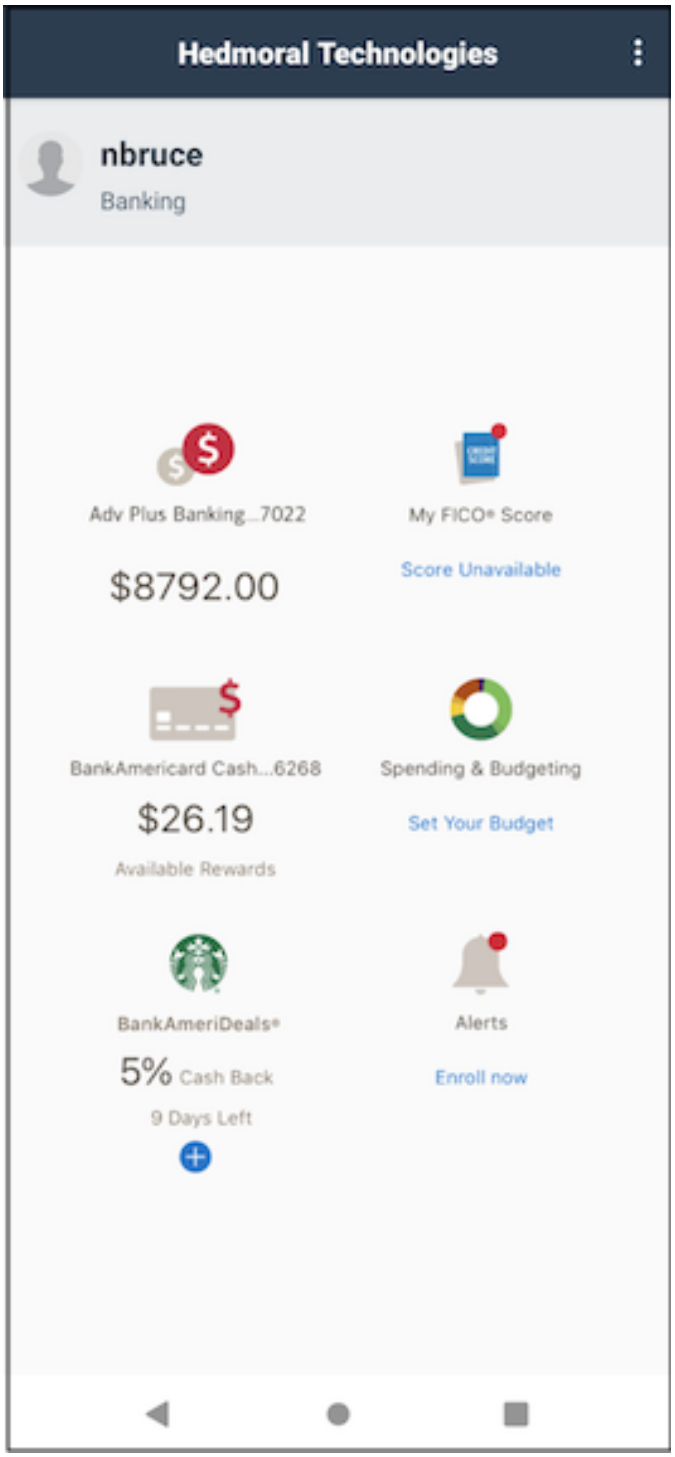
She selects "Use this device with Fingerprint or PIN". Now, she must verify her fingerprint by touching the fingerprint sensor on her device. She is displayed with the following screen, where she verifies her fingerprint:



Now, the IDSP's Hedmoral technology app verifies Nina's fingerprint. She is displayed with the following screen:



Upon successfully verifying her fingerprint, she gains access to the protected application.



The next time that she attempts to log in with the mobile device, she is prompted to enter her password and authenticate with her fingerprint. She is not prompted to any other form of authentication.

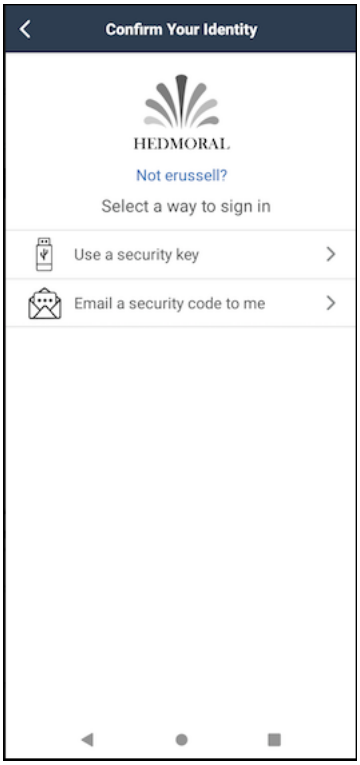
Security Admins want to easily build Authentication Policy that works across both Web and Mobile channels, providing a cohesive customer experience

Assumption:

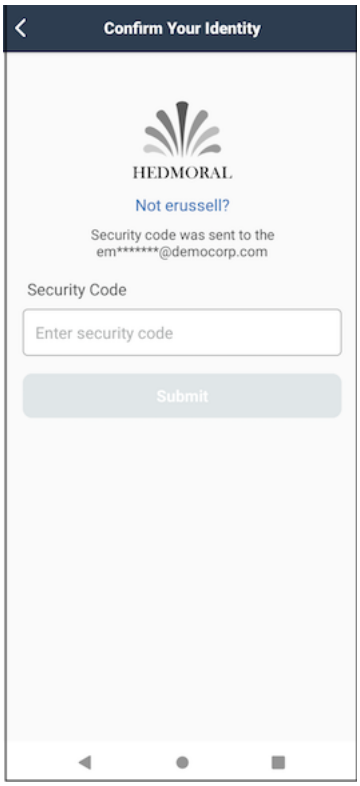
Emily Russell (erussell) is a member of the HR Team. She logs in to the Sample application using Password, followed by OTP factor authentication. When she logs into the Sample application next time using her Mobile device, she is able to leverage the authentication factors that she had registered with the web app.

User Flow:

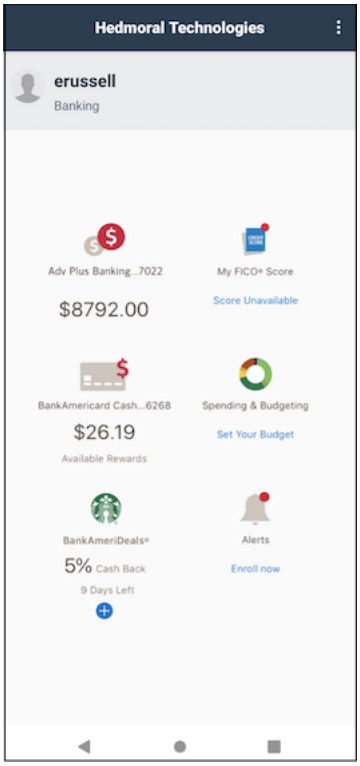
Emily Russell logs into the mobile application using a password. Upon successfully authenticating with the password, she is presented with the following screen where she must select one of the two second-factor authentication options. She selects Email OTP flow.



After she selects Email OTP, she is displayed with the following screen, where she is required to select Email Id and click Submit to get the OTP delivered.



She selects her email id where the OTP gets delivered. After successfully authenticating the second factor, she gains access to the Sample application.



Migration to Password-less

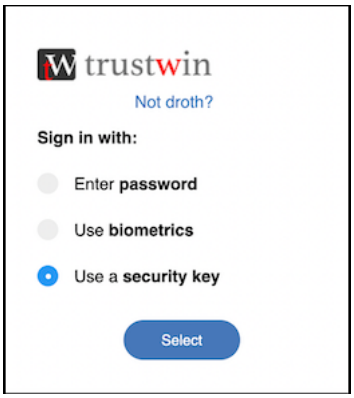
Business Owners would like to have their customers migrate to using password-less authentication but provide the ability in the interim to select either password or password-less factors.

Assumption:

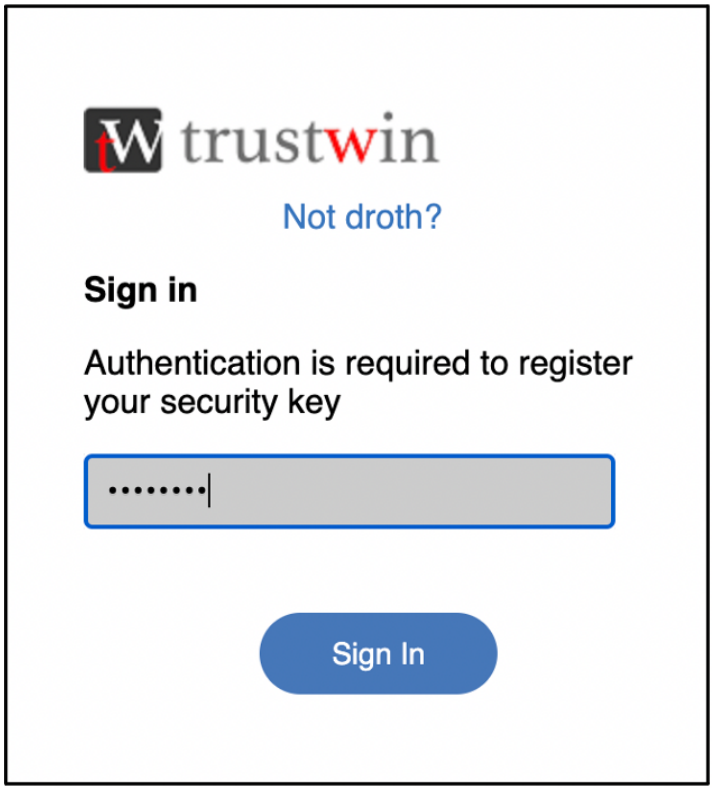
Dean Roth logs into the Sample application and is provided with these authentication factors, password, biometrics, and security key, as his business owner will soon switch away from the password authentication factor. Therefore, he selects the biometric authentication factor and does an inline enrolment to keep himself ready to switch his authentication factor to a password-less factor whenever his business requires him to do so.

User Flow:

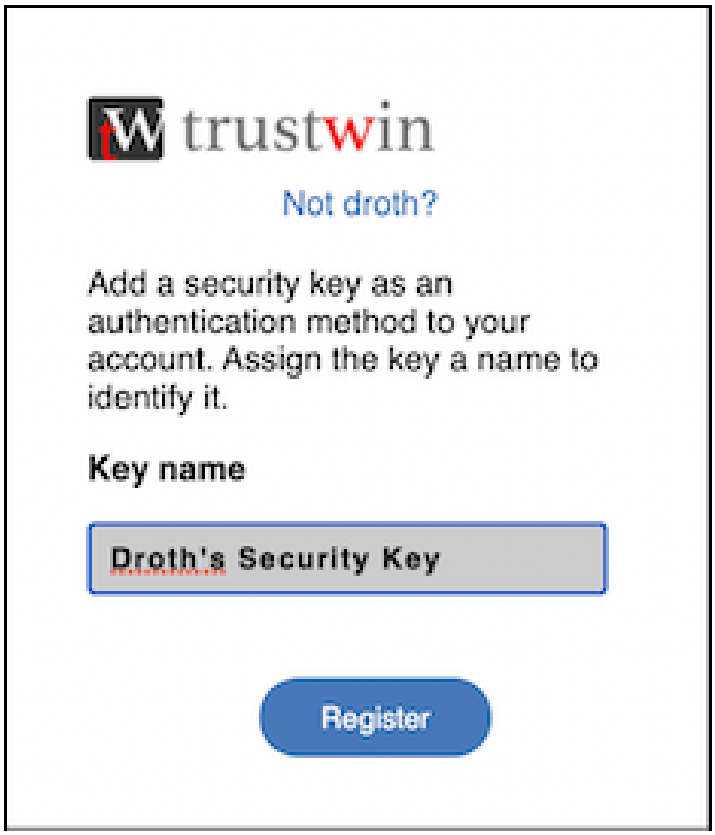
Dean Roth logs into the Sample application and opts to register for the Security Key (password-less). He goes ahead with inline registration from the factor selection list that is displayed to him.



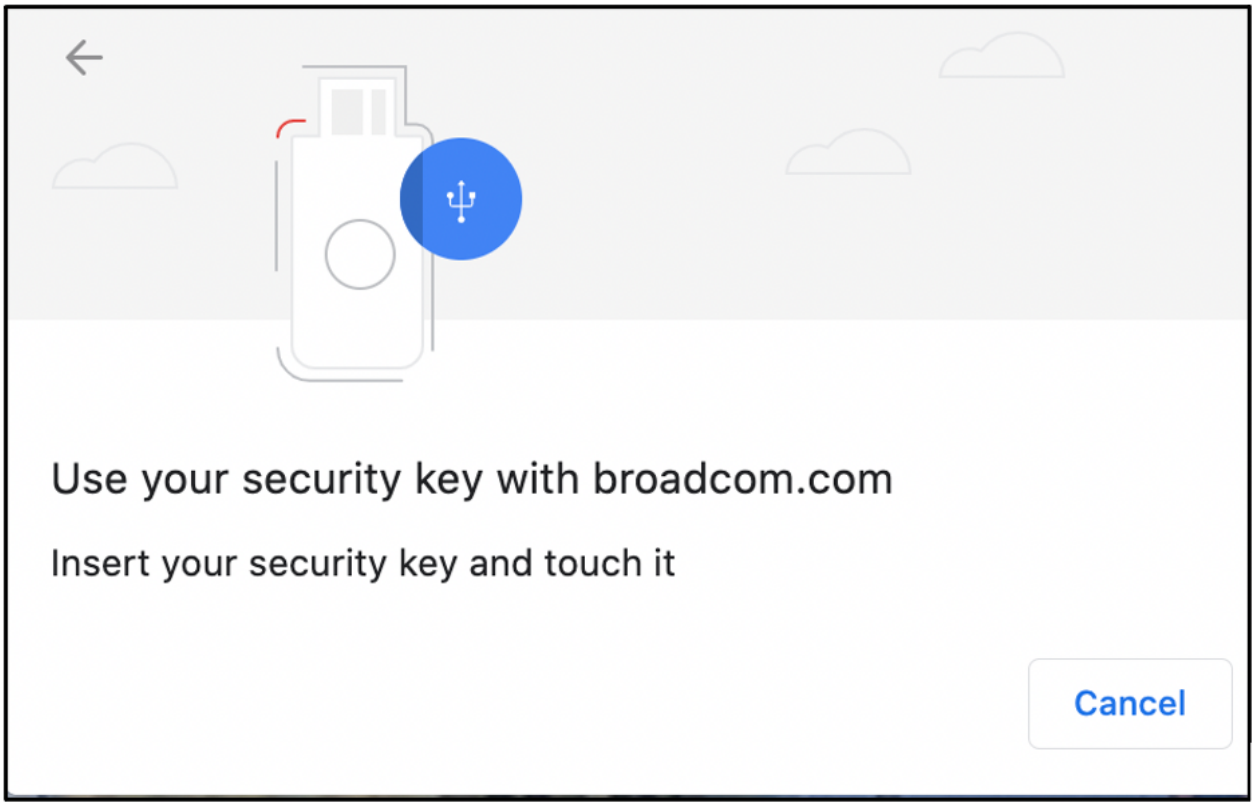
Since Dean has not registered for the security key, he is required to carry out the mandatory Password authentication as part of the security key inline enrolment. The following figure shows the mandatory password screen where Dean authenticates using his password before he moves on to security key registration.



In the following figure, Dean registers his security key on his Mac computer.



After registering his device for security key verification, he is displayed with the validation screen.



He authenticates by tapping the yubikey on his Mac computer. He successfully registers and gets the password-less factor ready for use, whenever needed.

Risk Use Case add images here

Security Admins want to increase security (step-up) when users access applications from untrusted networks (such as hotels or coffee shops)

Assumption:

Nina Bruce (nbruce) logs into the application from an untrusted IP address and thereby has been identified as a high risk user profile. She is asked to perform additional factor authentication by performing Password authentication, followed by OTP. Usually, she is only asked to perform password authentication. Her email ID and phone number have been updated in the user directory prior to the authentication.

User Flow:

Nina Bruce logs in to the application with a password (something she knows). Upon successfully authenticating with the password, she is prompted to perform an OTP authentication (something she has). She is required to choose either, SMS or EMAIL to get the OTP delivered. She chooses SMS, where the OTP gets delivered. She successfully authenticates with the second factor and gains access to the protected application.

Push Use Case

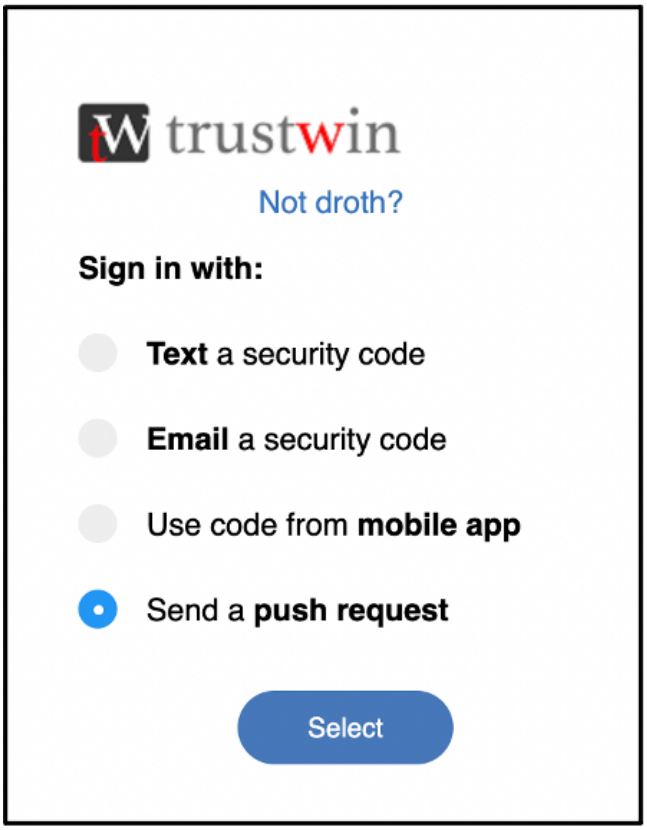
Business Owners want to provide the option of inline push registration to the users who must use two-factor authentication

Assumption:

Dean Roth (droth) belongs to the Customer group and has access to Personally Identifiable Information (PII) of customers. Therefore, he has been requested to enroll for two-factor authentication. He has not registered his credential for two-factor authentication, so he is prompted to perform inline registration of a device to receive push notifications as his second factor.

User Flow:

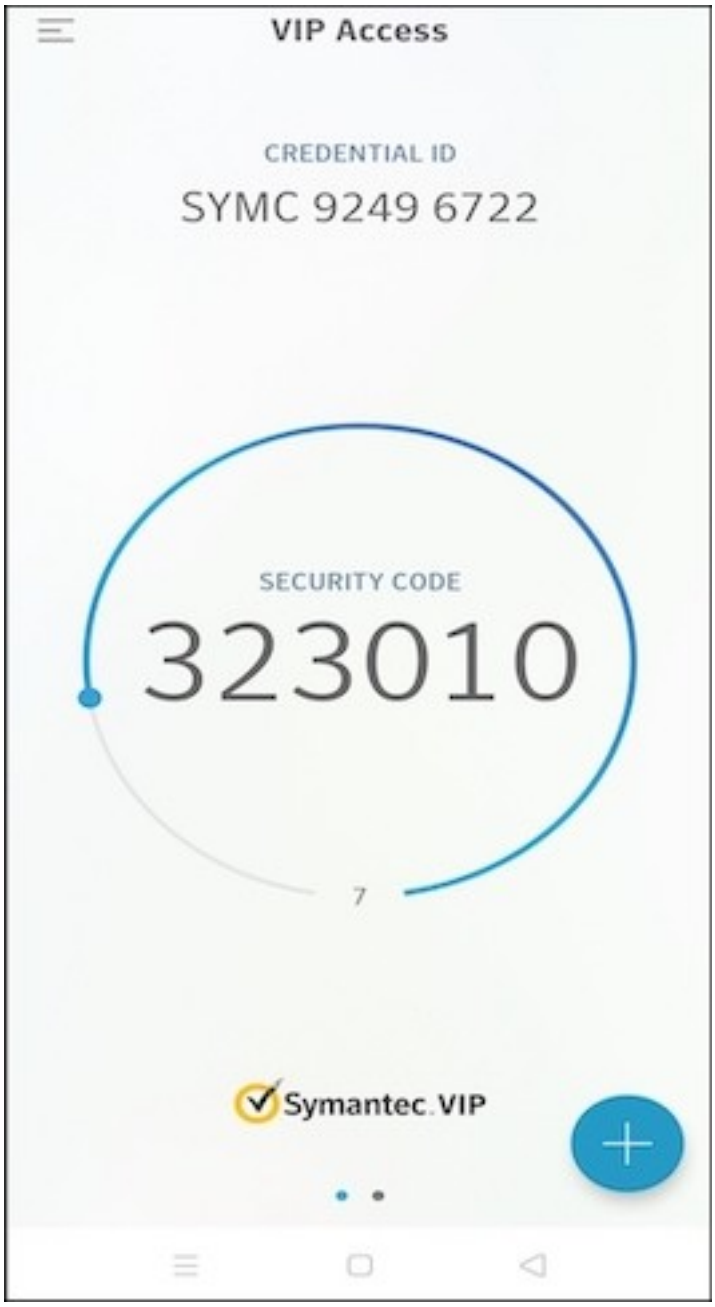
Dean Roth logs into the Sample application with username and password. Upon completing the password authentication, he is prompted to perform a second-factor authentication. He is displayed with the following factors for authentication from which he selects push as his second authentication factor.



Upon successfully authenticating with the password, he is prompted to perform an inline registration of his mobile device to receive push notifications. But before he does that, he must download the VIP Access app to perform push authentication with .

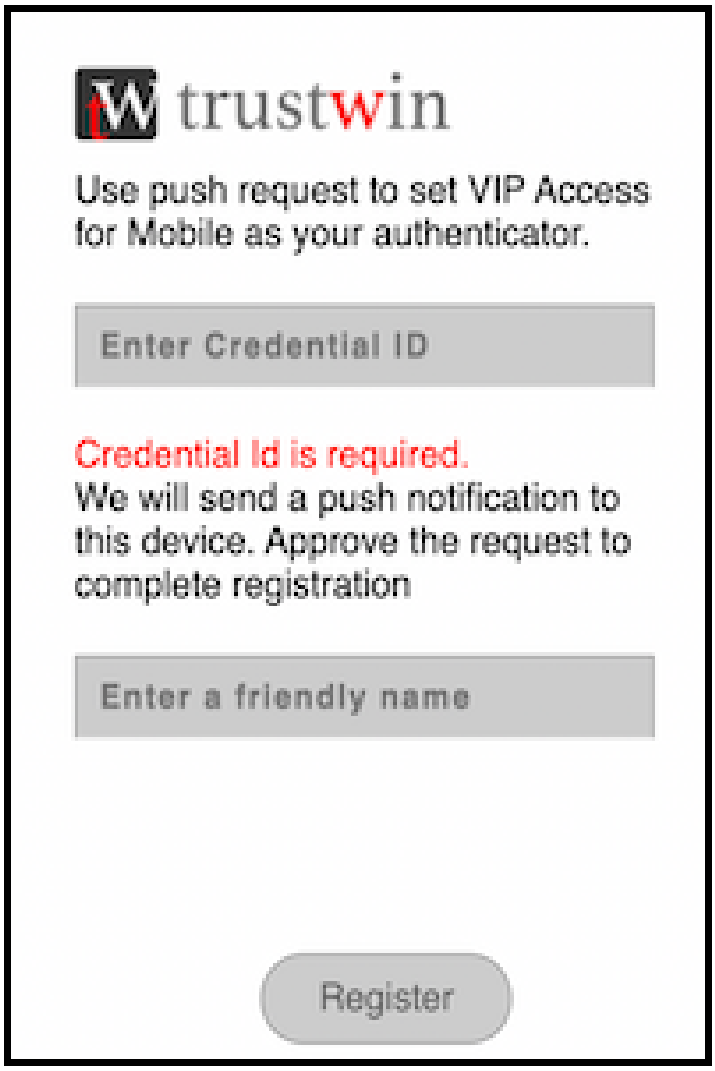
Screen From VIP Access Mobile/Push App

Dean downloads the VIP Access App from the play store. Upon installation, the app creates a credential ID for that particular installation and generates the OTP. The following is the UI screen from VIP Access App which generates the credential ID and OTP.



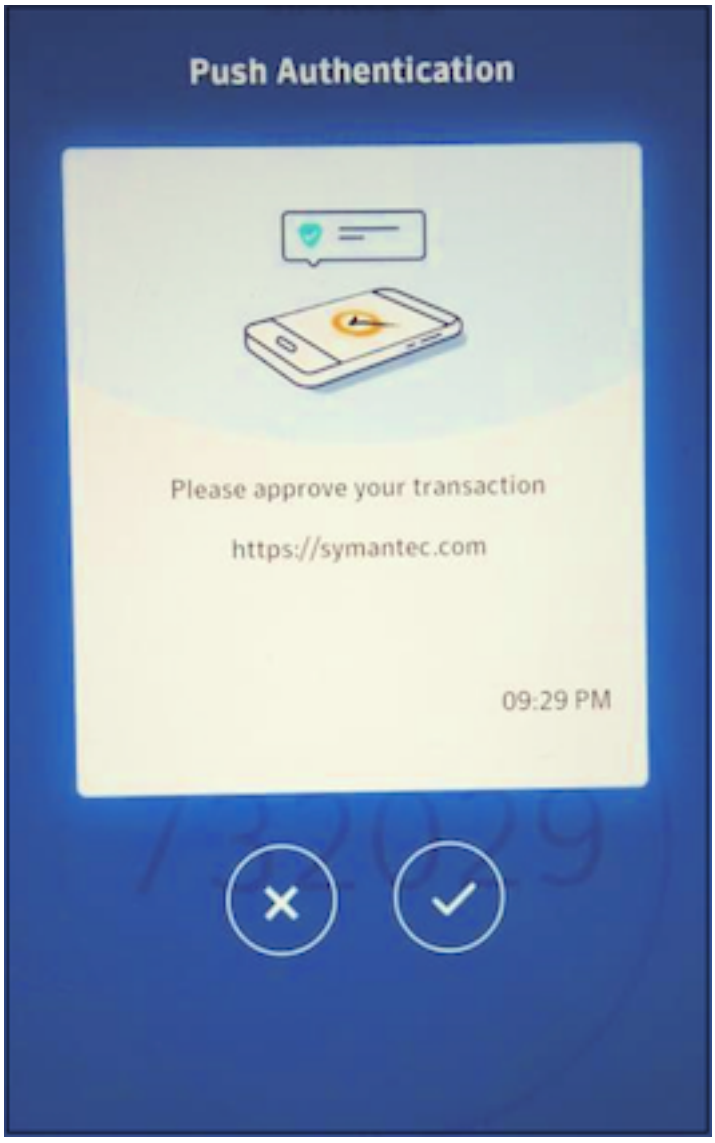
Now coming back to the demo use case, Dean is displayed with the IDSP registration screen where he must enter the following details that he obtained from the VIP Access App:

- Credential ID
- Friendly Name



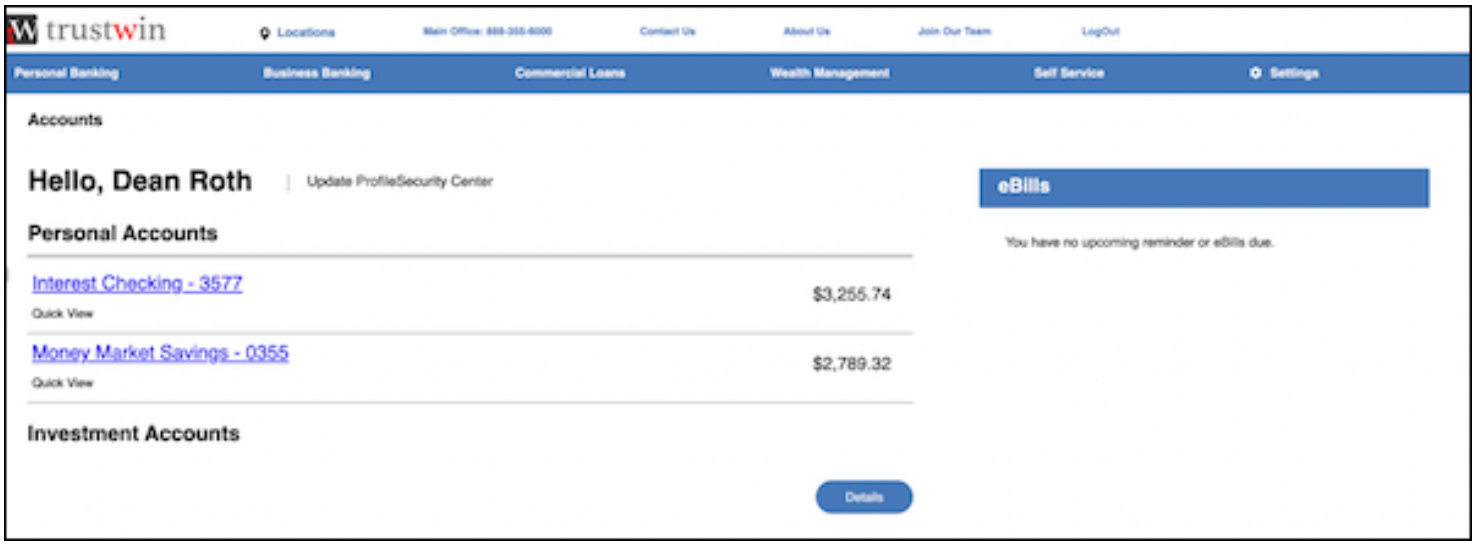
Upon entering the credential Id and name of the device, he is displayed with the following screen. In the meantime, a push notification is sent to Dean's mobile device.

He receives the Push notification on his mobile device which displays the following screen.



He confirms the push message by clicking, ✓.

After confirming the push notification, IDSP registers his mobile device and he gains access to the Sample application. The following screen is displayed to him.



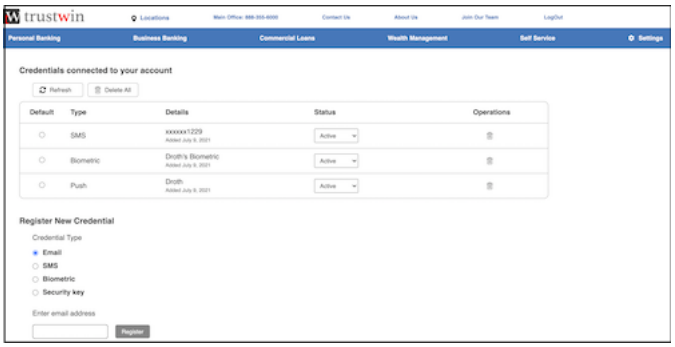
The next time Dean Roth signs in, he enters the password and selects push from the factor selection list. sends push notification to his mobile device which he approves and gains access to the Sample application.

SiteMinder and Use Cases

For SiteMinder and IDSP use cases, see Integration of SiteMinder with IDSP.

Self Service

The Self Service tab in the Sample Web application allows you to create and manage credentials that are linked to your user account.



You can perform the following activities in Self Service:

Checking Credential Status

Use the Self Service tab to check the status of the credentials that are registered with your account. A list of credentials will be displayed in a tabular format with their `Type` , `Details` , and `Status` .

Modify Credential Status

To modify the status of your credential into one of these types; `Active/Inactive` , set the desired choice from the `Status` drop-down in the table.

Registering New Credentials

To add a new credential, select a credential type from the list.

For example, to add an Email Id, do the following:

1. Enter the Id in the box that is displayed and click Register.
2. You are prompted to validate the credential by entering the OTP that has been sent to your Email.
3. Validate successfully with the OTP.
   The newly registered Email Id reflects in the Credential table. The status of the credential will change from `Initial` to `Active` after the validation. The format of the email Id should adhere to the standard protocol.

Deleting Credentials

To delete a specific credential, select the radio button next to the credential and clicking the delete icon under the “Operations” column in the table.

Use the `Delete All` option to delete all your registered credentials at once.

> **NOTE**
> The Refresh button can be used to fetch the latest list of credentials that are connected to your account.

Deploying Sample App

Know about different options to deploy the Symantec Identity Security Platform Sample App.

When you plan to deploy the Sample App for testing the IDSP's capabilities, you must first decide in which mode you would like to deploy the IDSP (SSP). Based on the deployment mode selected for IDSP, you can decide how Sample app can be deployed.

IDSP can be deployed in two modes:

- ***Demo Mode*** - In this mode you can only test the solutions capabilities using sample users and groups. This is a dedicated deployment for demo purposes.
- ***Non-Demo Mode*** - In this mode of deployment, you can perform activities in production. This is the standard IDSP deployment that can be used in a production environment. This environment does not auto create demo artifacts on the default tenant.

The IDSP Sample app can be deployed in both these modes, but to test the solutions capabilities, we recommend to deploy Sample application when the IDSP is deployed in the demo mode.

The demo environment comes with an embedded Internal Identity store. To know more about it, see here.

If you want the ootb demo artifacts (users and applications) to be auto created for you, you can either deploy IDSP in demo mode or create a tenant with demo setup enabled.

Deploy the Sample App in the following ways:

- Deploying Sample App in the IDSP namespace in Demo Mode (auto configured demo deployment).
- Deploying Sample App in the IDSP namespace in a Non-Demo mode by creating a separate tenant to be used only for demo purposes.
- Deploying Sample App in a different namespace in a Non-Demo mode (creating the Sample application, specifying custom URLs etc.).

Deploying Sample App in Symantec Identity Security Platform (IDSP) Namespace

Learn the steps required to deploy a Sample App in the same namespace where Symantec Identity Security Platform is deployed.

Prerequisites

IDSP should be deployed in the demo mode.

Ensure you have the following environment variables set before running the commands in this guide:

Variable	Description
RELEASENAME	The Helm release name of your IDSP deployment.
NAMESPACE	The Kubernetes namespace where IDSP is deployed.
SA_RELEASENAME	The Helm release name for the Sample App.
SA_NAMESPACE	The Kubernetes namespace for the Sample App which is same as the IDSP namespace.
HELM_REPO	The URI of your Helm repository which is same as the IDSP Helm repository.

NOTE
To check the environment variables used during the IDSP deployment, see Configuring the Environment Variables.

Deploying IDSP

- To deploy IDSP in the demo mode, add the following command line parameter to the IDSP helm install command:

```
--set ssp.deployment.size="demo"
```

This information is also covered in this topic: Additional Parameters to consider adding before deploying the IDSP Helm Chart.

When IDSP is deployed in the demo mode, it creates a set of users and groups, and a demo-client app in the default tenant. The demo client's client ID and secret credentials are stored in a Kubernetes secret in this format: `<SSP-RELEASENAME>-ssp-secret-democlient`.

Retrieve and set the client id and secret of the out-of-the-box DemoClient as environment variables, by running these commands on the same Kubernetes cluster where Symantec Identity Security Platform is deployed:

```
export SA_CLIENTID=$(kubectl get secret ${RELEASENAME}-ssp-secret-democlient \
-n "${NAMESPACE}" -o jsonpath="{.data.clientId}" | base64 --decode)

export SA_CLIENTSECRET=$(kubectl get secret ${RELEASENAME}-ssp-secret-democlient \
-n "${NAMESPACE}" -o jsonpath="{.data.clientSecret}" | base64 --decode)
```

Unlike the non-demo IDSP deployment, the Kubernetes secrets containing the default tenant's client Ids and secrets do not get deleted after 48 hours. When deploying the Sample app in the same namespace as IDSP, the demo client secret can be used as a default for the Sample app's client Ids and secrets.

NOTE
If you are deploying the sample-app into the same namespace as IDSP and encountering issues with Kubernetes clusters that return CNAMEs instead of service EXTERNAL-IP (such as Amazon's EKS), and the IDSP fqdn is not registered in DNS but defined locally in the workstation's /etc/host file, the IDSP service IP will not be set automatically. To set it, use "--set ssp.serviceIp=xxx.xxx.xxx.xxx" or use the helm parameter, "--enable-dns" to enable the chart to discover the IP automatically.

Deploying Sample App

When IDSP is deployed in demo mode, deploying the IDSP's SampleAPP chart (ssp-sample-app) can be streamlined.

In this mode, you can deploy the Sample app by specifying the `sspReleaseName: <value>` value in the **Helm values YAML file** or alternatively, you can use the `--set sspReleaseName=<value>` Helm command line parameter in the Sample app helm install command.

Deploying the Sample app chart into the IDSP namespace using the "sspReleaseName" option uses the following default values:

Parameter / Component	Default Value / Path
ClientId and **ClientSecret**	Taken from the IDSP demo client secret.
SSP service host	Taken from the IDSP ingress (the service URL uses the "default" tenant).
ServiceIP	Taken from IDSP ingress.
IDSP Web Sample	sample app host: sampleapp-***ssp-fqdn****/sample-app*
SPI Swagger Docs host	sampleapp-***ssp-fqdn***
Accessing SPI host	sampleapp-***ssp-fqdn***
IDSP Sample RP	• sampleapp-***ssp-fqdn***/sample-rp/home • sampleapp-***ssp-fqdn***/sample-rp/oidc/login • sampleapp-***ssp-fqdn***/sample-rp/saml/login

Information about the demo users and the demo use cases that you can try out in the demo environment are referenced in this page, see Demo Users and Demo Use Cases

(Optional Step) Configuring an Ingress SSL certificate for the Sample App

1. If you do not have a certificate, you can skip this step, as a self-signed certificate will be used when accessing the Sample Web Application.
   If you have a certificate from a trusted Certificate Authority (CA), configure the following environment variables to point to the key and cert files.
   ```
   export SA_KEYFILE="<keyfile>"
   export SA_CERTFILE="<certfile>"
   ```
   Where,
   - <keyfile> - The path to the certificate key file. (private)
   - <certfile> - The path to the certificate file. (public)

   NOTE
   The certificate ***Subject*** or ***Subject Alternative Name (SAN)*** should match the FQDN name of the Sample Web Application. To check that the SAN matches the FQDN name, use the following command:
   ```
   openssl x509 -in ${SA_CERTFILE} -noout -text
   ```
   Once the certificate details are displayed, look for the value of "CN=" in the ***Subject***, or ***Subject Alternate Name*** .
2. If you have a certificate from a trusted CA to use with the Sample Web Application for SSL, then create the secret in the same namespace where the Sample Web Application will be deployed.

   NOTE
   If you do not have a certificate, you can skip this step as a self-signed certificate will be used when accessing the Sample Web Application.

   Run this command to create the secret:
   ```
   kubectl create secret tls sampleapp-general-tls --cert "${SA_CERTFILE}" \
   --key "${SA_KEYFILE}" -n "${SA_NAMESPACE}"
   ```
3. (**Optional step**) If you must authenticate to connect to your container registry, add this command line parameter to the Sample app helm command:
   ```
   --set global.registry.existingSecrets[0].name="ssp-registrypullsecret"
   ```

Deploying the Sample App Helm Chart

Deploy the Sample app helm chart using the following command. If you configured a custom SSL certificate or a registry pull secret in the previous steps, ensure you include those parameters.

For example, the Sample app helm command would look like the following after adding the optional commands:

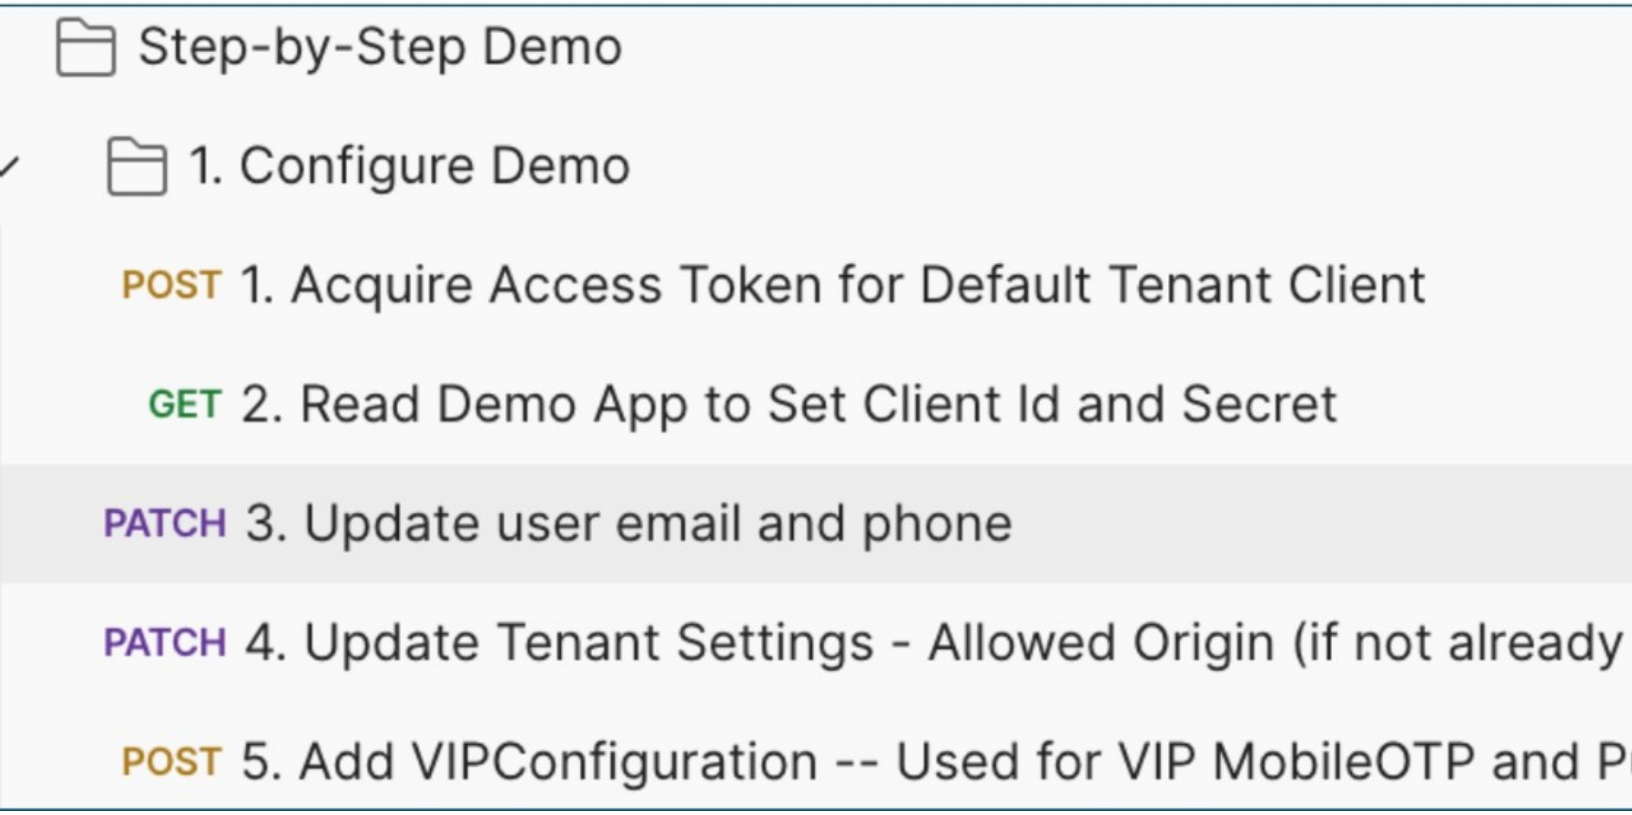
```
helm install "${SA_RELEASENAME}" -n "${SA_NAMESPACE}" ${HELM_REPO}/ssp-sample-app \
--set sspReleaseName=<value> \
--set ingress.tls.secretName=sampleapp-general-tls \
--set global.registry.existingSecrets[0].name="ssp-registrypullsecret"
```

NOTE

- The SMS OTP is preconfigured to use Twilio to send text messages for SMS OTP. Ensure to allow egress traffic to the Twilio service on the internet.
- If you would like to use the Email OTP use cases, ensure to configure an SMTP service provider in IDSP. See Managing Message Provider Configurations.
- The demo users created are part of the demo setup, have fictitious emails, and phone numbers. These emails, and phone numbers are not verified and therefore will not be used to send OTP messages. The real email or phone numbers can be configured using the Admin console, or the "/scim2/v1/Users" API, or using inline enrollment.
- To run the demo use cases, you must do the following:
  a. Set valid email and phone numbers to **nbruce** and **edunn.**
  b. Leave the user "**erussell"** without verified email and phone values, to display SMS/Email inline enrollment.

Using Postman to update the email Id's of the demo users

1. Update the SetEnvironment request script (in the *Tests* tab) to include the username, the demo default password, and the email and mobile phone numbers that you intend to set.
2. Aquire the Tenant Access Token.
3. Use "**Update user email and phone**" request to update the user's email and phone number, and verify them so that they can be used for OTP authentication.
   See the following image to reference the steps that you must perform in the Postman:



NOTE
Repeat these steps for multiple users.

Deploying Sample app in the IDSP namespace, and creating a new tenant for demo purposes

When the IDSP is deployed in non-demo mode, you can create a dedicated tenant enabling the demo setup, and by specifying the following parameter in the tenant payload:

```
demoSetup: true
```

For more information on Creating a Tenant, see Managing Tenants section.

- Creating the demo tenant, automatically sets the tenant setting, ***Allowed Origin*** (https://sampleapp-<sspfqdn>), creates the demo client app with the following details.
  - ***SAML EntityID (samlEntityId)***: https://sampleapp-<sspfqdn>
  - ***SAML Assertion Consumer Service URL (samlAcsUrl)***: https://sampleapp-<sspfqdn>/sample-rp/saml/acs
  - ***OpenID redirectURIs***: https://sampleapp-<sspfqdn>/sample-rp/oidc/callback
  - ***App Home URL***: https://sampleapp-<sspfqdn>/sample-rp/hom
- Save the demo client ID and secret returned by the create tenant API to be used during the Sample app deployment.

Once the demo tenant is created, deploy the sample app on the same Kubernetes namespace where the IDSP chart is deployed by using the following commands:

```
--set sspReleaseName=<value> \
--set demoTenant=<name of the demo tenant> \
--set ssp.clientId=<SA_CLIENTID> \
--set ssp.clientSecret=<SA_CLIENTSECRET}>
```

Where,

- <SA_CLIENTID> and <SA_CLIENTSECRET}> - these are the client Id and secret of the demo application.

Custom Deployment of the Sample App

Learn the steps to deploy the Sample application in a namespace that is different from the namespace where Symantec Identity Security Platform is deployed.

When a Sample app is deployed in the same namespace, it extracts some of its default values from the existing IDSP deployment. When deploying a Sample app on a different namespace or even a different cluster, you are required to specify additional parameters.

Purpose

The IDSP Sample Web application lets you set up a demo environment and test the multi-factor authentication flows offered by the solution. The sample web application is available and can be easily deployed on native cloud environment, or OpenShift.

Prerequisite

To be able to run the demo environment, ensure that you have deployed the following application:

- IDSP

  NOTE

  - If you are deploying Sample Web Application in a different cluster, ensure the prerequisites are met
  - The Sample Web Application supports RememberMe and Trusted Devices functionality. See RememberMe/ Trusted Devices.

This topic includes the following sections:

- Configuring Environment Variables
- Deploying Ingress for Sample Web Application
- Accessing the Sample Web Application
- Updating CORS Setting to Reflect Sample Web Application's FQDN
- Using the Sample Web Application

Configuring Environment Variables

Set up your system environment variables so that you can use them in the commands that are used in deploying the Sample Web Application. These commands can be executed in your native cloud providers, or OpenShift; you could also use a cloud shell.
Follow these steps:

1. Configure the following environment variables:

   NOTE
   Note that variables, RELEASENAME, and NAMESPACE refer to the IDSP helm release-name and namespace respectively, whereas the SA_RELEASENAME and SA_NAMESPACE refer to the Sample Web Application helm release-name and namespace.

   ```
   export SA_RELEASENAME="<sampleapp-release-name>"
   export SA_NAMESPACE="<sampleapp-namespace>
   export SA_FQDN="<sampleapp-fqdn>"
   ```

   Where,

- <sampleapp-release-name> - This is a name that you chose to identify your Sample Web Application deployment. In helm, a Release is an instance of a chart-deployment running in a Kubernetes cluster. The release name helps identify this particular deployment instance.
- <sampleapp-namespace> - This is the namespace for the Sample Web Application.
- <sampleapp-fqdn> - This is the Fully Qualified Domain Name that is used to access the Sample Web Application. If you are using your own certificate for the Sample Web Application, the certificate subject or alternate name should match this fqdn.

2. If you have a certificate from a trusted Certificate Authority (CA), configure the following environment variables to point to the key and cert files.

```
export SA_KEYFILE="<keyfile>"
export SA_CERTFILE="<certfile>"
```

Where,

- <keyfile> - The path to the certificate key file. (private)
- <certfile> - The path to the certificate file. (public)

NOTE

- The certificate ***Subject*** or ***Subject Alternative Name (SAN)*** should match the FQDN name of the Sample Web Application. To check that the SAN matches the FQDN name, use the following command:

```
openssl x509 -in ${SA_CERTFILE} -noout -text
```

Once the certificate details are displayed, look for the value of "CN=" in the ***Subject***, or ***Subject Alternate Name*** .

- If you do not have a certificate, you can skip this step, as a self-signed certificate will be used when accessing the Sample Web Application.

Deploying Ingress for Sample Web Application

Before deploying the Sample Web Application, set up the Ingress for the Sample Web Application.

NOTE

If you already have an Ingress setup in the cluster where you plan to deploy the Sample Web Application, then you can use the same Ingress.

For Ingress deployment steps, see Deploying Ingress.

Deploying the Sample Web Application

1. Create a namespace for the Sample Web Application.

```
kubectl create ns "${SA_NAMESPACE}"
```

2. If you have a certificate from a trusted CA to use with the Sample Web Application for SSL, then create the secret in the same namespace where the Sample Web Application will be deployed.

NOTE

If you do not have a certificate, you can skip this step as a self-signed certificate will be used when accessing the Sample Web Application.

Run this command to create the secret:

```
kubectl create secret tls sampleapp-general-tls --cert "${SA_CERTFILE}" \
--key "${SA_KEYFILE}" -n "${SA_NAMESPACE}"
```

3. To retrieve the IDSP "serviceUrl", use the following command:

NOTE

- Export the variables, ${NAMESPACE}, ${RELEASENAME}, and ${SSP_FQDN}. These are the IDSP (ssp) variables which you may have used during IDSP Helm chart deployment. See Setting up the Environment Variables .
- Execute this command on the IDSP Kubernetes cluster. If you are deploying the Sample app into a different cluster, you can run the command below on the ssp cluster and use these values when deploying Sample app.
- The command assumes that the IDSPtenant name is "default".
- "serviceUrl" (SSP_URL) is the url that the Sample Web Application uses in order to access the IDSP service. This url is composed of the service base url (https://${SSP_FQDN}/), followed by the tenant name with a trailing slash (https://${SSP_FQDN}/<tenatname>/). For example, https://ssp.iam.example.com/default/.

```
export SSP_FQDN=$(kubectl get ingress -n ${NAMESPACE} ${RELEASENAME}-ssp-ingress -o
 jsonpath={.spec.rules[].host})&&echo SSP_FQDN=${SSP_FQDN}
export SSP_URL=https://${SSP_FQDN}/default/&&echo SSP_URL=${SSP_URL}
```

4. Retrieve the client id and secret of the DemoClient App by navigating to the applications section in the Admin Console, identifying the app, and copying these values and setting them as environment valiables, SA_CLIENTID and SA_CLIENTSECRET respectively.
5. ***Registering a Pull Secret:***
   If you are required to use registry credentials to pull images from your container registry:
   – By default, the Sample Web Application deployment pulls images from the Broadcom container registry which requires authentication. The following command creates a docker-registry secret named, "ssp-reg-pullsecret" to store the registry credentials that would be used by Kubernetes to pull the images:

```
kubectl create secret docker-registry ssp-registrypullsecret -n ${SA_NAMESPACE} \
--docker-server="https://securityservices.packages.broadcom.com/" \
--docker-username="<username>" \
--docker-password="<password>" \
--docker-email="<your-email-address>"
```

NOTE

- Replace <username> and <password> which are the credentials that are required to log in to the Docker registry where the IDSP images are stored. The credentials for the Broadcom Docker registry are provided by Broadcom.
- The Sample App chart images are stored in the same registry as the IDSP (ssp) images. As a result, the same credentials are used to retrieve the images. However, because these two charts are deployed in different namespaces, the secret containing the credentials must be created in both IDSP (ssp) and Sample App namespaces.
- If you decide to use your own private registry and your registry requires authentication as well, you can use a similar command using your own docker server URL and credentials.

6. Get the latest Sample App helm chart updates by running this command:

```
helm repo add ssp_helm_charts https://ssp_helm_charts.storage.googleapis.com
helm repo update
```

7. Deploy the Sample Web Application.

```
helm install "${SA_RELEASENAME}" -n "${SA_NAMESPACE}" ${HELM_REPO}/ssp-sample-app \
--set ssp.serviceUrl="${SSP_URL}" \
--set ssp.clientId="${SA_CLIENTID}" \
--set ssp.clientSecret="${SA_CLIENTSECRET}" \
--set ingress.host="${SA_FQDN}" \
--set ingress.tls.host="${SA_FQDN}" \
--set ingress.tls.secretName=sampleapp-general-tls \
--set global.registry.existingSecrets[0].name="ssp-registrypullsecret"
```

NOTE

- The following command line parameters are optional:

```
--set samplerp.clientId="449b325c-96ee-4994-b0c2-827edf1b088c" \
--set samplerp.clientSecret="dc734a17-9ed6-4b90-a702-6b8853f78626" \
--set ssp.serviceIp="kubectl get svc -n ingress |awk 'NR==2 {print $4}'"
```

  - If you do not specify the "samplerp" clientId and clientSecret, the Sample app chart defaults to use the same clientId and secret that was provided for the sampleapp.
  - Specify the IDSP's service IP (ssp.serviceIp) when the IDSP FQDN is not resolvable from within the cluster. For instance, when the IDSP FQDN is only resolvable by the client machine using a local "/etc/hosts name" resolution.
- If you do not specify the ${SA_CLIENTID} and ${SA_CLIENTSECRET} here while installing the Sample app, then you must set it after the installation is complete, by clicking the Settings gear at the top left of the Sample Web Application's login page.

NOTE

For deploying Sample app in the OpenShift platform, carry out these additional steps:

- Set the following environment variables.

```
read -d '/' -r SA_UID < <(kubectl get ns ${SA_NAMESPACE} -o
 jsonpath='{.metadata.annotations.openshift\.io/sa\.scc\.uid-range}')
read -d '/' -r SA_GID < <(kubectl get ns ${SA_NAMESPACE} -o
 jsonpath='{.metadata.annotations.openshift\.io/sa\.scc\.supplemental-groups}')
export SA_FSGROUP=${SA_GID}
```

- Pass the following additional parameters in the Sample Web Application helm install command.

```
--set global.securityContext.runAsUser=${SA_UID} \
--set global.securityContext.runAsGroup=${SA_GID} \
--set global.securityContext.fsGroup=${SA_FSGROUP}
```

- To use OpenShift Routes in the Sample App, use the following parameter when deploying the sample app chart:

```
--set ingress.type=openshiftroute --set ingress.ingressClassName=openshift-default
```

8. Post deployment, Helm provides details regarding the deployment. If you wish to view this deployment information, use the following command:

```
helm get notes -n <namespace>  <sampleapp release name>
```

Accessing the Sample Web Application

Accessing the Sample Web Application is done through the Kubernetes cluster Ingress which routes requests to the Sample Web Application service based on the request's FQDN. This FQDN should match the Sample Web Application's FQDN that was specified during the deployment of the App.

To make the Sample Web Application accessible through a web browser, add the FQDN of the Sample Web Application and its IP Address to your Cloud DNS or your local DNS (In case, you are unable to update your DNS, you can update the "/etc/hosts" file on the machine where you are run your browser to allow local name resolution). The Sample Web Application FQDN should be resolved to the Ingress IP Address that can be retrieved by performing the following step:

1. To get the Ingress IP address, run the following command:

```
kubectl get svc -n ingress ingress-nginx-controller
```

   Where, ingress-*nginx-controller* is the name of the ingress controller Kubernetes service. The ingress IP address is listed under the "EXTERNAL_IP" column. When running this command on a cloud provider cluster, the "EXTERNAL_IP" may take a few minutes to be displayed since the service load balancer must be provisioned.

After you complete the deployment and update the FQDN and IP Address in your cloud DNS or your local DNS "/etc/hosts" file, the Sample Web Application can be accessed.

There are two URLS available for you to access the Sample App.

- ***Sample App URL***: This URL can be used to test the demo use cases in a programmatic way.
  `https://<sampleapp-fqdn>/sample-app/`
- ***Sample RP URL***: This URL can be used by developers to test the demo capabilities by invoking authentication using the protocol flows, SAML, and OIDC.
  `https://<sampleapp-fqdn>/sample-rp/home`

NOTE
The Sample Web Application is accessible at this point but requires performing the following steps to operate correctly.

Updating CORS Setting to Reflect Sample Web Application's FQDN

Cross-origin resource sharing (CORS) is a mechanism that allows restricted resources on a web page to be requested from another domain outside the domain from which the first resource was served. The list of "allowedOrigin" identifies the permitted origins to call IDSP APIs.

You are required to edit the CORS setting to add the Fully Qualified Domain Name (FQDN) of the Sample Web Application. This step is required if you are installing the Sample Web Application into an FQDN different from IDSP.

1. To set the CORS setting, update the "allowedOrigins" property (accepts a comma-separated list of urls) available in "tenant" settings with the required and valid http/https URLs.
2. Use the following "PATCH" call to update the payload with the Sample Web Application's FQDN URL.

   NOTE

   - Before running the following command, ensure that the variables, ${SSP_FQDN} in Configuring the Environment Variables and ${SSP_AT} as mentioned in the Obtaining Access Token for System Admin Tasks section.
   - Replace the "https://sampleapp.example:4200" with the actual URL as specified in the variable, ${SA_FQDN} provided to the *ingress.host* parameter during Sample App deployment.
   - The following cURL command uses *"--insecure"* parameter to ignore SSL verification. If your IDSP deployment uses trusted certificates, you can remove this parameter.

   Example of a cURL Request displaying the Tenant Settings PATCH payload

```
curl --insecure -L -X PATCH "https://"${SSP_FQDN}"/default/admin/v1/Configs" \
-H 'Content-Type: application/json' \
-H "Authorization: Bearer ${SSP_AT}" \
-d '[
       {
           "name": "allowedOrigins",
           "value": "https://sampleapp.example.com:4200"
       }
 ]'
```

   Example of cURL Response

```
[
 {
     "name": "persistEnrolledFactorsinIDP",
     "value": "false",
     "origin": "global"
 },
 {
     "name": "azCodeExpirySecs",
     "value": "120",
     "origin": "global"
```

```
  },
  {
      "name": "isInlineOTPEnrollmentToBePersisted",
      "value": "true",
      "origin": "global"
  },
  {
      "name": "refreshTokenExpiryDays",
      "value": "7",
      "origin": "global"
  },
  {
      "name": "pushRegTimeoutSecs",
      "value": "300",
      "origin": "global"
  },
  {
  "name": "allowedOrigins",
      "value": "https://sampleapp.example.com:4200",
      "origin": "tenant"
  },
  {
      "name": "isInlineEnrollmentAllowed",
      "value": "true",
      "origin": "global"
  },
  {
      "name": "idTokenExpirySecs",
      "value": "21600",
      "origin": "global"
  },
  {
      "name": "pushAuthTimeoutSecs",
      "value": "300",
      "origin": "global"
  },
  {
      "name": "accessTokenExpirySecs",
      "value": "3600",
      "origin": "tenant"
  },
  {
      "name": "useOriginalIdentityTokenExpiry",
      "value": "false",
      "origin": "global"
  },
  {
      "name": "inlineEnrollmentFactorsRequired",
      "value": "PASSWORD",
      "origin": "global"
  }
]
```

Using the Sample Web Application

NOTE

The IDSP deployment automatically provisions a *DemoClient* app and a demo authentication policy. If you want to create your own application and authentication policy, perform the following steps. To continue with the pre-provisioned DemoClient app, **skip steps 1 and 2**. To know more about DemoClient, click here.

1. Create the Sample Web Application in the IDSP using the following cURL request:

   NOTE
   Before running the following command, ensure that the variables, ${SSP_FQDN} in Configuring the Environment Variables and ${SSP_AT} as mentioned in the Obtaining Access Token for System Admin Tasks section.

   Example of cURL Request

```
curl --insecure -L -X POST "https://"${SSP_FQDN}"/default/admin/v1/Apps" \
-H 'Content-Type: application/json' \
-H "Authorization: Bearer ${SSP_AT}" \
-d '{
 "status": "active",
 "name": "app",
 "description": "Default Application for Security",
 "clientType": "CONFIDENTIAL",
 "allowedOpenIDScopes": [
     "openid",
     "email",
     "profile"
 ],
 "redirectURIs": [
     "https://www.example.com"
 ],
 "allowedGrantTypes": [
     "implicit",
     "authorization_code",
     "urn:ietf:params:oauth:grant-type:jwt-bearer",
     "client_credentials"
 ],
 "allowedOperations": [
     "introspect", "onbehalfof"
 ],
 "skipIssuerAudienceForIT": true,
 "userInfoEndpointResponseFormat": "PLAIN_JSON"
       }'
```

   The response payload fetches the Client ID and Client Secret values. Note these values, as these values will be used when you sign in to the Sample Web Application. For more information on the creation of the application, click here.

   Example of cURL Response

```
{
 "status": "active",
 "name": "app",
 "description": "Default Application for Security",
 "clientType": "CONFIDENTIAL",
 "allowedOpenIDScopes": [
     "openid",
     "profile",
     "email"
```

```
    ],
    "redirectURIs": [
        "https://www.example.com"
    ],
    "allowedGrantTypes": [
        "implicit",
        "client_credentials",
        "authorization_code",
        "urn:ietf:params:oauth:grant-type:jwt-bearer"
    ],
    "userInfoEndpointResponseFormat": "PLAIN_JSON",
    "skipIssuerAudienceForIT": true,
    "allowedOperations": [
        "introspect",
        "onbehalfof"
    ],
    "appId": "06c3cd12-20d2-4c89-8cc8-df429e3945e4",
    "createdBy": {
        "principalType": "CLIENT",
        "principalId": "006eddf2-ea8d-46b6-8c9b-2c355bf81aa2",
        "principalName": "defaulttenantclient"
    },
    "createdDateTime": "2020-06-23 04:28 AM UTC",
    "updatedDateTime": "2020-06-23 04:28 AM UTC",
    "secret": "c380f534-144d-44ac-b9e2-47a1dcfac5e1",
    "clientId": "5770ce5b-7252-4b9b-a7bd-da624c891fca"
}
```

2. Use the following cURL request to create a policy and associate it to the application created in the previous step:

NOTE

- This request creates a basic policy that contains only one rule. You should make use of the demo policy that is embedded in the Sample Web Application to be able to use all the use cases mentioned here. To see the detailed embedded policy, click Sample Policy Used for Demo
- Before running the following command, ensure that the variables, ${SSP_FQDN} in Configuring the Environment Variablesand ${SSP_AT} are set as mentioned in the Obtaining Access Token for System Admin Tasks section.

Example of cURL Request

```
cURL --insecure -L -X POST "https://"${SSP_FQDN}"/default/admin/v1/AuthPolicies" \
-H 'Content-Type: application/json' \
-H "Authorization: Bearer ${SSP_AT}" \
-d '{
    "description": "Sample policy record",
    "status": "active",
    "policyName": "Sample policy",
    "apps": [
        {
            "id": "06c3cd12-20d2-4c89-8cc8-df429e3945e4"
        }
    ],
    "rules": [
        {
            "conditions": {
                "action": {
```

```
                "operator": "in",
                "value": [
                    "login"
                ]
            },
            "principal": {
                "group": {
                    "operator": "in",
                    "value": [
                        "HR"
                    ]
                }
            },
            "ipAddress": {
                "operator": "in",
                "value": [
                    "10.0.0.0/24"
                ]
            },
            "channel": {
                "operator": "in",
                "value": [
                    "mobile"
                ]
            },
            "riskThreshold": {
                "operator": "ge",
                "value": 60
            }
        },
        "result": {
            "effect": "allow",
            "obligations": [
                "PASSWORD",
                "OTP"
            ],
            "msg": "This policy is for login in web channel"
        }
    }
]
      }'
```

Example of cURL Response

```
{
 "policyId": "3b6dd3f3-307e-492c-aaac-2606a885d66f",
 "policyName": "Sample policy",
 "description": "Sample policy record",
 "status": "active",
 "matchAnyApp": false,
 "apps": [
     {
         "name": "app",
         "id": "06c3cd12-20d2-4c89-8cc8-df429e3945e4"
```

```
        }
    ],
    "rules": [
        {
            "conditions": {
                "principal": {
                    "group": {
                        "operator": "in",
                        "value": [
                            "HR"
                        ]
                    }
                },
                "action": {
                    "operator": "in",
                    "value": [
                        "login"
                    ]
                },
                "ipAddress": {
                    "operator": "in",
                    "value": [
                        "10.0.0.0/24"
                    ]
                },
                "channel": {
                    "operator": "in",
                    "value": [
                        "mobile"
                    ]
                },
                "riskThreshold": {
                    "operator": "ge",
                    "value": 60
                }
            },
            "result": {
                "effect": "allow",
                "reAuthenticate": "false",
                "obligations": [
                    "PASSWORD",
                    "OTP"
                ],
                "msg": "This policy is for login in web channel"
            }
        }
    ],
    "createdBy": {
        "principalType": "CLIENT",
        "principalId": "006eddf2-ea8d-46b6-8c9b-2c355bf81aa2",
        "principalName": "defaulttenantclient"
    },
    "createdDate": "2020-06-23 04:31:42"
```

```
}
```

3. Use the following URL to access the Sample Web Application in the browser:
   `https://<sampleapp-fqdn>/sample-app`

   NOTE
   If you have not installed the SSP server with an SSL certificate, the Sample Web Application has a certificate error accessing the SSP service. Before proceeding with the Sample Web Application, use the browser to access the SSP service' tenant URL ${SSP_URL} and accept the certificate exception. This lets the browser remember this exception.

After you have successfully completed all the steps that are mentioned here, you can test the web use cases that are described here.

Steps to Modify Client Secret and Client Id

To change the Client Secret and Id, follow these steps:

1. Use the following URL to access the Sample Web Application in the browser:
   `https://<sampleapp-fqdn>/sample-app`
2. Click the Settings gear and perform the following steps:
   a. Enter your Client Id, Client Secret, and the base URL.

      NOTE

      - The Client Id and the Client Secret details can be fetched from step 1. For more information, see Managing Applications.
      - The base URL is the default IDSP URL.

   b. (Optional step) Enter the client IP Address of the Sample Web Application. Use this option to test risk roles. For example- Testing negative country scenarios.
   c. Clicking the Generate button is optional as the application automatically generates the access token upon page load. You can now use the generated access token to perform the authentication flows.

Deploying Demo Mobile Application (Android and iOS)

Learn how to set up the demo Mobile client app in your work environment and use it to receive notifications and perform authentication in the solution.

This topic includes the following sections:

- Hedmoral Mobile Android Application
- Hedmoral Mobile iOS Application

NOTE

- Passkey authentication is unavailable in Hedmoral application (iOS and Android).
- If you have already registered a FIDO credential over a web channel, and now you are attempting to register another FIDO credential through the Hedmoral app, in such a case, the authenticator returns a "credential not found" error. Therefore, before attempting to register a new FIDO credential on the Hedmoral app, you must first erase all currently registered FIDO credentials from Symantec Identity Security Platform. However, if you already registered a FIDO credential through the Hedmoral app and are attempting to add a new FIDO credential through the web app, it does not return any error and the flow is handled successfully.

Hedmoral Mobile Android Application

You can use the Android Mobile application (also known as Hedmoral Technologies app) to perform multi-factor authentication flows in IDSP. The supported authentication flows are Password, FIDO security key and biometric, Mobile OTP (includes VIP Access and Hedmoral), Server OTP (includes Email/SMS) and Push. The application also supports risk-based scenarios such as step-up (reauthentication), RememberMe, Trusted Devices, Public Client, and the Self-Service feature. To know more about these features, see the links that are provided in the reference section at the end of the page.

Prerequisites

To be able to run the Hedmoral Mobile Android App, ensure that you have met the following prerequisites:

- Obtained an Android device with Android 7.0 (Marshmallow) and above installed on it
- Deployed IDSP in your specific backend server (local or cloud environment)

Obtain Client Id and Secret

1. Retrieve the client id and secret for the out of the box, DemoClient (search for Demo Client) by running this command:

   ```
   kubectl get secret ${RELEASENAME}-ssp-secret-democlient -n ${NAMESPACE} -o jsonpath="{.data.clientId}" |
    base64 --decode; echo
   kubectl get secret ${RELEASENAME}-ssp-secret-democlient -n ${NAMESPACE} -o jsonpath="{.data.clientSecret}"
    | base64 --decode; echo
   ```

   The Client Id and Secret values that you have obtained should be entered in the Mobile Configurations Screen after you complete your installation. However, if you are using your mobile application as a ***Public Client***, you can ignore generating the secret. To know more about the public client, see Client Types.

Mobile Application Download Location

You can download the latest Mobile application from the Support Portal > My Downloads.

How to Install Mobile Application Using the APK File

Follow these steps to install the Mobile app:

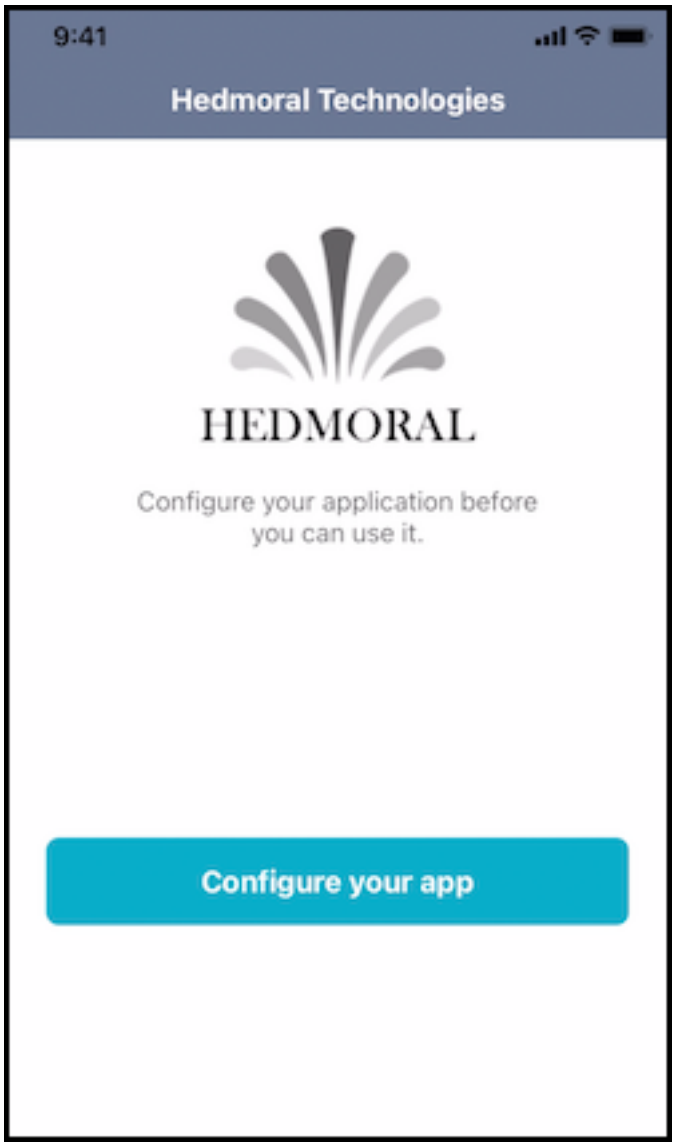
1. Navigate to the Validation site.
2. Copy the Android Package Kit, "APK" file from the "Clients" folder to your mobile device.
3. On your device, go to Menu > Settings > Security and check the **"Allow installation of apps from unknown sources"** option.
4. Tap the "APK" file and then click "INSTALL". The app begins installing on your device.
5. Look for the "Hedmoral Technologies" app in the Menu.

How to update the Hedmoral App with Configuration Details

After successfully installing the Hedmoral Mobile application on your phone, follow these steps:

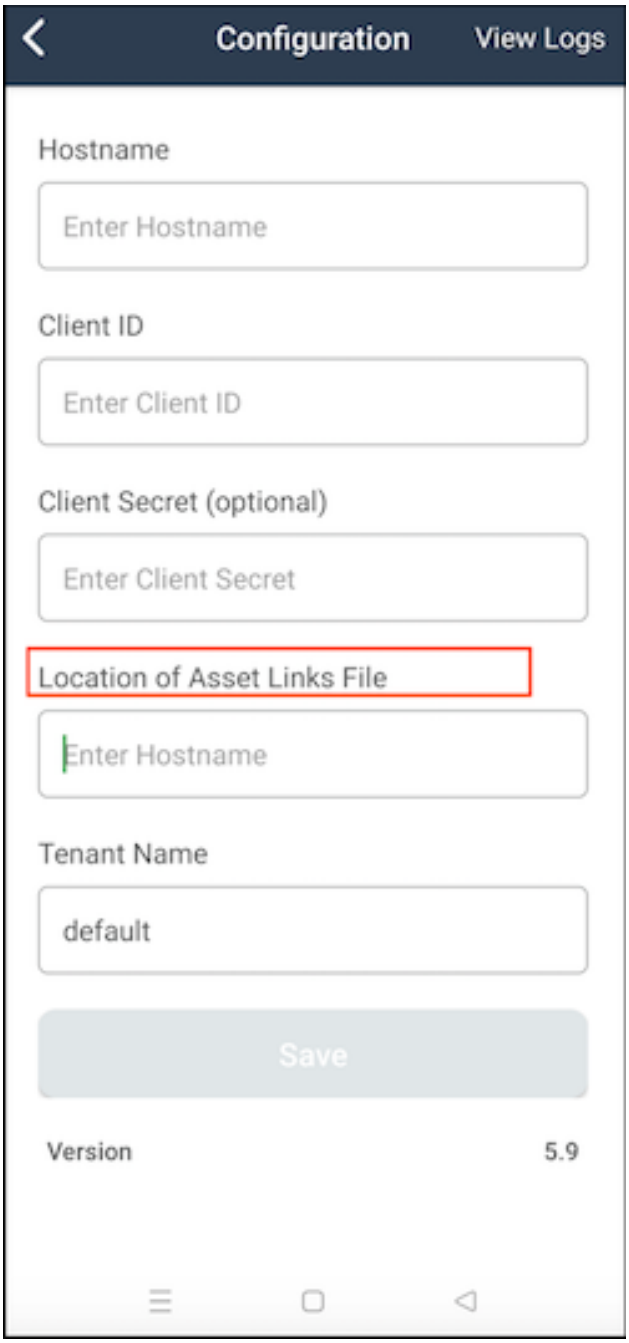
1. Open the application.
   The "Configure your app" screen is displayed.

Figure 10: Hedmoral Mobile App-Configure your app screen



2. Click the "Configure your app" field. The Configuration screen is displayed.
3. In the Configuration screen as shown here, enter the following details:

Figure 11: Hedmoral Mobile App-Configuration screen



a. Hostname: This is the IDSP server hostname.

NOTE

The supported hostname formats are as follows:

- ***Format 1: https://<Proxy Server URL>***
  Example: https://myProxy/Auth
  Where the host and tenant names are resolved by the Proxy server.
- ***Format 2: https://<hostname>***
  Example: https://myhost.com

When tenant is not part of the hostname, a tenant must be entered in the **Tenant Name** field.

- ***Format 3: <hostname>***
  Example: myhost.com
  In this case, the URI is optional. Since the tenant is not part of the hostname, a tenant must be entered in the **Tenant Name** field.

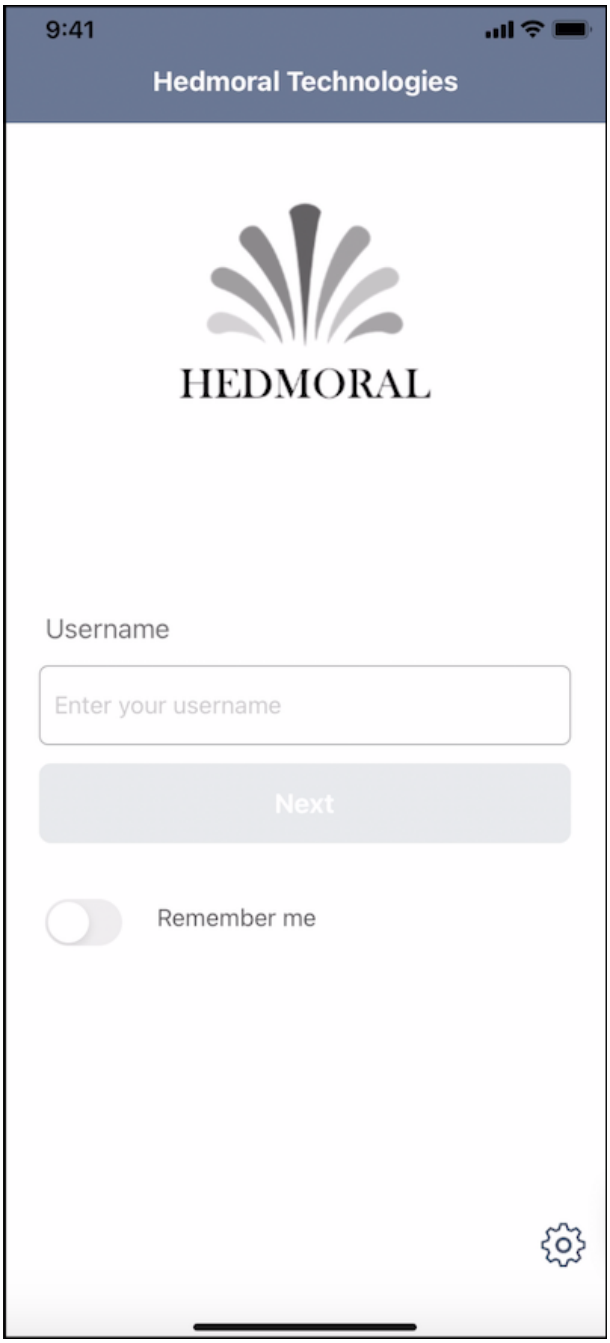
b. Client ID: This is obtained in the prerequisite section.
c. Client Secret: This field is optional if your mobile application is using the public client.
d. Location of Asset Links File: Provide the location where you have deployed the assetlinkjson.

   NOTE
   This field is only displayed for Hedmoral Android application.

e. Tenant Name: This is populated automatically as default. However, if you are using another tenant name, then update the same in this field.
f. Click Save. Upon saving, the Username screen is displayed.

4. Now, enter your credentials and log in to the application. <replace the username screen here>

Figure 12: Hedmoral Mobile App-Username screen



5. (Optional step) To check and update the configuration details, you can click the settings icon on the login screen.
6. (Optional step) To see the logs, click the **View Logs** in the configuration screen. The log information is helpful in troubleshooting issues. You can choose to share the logs in several ways, such as Gmail, WhatsApp, Mail, Message, etc.

Hedmoral Mobile iOS Application

As a user you can use the iOS Mobile application to execute, multi-factor authentication flows enabled by the solution. The supported authentication flows are Password, Platform Authenticators - (FIDO Face and Touch ID with a PIN as a fallback option), Mobile OTP (includes VIP Access and Hedmoral), Server OTP (includes Email/SMS) and Push. The application also supports risk-based scenarios such as step-up (reauthentication), RememberMe, Trusted Devices, Public

Client, and the Self-Service feature. To know more about these features, see the links that are provided in the reference section at the end of the page.

Prerequisites

To be able to run the Hedmoral Mobile iOS App for multi-factor authentication, ensure that you have met the following prerequisites:

- You have been invited to participate in the Apple TestFlight program and have downloaded the TestFight app from the Apple store to your phone. This allows you to download the Hedmoral Mobile app for iOS.
- Obtained an iOS device with iOS operating system 13 and above installed on it
- Deployed IDSP in your specific backend server (local or cloud environment)

Obtain Client Id and Secret

Follow the steps provided in the Android section.

How to update the iOS Hedmoral App with Configuration Details

Follow the steps provided in the Android section.

Now you can start testing the Mobile use cases described here using the IDSP app.

- Public Clients
- Risk Evaluation
- Self-Service

Upgrading Symantec Identity Security Platform Sample Web App

Learn the steps to upgrade Symantec Identity Security Platform Sample Web application.

Follow these steps to upgrade the sample chart:

The version of IDSP has to be equal or greater than the version of the Sample App. Therefore, make sure you upgrade the IDSP deployment before upgrading the Sample App.

1. Set the Release Name and Namespace of the IDSP Sample App service that was used during the deployment as environment variables:

   ```
   export SA_RELEASENAME="<sampleapp-release-name>"
   export SA_NAMESPACE="<sampleapp-namespace>"
   ```

   where,
   - <sampleapp-release-name> -The ***Sample App Release Name*** that was used during the solution's deployment.
   - <sampleapp-namespace> - The ***Sample App Namespace*** used during the solution's deployment. See Deploying Sample Web App for more details.

     NOTE
     In case you do not remember the values for Sample App Release name and Namespace that were used during the deployment, use the following command to get those values:
     helm ls --all-namespaces
2. To get the versions of the Sample App charts that are currently deployed, run this command:

   ```
   helm ls -n ${SA_NAMESPACE}
   ```

```
# helm ls -n samplapp
NAME            NAMESPACE   REVISION   UPDATED                                   STATUS     CHART                    APP VERSION
ssp-sample      samplapp    1          2021-11-15 04:57:29.273625026 -0500 EST deployed   ssp-sample-app-1.0.2430 1.0.2430
```

3. Ensure that the helm is pointing to the correct IDSP helm repository where the charts can be found:

   ```
   helm repo add ssp_helm_charts https://ssp_helm_charts.storage.googleapis.com
   ```

   NOTE
   It is safe to run the above command more than once even if the repo was already added before.

4. To get the latest information about the IDSP charts available in the chart repositories, use this command:

   ```
   helm repo update
   ```

5. To get the list of all available sample app helm chart versions in the ssp_helm_charts repo, run this command:

   ```
   helm search repo ssp_helm_charts/ssp-sample-app --versions
   ```

```
# helm search repo ssp_helm_charts --versions | grep "sample-app"
ssp_helm_charts/ssp-sample-app          1.0.2430        1.0.2430        2021.Nov.01 - Helm chart to deploy a sample app...
ssp_helm_charts/ssp-sample-app          1.0.2287        1.0.2287        2021.Jul.01 - Helm chart to deploy a sample app...
ssp_helm_charts/ssp-sample-app          1.0.2002        1.0.2002        2021.Apr.01 - Helm chart to deploy a sample app...
ssp_helm_charts/ssp-sample-app          1.0.1925        1.0.1925        2021.Feb.01 - Helm chart to deploy a sample app...
```

6. To get the user-supplied deployment values that were used during the deployment of the IDSP sample chart and save it in the *"sample-override.yaml" file, run this command:*

   ```
   helm get values ${SA_RELEASENAME} -n ${SA_NAMESPACE} >sampleapp-override.yaml
   ```

7. To upgrade to the latest version of IDSP Sample app chart, run this command:

   ```
   helm upgrade ${SA_RELEASENAME} ssp_helm_charts/ssp-sample-app -n ${SA_NAMESPACE}  -f sampleapp-
   override.yaml
   ```

```
$ helm upgrade ${SA_RELEASENAME} ssp_helm_charts/ssp-sample-app -n ${SA_NAMESPACE} -f sampleapp-override.yaml
Release "sampleapp" has been upgraded. Happy Helming!
NAME: sampleapp
LAST DEPLOYED: Fri Oct 16 09:42:23 2020
NAMESPACE: dev-sample
STATUS: deployed
REVISION: 4
TEST SUITE: None
NOTES:
Thank you for installing ssp-sample-app.
  Access sample app here: https://sampleapp.aws.ssp.security.broadcom.com/sample-app
```

   To upgrade to a specific version of IDSPchart, run this command:

   ```
   helm upgrade ${SA_RELEASENAME} ssp_helm_charts/ssp-sample-app -n ${SA_NAMESPACE}  -f sampleapp-
   override.yaml --version <CHART VERSION>
   ```

   <CHART VERSION> -This is the value that appears in the output of the helm search (helm search repo ssp_helm_charts/ssp-sample-app --versions) command.

8. To verify that the IDSP Sample App chart was upgraded to the desired version, run this command:

   ```
   helm ls -n ${SA_NAMESPACE}
   ```

Developer Resources

Learn how to make your first API call using Symantec Identity Security Platform, and integrate it with sample mobile/web/custom web/custom service providers, custom authenticators and about SDKs that the solution provides.

API Security Using OAuth2

Learn how to secure the Symantec Identity Security Platform REST APIs based on OAuth2 and OpenID industry standards, relying on JWT-based Access Token to control access to REST APIs. Learn about tokens, supported client types and grant types, and endpoints exposed by IDSP.

This lets developers authenticate users using Open ID Connect or other means to securely assert the identity, and then acquire access tokens to authorize access to the APIs.

- As the OAuth Resource Server, IDSP supports a rich set of administrative APIs to manage its resources and configuration.
- As the OAuth Authorization Server, IDSP supports client-only-based token issuance, as well as user-based token issuance to support identity propagation requirements.

> **NOTE**
> The use of OpenID Connect flows can be used independently of REST API access to handle identity assertion requirements.

This topic includes the following sections:

- General Notes for building or integrating client apps
- Prerequisites

General Notes for building or integrating client apps

As a developer, you are building applications using IDSP APIs or integrating your client apps using OpenID Connect standard. To perform these tasks, you should remember to do the following:

- Enabling CORS:
  - If your application's Fully Qualified Domain Name (FQDN)/Host is different from IDSP's, you must add your client app's FQDN by updating the "allowedOrigins" setting at the tenant level to enable the CORS standard to function properly.

    - To configure your client app's AllowedOrigins, use the PATCH "/admin/v1/Configs" API. See Settings page to know about allowedOrigins setting and see Applications to check the steps to update allowedOrigins setting.
- If your client app uses OpenID Connect to integrate with IDSP, make sure the app resource has the following configured:
  – redirectURI, allowedOpenIDScopes, allowedGrantTypes, and allowedOperations. These topics have been discussed in the subsequent sections in this page.
- If your client app uses the IDSP REST API to orchestrate authentication flow, the application has to be authorized with required privileges. Therefore, ensure that the client app is granted required privileges by adding it to the "AuthenticationClient" authorization policy. This policy gives privilege to invoke the authentication APIs. See Authentication and Authorization REST API (Scopes/Privileges) for more details.

Prerequisite

Install cURL to execute the samples provided in the sections below.

> **NOTE**
> A recommended way to verify the service URL is by running the service discovery curl command.

Introduction to Symantec Identity Security Platform Rest APIs and Scopes

Learn about Symantec Identity Security Platform Rest APIs and Privileges.

REST APIs allow applications to interact with IDSP resources using standard HTTP methods. Access to these APIs is controlled by OAuth scopes, which define the specific permissions required to perform operations.

This page includes the following sections:

- Rest API Endpoints
- Authentication and Authorization (Scopes/Privileges)
- Scope Management and Usage
- Scope Notation
- API Response Code
- Rest APIs and Associated Privileges

REST API Endpoints

You access the IDSP REST APIs using a URL endpoint based on the following syntax:

```
https://${SSP_FQDN}/<tenant>/<function>/v1/<operation>
```

- `<host>` : The FQDN of the ingress endpoint exposed by the deployed cluster.
- `<tenant>` : Is set to "default".
- `<function>` : Is one of the deployed micro-services listed in the API table.
- `<operation>` is the one of the business operations listed in the API table

For example, the API endpoint to create an Application resource is -
`https://example.com/default/admin/v1/Apps`

To use the REST APIs, an application requests an Access Token with the desired privileges (OAuth scopes) and then invokes the REST API. The API requests supplies the Access Token in the Authorization header as `Bearer <token>`.

> **NOTE**
> **Requirements for OpenShift Environment**
>
> In the OpenShift environment, when invoking tenant-specific APIs, it is mandatory to provide the "X-TENANT-NAME" header in the API request, else the API request fails with "400 BAD REQUEST" status.
>
> **Key Points**:
>
> - The tenant identified by "X-TENANT-NAME" must exist in the system
> - SSL certificate must be issued for the SSP_FQDN host
> - All tenant-specific API clients must include the "X-TENANT-NAME" header in their requests
>
> For more information, see Deploying Ingress Controller on Openshift

Authentication and Authorization (Scopes/Privileges)

REST APIs are protected by privileges ("scopes") exposed by IDSP. Application clients specify scopes as required in order to invoke REST API when initiating flows to request an access token. Once the request has been validated, the authorization server returns an access token containing the requested and authorized scopes.

Scope Management and Usage

Scopes are a list of case-sensitive strings that are defined by the Authorization server to specify the access privileges requested by the client/user.

The following section describes how these scopes are managed and used:

- **If the requested scope is not entitled**: If the requested scope is not entitled to the client/user, the client/user will be issued an access token with the list of all relevant scopes.
- **No scope passed in request**: If the client/user does not pass any scope in the request, the issued access token contains "urn:iam:m.me" scope and all APIs which are mapped to this scope will be authorized.
- **Subset of scopes**: If the client/user wants to make use of only a subset of the scope that is assigned to them, they can specify the list of scope (separated by space) in the body of the request. If the "scope" body contains the value "urn:iam:myscopes", then the client/user is issued the access token containing all the scopes which are associated with them.
- **Best Practice**: As a best practice, you should only request access for what you absolutely need.

Scope Notation

- **urn:iam:g.* scope**: Represent system-level privileges required to execute APIs that manage the operational state of the system. These scopes are granted by the System Admin and Infra Admin Authorization Policies.
- **urn:iam:t.* scope**: Represent tenant-level privileges required to execute APIs that implement the business of the system. These scopes are granted by the Tenant Admin Authorization Policy.
- **urn:iam:m.me scope**: Represent tenant-level privileges required to execute APIs that implement self-service operations on an end user. All such operations use the identity from the access token's "sub" claim. There is no

specific Admin Authorization Policy for these scopes. Instead, all ID propagation access token flows automatically add the "urn:iam:m.me" scope to any access token issued when the token's "sub_type" is "user".

- **urn:iam:myscopes (special convenience scope)**: Unlike requesting specific privileges to ensure access tokens get generated using the "least privilege" model, requesting the special convenience scope `urn:iam:myscopes` instructs the authorization server to return all authorized privileges.
  Greater care should be taken with this type of token. For example, these tokens should have a limited lifespan.

API Response Code

REST APIs are available for controllers and resources. The error codes returned by the REST API are as follows:

- **Controllers -** Examples of controllers: `/authenticate`. For controllers, the supported HTTP response codes are:
  - Success - 200
  - Failure - 401, 404, 429, 500
- **Resources -** Examples of resources: `/Users`, `/Groups`, `/policies`. For resources, the supported HTTP response codes are:
  - Success:
    - GET, PUT - 200
    - POST - 201
    - DELETE - 204
  - Failure - 401, 404, 409, 429, 500

For specific API details, see Swagger UI API References.

Rest APIs and Associated Privileges

To grant access to REST APIs, administrators can authorize different types of entities:

- Clients (applications or services)
- User groups (collections of users with similar roles)
- Individual users (through identity propagation)

This is done by adding or removing these entities from authorization policies that correspond to specific Admin Roles.

Built-in Privilege Mapping:

The system comes with a predefined mapping that connects each Admin Role to the specific privileges needed to call particular REST APIs. This mapping is configured out-of-the-box and determines which API endpoints each role can access.

The following topics show REST API mappings with their function-based privileges:

- ACCESS API Privileges
- ADMIN API Privileges
- AUTH API Privileges
- CAEP API Privileges
- FACTOR API Privileges
- IARISK API Privileges
- IASERVICES API Privileges
- IDENTITY API Privileges
- IDSTORE API Privileges
- LDAP API Privileges
- ME API Privileges
- OAUTH2 API Privileges
- RISK API Privileges
- SCIM 2.0 API Privileges
- UI API Privileges

ACCESS APIs

Learn about Symantec Identity Security Platform API endpoints and their associated informations like privileges, supported HTTP methods, descriptions etc.

ACCESS Function

API Description	API URI	Global / Tenant / Me	HTTP Method	API Scope
Get User's Applications	/access/v1/Apps/{userLoginName}	T	GET	urn:iam:t.authenticate
Get My Applications	/access/v1/MeApps	M	GET	urn:iam:m.me
Get My App Roles	/access/v1/MeAppRoles	M	GET	urn:iam:m.me urn:iam:m.meclient
Get My App Privileges	/access/v1/MeAppPrivileges	M	GET	urn:iam:m.me urn:iam:m.meclient

ADMIN API Privileges

This section covers the **ADMIN REST API** endpoints and the specific authorization privileges required to access them.

The following table maps **ADMIN APIs** to their required scopes and supported HTTP methods:

API Description	API URI	Global / Tenant / Me	HTTP Method	API Scope
Get All Applications	/admin/v1/Apps	T	GET	urn:iam:t.apps
Create Application	/admin/v1/Apps	T	POST	urn:iam:t.apps
Get Application by ID	/admin/v1/Apps/{appId}	T	GET	urn:iam:t.apps
Update Application	/admin/v1/Apps/{appId}	T	PUT	urn:iam:t.apps
Delete Application	/admin/v1/Apps/{appId}	T	DELETE	urn:iam:t.apps

API Description	API URI	Global / Tenant / Me	HTTP Method	API Scope
Check Application Existence	/admin/v1/Apps/{appName}	T	HEAD	urn:iam:t.apps
Get Authentication Policies	/admin/v1/AuthPolicies	T	GET	urn:iam:t.authpolicies
Create Authentication Policy	/admin/v1/AuthPolicies	T	POST	urn:iam:t.authpolicies
Get Policy by ID	/admin/v1/AuthPolicies/{policyId}	T	GET	urn:iam:t.authpolicies
Update Policy	/admin/v1/AuthPolicies/{policyId}	T	PUT	urn:iam:t.authpolicies
Patch Policy	/admin/v1/AuthPolicies/{policyId}	T	PATCH	urn:iam:t.authpolicies
Delete Policy	/admin/v1/AuthPolicies/{policyId}	T	DELETE	urn:iam:t.authpolicies
Check Policy Existence	/admin/v1/AuthPolicies/{policyName}	T	HEAD	urn:iam:t.authpolicies
Evaluate Authentication Policy	/admin/v1/AuthPoliciesEvaluator	T	POST	urn:iam:t.authpolicies
Get App Authentication Policies	/admin/v1/AppsAuthPolicies	T	GET	urn:iam:t.apps
Get App Auth Policies	/admin/v1/AppsAuthPolicies/{appId}	T	GET	urn:iam:t.apps
Assign Auth Policy to App	/admin/v1/AppsAuthPolicies/{appId}	T	PATCH	urn:iam:t.apps
Remove Auth Policy from App	/admin/v1/AppsAuthPolicies/{appId}	T	DELETE	urn:iam:t.apps
Get Authorization Policies	/admin/v1/AuthZPolicies	T	GET	urn:iam:t.authzpolicies urn:iam:g.authzpolicywriter
Create Authorization Policy	/admin/v1/AuthZPolicies	T	POST	urn:iam:t.authzpolicies urn:iam:g.authzpolicywriter
Get AuthZ Policy by ID	/admin/v1/AuthZPolicies/{policyId}	T	GET	urn:iam:t.authzpolicies urn:iam:g.authzpolicywriter
Update AuthZ Policy	/admin/v1/AuthZPolicies/{policyId}	T	PUT	urn:iam:t.authzpolicies urn:iam:g.authzpolicywriter
Patch AuthZ Policy	/admin/v1/AuthZPolicies/{policyId}	T	PATCH	urn:iam:t.authzpolicies urn:iam:g.authzpolicywriter
Delete AuthZ Policy	/admin/v1/AuthZPolicies/{policyId}	T	DELETE	urn:iam:t.authzpolicies urn:iam:g.authzpolicywriter
Check AuthZ Policy Existence	/admin/v1/AuthZPolicies/{policyId}	T	HEAD	urn:iam:t.authzpolicies urn:iam:g.authzpolicywriter
Search Users	/admin/v1/Users	T	GET	urn:iam:t.accountadmin urn:iam:t.users urn:iam:t.userdata
Get User by ID	/admin/v1/Users/{userId}	T	GET	urn:iam:t.accountadmin urn:iam:t.users urn:iam:t.userdata
Delete User	/admin/v1/Users/{userId}	T	DELETE	urn:iam:t.accountadmin urn:iam:t.users urn:iam:t.userdata
Get User Lock Status	/admin/v1/UserLocker/{userId}	T	GET	urn:iam:t.users urn:iam:t.accountadmin
Set User Lock Status	/admin/v1/UserLocker/{userId}	T	POST	urn:iam:t.users urn:iam:t.accountadmin
Get User Disable Status	/admin/v1/UserDisabler/{userId}	T	GET	urn:iam:t.users urn:iam:t.accountadmin

API Description	API URI	Global / Tenant / Me	HTTP Method	API Scope
Set User Disable Status	/admin/v1/UserDisabler/{userId}	T	POST	urn:iam:t.users urn:iam:t.accountadmin
Update User Password	/admin/v1/PasswordUpdater	T	PUT	urn:iam:t.users
Get Admin Roles	/admin/v1/AdminRoles	T	POST	urn:iam:t.users urn:iam:t.groups urn:iam:t.apps urn:iam:t.adminroles
Get All Admin Roles	/admin/v1/AdminRolesDelegator	T	GET	urn:iam:t.users urn:iam:t.groups urn:iam:t.apps urn:iam:t.adminroles
Grant Admin Role	/admin/v1/AdminRolesDelegator	T	POST	urn:iam:t.users urn:iam:t.groups urn:iam:t.apps urn:iam:t.adminroles
Revoke Admin Role	/admin/v1/AdminRolesDelegator	T	DELETE	urn:iam:t.users urn:iam:t.groups urn:iam:t.apps urn:iam:t.adminroles
Get My Admin Roles	/admin/v1/MyAdminRoles	M	GET	urn:iam:m.me urn:iam:m.meclient
Get App Roles	/admin/v1/AppRoles	T	POST	urn:iam:t.users urn:iam:t.groups urn:iam:t.apps urn:iam:t.adminroles
Get App Privileges	/admin/v1/AppPrivileges	T	POST	urn:iam:t.users urn:iam:t.groups urn:iam:t.apps urn:iam:t.adminroles
Grant App Role	/admin/v1/AppRolesDelegator	T	POST	urn:iam:t.users urn:iam:t.groups urn:iam:t.apps urn:iam:t.adminroles
Revoke App Role	/admin/v1/AppRolesDelegator	T	DELETE	urn:iam:t.users urn:iam:t.groups urn:iam:t.apps urn:iam:t.adminroles
Get All Certificates	/admin/v1/Certs	T	GET	urn:iam:t.certs
Upload Certificate	/admin/v1/Certs	T	POST	urn:iam:t.certs
Get Certificate by ID	/admin/v1/Certs/{certId}	T	GET	urn:iam:t.certs
Update Certificate	/admin/v1/Certs/{certId}	T	PUT	urn:iam:t.certs
Delete Certificate	/admin/v1/Certs/{certId}	T	DELETE	urn:iam:t.certs
Get All Secrets	/admin/v1/Secrets	T	GET	urn:iam:t.secrets
Add Secret	/admin/v1/Secrets	T	POST	urn:iam:t.secrets
Get Secret by ID	/admin/v1/Secrets/{secretId}	T	GET	urn:iam:t.secrets

API Description	API URI	Global / Tenant / Me	HTTP Method	API Scope
Update Secret	/admin/v1/Secrets/{secretId}	T	PUT	urn:iam:t.secrets
Delete Secret	/admin/v1/Secrets/{secretId}	T	DELETE	urn:iam:t.secrets
Get Secret in Base64	/admin/v1/SecretsGetter/{secretId}	T	GET	urn:iam:t.secretsgetter
Get All Keys	/admin/v1/Keys	T	GET	urn:iam:t.secrets
Update Key	/admin/v1/Keys/{keyId}	T	PUT	urn:iam:t.secrets
Enable/Disable Key	/admin/v1/Keys/{keyId}	T	PATCH	urn:iam:t.secrets
Update Tenant Settings	/admin/v1/Configs	T	PATCH	urn:iam:t.configs
Get Tenant Settings	/admin/v1/Configs	T	GET	urn:iam:t.configs

AUTH API Privileges

This section covers the **AUTH REST API** endpoints and the specific authorization privileges required to access them.

The following table maps **AUTH REST APIs** to their required scopes and supported HTTP methods:

API Description	API URI	Global / Tenant / Me	HTTP Method	API Scope
Authentication Initiation	/auth/v1/authenticate	T	POST	urn:iam:t.authenticate
Authentication Simulator	/auth/v1/AuthenticateSimulator	T	POST	urn:iam:t.authenticate
User Authenticator	/auth/v1/UserAuthenticator	T	POST	urn:iam:t.authenticate
Multi-Factor Authentication	/auth/v1/SelectedFactor	T	POST	urn:iam:t.authenticate
UI Locale Content	/auth/v1/UILocaleContent	T	POST	urn:iam:t.authenticate
Tenant Branding Settings	/auth/v1/BrandingSettings/idp	T	GET	urn:iam:t.authenticate
Branding Settings	/auth/v1/BrandingSettings	T	GET	urn:iam:t.authenticate
Get My Trusted Devices	/auth/v1/MeTrustedDevices	M	GET	urn:iam:m.me
Get My Trusted Device	/auth/v1/MeTrustedDevices/{deviceId}	M	GET	urn:iam:m.me
Delete My Trusted Device	/auth/v1/MeTrustedDevices/{deviceId}	M	DELETE	urn:iam:m.me
Data Decryption	/auth/v1/DecryptData	T	POST	urn:iam:t.authenticate
Client Nonce Helper	/auth/v1/ClientNonceGenerator	T	POST	urn:iam:t.configs
Server Nonce Helper	/auth/v1/NonceGenerator	T	POST	urn:iam:t.authenticate
Get My Sessions	/auth/v1/MeSessions	M	GET	urn:iam:m.me
Revoke My Sessions	/auth/v1/MeSessions	M	DELETE	urn:iam:m.me
Get My Session by ID	/auth/v1/MeSessions/{sessionId}	M	GET	urn:iam:m.me
Revoke My Session	/auth/v1/MeSessions/{sessionId}	M	DELETE	urn:iam:m.me
Get My Refresh Tokens	/auth/v1/MeRefreshTokens	M	GET	urn:iam:m.me
Revoke My Refresh Tokens	/auth/v1/MeRefreshTokens	M	DELETE	urn:iam:m.me
Get My Refresh Token	/auth/v1/MeRefreshTokens/{sessionId}	M	GET	urn:iam:m.me
Revoke My Refresh Token	/auth/v1/MeRefreshTokens/{sessionId}	M	DELETE	urn:iam:m.me
Revoke My Sessions and Tokens	/auth/v1/MeSessionsAndRefreshTokens	M	DELETE	urn:iam:m.me
My Refresh Tokens Helper	/auth/v1/MeRefreshTokensHelper	M	GET	urn:iam:m.me

CAEP API Privileges

This section covers the **CAEP REST API** endpoints and the specific authorization privileges required to access them.

The following table maps **CAEP REST APIs** to their required scopes and supported HTTP methods:

API Description	API URI	Global / Tenant / Me	HTTP Method	API Scope
CAEP Security Events	/caep/v1/Events	T	POST	urn:iam:t.securityevents

FACTOR API Privileges

This section covers the **FACTOR REST API** endpoints and the specific authorization privileges required to access them.

The following table maps **FACTOR REST API** to their required scopes and supported HTTP methods:

API Description	API URI	Global / Tenant / Me	HTTP Method	API Scope
Password Authentication	/factor/v1/PasswordAuthenticator	T	POST	urn:iam:t.authenticate
Custom Authentication	/factor/v1/CustomAuthenticator	T	POST	urn:iam:t.authenticate
Attribute Based Factor	/factor/v1/Authenticator	T	POST	urn:iam:t.authenticate
OTP Registration	/factor/v1/OTPRegistrar	M	POST	urn:iam:m.me urn:iam:t.authenticate
OTP Generation	/factor/v1/OTPGenerator	M	POST	urn:iam:m.me urn:iam:t.authenticate
OTP Verification	/factor/v1/OTPVerifier	M	POST	urn:iam:m.me urn:iam:t.authenticate
Update My Password	/factor/v1/MePasswordUpdater	M	PUT	urn:iam:m.me urn:iam:t.authenticate
Mobile OTP Registration	/factor/v1/MobileOTPRegistrar	M	POST	urn:iam:m.me urn:iam:t.authenticate
VIP Credential Registration	/factor/v1/VIPCredentialRegistrar	M	POST	urn:iam:m.me urn:iam:t.authenticate
Mobile OTP Verification	/factor/v1/MobileOTPVerifier	M	POST	urn:iam:m.me urn:iam:t.authenticate
OCRA Transaction Verification	/factor/v1/OCRATransactionVerifier	M	POST	urn:iam:m.me
Initiate Push Registration	/factor/v1/PushRegistrarInitiator	M	POST	urn:iam:m.me urn:iam:t.authenticate
Get Push Registration Status	/factor/v1/PushRegistrarStatus	M	GET	urn:iam:m.me urn:iam:t.authenticate
Register Device for Push Notification	/factor/v1/PushRegistrar	M	POST	urn:iam:m.me urn:iam:t.authenticate
Push Notification Generation	/factor/v1/PushGenerator	M	POST	urn:iam:m.me urn:iam:t.authenticate
Verify Push Notification	/factor/v1/PushVerifier	M	POST	urn:iam:m.me urn:iam:t.authenticate
Push Status Check	/factor/v1/PushStatus	M	POST	urn:iam:m.me urn:iam:t.authenticate
FIDO Authentication Challenge	/factor/v1/ FIDOAuthChallengeGenerator	M	POST	urn:iam:m.me urn:iam:t.authenticate
FIDO Authentication Verification	/factor/v1/FIDOAuthChallengeVerifier	M	POST	urn:iam:m.me urn:iam:t.authenticate
FIDO Registration Challenge	/factor/v1/ FIDORegChallengeGenerator	M	POST	urn:iam:m.me urn:iam:t.authenticate
FIDO Registration Verification	/factor/v1/FIDORegChallengeVerifier	M	POST	urn:iam:m.me urn:iam:t.authenticate
Get My Credentials	/factor/v1/MeCreds	M	GET	urn:iam:m.me

API Description	API URI	Global / Tenant / Me	HTTP Method	API Scope
Get My Credential	/factor/v1/MeCreds/{credId}	M	GET	urn:iam:m.me
Update My Credential	/factor/v1/MeCreds/{credId}	M	PUT	urn:iam:m.me
Delete My Credential	/factor/v1/MeCreds/{credId}	M	DELETE	urn:iam:m.me
Generate FIDO Transaction Signing Challenge	/factor/v1/FIDOTransactionSigningChallengeGenerator	T	POST	urn:iam:t.authenticate
Verify FIDO Transaction Signing Challenge	/factor/v1/FIDOTransactionSigningChallengeVerifier	T	POST	urn:iam:t.authenticate

IARISK API Privileges

This section covers the **IARISK REST API** endpoints and the specific authorization privileges required to access them.

The following table maps **IARISK REST API** to their required scopes and supported HTTP methods:

API Description	API URI	Global / Tenant / Me	HTTP Method	API Scope
Get My Known Devices	/iarisk/v1/MeKnownDevices	M	GET	urn:iam:m.me
Delete My Known Devices	/iarisk/v1/MeKnownDevices	M	DELETE	urn:iam:m.me
Get My Known Device	/iarisk/v1/MeKnownDevices/{deviceId}	M	GET	urn:iam:m.me
Delete My Known Device	/iarisk/v1/MeKnownDevices/{deviceId}	M	DELETE	urn:iam:m.me
Get User Known Devices	/iarisk/v1/KnownDevices/{userId}	T	GET	urn:iam:t.users urn:iam:t.userdata
Delete User Known Devices	/iarisk/v1/KnownDevices/{userId}	T	DELETE	urn:iam:t.users urn:iam:t.userdata
Get User Known Device	/iarisk/v1/KnownDevices/{userId}/{deviceId}	T	GET	urn:iam:t.users urn:iam:t.userdata
Delete User Known Device	/iarisk/v1/KnownDevices/{userId}/{deviceId}	T	DELETE	urn:iam:t.users urn:iam:t.userdata
IA Risk User Evaluation	/iarisk/v1/UserRiskScoreEvaluator	T	POST	urn:iam:t.risk
Post User Risk Evaluation	/iarisk/v1/PostUserRiskScoreEvaluator	T	POST	urn:iam:t.risk
Client Risk Evaluation	/iarisk/v1/ClientRiskScoreEvaluator	T	POST	urn:iam:t.risk
Post Client Risk Evaluation	/iarisk/v1/PostClientRiskScoreEvaluator	T	POST	urn:iam:t.risk
Evaluate Machine Risk Score	/iarisk/v1/MachineRiskScoreEvaluator	T	POST	urn:iam:t.risk
Post Machine Risk Score Evaluation	/iarisk/v1/PostMachineRiskScoreEvaluator	T	POST	urn:iam:t.risk
Set Risk Threshold	/iarisk/v1/RiskThreshold	T	PUT	urn:iam:t.configs
Update Risky Countries	/iarisk/v1/RiskyCountries	T	PUT	urn:iam:t.configs
Manage IP List	/iarisk/v1/IPList	T	GET	urn:iam:t.configs

API Description	API URI	Global / Tenant / Me	HTTP Method	API Scope
Set Allowed IP List	/iarisk/v1/IPList/ALLOWED	T	PUT	urn:iam:t.configs
Set Blocked IP List	/iarisk/v1/IPList/BLOCKED	T	PUT	urn:iam:t.configs
Manage Risk Policies	/iarisk/v1/Policies	T	GET	urn:iam:t.configs
Manage Login Risk Policies	/iarisk/v1/Policies/login	T	GET	urn:iam:t.configs
Update Risk Rules	/iarisk/v1/RiskRules	T	PUT	urn:iam:t.configs
Get User Risk Score	/iarisk/v1/UserRiskScore	T	GET	urn:iam:t.risk

IASERVICES API Privileges

This section covers the **IASERVICES REST API** endpoints and the specific authorization privileges required to access them.

The following table maps **SCIM 2.0 APIs** to their required scopes and supported HTTP methods:

API Description	API URI	Global / Tenant / Me	HTTP Method	API Scope
Confirm Risk Assessment	/iaservices/risk/v1/confirm	T	POST	urn:iam:t.risk

IDENTITY API Privileges

This section covers the **IDENTITY REST API** endpoints and the specific authorization privileges required to access them.

The following table maps **IDENTITY REST APIs** to their required scopes and supported HTTP methods:

API Description	API URI	Global / Tenant / Me	HTTP Method	API Scope
Validate User Password	/identity/v1/UserPasswordValidator	T	POST	urn:iam:t.identityclient urn:iam:t.authenticate
Change User Password	/identity/v1/UserPasswordChanger	T	POST	urn:iam:t.userpasswordadmin urn:iam:t.authenticate
Generate Temporary Password	/identity/v1/UserPasswordGenerator	T	POST	urn:iam:t.identityclient urn:iam:t.authenticate
Initiate Email Verification	/identity/v1/EmailVerificationInitiator	T	POST	urn:iam:t.identityclient urn:iam:t.authenticate urn:iam:g.securitytokens
Verify Email	/identity/v1/EmailVerifier	T	POST	urn:iam:t.identityclient urn:iam:t.authenticate
Initiate Phone Verification	/identity/v1/PhoneVerificationInitiator	T	POST	urn:iam:t.identityclient urn:iam:t.authenticate urn:iam:g.securitytokens
Verify Phone Number	/identity/v1/PhoneVerifier	T	POST	urn:iam:t.identityclient urn:iam:t.authenticate

API Description	API URI	Global / Tenant / Me	HTTP Method	API Scope
Get Verified Credentials	/identity/v1/VerifiedCredentials	T	GET	urn:iam:t.identityclient urn:iam:t.authenticate urn:iam:t.users
Update My Password	/identity/v1/MePasswordUpdater	M	PUT	urn:iam:m.me
My Registration	/identity/v1/MeRegistration	M	POST	urn:iam:m.me
Initiate My Email Verification	/identity/v1/ MeEmailVerificationInitiator	M	POST	urn:iam:m.me
Verify My Email	/identity/v1/MeEmailVerifier	M	POST	urn:iam:m.me
Initiate My Phone Verification	/identity/v1/ MePhoneVerificationInitiator	M	POST	urn:iam:m.me
Verify My Phone	/identity/v1/MePhoneVerifier	M	POST	urn:iam:m.me
Get My Verified Credentials	/identity/v1/MeVerifiedCredentials	M	GET	urn:iam:m.me
Validate My Password	/identity/v1/MePasswordValidator	M	POST	urn:iam:m.me
Change My Password	/identity/v1/MePasswordChanger	M	POST	urn:iam:m.me
Initiate Password Reset	/identity/v1/PasswordResetInitiator	T	POST	urn:iam:t.users urn:iam:t.identityclient urn:iam:t.authenticate urn:iam:g.securitytokens
Validate Password Reset	/identity/v1/PasswordResetValidator	T	POST	urn:iam:t.identityclient urn:iam:t.authenticate
Change Password via Reset	/identity/v1/PasswordResetChanger	T	POST	urn:iam:t.identityclient urn:iam:t.authenticate
Identity Entity Management	/identity/v1/entity	T	GET	urn:iam:t.identity
Identity Authorization	/identity/v1/authorization	T	POST	urn:iam:t.identity
Identity Query	/identity/v1/query	T	POST	urn:iam:t.identity
Identity Relationship Management	/identity/v1/relationship	T	GET	urn:iam:t.identity
Identity Schema Management	/identity/v1/schema	T	GET	urn:iam:t.identity
My Schema Helper	/identity/v1/MeSchemaHelper	M	GET	urn:iam:m.me
My Subdelegations	/identity/v1/MeSubdelegations	M	GET	urn:iam:m.me urn:iam:m.meclient
Subdelegations Management	/identity/v1/Subdelegations	M	GET	urn:iam:m.me urn:iam:m.meclient
Admin Roles Subdelegator	/identity/v1/AdminRolesSubdelegator	M	POST	urn:iam:m.me urn:iam:m.meclient
Resource Subdelegator	/identity/v1/ResourceSubdelegator	M	POST	urn:iam:m.me urn:iam:m.meclient
Subdelegations Helper	/identity/v1/SubdelegationsHelper	T	GET	urn:iam:t.diagnosticsadmin
Manage Service Accounts	/identity/v1/ServiceAccounts	T	GET	urn:iam:t.identityclient
My Service Accounts	/identity/v1/MeServiceAccounts	M	GET	urn:iam:m.me
My Service Account Locker	/identity/v1/MeServiceAccountLocker	M	POST	urn:iam:m.me

IDSTORE API Privileges

This section covers the **IDSTORE REST API** endpoints and the specific authorization privileges required to access them.

The following table maps **IDSTORE REST APIs** to their required scopes and supported HTTP methods:

API Description	API URI	Global / Tenant / Me	HTTP Method	API Scope
Search for Users	/idstore/v1/Users	T	GET	urn:iam:t.idstoreadmin urn:iam:t.idstorebrowser
Search for Groups	/idstore/v1/Groups	T	GET	urn:iam:t.idstoreadmin urn:iam:t.idstorebrowser
User Locker	/idstore/v1/UserLocker	T	POST	urn:iam:t.idstoreadmin

LDAP API Privileges

This section covers the **LDAP REST API** endpoints and the specific authorization privileges required to access them.

The following table maps **LDAP APIs** to their required scopes and supported HTTP methods:

API Description	API URI	Global / Tenant / Me	HTTP Method	API Scope
Authenticates user against ldap	/ldap/v1/authenticate	T	POST	urn:iam:t.authenticate

ME API Privileges

This section covers the **ME REST API** endpoints and the specific authorization privileges required to access them.

The following table maps **ME REST APIs** to their required scopes and supported HTTP methods:

API Description	API URI	Global / Tenant / Me	HTTP Method	API Scope
Get My Settings	/me/v1/Settings	M	GET	urn:iam:m.me
Update My Settings	/me/v1/Settings	M	PUT	urn:iam:m.me
Get My Preferences	/me/v1/Preferences	M	GET	urn:iam:m.me
Update My Preferences	/me/v1/Preferences	M	PUT	urn:iam:m.me
Get My App Tiles	/me/v1/AppTiles	M	GET	urn:iam:m.me
Create My App Tile	/me/v1/AppTiles	M	POST	urn:iam:m.me
Update My App Tile	/me/v1/AppTiles/{tileId}	M	PUT	urn:iam:m.me
Delete My App Tile Group	/me/v1/AppTiles/Group	M	DELETE	urn:iam:m.me
Service Account Schema Helper	/me/v1/ ServiceAccountSchemaHelper	M	GET	urn:iam:m.me
My Expression Validator	/me/v1/ExpressionValidator	M	POST	urn:iam:m.me

OAUTH2 API Privileges

This section covers the **OAUTH REST API** endpoints and the specific authorization privileges required to access them.

The following table maps **OAUTH 2.0 APIs** to their required scopes and supported HTTP methods:

API Description	API URI	Global / Tenant / Me	HTTP Method	API Scope
OAuth Authorization Server Discovery	/.well-known/oauth-authorization-server		GET	No scope required
OpenID Connect Discovery	/.well-known/openid-configuration		GET	No scope required
JSON Web Key Set	/oauth2/v1/jwks		GET	No scope required
OAuth Authorization (non-PKCE)	/oauth2/v1/authorize		GET	No scope required
OAuth Authorization (PKCE)	/oauth2/v1/authorize		POST	No scope required
Token Request GET	/oauth2/v1/token		GET	No scope required
OAuth Token Endpoint	/oauth2/v1/token		POST	No scope required
UserInfo Endpoint	/oauth2/v1/userinfo	M	GET	urn:iam:m.me openid
UserInfo Endpoint	/oauth2/v1/userinfo	M	POST	urn:iam:m.me openid
OAuth Logout	/oauth2/v1/logout		GET	No scope required
Token Introspection	/oauth2/v1/introspect		POST	No scope required
Token Revocation	/oauth2/v1/revoke		POST	No scope required
Dynamic Client Registration	/oauth2/v1/register	T	POST	urn:iam:t.dcr
Delete Client	/oauth2/v1/register/{clientId}	T	DELETE	urn:iam:t.dcr
Client Secret Rotation	/oauth2/v1/rotatesecret		POST	No scope required
Device Code User Confirmation	/oauth2/v1/devicecode		GET	No scope required
Device Code Flow	/oauth2/v1/devicecode		POST	No scope required
Personal Token	/oauth2/v1/personaltoken		POST	No scope required
Identity Provider	/oauth2/v1/idp	T	POST	urn:iam:t.authenticate
Bring Your Own Identity	/oauth2/v1/byoi	T	POST	urn:iam:t.authenticate

RISK API Privileges

This section covers the **RISK REST API** endpoints and the specific authorization privileges required to access them.

The following table maps **RISK APIs** to their required scopes and supported HTTP methods:

API Description	API URI	Global / Tenant / Me	HTTP Method	API Scope
Evaluate Risk	/risk/v1/UserRiskScoreEvaluator	T	POST	urn:iam:t.risk
Update Risk	/risk/v1/UserRiskScoreUpdater	T	POST	urn:iam:t.risk
Get users risk score	/risk/v1/UserRiskScoreGetter	T	GET	urn:iam:t.risk

SCIM 2.0 API Privileges

This section covers the **SCIM 2.0 REST API** endpoints and the specific authorization privileges required to access them.

The following table maps **SCIM 2.0 APIs** to their required scopes and supported HTTP methods.

API Description	API URI	Global / Tenant / Me	HTTP Method	API Scope
SCIM Get Users	/scim2/v1/Users	T	GET	urn:iam:t.users
SCIM Create User	/scim2/v1/Users	T	POST	urn:iam:t.users
SCIM Get User by ID	/scim2/v1/Users/{userId}	T	GET	urn:iam:t.users
SCIM Update User	/scim2/v1/Users/{userId}	T	PUT	urn:iam:t.users
SCIM Patch User	/scim2/v1/Users/{userId}	T	PATCH	urn:iam:t.users
SCIM Delete User	/scim2/v1/Users/{userId}	T	DELETE	urn:iam:t.users
SCIM Get Groups	/scim2/v1/Groups	T	GET	urn:iam:t.groups
SCIM Create Group	/scim2/v1/Groups	T	POST	urn:iam:t.groups
SCIM Get Group by ID	/scim2/v1/Groups/{groupId}	T	GET	urn:iam:t.groups
SCIM Update Group	/scim2/v1/Groups/{groupId}	T	PUT	urn:iam:t.groups
SCIM Patch Group	/scim2/v1/Groups/{groupId}	T	PATCH	urn:iam:t.groups
SCIM Delete Group	/scim2/v1/Groups/{groupId}	T	DELETE	urn:iam:t.groups
SCIM Update My Profile	/scim2/v1/Me	M	PUT	urn:iam:m.me
SCIM Search Users	/scim2/v1/Users/.search	T	POST	urn:iam:t.users urn:iam:t.identityclient
SCIM Search Groups	/scim2/v1/Groups/.search	T	POST	urn:iam:t.groups urn:iam:t.identityclient
SCIM Bulk Operations	/scim2/v1/Bulk	T	POST	urn:iam:t.users urn:iam:t.groups
SCIM Get Schemas	/scim2/v1/Schemas	T	GET	urn:iam:t.users urn:iam:t.groups urn:iam:t.identityclient
SCIM Service Provider Config	/scim2/v1/ServiceProviderConfig	T	GET	urn:iam:t.users urn:iam:t.groups urn:iam:t.identityclient
SCIM Resource Types	/scim2/v1/ResourceTypes	T	GET	urn:iam:t.users urn:iam:t.groups urn:iam:t.identityclient
SCIM2 CAEP Events	/scim2/v1/Caep	T	POST	urn:iam:t.securityevents
SCIM2 Me Resource	/scim2/v1/Me	M	GET	urn:iam:m.me
SCIM2 Users Resource	/scim2/v1/Users	T	GET	urn:iam:t.users
SCIM2 Strict Users Resource	/scim2/v1/strict/Users	T	GET	urn:iam:t.users
SCIM2 Groups Resource	/scim2/v1/Groups	T	GET	urn:iam:t.groups
SCIM2 Strict Groups Resource	/scim2/v1/strict/Groups	T	GET	urn:iam:t.groups
SCIM2 Users Search	/scim2/v1/Users/.search	T	POST	urn:iam:t.users urn:iam:t.identityclient
SCIM2 Strict Users Search	/scim2/v1/strict/Users/.search	T	POST	urn:iam:t.users urn:iam:t.identityclient
SCIM2 Groups Search	/scim2/v1/Groups/.search	T	POST	urn:iam:t.groups urn:iam:t.identityclient

API Description	API URI	Global / Tenant / Me	HTTP Method	API Scope
SCIM2 Strict Groups Search	/scim2/v1/strict/Groups/.search	T	POST	urn:iam:t.groups urn:iam:t.identityclient
SCIM2 Bulk Operations	/scim2/v1/Bulk	T	POST	urn:iam:t.users urn:iam:t.groups
SCIM2 Strict Bulk Operations	/scim2/v1/strict/Bulk	T	POST	urn:iam:t.users urn:iam:t.groups
SCIM2 Schemas	/scim2/v1/Schemas	T	GET	urn:iam:t.users urn:iam:t.groups urn:iam:t.identityclient
SCIM2 Service Provider Config	/scim2/v1/ServiceProviderConfig	T	GET	urn:iam:t.users urn:iam:t.groups urn:iam:t.identityclient
SCIM2 Resource Types	/scim2/v1/ResourceTypes	T	GET	urn:iam:t.users urn:iam:t.groups urn:iam:t.identityclient
SCIM2 Strict Me Resource	/scim2/v1/strict/Me	M	GET	urn:iam:m.me
SCIM2 Strict Users Resource	/scim2/v1/strict/Users	T	GET	urn:iam:t.users
SCIM2 Strict Groups Resource	/scim2/v1/strict/Groups	T	GET	urn:iam:t.groups
SCIM2 Strict Users Search	/scim2/v1/strict/Users/.search	T	POST	urn:iam:t.users urn:iam:t.identityclient
SCIM2 Strict Groups Search	/scim2/v1/strict/Groups/.search	T	POST	urn:iam:t.groups urn:iam:t.identityclient
SCIM2 Strict Bulk Operations	/scim2/v1/strict/Bulk	T	POST	urn:iam:t.users urn:iam:t.groups
SCIM2 Strict Schemas	/scim2/v1/strict/Schemas	T	GET	urn:iam:t.users urn:iam:t.groups urn:iam:t.identityclient
SCIM2 Strict Service Provider Config	/scim2/v1/strict/ ServiceProviderConfig	T	GET	urn:iam:t.users urn:iam:t.groups urn:iam:t.identityclient
SCIM2 Strict Resource Types	/scim2/v1/strict/ResourceTypes	T	GET	urn:iam:t.users urn:iam:t.groups urn:iam:t.identityclient
SCIM2 Password Authenticator	/scim2/v1/PasswordAuthenticator	T	POST	urn:iam:t.users urn:iam:t.identityclient

UI API Privileges

This section covers the **UI REST API** endpoints and the specific authorization privileges required to access them.

The following table maps **UI REST API** to their required scopes and supported HTTP methods:

API Description	API URI	Global / Tenant / Me	HTTP Method	API Scope
Export DER Certificate	/ui/v1/adminconsole/export-der	T	GET	urn:iam:t.any
Download Admin Console Content	/ui/v1/adminconsole/download-content	T	GET	urn:iam:t.any

Tokens

Learn about Tokens in Symantec Identity Security Platform.

This topic includes the links to the following topics:

- Access Token
- Identity Token
- Refresh Token
- Custom Claims
- Revoke Token
- Using Tokens to Drive Generic Authorization

Access Token

Learn about Symantec Identity Security Platform Access Tokens.

This topic includes the following sections:

- Access Token
- Access Token Examples
- Custom Access Token Expiry and Associated Examples

Access Tokens are bearer security instruments used by REST API clients to gain access to protected APIs. An Access Token is a signed JWT, authorized and issued by IDSP. It represents a client's right to use specific privileges (called OAuth scopes) for the lifetime of the Access Token. Access Tokens have a limited lifetime, controlled by application property (**metadata**) or tenant configuration settings (**accessTokenExpirySecs**) to meet the requirements of corporate security policies. See Managing Applications for "**urn:iam:app:oauthAccessTokenExpirySecs**" app metadata attribute or see Managing Settings for ***"accessTokenExpirySecs"*** setting details. Once a token expires, the client must acquire another Access Token. The following table lists the contents of the Access Token.

Access Token Claims

Claim	Description
tok_type	Claim indicating the type of the token. Token type: AT
sub_type	This claim indicates the type of the subject for which this access token is issued. Token sub type: • USER • CLIENT
ver	Token schema version

Claim	Description
sub	Subject Identifier for which the access token is generated • <user_guid> or app-specific value, if sub_type is USER. If no app-specific token subject mapping attribute is available, then this is the user's GUID (user_guid). Otherwise, this is the value of the physical id store attribute mapped to the logical id store attribute specified by the app's token sub mapping attribute (userTokenSubAttributeMappingName). • Client GUID if sub_type is CLIENT • based on the configuration of "urn:iam:app:oauthCustomSubject" app metadata, this claim can supports Dynamic Substitutions such as ${clientContext.xxx}, ${idProfile.IDprop}
azp	Authorized party - the party to which the ID Token was issued. If present, it MUST contain the OAuth 2.0 Client ID of this party. This Claim is only needed when the ID Token has a single audience value and that audience is different than the authorized party. It MAY be included even when the authorized party is the same as the sole audience. The azp value is a case sensitive string containing a StringOrURI value.
iss	Issuer Identifier for the Issuer of the response. The iss value is a case sensitive URL using the https scheme that contains scheme, host, and optionally, port number and path components and no query or fragment components. Issuer URL representing the signing authority, in the format: https://<platform-base-url>>/<tenant-name>/
nbf	Time until when JWT cannot be accepted. Its value is a JSON number representing the number of seconds from 1970-01-01T0:0:0Z as measured in UTC until the date/time.
iat	The time at which the JWT was issued. Its value is a JSON number representing the number of seconds from 1970-01-01T0:0:0Z as measured in UTC until the date/time.
exp	Expiration time on or after which the ID Token MUST NOT be accepted for processing. The processing of this parameter requires that the current date/time MUST be before the expiration date/time listed in the value. Implementers MAY provide for some small leeway, usually no more than a few minutes, to account for clock skew. Its value is a JSON number representing the number of seconds from 1970-01-01T0:0:0Z as measured in UTC until the date/time. See RFC 3339 [RFC3339] for details regarding date/times in general and UTC in particular.
jti	A unique identifier for the token, which can be used to prevent reuse of the token. These tokens MUST only be used once, unless conditions for reuse were negotiated between the parties; any such negotiation is beyond the scope of this specification.
client_name	Name of the client
client_tid	Client's tenant name
tid	Resource Tenant Name at the time request for Identity Token was made
aud	Audience(s) that this Access Token is intended for.
scope	The set of scopes exposed by your application for which the application has requested (and received) consent. This claim is space delimited string containing scopes.
user_loginid	User Identifier (only when `sub="user"`)
user_universalid	User's universal id identifier used to map across different identity namespaces (only when `sub="user"`)
azpacr	How client is authenticated at AZ Server: • 0 =public clients • 1 = for confidential clients
user_riskscore	User risk score evaluated (only when `sub="user"`)
idp_type	Identity provider type using which user is authenticated (only when `sub="user"`)
idp_name	Identity provider name using which user is authenticated (only when `sub="user"`)
idp_guid	Identity provider id using which user is authenticated (only when `sub="user"`)

Claim	Description
user_acr	Obtained from IT.acr Example: "user_acr": "0"
user_amr	Obtained from IT.amr Example: "user_amr": ["PWD"]
user_aal	Obtained from IT.aal Example: "user_all": "AAL1"
clientTransactionId	The client transaction received in the /authorize and/or /token endpoint. If no client transaction is received from RP, the SSP's transaction id with a prefix 'ssp:' gets populated
user_authlevel	The authLevel configured in the Policy result gets populated in the Access Token only when the claim, sub_type="user".
user_guid	GUID representing user's internal identifier in IDSP.
scoping_constraints	The scope constraints configured in the Authorization policy using the ".../admin/v1/AdminScopeConstrainer API gets populated in the Access Token. For more information on Scoping Constraints, see the Managing Scoping Constraints section.

Example of a Client Access Token obtained from the Client Credentials flow

Header Parameters in Access Token:

```
{
"x5t#S256": "d-TBloYpys_k122k8gXrQnmfeXb0FxiwKo_6Svw5fTE",
"x5t": "SuWQHOUnyRz3CtYEs3axMkcLFx0",
"kid": "SigningKey",
"alg": "RS256"
}
```

NOTE

The headers x5t and x5t#S256 are added in the header based on the "supportedJoseHeaderParams" configured in the Application. The supportedJoseHeaderParams option supports comma separated - x5t, x5t#s256, x5c Jose header parameters. If this option is left empty, then x5t and x5t#S256 are added in the JOSE Header of JWS tokens by default.

Custom Access Token Expiry

You can define a custom expiration value for access tokens when making a request to IDSP. By default, access tokens expire after one hour, but this can be adjusted either in the Application's metadata attribute or in the Tenant Settings.

In the application, the metadata attribute is labeled as "**urn:iam:app:oauthAccessTokenExpirySecs**," while in the Tenant Settings, it is labeled as "**accessTokenExpirySecs**." For more details, see Managing Applications or see Managing Settings for setting details.

When including a custom expiration value in the access token request, the following points should be considered:

- If only the Tenant setting is configured and the Application's metadata attribute is not, the custom expiration value overrides the Tenant setting if its value is shorter than the tenant setting value. If the custom expiration exceeds the Tenant setting, the Tenant setting takes precedence.
- If both the Application's metadata attribute and Tenant setting are configured, the app metadata value takes precedence. In this case, if the custom expiration value is shorter than the app metadata value, it overrides. If the custom expiration exceeds the application metadata attribute value, the application metadata configuration takes precedence.

  However, the custom expiration is still bound by the overall access token expiration configured in the settings. This parameter can be used in any of the supported flows.

Example of custom access token expiry

The following sample displays the custom expiry timeframe added to a token request.

```
curl -k --request POST \--url 'https://example.com/default/oauth2/v1/token' \--header 'Content-Type:
 application/x-www-form-urlencoded' \-u "6cb446b9-33bf-4b97-a6e1-e7ad389974d2:2ef66db2-1e51-4868-8c72-
bd57ce7f69dc" \--data-urlencode 'grant_type=client_credentials' \--data-urlencode 'scope=urn:iam:myscopes'--
data-urlencode'expirySeconds=120'
```

This is the response to the requested token.

```
{
 "access_token": "eyJ4NXQjUzI1NiI6ImNJ......",
 "token_type": "Bearer",
 "expires_in": 120
}
```

Identity Token

Learn about Symantec Identity Security Platform Identity Tokens.

This topic includes the following sections:

- Identity Token
- Identity Tokens Examples
- Handling Identity Tokens
- Short-Lived Identity Token

Identity Tokens

Identity Tokens represent the user whose identity has been authenticated by IDSP, either through the OpenID Connect flow or programmatically through the REST API. This token is a signed JWT, authenticated and issued by IDSP Identity Tokens have a limited lifetime, controlled by application property (**metadata**), or tenant configuration setting ((**idTokenExpirySecs**) to meet the requirements of corporate security policies. See Managing Applications for "**urn:iam:app:oauthIdentityTokenExpirySecs**" application's metadata attribute or see Managing Settings for ***"idTokenExpirySecs"*** setting details. Once a token expires, the client has the responsibility to acquire another identity token by re-authenticating the user.

When validating the signature of the Identity Token Hint provided into "/authorize" or "/token" (JWT-BEARER grant), the certificate used for validating the token signature is looked up in this order: x5t+sha256, x5t, kid+alias, and finally the issuer claim.

The following table lists the contents of the Identity Token:

Identity Token contents

Name	Claim Description (openid.net)
tok_type	Claim indicating the type of the token Token type: `IT`
iss	Issuer Identifier for the Issuer of the response. The iss value is a case sensitive URL using the https scheme that contains scheme, host, and optionally, port number and path components and no query or fragment components Issuer URL representing the signing authority, in the format: https://<SSP_HOST>/<tenant-name>/
sub	Subject Identifier. <user_guid> or app-specific value. If no app-specific token subject mapping attribute is available, then this is the user's GUID (user_guid). Otherwise, this is the value of the physical id store attribute mapped to the logical id store attribute specified by the app's token sub mapping attribute (userTokenSubAttributeMappingName).
user_loginid	User’s id used during authentication
user_universalid	User's universal id identifier, used to map across different identity namespaces
tid	Resource Tenant Name at the time request for Identity Token was made
at_hash	Access Token hash value if Access Token was issued as part of the OpenID Connect request.
client_name	Name of the client requesting the OpenID Connect flow
azp	Authorized party - the party to which the ID Token was issued. If present, it MUST contain the OAuth 2.0 Client ID of this party. This Claim is only needed when the ID Token has a single audience value and that audience is different than the authorized party. It MAY be included even when the authorized party is the same as the sole audience. The azp value is a case sensitive string containing a StringOrURI value.

Name	Claim Description (openid.net)
aud	Audience(s) that this ID Token is intended for. It MUST contain the OAuth 2.0 client_id of the Relying Party as an audience value. It MAY also contain identifiers for other audiences. In the general case, the aud value is an array of case sensitive strings. In the common special case when there is one audience, the aud value MAY be a single case sensitive string.
iat	Time at which the JWT was issued. Its value is a JSON number representing the number of seconds from 1970-01-01T0:0:0Z as measured in UTC until the date/time.
nbf	Time until when JWT cannot be accepted. Its value is a JSON number representing the number of seconds from 1970-01-01T0:0:0Z as measured in UTC until the date/time.
auth_time	Time when the End-User authentication occurred. Its value is a JSON number representing the number of seconds from 1970-01-01T0:0:0Z as measured in UTC until the date/time. When a max_age request is made or when auth_time is requested as an Essential Claim, then this Claim is REQUIRED; otherwise, its inclusion is OPTIONAL. (The auth_time Claim semantically corresponds to the OpenID 2.0 PAPE [OpenID.PAPE] auth_time response parameter.)
sid*	Session ID assigned by the Login service. Login/AuthN issuing IT always returns the SID associated with the user's session
session_exp	Session ID assigned by the Login service. Login/AuthN issuing IT always returns the SID associated with the user's session
idp_type	Type of IDP. Possible values are `ldap`, `local`, `fed`
idp_name	Name of the IDP
idp_guid	GUID of the IDP
nonce	String value used to associate a Client session with an ID Token, and to mitigate replay attacks. The value is passed through unmodified from the Authentication Request to the ID Token. If present in the ID Token, Clients MUST verify that the nonce Claim Value is equal to the value of the nonce parameter sent in the Authentication Request. If present in the Authentication Request, Authorization Servers MUST include a nonce Claim in the ID Token with the Claim Value being the nonce value sent in the Authentication Request. Authorization Servers SHOULD perform no other processing on nonce values used. The nonce value is a case sensitive string. Not present when IT is generated by /authenticatePresent when IT is returned by /Authorize from OIDC
exp	Expiration time on or after which the ID Token MUST NOT be accepted for processing. The processing of this parameter requires that the current date/time MUST be before the expiration date/time listed in the value. Implementers MAY provide for some small leeway, usually no more than a few minutes, to account for clock skew. Its value is a JSON number representing the number of seconds from 1970-01-01T0:0:0Z as measured in UTC until the date/time. See RFC 3339 [RFC3339] for details regarding date/times in general and UTC in particular.
jti	A unique identifier for the token, which can be used to prevent reuse of the token. These tokens MUST only be used once, unless conditions for reuse were negotiated between the parties; any such negotiation is beyond the scope of this specification.

<table>
<tr><th>Name</th><th>Claim Description (openid.net)</th></tr>
<tr><td>aal*</td><td>Authentication Assurance assurance</td></tr>
<tr><td>acr</td><td>Authentication Context Class Reference value requested and authenticated at.</td></tr>
<tr><td>amr</td><td>Authentication Methods References. JSON array of strings that are identifiers for authentication methods used in the authentication. For instance, values might indicate that both password and OTP authentication methods were used. The definition of particular values to be used in the amr Claim is beyond the scope of this specification. Parties using this claim needs to agree upon the meanings of the values used, which may be context-specific. The amr value is an array of case sensitive strings.Standard amr values are captured from https://tools.ietf.org/html/draft-ietf-oauth-amr-values-02
The following table contains the authentication factors and their mappings with the AMR values in IDSP:
<table><tr><th><u>Authentication Factors</u></th><th>AMR Values</th></tr><tr><td>Password</td><td>PWD</td></tr><tr><td>SMSOTP, EmailOTP</td><td>OTP</td></tr><tr><td>Push</td><td>PUSH</td></tr><tr><td>MobileOTP</td><td>MOTP</td></tr><tr><td>Biometric</td><td>FIDO</td></tr><tr><td>Security Key</td><td>HWK</td></tr></table></td></tr>
<tr><td>user_riskscore</td><td>Risk score of the user computed during the authentication flow</td></tr>
<tr><td>ver</td><td>Token schema version number</td></tr>
<tr><td>email</td><td>User's email Id
Note:
• LDAP Config should have email mapping for the id store attribute.
• App configuration must have 'skipEmailForIT' as 'false'.</td></tr>
<tr><td>user_authlevel</td><td>The authLevel configured in the Policy result gets populated in the Identity Token.</td></tr>
<tr><td>user_guid</td><td>GUID representing user's internal identifier in IDSP.</td></tr>
</table>

Example of an Identity Token obtained from OpenID Connect's Authorize flow

Header Parameters in Identity Token

```
{
 "x5t#S256": "d-TBloYpys_k122k8gXrQnmfeXb0FxiwKo_6Svw5fTE",
 "x5t": "SuWQHOUnyRz3CtYEs3axMkcLFx0",
 "kid": "SigningKey",
 "alg": "RS256"
}
```

NOTE
The headers x5t and x5t#S256 are added in the header based on the "supportedJoseHeaderParams" configured in the Application. The supportedJoseHeaderParams option supports comma separated - x5t,

x5t#s256, x5c Jose header parameters. If this option is left empty, then x5t and x5t#S256 are added in the JOSE Header of JWS tokens by default.

Body of Identity Token

```

Handling Identity Tokens

The following section explains how an Identity Token JWT is processed in the following flows:

- JWT-BEARER grant (programmatic flow)
- /authorize (web flow)
- /authenticate REST API (programmatic flow)

The Identity Token JWT should conform to the OpenID Identity Token specification as outlined in the OpenID Connect Core specification. The JWT may be either signed, encrypted, or both. The flow validates the token's signature, expiration, audience, and then establishes the user identity according to the process stated in the following section.

Steps to handle Identity Tokens:

If the Identity Token was issued by IDSP (issuer claim indicates the IDSP's tenant issuer), the claims already contain the necessary information to establish the identity. No special processing is required. Otherwise, for identity tokens issued by any other issuer, the processing is as follows:

1. **If the IDP is Not Found**:

- **ZFP flow**: The `idp_id` and `user_loginid` are derived from the Identity Token (IT), with the sub claim used as a fallback for the `user_loginid` .
- **Non-ZFP flow**: The `idp_id` and `user_loginid` are taken from the Identity Token. Currently, there is no fallback to the sub claim for `user_loginid` . During the JWT-BEARER /token flow, the `user_loginid` must be successfully disambiguated against an Identity Store, otherwise the JWT-BEARER request fails.

2. **If the IDP is Found**:
   - **ZFP flow**: The `idp_id` is taken from the IT unless overridden by the IDP's `idp_id` if the IDP has the `"zfpUsesIdpAsIdentitySource=true"` metadata (this is set to false by default). The `user_loginid` is derived from the IT's claim that corresponds to the IDP's Token Subject Claim, with a fallback to sub. This is the current behavior for Siteminder or IDSP ZFP integration.
   - **Non-ZFP flow**: The `idp_id` and `user_loginid` are determined through a lookup in the ID Store using IT's claim that corresponds to the IDP's Account Mapping Attribute, with a fallback to user_loginid claim. The search looks for the value of the IT's claim that matches the IDP's Token Subject Claim, falling back to sub.

Short-Lived Identity Tokens

A short-lived identity token is a regular identity token issued by IDSP with shorter expiration time that is controlled by a tenant setting, and is not subjected to tracking. This identity token type is primarily used for ID propagation and to address security issues of replay attacks. Short-lived identity tokens have a default expiry of 30 seconds, which may be changed using the tenant setting, '***ssoIdPropTokenExpirySeconds***'. The property value can be modified to a range between 10 and 60 seconds.

> **NOTE**
> With the 'openid' and 'urn:iam:sso:idprop' scope, the refresh token grant flow can generate short-lived identity tokens in a manner similar to the jwt-bearer flow shown in the following example.

To generate short-lived identity tokens, set the open id scope in the application to "urn:iam:sso:idprop," where 'openid' is required to generate the "id_token" and the scope - 'urn:iam:sso:idprop' specifies that the identity token should be short-lived.

Configurations required in the application to generate a short lived identity token for jwt-bearer grant

- To generate short-lived identity token using the "oauth2/v1/token" API, configure the following in the application:
  - **allowed OpenID scope** - 'openid'
  - **allowed OpenID custom scope** - 'urn:iam:sso:idprop'
  - **clientType** - 'Trusted', 'Confidential', or 'Public'
  - **allowed operations** - 'offlineit' if the client is configured as Confidential or Public

Sample request of short-lived identity token in the jwt-bearer flow

Request

```
curl -k --request POST \
--url 'https://example.com/default/oauth2/v1/token' \
--header 'Content-Type: application/x-www-form-urlencoded' \
-u "6cb446b9-33bf-4b97-a6e1-e7ad389974d2:2ef66db2-1e51-4868-8c72-bd57ce7f69dc" \
--data-urlencode 'grant_type=urn:ietf:params:oauth:grant-type:jwt-bearer' \
--data-urlencode 'scope=openid urn:iam:sso:idprop' \
--data-urlencode 'assertion=eyJ4NXQjUzI1.........5y3fw'
```

Response

```
{
"access_token": "eyJ4NXQjUzI1NiI6IjZqZlh5bHV6QnZmX0NOSkJnY...",
"id_token": "IJ4NeyQjUzX1NiI6IjZqZlh5bHV6QnOSkJnYZmX0N..."
}
```

Refresh Token

Learn about Symantec Identity Security Platform Refresh Token

This topic includes the following sections:

- Refresh Token
- Steps to obtain a Refresh Token
- Step to obtain a new Access Token using the Refresh Token grant
- Step to obtain both, new Access Token and new Refresh Token using the Refresh Token grants

Refresh Tokens are credentials used to re-generate an Access Token without re-authenticating, when the current access token becomes invalid or expires. When using the Refresh Token, you may request for the same scopes that were requested during the initial authentication or narrow down the scopes depending on your requirement. Refresh Tokens have a limited lifetime, controlled by application property (**metadata**), or tenant configuration setting (**refreshTokenExpiryDays**) to meet the requirements of corporate security policies. See Managing Applications for "**urn:iam:app:oauthRefreshTokenExpiryDays**" application's metadata attribute or see Managing Settings for ***"refreshTokenExpiryDays"*** setting details. Refresh Tokens are secrets and not JWT. To make use of the Refresh Token functionality, you should update the following endpoints with the scope, "**offline_access**":

- "/authorize"
- "/token"

> **NOTE**
> To know about additional settings related to the refresh token, look for the following settings in the Managing Settings page.
>
> - keepOldRefreshTokenOnRefreshTokenFlowWithOfflineAccess
> - keepOldSessionIdOnNewRefreshTokenFlowWithOfflineAccess

> **NOTE**
> To ensure accurate and reliable IP address usage in complex network environments (which may alter user IP information due to firewalls or load balancers), leverage the IDSP application metadata. To know more, see HTTP Header and End User IP Address Usage.

Steps to obtain a Refresh Token

The following step shows an example of how to send a Refresh Token request using "/token" and "/authorize" endpoint.

Perform the following step:

1. In the "/token" endpoint or "/authorize" request body, enter the scope as "**offline_access**" and invoke the API. The Refresh Token will be obtained.

   > **NOTE**
   > The "**offline_access**" scope only works with '**authorization_code**', '**jwt-bearer**' or '**device_code**' grant_types.

   Example of a Refresh Token request format in the "/token" endpoint:

   ```
   curl -k --request POST --url 'https://example.com/default/oauth2/v1/token' --header 'Content-Type:
    application/x-www-form-urlencoded' -u "6cb446b9-33bf-4b97-a6e1-e7ad389974d2:2ef66db2-1e51-4868-8c72-
   bd57ce7f69dc" --data-urlencode 'grant_type=authorization_code' --data-urlencode
    'code=sodgnomNDVB723a3dPRwMBGHTYHB' --data-urlencode 'scope=offline_access'
   ```

   Example of a Refresh Token request format in the "/authorize" endpoint:

   ```
   https://example.com/default/oauth2/v1/authorize?response_type=code&client_id=6cb446b9-33bf-4b97-a6e1-
   e7ad389974d2&redirect_uri=https://
   www.example.com&scope=urn:iam:myscopesopenidemailoffline_access&state=mystate
   ```

   Example of a Refresh Token response format:

   ```
   {
   ```

```
"access_token" : "eyJ4NXQjUzI1NiI6ImNJbUNYN1FyRy1BUUpkWWZ2Wlctd1...X6HEbM-Hdh-hzXqHA"

"token_type" : "Bearer",

"expires_in" : 3600,

"id_token" : "eyJ4NXQjUzI1NiI6ImNJbUNYN1FyRy1BUUpkWWZ2W....3qliSzy_Khn2wgqQ2bg2t8Keg",

"refresh_token": "m5370ROmNDVB7a3dPRwMs5FDTZjfFc"

}
```

Step to obtain a new Access Token using the Refresh Token grant

Perform the following step:

1. In the "/token" endpoint request body, enter the value of the Refresh Token that you obtained in the previous section and invoke the "/token" API. The new Access Token is obtained.
   Example of a request body that includes the refresh_token which is used to obtain the new Access Token:

   ```
   curl -k --request POST --url 'https://example.com/default/oauth2/v1/token' --header
    'Content-Type: application/x-www-form-urlencoded' -u "6cb446b9-33bf-4b97-a6e1-
   e7ad389974d2:2ef66db2-1e51-4868-8c72-bd57ce7f69dc" --data-urlencode 'grant_type=refresh_token' --data-
   urlencode 'refresh_token=m5370ROmNDVB7a3dPRwMs5FDTZjfFc' --data-urlencode 'scope=<subset of scopes>'
   ```

   The following table shows the request parameters required for getting the new Access Token:

Name	Description
client_id	Client Id of the client that was registered with IDSP.
client_secret	Client secret that is associated with the client_id.
grant_type	The grant type supported for generating a new Access Token using the Refresh Token is "**refresh_token**". This grant type can be used only with 'authorization_code', 'jwt-bearer' or 'device_code' grant type.
refresh_token	Value of the Refresh Token.
scope	Subset of scopes.

   Example of a response body which grants the new Access Token:

   ```
   {

   "access_token" : "eyJ4NXQjUzI1NiI6ImNJbUNYN1FyRy1BUUpkWWZ2Wlctd1...X6HEbM-Hdh-hzXqHA",

   "token_type" : "Bearer",

   "expires_in" : 3600

   }
   ```

Step to obtain both, new Access Token and new Refresh Token using the Refresh Token grants

Perform the following step:

1. In the "/token" endpoint request body, enter the grant type as "refresh_token" and the value of the "refresh_token" that you have obtained from the "Step to obtain Refresh Token" section.

```
curl -k --request POST --url 'https://example.com/default/oauth2/v1/token' --header
 'Content-Type: application/x-www-form-urlencoded' -u "6cb446b9-33bf-4b97-a6e1-
e7ad389974d2:2ef66db2-1e51-4868-8c72-bd57ce7f69dc" --data-urlencode 'grant_type=refresh_token ' --data-
urlencode 'refresh_token=m5370ROmNDVB7a3dPRwMs5FDTZjfFc' --data-urlencode 'scope=<subset of scopes>'
```

   NOTE
   To obtain a new Refresh Token, passing ***scope= "offline_access"*** in the "/token" endpoint is mandatory.

   Example of a response body that grants the new Access Token and the Refresh Token:

```
{

"access_token" : "eyJ4NXQjUzI1NiI6ImNJbUNYN1FyRy1BUUpkWWZ2Wlctd1...X6HEbM-Hdh-hzXqHA",

"token_type" : "Bearer",

"expires_in" : 3600,

"refresh_token": "tGzv3JOkF0XG5Qx2TlKWIA"

}
```

Reference Links

- Personal Refresh Tokens (PRT)

Personal Refresh Token (PRT)

Personal Refresh Tokens (PRTs) enable users to request long-lived tokens that allow client applications to generate Access Tokens with custom data.

Personal Refresh Tokens (PRTs) are long-lived tokens tied to a specific user and client application, primarily used for offline access. It allows an user to request a long-lived token enabling an app client in possession of such Refresh Token (RT) to then generate Access Tokens with custom claims containing app's custom data (Client Context) stored in RT.

This topic includes the following sections:

- Define custom claims
- Configure app metadata to set the expiry of the Personal Refresh Token
- Pass scopes in ".../oauth2/v1/token" endpoint (using Authorization Code Flow)
- Pass dynamic values to the Client Context in ".../oauth2/v1/token" in Authorization Code Flow
- Introspect of resulting PRT
- Redeem Personal Refresh Token (PRT)
- Manage Personal Refresh Token (PRT)

Define custom claims

Navigation path to the Apps in the Admin Console:
Select the Application > OAuth/OpenID > Custom Claims

In the Custom Claims section, define your additional, non-standard claims which may be included in the Access Token and/or Identity Token based on your configuration. These custom claims can also use the RT's Client Context provided by the application during RT initialization or while calling the ".../oauth2/v1/token" endpoint.

When a client application is authorized to use the "/token" endpoint, with the OpenID Connect "offline_access" scope used to receive an RT, it can include custom "Client Context" information. This "Client Context" information is then securely stored by the Authorization Server and associated with the Refresh Token (RT) making it available when issuing new AT's. When that RT is later used to get a new Access Token, the Authorization Server can retrieve and use the associated Client Context.

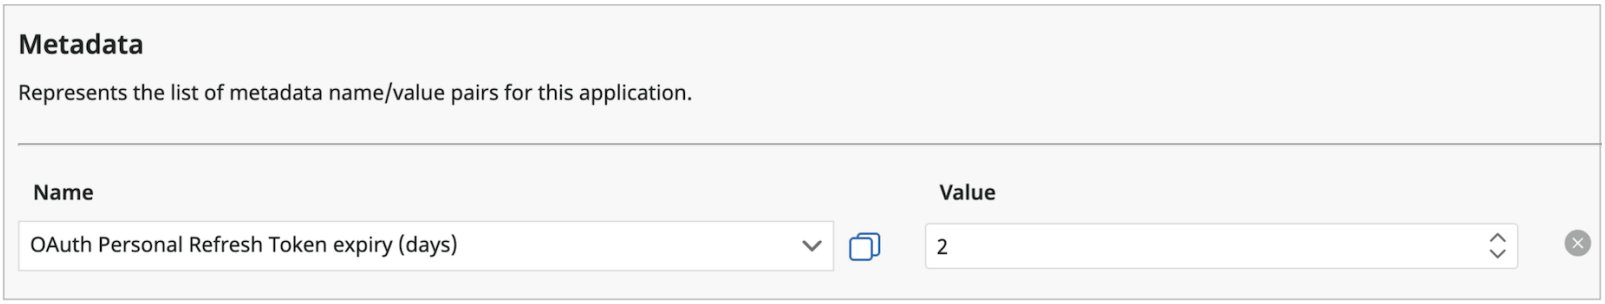
Configure app metadata to set the expiry of the Personal Refresh Token

By default, the PRT is set to have an expiry of 7 days. The application can be configured to allow different RT expiry by configuring the "**OAuth Personal Refresh Token expiry (days)**" metadata. The application client can ask for an RT with an expiration equal or less than this value using the "**expiryDays**" request param.

Navigation path to the app metadata in the **Admin Console**:
Select the Application > General > Metadata

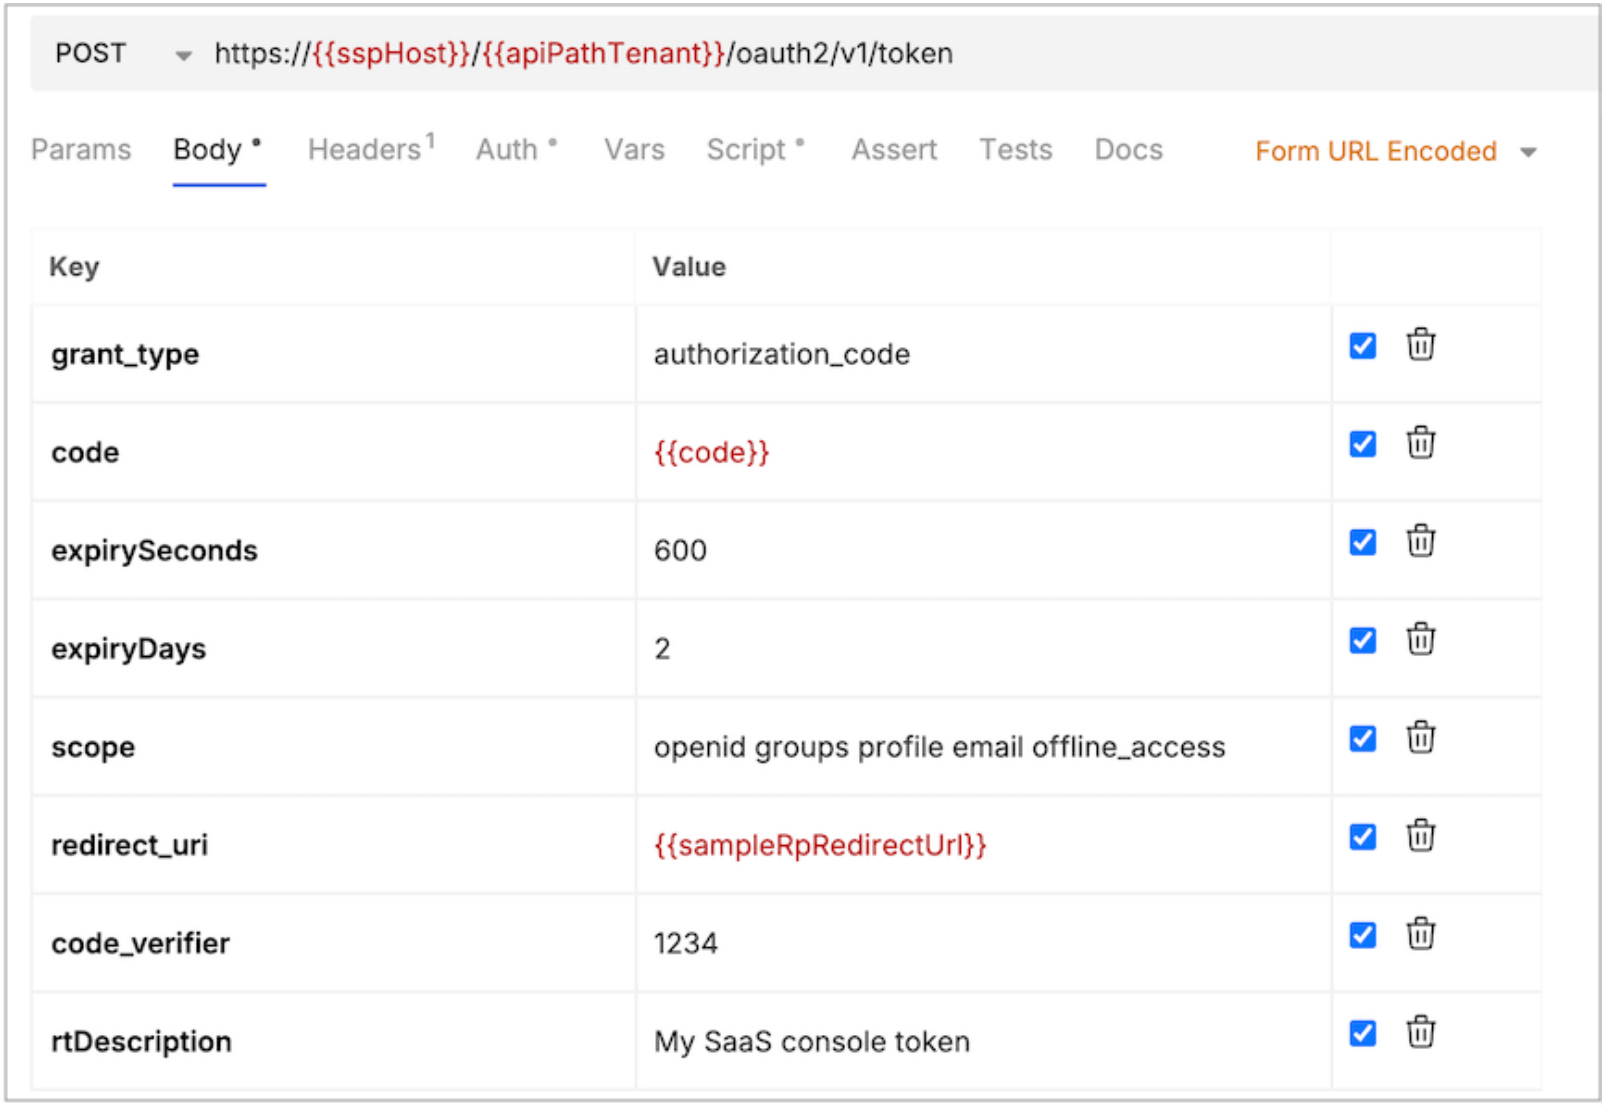
The following illustration displays how you can define the app metadata:

Figure 13: app metadata config in PRT



To configure the expiry **using the API**, the app client needs to invoke "/token" with "**expiryDays**" request param whose value must be equal to or less than the value in effect for the app client.

Figure 14: Passing "expiryDays" in header params



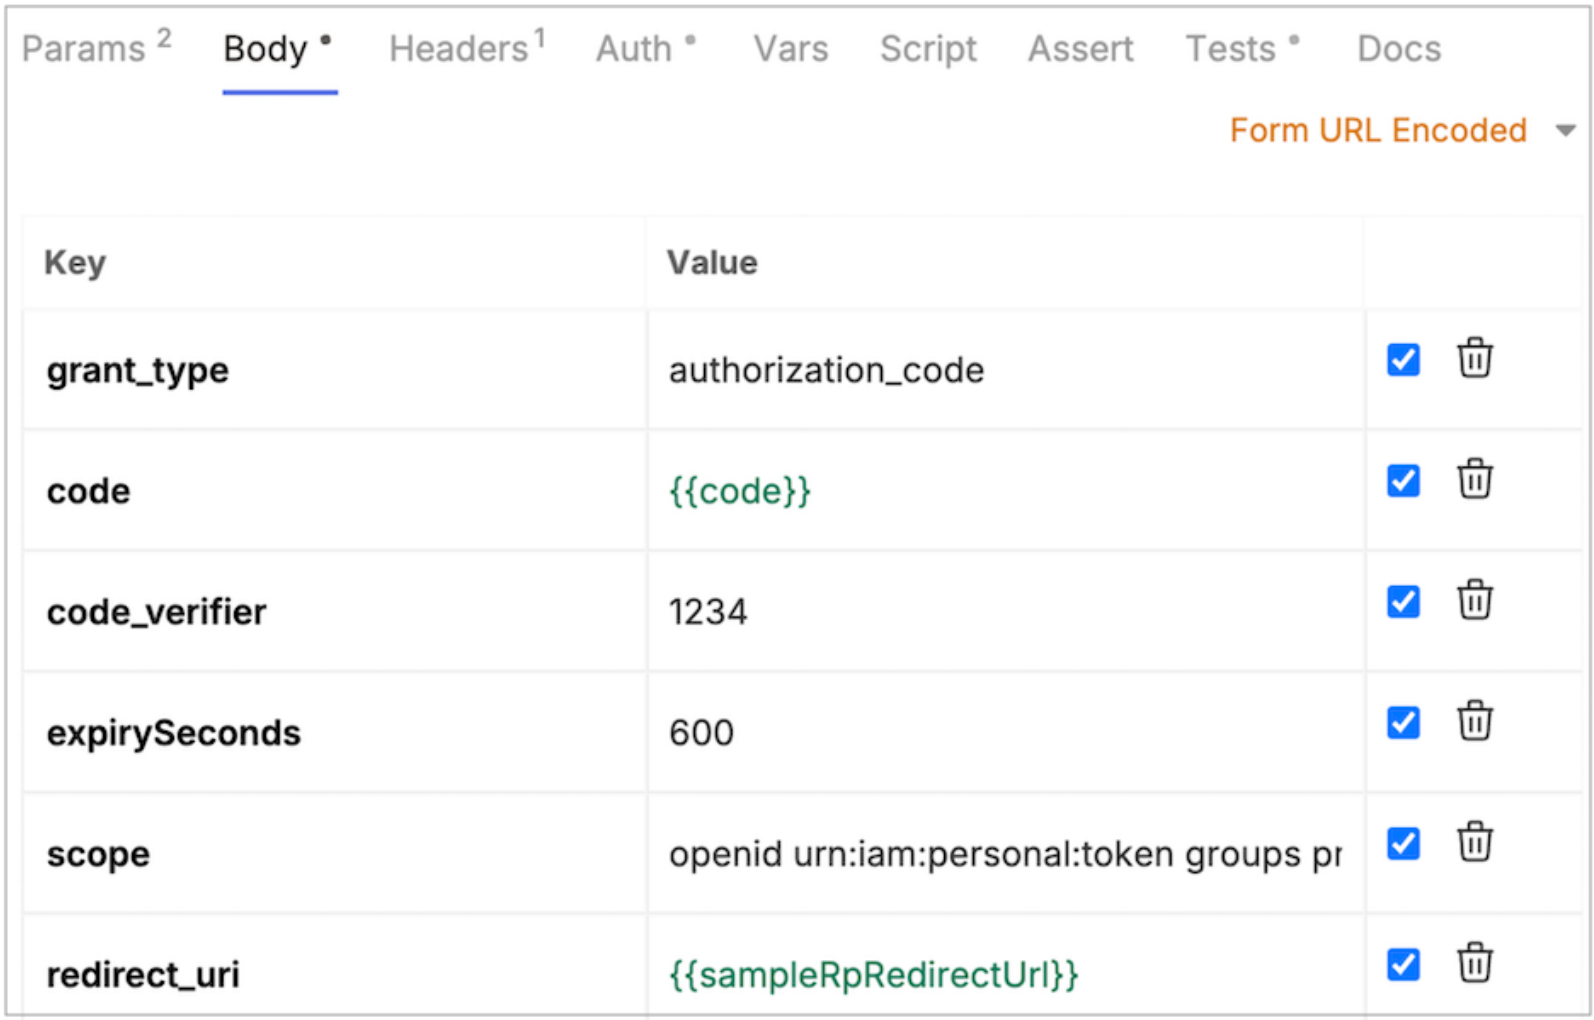
The PRTs expiry is determined by the application's metadata configuration, if not set then it falls back to the "**refreshTokenExpiryDays**" tenant settings. This setting is covered here.

Pass scopes in ".../oauth2/v1/token" endpoint (using Authorization Code Flow)

The client must include two specific "scopes" in the "/token" endpoint to request for a PRT:

- **"offline_access"**: This scope is required to obtain a Refresh Token, which allows the client to get new Access Tokens without the user having to re-authorize.
- "**urn:iam:personal:token**": This is a custom scope that indicates the client is requesting a Personal Refresh Token (PRT), which has specific characteristics for end-user management.

Figure 15: Defining Scopes in PRT

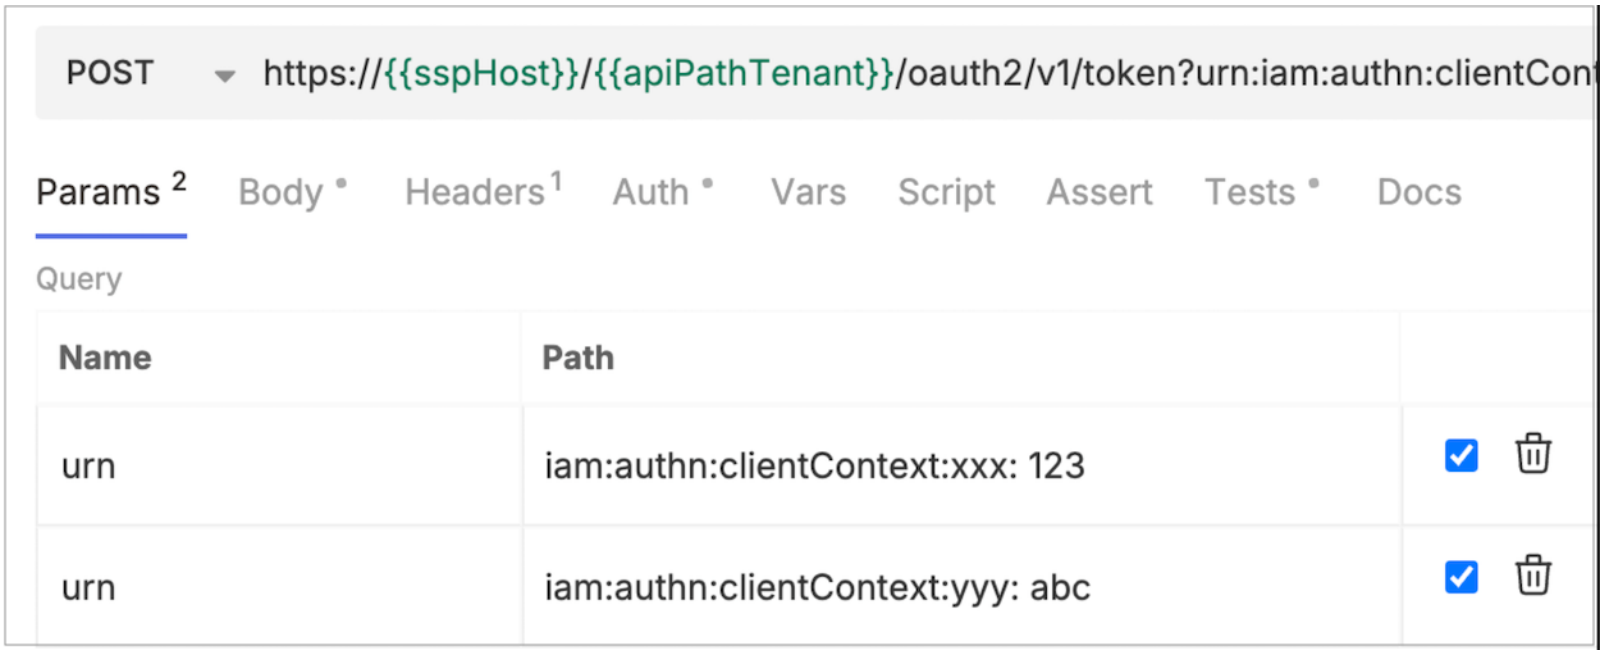


Pass dynamic values to the client context in ".../oauth2/v1/token" in authorization code clow

The client can include one or more URL-encoded query string parameters in the format "urn:iam:authn:clientContext:xxx=123" (this is an example value). These parameters are used to embed custom data (the "Client Context") into the PRT being created. In the example, "xxx" represents the key for the custom data, and "123" is the corresponding value. Similarly, there is another example, "urn:iam:authn:clientContext:xxx=abc" where "yyy" represents the key for the custom data, and "abc" is the corresponding value.

The following illustration displays how you can define the client context:

Figure 16: PRTClientContextConfig



The client can include multiple such parameters to store a list of key-value pairs in the PRT's Client Context.

Introspect of resulting PRT

After the refresh token is generated using the ".../oauth2/v1/token", this token can be used in the ".../oauth2/v1/introspect" endpoint with PRT o check if the client context values have passed correctly to the token. The following example shows the response containing PRT's Client Context from which custom claims are obtained when generating Access Token for this PRT.

```
/Introspect of resulting PRT
{

  "active": true,

 "personalRefreshToken": true,
  "urn:iam:authn:clientContext": [
     {
         "key": "myXXX",

Redeem Personal Refresh Token (PRT)

To redeem a PRT for access token containing PRT's custom claims, the app client needs to invokes ".../oauth2/v1/token" with the regular Refresh Token grant. The claim mapping as configured on the app causes custom claim "**myXXX**" to be given value "123" as represented by PRT's Client Context containing key "**xxx"** with the value of "123".

Manage Personal Refresh Token (PRT)

There are two ways to manage the generated PRT, these are :

- Retrieve the PRTs of an user
- Revoke PRT of an User

Retrieve the PRTs of an user

To retrieve only the PRT of an user, invoke the following endpoint with "**revokepersonaltokens=true**" query string parameter:

```
GET https://{{sspHost}}/{{apiPathTenant}}/admin/v1/UsersRefreshTokens/{{REPLACE-BY-USERID-OR-USERLOGINID}}
```

This endpoint response returns the PRTs.

Revoke PRT of an User

To revoke the PRT of an user, invoke the following endpoint with "**showpersonaltokens=true**" query string parameter:

```
DELETE https://{{sspHost}}/{{apiPathTenant}}/admin/v1/UsersRefreshTokens/{{REPLACE-BY-USERID-OR-USERLOGINID}}
```

This endpoint response returns 204.

Custom Token Claims

Learn about Symantec Identity Security Platform Custom Token Claims

Custom Token Claims

IDSP provides the ability to define custom claims for a SAML/OIDC application using the "claims" property (for OIDC App) and "samlAssertionClaims" (for SAML app) on ".../auth/v1/authenticate" resource. These custom claims are included in the Identity and/or Access tokens that are generated by IDSP on behalf of an application as a relying party.

"claims" Property Syntax (for OIDC app):

```
"claims": [
            {
              "name": "<claim-name>",
              "target": "<comma-separated-token-types>",
              "source": "${<namespace>.<property>}"
            }
          ]
```

"samlAssertionClaims" Property Syntax (for SAML app):

```
"samlAssertionClaims": [
            {
              "name": "<claim-name>",
              "source": "${<namespace>.<property>}"
            }
          ]
```

- **name:** Specifies the name of the custom claim to be included in the token. As a good practice, prefix the custom claim name with a special character such as "_".
- **target:** Specifies the target token type for the custom claim. The input values for the token types are "it" for Identity Token and "at" for Access Token. This property is applicable for OIDC apps only.
- **source:** The supported namespaces and their flows for the custom claims are as follows:
  - **idProfile:** The idProfile namespace represents user profile attributes and it is available in both non-ZFP and ZFP flows.
    - **Non-ZFP Flow:** In a non-ZFP flow, idProfile includes all logical user attributes as configured in an ID store object for LDAP/SCIM ID Store.
    - **ZFP Flow:** In a ZFP flow, the idProfile includes user attributes that are a subset of claims as present in the incoming Identity Token.

      The list includes the following claims, subject to being present in the token:
      - **OpenID Claims:** NAME, GIVEN_NAME, MIDDLE_NAME, FAMILY_NAME, NICK_NAME, PREFERRED_USERNAME, PROFILE, PICTURE, WEBSITE, GENDER, BIRTHDATE, ZONEINFO, LOCALE, UPDATED_AT, EMAIL, EMAIL_VERIFIED, ADDRESS, PHONE_NUMBER, PHONE_NUMBER_VERIFIED
      - **Custom Claims:** USER_UNIVERSALID, USER_LOGINID, USER_GUID, USER_DN, IDP_NAME, IDP_TYPE, IDP_GUID, IDP_USER_GUID
      - **Standard Claims:** SUB
  - **idToken:** The idToken namespace is available in every flow where a request for a token has been made with an Identity Token (or Identity Token Hint), depending on the request. This namespace exposes the entire claim set present in the token, for top-level claims only.
  - **appMetadata:** The appMetadata namespace represents application metadata attributes, and it is available in every flow.
  - **clientContext:** The clientContext namespace represents the custom context passed in using one of the following flows:
    - **Request Payload in Authenticate API**: The clientContext property can be passed into the ".../auth/v1/authenticate" call in the request payload. For example -

```
{
        "subject": "nbruce",
        "channel": "web",
        "action": "authenticate",
        "rememberMe": true,
        "urn:iam:authn:clientContext": [
          {
            "key": "email",
            "value": "user1@example.com"
          }
        ]

    }
```

    - **As a claim in the "id_token_hint" Parameter**: The clientContext property can be passed as a query parameter to ".../oauth2/v1/authorize" or can be passed into ".../auth/v1/authenticate" API call through the "existingIDToken" or "id_token_hint" payload parameters. The following example represents the decoded id_token_hint with clientContext claim:

```
{
 "sub": "dd433ba1-b9ed-46bf-9d3e-15759d6bf89b",
 "idp_name": "idp_aa",
 "user_dn": "cn=user1,ou=Employees,o=democorp,c=us",
 "amr": [
   "PWD"
```

```
  ],

  "auto_inline_enrollment": true,
  "aud": [
    "ceee9ad0-9414-422d-a264-179a85cbf4db",
    "ad179147-fce0-4e09-a1cf-7830cfe3b4a3",
    "72316d69-9749-4ef7-a9bb-d92e433efe28"
  ],
  "nbf": 1711336816,
  "urn:iam:authn:clientContext": [
    {
      "key": "email",
      "value": "user1@example.com"
    }
  ],
  "urn:iam:authn:userData": [
    {
      "key": "KeyID",
      "value": [
        "500076885"
      ]
    }
  ]
}
```

- **As a "`urn:iam:authn:clientContext`" Query Parameter**: The clientContext property can be passed into the following endpoints:
  - ".../oauth2/v1/authorize"
  - ".../oauth2/v1/token"
  - ".../saml/v1/idp/login"
  - ".../launch/v1/Apps/{appid}"

The clientContext is passed as a URL-encoded value. Optionally, it can be encrypted before encoding using one of the following methods:

- {x5c}: Encrypted using the tenant's public key. The encrypted value is obtained by calling ".../admin/v1/ClientNonceGenerator(value)".
- {secret-alias>}: AES-based data encryption using a customer-supplied secret identified by <secret-alias>.
  - Key: Must be a multiple of 16 bytes in length (for example, 16, 32, or 48 bytes).
  - IV (Initialization Vector): Derived from the first 16 bytes of the key, starting at offset 0.

The following example represents the url-encoded form of {x5c}, indicating that the subsequent value is encrypted using the {x5c} format:

```
https://{{sspHost}}/{{apiPathTenant}}/oauth2/v1/token?urn:iam:authn:clientContext:encOrgToken=
%7Bx5c%7DYzRTM6jAilpQmm1CREo8f%2FBKPxYswfRTqsO796bfkmSmlpvwCVA1ylVinZdU
%2BbhrIhriE6bZkON%2Bb9CF3If9lLc7L3BovLsqSqfKASzskiWBqZU9m38AKMPmyhw%2BKxuGEfIGKX
%2FL5d4FEz2yMnDiCQFiCAaczV1%2FaKscEiQpgL7hqBoej44Gf4wYP6uPt4O7ul3VECV4bOv9Btp7J1d0eG6tL7FmGZ6bYo7wqJFBQSqVeBji
%2BoEwz53inh%2BlwMrZGbybRoIFkAZKz4Z5DPl1VgDGgDOpaT4%2B6BqkggT4ErpAJMQA8P7lWqaVqcX65QnBJmw4ZR88P5KA%3D
%3D%0A
```

This table maps various authentication and authorization flows to the types of data (user profile, application metadata, and dynamic client context) that are available and can be used to populate **custom claims** within issued Access Tokens and ID Tokens. It also specifies the conditions under which this data is included or utilized in each flow.

Flow			
	idProfile	idToken	appMetadata
/authenticate REST API (IT)	yes	yes (if Identity Token Hint is passed into /authenticate)	yes
OAuth Client Credentials (AT)	n/a	n/a	yes
OAuth AZ Code (IT, AT)	yes	yes (if Identity Token Hint is passed into /authorize)	yes
OAuth Device Code (IT, AT)	yes	n/a	yes
OAuth Refresh Token (AT)	yes	n/a	yes
OAuth JWT-BEARER (AT)	yes	yes (if Identity Token Hint is passed into JWT-BEARER)	yes
OAuth Implicit (IT, AT)	yes	yes (if Identity Token Hint is passed into /authorize)	yes

Clients requesting admin-approved user profile attributes

Clients, such as applications, can request administratively permitted user profile attributes (or "scopes") in their tokens using custom token claims.

Administrators - Administrators set up the ability for clients to request specific user profile attributes through the definition of a custom claim.

The Application administrator defines a custom claim with the name `urn:iam:idprofile:requested` . The value of this custom claim can be any character except for a blank value. This custom claim indicates that the client (app/service) is allowed to request specific attributes (user profile scopes) and have them returned in the tokens.

Client Request: Clients use predefined syntax or fields to request the user profile attributes, which are included as custom claims in the tokens issued by the IDSP.

- **OIDC Client** - For OpenID Connect (OIDC) clients (apps), they request specific user profile attributes by specifying the following syntax: "`urn:iam:idprofile:<id-profile-attribute>`" . Here, id-profile-attribute is the actual profile attribute (scope) the client wants.
- **Programmatic Client (API)** -
  - For clients that authenticate programmatically (For example, API clients using /authenticate), the request is made differently.
  - The client uses the request's authContext parameter to pass the requested attributes. The field's key is `requestIdProfileAttributes` , and the value is a comma-separated list (CSV) of logical ID profile attributes that the client wants to receive.
- **Token Issuance** -
  - The IDSP (authentication system) issues tokens—whether they are ID tokens (IT) or Access tokens (AT)—that contain the requested identity profile attributes.
  - These tokens include custom claims that represent the client-requested attributes, allowing the client to receive and use this information securely.

Example of custom claims in SCIM Config Resource

The following example demonstrates the use of two custom claims.

- "branchName" (IT/AT) whose data source is represented by the "branchName" ID Store attribute. Notice the "branchName" logical attribute being part of the attribute mapping in the SCIM ID Store configuration.
- "productEntitlement" (AT) whose data source is represented by the "productEntitlement" claim in the Identity Token (when such IT is used to generate AT)

Example of custom claims in "/Authenticate API" and "Identity Token Hint" (ITH)

This example demonstrates the use of clientContext in two modes:

- programmatic authentication (/authenticate accepting clientContext)
- Identity Token Hint that could be passed into OpenID Connect's /authorize as id_token_hint parameter

```
https://${SSP_FQDN}/{{apiPathTenant}}/auth/v1/authenticate
{
   "subject": "mhunter",
   "action": "authenticate",
```

```
   "ipAddress": "1.1.1.2",
   "channel": "web",
   "acrValues" : ["urn:iam:acr:aal:aal1"],
   "existingIDToken": "<ith>",
   "clientContext": [
       {
           "key": "clientCustomData2",
           "value": "gga323a24"
       }
   ],
   "authContext": [
       {
           "key": "useTenantKeyForITEncryption",
           "value": "false"
       },
       {
           "key": "requestGroupsInIT",
           "value": "true"
       },
       {
           "key": "requestClientContextInIT",
           "value": "true"
       },
       {
           "key": "requestUserDataInIT",
           "value": "true"
       }
   ]
}
```

Revoke Token

Learn about Symantec Identity Security Platform Token Lifecycle Management and how Revoke Tokens work.

This topic includes the following sections:

- Token Lifecycle Management
- Revoke Token

Token Lifecycle Management

Revocation is an important aspect of Token Lifecycle Management. When a token is revoked, the authorization server is intimated that the token is no longer needed. This helps the authorization server to clean up any security credentials that are associated with the token and also prevents unknown users from reusing the token.

Token Validation Semantics

The following token validation semantics is used to revoke a token in IDSP:

- Check for Token Validity (TV)
  - Signature
  - Expiry
- Check for Token Scope (TS)
  - Audience
  - Different validation semantics per token type
- Check for Token Revocation (TR)
  - Revocation Status (AT/IT)
    - valid jti claim
  - Session status (AT/IT)
    - valid sid claim
  - Presence in DB (RT/AZCode)

The following table depicts the token validation semantics (TV/TS/TR) for different kinds of tokens:

Token Type	Supported Behavior				
	Revoking Tokens	Generating Tokens			
	/revoke	/introspect	/userinfo	/token JWT-Bearer grant	/toke Cod
Access Token (AT)	revokes at.jti Do not revoke at.sid if present	y TV TS is N/A TR (check for non revoked jti, and sid if present)	y TV TS (oidc scope as per allowedOidcScopes) TR on AT (check for non revoked jti, and sid if present)	TS/TV n/a add sid (guid) to RT at create time when offline_access is requested TR on IT (check for non revoked jti, and sid if present)	TS/T add (guic at cr time offlin is re TR c Cod
Identity Token (IT)	Revokes it.jti Revokes it.sid	y TV TS is N/A TR (check for non revoked jti and sid)	n/a	y TV TS (issuer) TR (check for non revoked jti and sid)	n/a
Refresh Token (RT)	deletes RT from DB Revokes rt.sid	y TV TS is N/A TR	n/a	n/a	n/a
AZ Code	n/a	n/a	n/a	n/a	y TV TS (TR

Revoke Token

Revoke Token is an authorization endpoint added to the OAuth Authorization server which lets the client indicate to the authorization server that a previously generated access token or refresh token is no longer needed. Therefore, the

token allows the authorization server to invalidate the token and clean up any security credentials associated with the authorization.

NOTE

- The revocation of the encrypted ID Token is not yet supported.
- For admin-based Token Revocation API, see Managing Token Revocation.

In order to request for revoke token in the APIs, you must first configure ***"trackAccessToken"*** and ***"trackIdentityToken"*** settings in IDSP. See Managing Settings for these setting details. The Revoke Token can be passed either in the authorization header or POST body. The following table shows the parameters that should be passed in the revoke request:

Name	Description
token	Specifies the Access Token or Refresh Token that must be revoked.
token_type_hint	Specifies the type of the token that must be revoked. Supported tokens are: **access_token, id_token** or **refresh_token**
Supported HTTP Methods	POST method

Example displaying revocation of Refresh Token

Example: Displays the revocation of a refresh token through the Revoke Token endpoint:

```
curl --location --request POST 'https://example.com/default/oauth2/v1/revoke' \
--header 'Content-Type: application/x-www-form-urlencoded' \
--header 'x-tenant-name: default' \
--header 'Authorization: Basic
 PHBhc3RlIGNsaWVudElkIGZyb20gYWJvdmUgY29tbWFuZD46PHBhc3RlIGNsaWVudFNlY3JldCBmcm9tIGFib3ZlIGNvbW1hbmQ+' \
--data-urlencode 'token=ZMgip58RpaWEVB5B9sCUjHrRkxw1xlPoYbLc' \
--data-urlencode 'token_type_hint=refresh_token'
```

Example of Revoke Token response:

```
HTTP 200 OK
```

Example of Revoke Token error response:

In the Tenant /Golbal Settings, when trackAccessToken or trackIdentityToken is set to false and you try to revoke an access token or identity token, then
the Authorization server responds with a 400 error code with the error message below.

```
{
error: “unsupported_token_type”,
error_description:”The authorization server does not support revocation of the presented token type”
}
```

Example of Revoke Token with Client Assertion as Client Credentials

The following sample shows a request payload for "/revoke" with client assertion as client credentials:

```
curl -k --request POST \
--url 'https://example.com/default/oauth2/v1/revoke' \
--header 'Content-Type: application/x-www-form-urlencoded' \
--header 'x-tenant-name: default' \
--data-urlencode 'token=eyJ4NXQjUzI1NiI6ImNJbUNYN1FyRy1BUUpkWWZ......'
```

```
--data-urlencode 'client_id=7b447d36-cac4-4a9e-b093-42f0d553d9f4' \
--data-urlencode 'client_assertion_type=urn:ietf:params:oauth:client-assertion-type:jwt-bearer' \
--data-urlencode 'client_assertion=ewogICJ4NXQjUzI1NiI6ICI4bkRSWURaUF9xcENwUz.....'
```

Using Tokens to Drive Generic Authorization

This content gives a comprehensive overview of different token types used in Symantec Identity Security Platform and how they can be used for generic authorization.

This topic includes the following sections:

- Using Tokens to Drive Generic Authorization
- Use Case 1- Acquiring Identity Token
- Use Case 2 - Acquiring Access Token
- Use Case 3 - Acquire Access Token with OpenID privileges to access authorized User Data

The following use cases are applicable to leverage basic tokenization constructs to drive entitlement (authorization) capabilities for an application with the following sample profile, developed to work with identities as shown below by a sample user identity profile in a sample store: The following demo client sample profile shows the added groups in "allowedOpenIDScopes" and the "itgroups" and "atgroups" in "allowedOperations".

> **NOTE**
> The maxGroupsInJWT configuration controls the maximum number of groups that can be returned in tokens. If the number of groups to which a user belongs exceeds the maxGroupInJWT configuration, then the token returns an empty “groups” claim along with the claim "hasgroups": true. This indicates that groups cannot be injected into the token even though the user belongs to those groups.

"democlient" Application Profile

```
{
     "status": "active",
     "name": "democlient",
     "description": "Demo client to perform tenant level operations for demo purpose.",

}
```

Use Case 1- Acquiring Identity Token

Identity Token can be acquired by:

- performing a fully programmatic flow (/authenticate flow)
- performing Web-based flow initiated by /authorize (3-legged OAuth / OpenID Connect)

It is possible for the resulting Identity Token to be requested and authorized to contain entitlements in the form of user groups. This is made possible by requesting special scope "**urn:iam:it:groups" - initially with the Web-flow and then also with the programmatic flow. For example:**

https://${SSP_FQDN}/{{apiPathTenant}}/oauth2/v1/authorize?scope=openid%20groups
*%20**urn:iam:it:groups**&client_id={{clientId}}&response_type=code&redirect_uri=https://www.example.com*

By requesting this scope in this flow, for ex PKCE-based AZ Code flow, the resulting Identity Token will be given a list of user groups as present in the Identity Store. For example, notice the list of user groups in this IT, and also the use of "hasgroups" to indicate the token does contain user groups. Once the Identity Token has been received by the application, access control decisions can be made using the group data.

- Authorization of the client to request such scope is controlled by the app's AllowedOperatons "itgroups"
- Groups are removed, and "hasgroups" claims are false, if the list of groups exceeds a certain size (typically to prevent Identity Token from exceeding 4 KB) even if the client is authorized to request user groups

Example of Identity Token

```
{
```

```
"at_hash": "Xh8yy6IBXIbJh_Hte5LqFQ",

]
}
```

Use Case 2 - Acquiring Access Token

The Access Token can be acquired for the purpose of redeeming such token against IDSP or against a 3rd party Resource Server. While Admin-specific permissions are beyond the scope of this overview, of special interest is acquiring an Access Token against 3rd party Resource Server or with which to request user data or entitlements via /userinfo. Acquiring an Access Token for user data/entitlements can be achieved by:

- requesting Access Token to be returned together with the Identity Token by /authorize. This works well when the Access Token must be used right away. When such an Access Token must be refreshed during the user's session, another /authorize call is made to seamlessly refresh the Access Token
- exchanging Identity Token for the Access Token using /token with JWT-BEARER grant, with an optional refresh token after which the Access Token can continue to get refreshed without the user needing to be "in session".

The Access Token can be requested to contain user groups. By requesting this scope in any flow using the "urn:iam:at:groups" claim, the resulting Access Token is given a list of user groups as present in the Identity Store. For example, notice the list of user groups in this AT, and also the use of "hasgroups" to indicate the token does contain user's groups. Once the Access Token has been received by the application, access control decisions can be made using the group data.

- Authorization of the client to request such scope is controlled by the app's AllowedOperations "atgroups"
- Groups are removed, and "hasgroups" claims are false, if the list of groups exceeds a certain size (typically to prevent Access Token from exceeding 4 KB) even if the client is authorized to request user groups

Example of Resulting Access Token

```
{
"sub": "f5c6e32f-e4af-4030-bf69-26eaeb936b3f",
"idp_name": "TestConfig",

],
"aud": "https://user.nbruce.id1.com/default/",
"nbf": 1625048423,
"user_aal": "AAL1",
"groups": [
 "Employees",
 "Admin"
],
"user_acr": "urn:iam:acr:aal1"
```

```
}
```

The audience claim "aud" of the Access Token is critical since it determines where the Access Token may be redeemed. When exchanging Access Token with 3rd party resource servers with whom the app is designed to work, the IDSP can be configured, and the client can request that the Access Token be given the audience associated with 3rd party resource servers that the client is administratively configured to invoke APIs, where the Access Token plays the role of the authorization credential. While this is not a full-blown 3rd party Resource Server support, this feature can be used to manage the trust scope of the Access Token requested by the client. For example, notice the audience claim of the resulting Access Token where the client requests that only application-specific (aka secondary) audiences be used in the resulting Access Token. Correlate this audience with the "secondaryAudiences" property of the application client given in the previous example. Also, note that such "3rd party" Access Token too can have user group information encoded in it. It is the responsibility of the 3rd party resource server (or its Policy Enforcement Point) to enforce such audience restrictions.

```
https://${SSP_FQDN}/{{apiPathTenant}}/oauth2/v1/authorize?scope=openid%20urn:iam:at:appaud
%20urn:iam:at:groups&client_id={{clientId}}&response_type=code&redirect_uri=https://www.example.com
```

Example of resulting Access Token with Custom Audience

```
{
"sub": "f5c6e32f-e4af-4030-bf69-26eaeb936b3f",

Use Case 3 - Acquire Access Token with OpenID privileges to access authorized User Data

The Access Token with which to access authorized user data via /userinfo can be acquired by requesting openid + other OpenID Connect and Custom scopes. A client is authorized for these operations by having properly configured "allowedOpenIDScopes" property as shown above.

- openid - request OpenID Connect authentication flow and return user identity in the Identity Token's "sub" claim
- email - allow access to user's email and verified_email data
- profile - allow access to user's profile attributes
- phone - allow access to user's phone and verified_phone data
- address - allow access to user's address
- groups - allow access to user's id store group data

For example, requesting these scopes via AZ Code flow allows the application to acquire the Identity Token (with user groups), and also Access Token with which it can invoke /userinfo to get user data to get user groups (or just get user groups via Access Token), while also requesting access to user's profile, address, email, or phone data.

```
https://${SSP_FQDN}/{{apiPathTenant}}/oauth2/v1/authorize?scope=openid%20email%20phone%20profile
%20groups%20urn:iam:it:groups
%20urn:iam:at:groups&client_id={{clientId}}&response_type=code&redirect_uri=https://www.example.com
```

Example of resulting Access Token

```
{

Client Types

Learn about the client types supported by Symantec Identity Security Platform.

IDSP supports the following Client Types:

- ***Public***
  - A Public Client is an application that initiates the authentication flow by passing only the client ID to process the authentication request. Public Client does not make use of the client secret and ignores the value, if provided. Examples of Public Client - Javascript based applications, Single Page Applications (SPA), or mobile clients.
  - The mobile apps can use a Public Client profile to initiate an authentication ceremony. This is consistent with the best practice covered by the native apps guideline as per https://tools.ietf.org/html/draft-ietf-oauth-native-apps-12
  - In IDSP, you can use the following grant types and request for specific scopes:
    - "ClientCreds" grant- With this grant type the application using the Public Client can obtain an access token with "t.authenticate" scope. This use of the Public Client is restricted to initiating authentication purpose only.
    - "JWT-BEARER" grant - With this grant type the application using the Public Client can obtain an access token with "m.me." scope. This use of the Public Client is restricted to self-service use cases, and not for performing any admin related tasks.
  - Public clients can submit their credentials using Basic Auth Authorization or POST body
- ***Confidential***
  - Clients that can be trusted to securely store their credentials such as client secrets. For example, web apps running on Web servers or App servers.

    NOTE
    A mobile app running on a user's mobile device can often be considered to be confidential as it belongs to a single user and has security controls to protect the device before the device can be used.
  - Confidential clients can submit their credentials using Basic Auth Authorization or POST body.
- ***Trusted***

Clients that are trusted to issue user assertions such as an ID Token Hint when initiating OpenID Connect interactions, or when submitting additional information about the user in certain API calls (such as when specifying a User's IP Address in user authentication API calls).

NOTE
Trusted clients are also considered confidential clients.

Refer to Managing Applications for more information on the Application resource containing the client definition.

Grant Types

Learn about the standard OAuth2 grant types supported by Symantec Identity Security Platform.

The following table shows the industry-recommended use of various OAuth grant types. The (✓) shows the recommended grand type that is suitable for the indicated apps. The grant types are linked to their respective sections, click each grant type for more information.

Grant Type	Protocols	Client Type	Single Page Apps	Native Apps	Microservices	Web App	Typical IoT Device
Client credentials	OAuth 2	public, confidential, trusted		✓ (Public Clients)	✓	✓	
Authorization code	OAuth 2.0 and OIDC	public, confidential, trusted				✓	
Authorization code With PKCE	OAuth 2.0 and OIDC	public, confidential, trusted	✓	✓			
Implicit (not recommended)	OAuth 2.0 and OIDC	public	✓				
Refresh Token	OAuth 2.0 and OIDC	public, confidential, trusted		✓	✓	✓	
JWT-Bearer	OAuth 2.0	public, confidential, trusted		✓	✓	✓	
STS-Confidential	OAuth 2.0	public, confidential, trusted					
Device Code	OAuth 2.0	public, confidential, trusted					✓

NOTE
Due to the inherent risks of returning access tokens in an HTTP redirect, it is not recommended to use the implicit flow. Public clients should be using the authorization code flow with the PKCE extension instead.

Allowed Operations

When configuring application clients, the following can be specified under *Allowed Operations* to control the client behavior:

- ***introspect*** - OAuth '**introspect'** endpoint works only when the client is allowed to perform this operation by having this configuration parameter enabled. Otherwise, the introspect endpoint returns an error response.
- ***onbehalfof*** - when the client is configured with '`onbehalfof`', the authorized scopes are computed by the authorization server on the basis of user's privileges only, instead of the intersection of user and client privileges.
- ***offlineit***: When '**offlineit**' is configured, the token endpoint returns the ID Token in the response of Refresh token and JWT-Bearer flows, if the openid scope is requested.
- ***itgroups*** - when the client is configured with '**itgroups'**, the application is allowed to include user groups in the identity token.
- ***atgroups*** - when the client is configured with '**atgroups'**, the application is allowed to include user groups in the access token.

Allowed OpenID Scopes

OpenID Connect (OIDC) scopes are a set of user attributes like email, phone that are used by an application during authentication to authorize access to the user. Each scope returns a set of user attributes, which are called claims. The scopes an application should request depend on which user attributes the application needs. Once the user authorizes the requested scopes, the claims are returned in an ID Token. IDSP supports the following OpenID scopes:

- openid - Indicates that the application intends to use OIDC to verify the user's identity.
- email - Configured email id where all the required mail notifications can be sent.
- profile - Option to personalize the email with the user's name, or picture.
- phone - Configured phone number where all the required SMS notifications can be sent.
- address - Configured postal address in the ID store.
- groups - Configured groups to which the user belongs.

Redirect URI

This is a list of allowed callback URLs where the authorization server sends the user once the app has been successfully authorized and granted an authorization code or access token. For example, https://www.example.com.

Client Credential Grant

The Client Credentials grant is used to obtain an Access Token on behalf of the client itself with no user present.

1. The client sends Client Credentials to the `/token` endpoint with `grant_type=client_credentials`, either in the Authorization header or in the POST body, depending on the client authentication method configured in the client definition
2. Symantec Identity Security Platform authenticates the client credentials and authorizes the client's requested scopes against the client's authorized privileges.
3. IDSP generates and returns the Access Token.

Request for all authorized scopes with client credentials passed in through the Authorization header:

```
curl -k --request POST \
--url 'https://example.com/default/oauth2/v1/token' \
--header 'Content-Type: application/x-www-form-urlencoded' \
-u "6cb446b9-33bf-4b97-a6e1-e7ad389974d2:2ef66db2-1e51-4868-8c72-bd57ce7f69dc" \
--data-urlencode 'grant_type=client_credentials' \
--data-urlencode 'scope=urn:iam:myscopes'
```

Response

```
{
  "access_token": "eyJ4NXQjUzI1NiI6Im......",
  "token_type": "Bearer",
  "expires_in": 3600
```

```
}

```

Authorization Code Grant

Learn about /authorize endpoint.

The Authorization Code grant is used to obtain an Access Token (and optionally an Identity Token in the case of the OpenID Connect flow) on behalf of the user identity identified by the Authorization Code obtained by previously invoking the `/authorize` endpoint. Optionally, to obtain a Refresh Token, pass "offline_access" as one of the scopes.

NOTE

- Authorization Code grant supports encryption of Identity Token. See JSON Web Encryption (JWE).
- To exchange Identity Token for Access Token at a third party Authorization Server, additional audience values may be required to be validated by that AZ Server. See **Secondary Audience** configuration in Managing Application.

1. The client sends Client Credentials to `/token` endpoint with `grant_type=authorization_code`, either in the Authorization header or in the POST body, depending on client authentication method configured in the client definition. The POST body also includes a JWT token with an assertion parameter.

   NOTE
   When the client exchanges an Authorization Code acquired using PKCE for an Access Token, it has to includes the Code Verifier.
2. Symantec Identity Security Platform authenticates the client credentials, verifies the signature of the JWT, and authorizes the client's requested scopes against the authorized privileges.

   NOTE
   If the client is acting On-Behalf-Of, the authorization check uses (and the resulting Access Token includes) the user's privileges only. Otherwise, the authorization check uses (and the resulting Access Token includes) the intersection of the client's and the user's privileges.
3. IDSP generates and returns the Access Token.

Request with client credentials passed in through the Authorization header and Authorization Code obtained previously from an `/authorize` request for `scope=openid` (see Client Credentials grant for an example of client credentials passed in through the POST body).

NOTE
With PKCE, the value of `code_verifier` is computed and added to the request (`--data-urlencode 'code_verifier=dGVzdA=='`)

Request

```
curl --location '"https://example.com/default/oauth2/v1/token">https://example.com/default/oauth2/v1/token' \
--header 'Content-Type: application/x-www-form-urlencoded' \
--header 'Authorization: Basic PHBhc3RlIGNsaWVudElkIGZyb20gYWJvdmUgY29tbWFuZD46d3Jvbmc=' \
--data-urlencode 'grant_type=authorization_code' \
--data-urlencode 'code={{code}}' \
--data-urlencode 'code_verifier=1234' \
--data-urlencode 'redirect_uri="https://example.com/sample-rp/oidc/callback">https://example.com/sample-rp/
oidc/callback' \
--data-urlencode 'scope=openid groups profile email'
```

Response

```
{
"access_token" : "eyJ4NXQjUzI1NiI6ImNJ......",
"token_type" : "Bearer",
"expires_in" : 3600,
"id_token" : "eyJ4NXQjUzI1NiI6Im....."
}

"idp_type": "ldap"
}
```

To know more about the "/authorize" API endpoint, see Authorize Endpoint .

JWT Bearer Grant

Learn about JWT Bearer grant.

The JWT-Bearer grant is used to obtain the Access Token on behalf of the user identity identified by the JWT assertion. As a result, the grant performs *identity propagation*. Optionally, to obtain a Refresh Token, pass "offline_access" as one of the scopes.

NOTE

- JWT-Bearer grant supports encryption of Identity Token. See JSON Web Encryption (JWE).
- To exchange Identity Token for Access Token at a third party Authorization Server, additional audience values may be required to be validated by that AZ Server. See **Secondary Audience** configuration in Managing Application.
- Only an assertion encrypted with Tenant's key is accepted. If the assertion is encrypted with any other public key, decryption fails as Symantec Identity Security Platform is not the holder of the key.

1. The client sends the Client Credentials to `/token` endpoint either in the Authorization header or in the POST body with `grant_type=urn:ietf:params:oauth:grant-type:jwt-bearer`, depending on the client authentication method configured in the client definition. The POST body also includes a JWT token with an `assertion` parameter.
2. IDSP authenticates the client credentials, verifies the signature of the JWT, and authorizes the client's requested scopes against the authorized privileges.

   NOTE
   If the client is acting On-Behalf-Of, the authorization check uses (and the resulting Access Token includes) the user's privileges only. Otherwise, the authorization check uses (and the resulting Access Token includes) the intersection of the client's and the user's privileges.
3. IDSP generates and returns the Access Token with the `sub` claim representing the propagated user identity.

Request for all authorized scopes with client credentials passed in via the Authorization header and user assertion representing `defaultadmin` user (see Client Credentials grant for an example of client credentials passed in through the POST body).
Example

```
curl -k --request POST \
--url 'https://example.com/default/oauth2/v1/token' \
--header 'Content-Type: application/x-www-form-urlencoded' \
-u "6cb446b9-33bf-4b97-a6e1-e7ad389974d2:2ef66db2-1e51-4868-8c72-bd57ce7f69dc" \
--data-urlencode 'grant_type=urn:ietf:params:oauth:grant-type:jwt-bearer' \
--data-urlencode 'scope=urn:iam:myscopes' \
--data-urlencode 'assertion=eyJ4NXQjUzI1..........5y3fw'

Device Code Grant

Learn about Device Code Grant.

The Device Code grant type allows OAuth clients to request user authorization from apps on devices with restricted input capabilities or a lack of a suitable browser. Smart TVs, media consoles, picture frames, and printers are examples of gadgets that lack a convenient input mechanism or a compatible browser for typical OAuth interactions. The device code authorization flow allows the user to review the authorization request in a secondary device, such as a smartphone that has the required input and browser capabilities to complete the user interaction.

Follow these steps to retrieve the access token using Device User Code Grant:

1. Client (Device App) issues a backchannel Authorize request with the required parameters which includes its client identifier. The Authorization server responds with the device_code, user_code, verification_uri, verification_uri_complete, expires_in, and interval. The following is the response of Device Code request API:

   NOTE

   - The ‘verification_uri’ is the 'deviceCodeflow' url configured in the app.
   - The client can generate a QR code using the value of ‘verification_uri_complete’.

```
{
 "device_code": "lhBX4HHZlaeZpBmbuBIoY81jrsHEOK",
 "user_code": "WDJBMJHT",
 "verification_uri": "https://${SSP_FQDN}/tenant/ui/v1/device",
 "verification_uri_complete": "https://${SSP_FQDN}/tenant/ui/v1/device?user_code=WDJBMJHT",
 "expires_in": 300,
 "interval": 5,
}
```

2. The client app asks the user to activate using their smartphone or computer.
   – The user requires to enter the user_code in the verification_uri that was generated in the 1st step. The user code (for example- "WDJBMJHT") is also generated in the above step.
   – The above step can also be achieved by, either accessing the verification_uri in the browser and entering the user code manually or accessing the verification_uri_complete (which auto-populates the user_code).
3. The UI invokes the backend Device User Code Verification URI. Upon success, the Authorization server redirects to the authentication flow to perform end-user authentication.

   NOTE
   Depending on the configuration, this authentication flow may redirect to your own login app if one was configured and deployed on the application entity representing the client, or else, the authentication flow is redirected to the default out-of-the-box login page.
4. On successful user authentication, the user is redirected to a page showing the "Success" message.
5. The client invokes the backchannel Token endpoint with ***grant_type=urn:ietf:params:oauth:grant-type:device_code*** and includes the device_code value that was generated in the first step.
6. The Token server generates and returns the Access Token. It also includes the Identity Token or the Refresh Token if the client has initially requested the "**openid**" scope or the "**offline_access**" scope respectively as part of invoking the Device Authorize endpoint.

Device Code APIs

The following APIs are used to retrieve the access token:

1. Device User Code Authorization
2. Device User Code Verification
3. Device User Code Access Token

These APIs have been explained in detail in the following sections.

Device User Code Authorization API

Device User Code Authorization API request: This API allows the user to create a device authorization request. The API generates the device code and the user code.

```
POST https://${SSP_FQDN}/{{tenantName}}/oauth2/v1/devicecode
```

NOTE

- To know the value of ${SSP_FQDN} environment variable, see Configuring IDSP Environment Variables.
- The default value for `<tenantName>` is "default".
- Replace the text {{text}} including {{}} characters with appropriate values, in all the endpoints shown in the above table.
  For example:
  `https://{{host}}/{{tenantName}}/oauth2/v1/devicecode`
  should look similar to:
  `https://example.com/default/oauth2/v1/devicecode`
- To know more about the scopes that are required to secure these APIs, refer to the Rest APIs and Associated Privileges section.

```
POST /oauth2/v1/devicecode HTTP/1.1
   Host: example.com
   Content-Type: application/x-www-form-urlencoded
   Authorization: Basic Auth
   client_id=1406020730&scope=openid
```

Where,

- client_id - The Client ID of the application. This client id is used to look up the allowed operations and to have the Device Code issued.
- client_secret - This indicates the client secret of the application. This is applicable in non-public clients only.
- scope - The device adds the required scopes to be granted in the Access token. Example values can be "openid" and "offline_access".

Device User Code Authorization API response:

```
{
 "device_code": "lhBX4HHZlaeZpBmbuBIoY81jrsHEOK",
 "user_code": "AQL9EIBH",
 "verification_uri": "https://${SSP_FQDN}/tenant/ui/v1/device",
 "verification_uri_complete": "https://${SSP_FQDN}/tenant/ui/v1/device?user_code=AQL9EIBH",
 "expires_in ": "300",
 "interval ": "60"
}
```

Where,

- device_code - The long string that the device uses to exchange for an access token. This is the user code received from the POST /devicecode API.
- user_code - The text that you enter at the URL that is listed as the value for verification_uri. This is the user code received from the POST /devicecode API.
- verification_uri - The end-user verification URI on the authorization server. This is the URL that the user must access from their device to start the sign-in process.
- verification_uri_complete - The device verification URL along with the embedded user_code on the Authorization server.
- expires_in - This indicates the number of seconds before the device_code and user_code expire.
- interval - This indicates the number of seconds the client should wait between polling the requests.

Device User Code Verification API

This is the device verification URL on the Authorization server which is invoked by the UI (front end "verification_uri"). This API validates the user code and initiates the user authentication flow.

```
GET https://${SSP_FQDN}/{{tenantName}}/oauth2/v1/devicecode?user_code={{user_code}}
```

Example of the request payload for GET /devicecode API:

```
GET /oauth2/v1/devicecode HTTP/1.1
   Host: example.com
   Content-Type: application/x-www-form-urlencoded
```

Device User Code Access Token API

This API generates the access:

```
POST https://${SSP_FQDN}/{{tenantName}}/oauth2/v1/token
curl -k --request POST \
--url 'https://example.com/default/oauth2/v1/token' \
--header 'Content-Type: application/x-www-form-urlencoded' \
-u "6cb446b9-33bf-4b97-a6e1-e7ad389974d2:2ef66db2-1e51-4868-8c72-bd57ce7f69dc" \
--data-urlencode 'grant_type=urn:ietf:params:oauth:grant-type:device_code' \
--data-urlencode 'device_code=uknSklnJPKenRZkRhMsZxJVdEnzEwF'\
--data-urlencode 'scope=urn:iam:myscopes'
```

Where,

- grant type- this is the device code grant type
- device code- this is the device code received from the POST /devicecode API
- client id- this is the Client ID of the application. This client id is used to look up the allowed operations and to have the Device Code issued.

  NOTE

  - In the case of a non-public client, enter the client_id and client_secret. In the case of a public client, enter only client_id.
  - You can pass the client_id and client_secret in the Authorization Header or pass the client _id in the request body.

The sample response of the /token API is shown below:

```
{
"access_token":"2YotnFZFEjr1zCsicMWpAA........",
"token_type":"Bearer",
"expires_in":3600,
"id_token":"tnFZFEjr1zCsicMWpAA.......",
"refresh_token":"tGzv3JOkF0XG5Qx2TlKWIA",
}
```

NOTE
If you provide the "offline_access" scope in the device authorization, then the token endpoint API generates the refresh_token.

Application Configuration

The following application property should be configured while creating an application in the solution:

Property Name	Description
allowedGrantTypes	This parameter allows the device code grant type- ***urn:ietf:params:oauth:grant-type:device_c***

deviceCodeFlowURL	(Optional) This is the customized UI URL required to enter the user code in OAUTH2.0 Device Au If the customized URL is not configured, then the default Symantec Identity Security Platform ***ver*** ***${SSP_FQDN}/tenant/ui/v1/device*** is used.

The relevant application properties are covered in Managing Applications .

Using Custom Device Code Flow URL

If you are using a custom device code flow URL, for example- "deviceCodeFlowURL":

"https://www.test.com/custom/device" then the Device Authorization response would look like the following:

```
{
 "device_code": "lhBX4HHZlaeZpBmbuBIoY81jrsHEOK",
 "user_code": "AQL9EIBH",
 "verification_uri": "https://www.test.com/custom/device",
 "verification_uri_complete": "https://www.test.com/custom/device?user_code=AQL9EIBH",
 "expires_in ": "300",
 "interval ": "60"
}
```

NOTE
For the "verification_uri_complete" - The user_code gets appended as a query parameter.

Device Code with Client Assertion

The following sample shows a request payload for "/devicecode" with client assertion as client credentials:

```
curl -k --request POST \
--url 'https://example.com/default/oauth2/v1/devicecode' \
--header 'Content-Type: application/x-www-form-urlencoded' \
--data-urlencode 'client_id=7b447d36-cac4-4a9e-b093-42f0d553d9f4' \
--data-urlencode 'client_assertion_type=urn:ietf:params:oauth:client-assertion-type:jwt-bearer' \
--data-urlencode 'client_assertion=ewogICJ4NXQjUzI1NiI6ICI4bkRSWURaUF9xcENwUz.....'
```

Custom UI Actions

While using custom device code flow, the UI should be able to handle these scenarios:

1. Your custom UI should display a field to enter the user_code.
   NOTE
   If the user_code is already present in the query parameter, then pre-populate the user_code in the UI control.
2. The following IDSP API should be invoked:
   `https://${SSP_FQDN}/<tenant>/oauth2/v1/devicecode?user_code=<Entered User Code>`
   - If the user code verification is a success, the API returns 302 with the location as a server redirect to the SignIn UI (Either default or configured flowURL in the App)
   - If the user code verification is a failure, the API returns 400 with an error code and message as a JSON response.
3. Upon user authentication:
   - If the authentication is successful, the UI redirects the user to the device code flow URL with "action"="success" query parameter.
     `Example: https://www.test.com/custom/device?action=success`
   - If the authentication fails, the UI redirects the user to the device code flow URL with "action"="failed" query parameter.
     `Example: https://www.test.com/custom/device?action=failure`

Global and Tenant Settings

Configure the following tenant and global level properties to enable Device Code grant.

NOTE
NOTE: Tenant Administrators can override the global settings using tenant settings.

Property Name	Property Scope	Property Description	Default Value	Comments
deviceCodeExpirySecs	Global (Tenant can override the setting)	This property represents the "expires_in" parameter which is generated as part of the response of POST / oauth2/v1/devicecode. It indicates the number of seconds before the device_code and user_code expire.	300 secs	Possible values: The range is 60secs-{deviceCodeExpiryMaxMins} (in secs)
devicePollingIntervalSecs	Global (Tenant can override the setting)	This property indicates the number of seconds the client should wait between polling requests.	5 secs	Possible values: The range is 5 sec - {deviceCodeExpiryMaxMins} (in secs)
deviceCodeExpiryMaxMins	Global	This property governs the maximum value that can be set for "deviceCodeExpirySecs" and "deviceCodePollingIntervalSecs" . The system internally translates the given mins to secs and checks the max value for deviceCodeExpirySecs / deviceCodePollingIntervalSecs at the time of property update.	5 mins	Possible values: 1 min to 60 mins

The relevant configuration settings are covered in Global/Tenant Settings.

PKCE Support in Device User Code Flow

In the case of PKCE Device Authorization request API, the authorization server performs the following tasks:

1. The client generates a code verifier, computes the code challenge, and sends the code challenge and code challenge method with the authorization request to the Device Authorization Endpoint.
2. Authorization Server at Device Authorization Endpoint records code challenge and code challenge method, and generates authorization code.
3. The client sends authorization grant_type, device_code, and code_verifier to Access Token Endpoint.
4. Authorization Server at Access Token Endpoint verifies that the request contains the code verifier parameter. Then, it validates the code verifier value with the code challenge and code challenge method that was sent in the authentication request at the authorization endpoint.

Example of Device User Code grant using PKCE

```
POST /oauth2/v1/devicecode HTTP/1.1
```

```
Host: example.com
Content-Type: application/x-www-form-urlencoded
client_id=1406020730&scope=openid
code_challenge=computedvalueofcodeverifier
code_challenge_method=plain|S256
```

Device User Code Error Codes

8100060	Invalid user code
8100061	Invalid request
8100062	Failed to create flowstate
8100063	User code expired
8100064	Missing/Invalid device code
8100065	The authorization for this token is pending
8100066	Polling too quickly
8100067	Forbidden request
8100068	Missing user code
8100074	Device code expired

The following error codes are specified for use with the device authorization grant in token endpoint responses:

authorization_pending	The authorization request is still pending as the end-user has not yet completed the user interaction. The client should repeat the access token request to the token endpoint.
slow_down	This error indicates that the polling is too fast. The polling in seconds is happening faster than the time configured in the setting- '**deviceCodePollingIntervalSecs**'.
access_denied	The authorization request was denied.
invalid_client	The client Id provided in the request is invalid.
expired_token	The "device_code" has expired, and the device authorization session has concluded. The client may commence a new device authorization request but should wait for user interaction before restarting to avoid unnecessary polling.
unsupported_grant_type	This error is displayed when the grant_type parameter is not specified, or the given value is incorrect.
invalid_grant	The grant type provided in the request is invalid. The grant type does not exist in IDSP.

Refresh Token Grant

Learn about the Refresh Token Grant.

This topic includes the following sections:

- Refresh Token
- Steps to obtain a Refresh Token
- Step to obtain a new Access Token using the Refresh Token grant
- Step to obtain both, new Access Token and new Refresh Token using the Refresh Token grants

Refresh Tokens are credentials used to re-generate an Access Token without re-authenticating, when the current access token becomes invalid or expires. When using the Refresh Token, you may request for the same scopes that were requested during the initial authentication or narrow down the scopes depending on your requirement. Refresh Tokens have a limited lifetime, controlled by application property (**metadata**), or tenant configuration setting (**refreshTokenExpiryDays**) to meet the requirements of corporate security policies. See Managing Applications for "**urn:iam:app:oauthRefreshTokenExpiryDays**" application's metadata attribute or see Managing Settings for ***"refreshTokenExpiryDays"*** setting details. Refresh Tokens are secrets and not JWT. To make use of the Refresh Token functionality, you should update the following endpoints with the scope, "**offline_access**":

- "/authorize"
- "/token"

NOTE
To know about additional settings related to the refresh token, look for the following settings in the Managing Settings page.

- keepOldRefreshTokenOnRefreshTokenFlowWithOfflineAccess
- keepOldSessionIdOnNewRefreshTokenFlowWithOfflineAccess

NOTE
To ensure accurate and reliable IP address usage in complex network environments (which may alter user IP information due to firewalls or load balancers), leverage the Symantec Identity Security Platform application metadata. To know more, see HTTP Header and End User IP Address Usage.

Steps to obtain a Refresh Token

The following step shows an example of how to send a Refresh Token request using "/token" and "/authorize" endpoint.

Perform the following step:

1. In the "/token" endpoint or "/authorize" request body, enter the scope as "**offline_access**" and invoke the API. The Refresh Token will be obtained.

   NOTE
   The "**offline_access**" scope only works with '**authorization_code**', '**jwt-bearer**' or '**device_code**' grant_types.

   Example of a Refresh Token request format in the "/token" endpoint:

   ```
   curl -k --request POST --url 'https://example.com/default/oauth2/v1/token' --header 'Content-Type:
    application/x-www-form-urlencoded' -u "6cb446b9-33bf-4b97-a6e1-e7ad389974d2:2ef66db2-1e51-4868-8c72-
   bd57ce7f69dc" --data-urlencode 'grant_type=authorization_code' --data-urlencode
    'code=sodgnomNDVB723a3dPRwMBGHTYHB' --data-urlencode 'scope=offline_access'
   ```

   Example of a Refresh Token request format in the "/authorize" endpoint:

   ```
   https://example.com/default/oauth2/v1/authorize?response_type=code&client_id=6cb446b9-33bf-4b97-a6e1-
   e7ad389974d2&redirect_uri=https://
   www.example.com&scope=urn:iam:myscopesopenidemailoffline_access&state=mystate
   ```

   Example of a Refresh Token response format:

   ```
   {

   "access_token" : "eyJ4NXQjUzI1NiI6ImNJbUNYN1FyRy1BUUpkWWZ2Wlctd1...X6HEbM-Hdh-hzXqHA"

   "token_type" : "Bearer",

   "expires_in" : 3600,

   "id_token" : "eyJ4NXQjUzI1NiI6ImNJbUNYN1FyRy1BUUpkWWZ2W....3qliSzy_Khn2wgqQ2bg2t8Keg",
   ```

```
"refresh_token": "m5370ROmNDVB7a3dPRwMs5FDTZjfFc"

}
```

Step to obtain a new Access Token using the Refresh Token grant

Perform the following step:

1. In the "/token" endpoint request body, enter the value of the Refresh Token that you obtained in the previous section and invoke the "/token" API. The new Access Token is obtained.
   Example of a request body that includes the refresh_token which is used to obtain the new Access Token:
   ```
   curl -k --request POST --url 'https://example.com/default/oauth2/v1/token' --header
    'Content-Type: application/x-www-form-urlencoded' -u "6cb446b9-33bf-4b97-a6e1-
   e7ad389974d2:2ef66db2-1e51-4868-8c72-bd57ce7f69dc" --data-urlencode 'grant_type=refresh_token' --data-
   urlencode 'refresh_token=m5370ROmNDVB7a3dPRwMs5FDTZjfFc' --data-urlencode 'scope=<subset of scopes>'
   ```
   The following table shows the request parameters required for getting the new Access Token:

Name	Description
client_id	Client Id of the client that was registered with IDSP
client_secret	Client secret that is associated with the client_id
grant_type	The grant type supported for generating a new Access Token using the Refresh Token is "**refresh_token**". This grant type can be used only with 'authorization_code', 'jwt-bearer' or 'device_code' grant type.
refresh_token	Value of the Refresh Token
scope	Subset of scopes.

   Example of a response body which grants the new Access Token:
   ```
   {

   "access_token" : "eyJ4NXQjUzI1NiI6ImNJbUNYN1FyRy1BUUpkWWZ2Wlctd1...X6HEbM-Hdh-hzXqHA",

   "token_type" : "Bearer",

   "expires_in" : 3600

   }
   ```

Step to obtain both, new Access Token and new Refresh Token using the Refresh Token grants

Perform the following step:

1. In the "/token" endpoint request body, enter the grant type as "refresh_token" and the value of the "refresh_token" that you have obtained from the "Step to obtain Refresh Token" section.
   ```
   curl -k --request POST --url 'https://example.com/default/oauth2/v1/token' --header
    'Content-Type: application/x-www-form-urlencoded' -u "6cb446b9-33bf-4b97-a6e1-
   e7ad389974d2:2ef66db2-1e51-4868-8c72-bd57ce7f69dc" --data-urlencode 'grant_type=refresh_token ' --data-
   urlencode 'refresh_token=m5370ROmNDVB7a3dPRwMs5FDTZjfFc' --data-urlencode 'scope=<subset of scopes>'
   ```
   NOTE
   To obtain a new Refresh Token, passing ***scope= "offline_access"*** in the "/token" endpoint is mandatory.
   Example of a response body that grants the new Access Token and the Refresh Token:

```
{

"access_token" : "eyJ4NXQjUzI1NiI6ImNJbUNYN1FyRy1BUUpkWWZ2Wlctd1...X6HEbM-Hdh-hzXqHA",

"token_type" : "Bearer",

"expires_in" : 3600,

"refresh_token": "tGzv3JOkF0XG5Qx2TlKWIA"

}
```

Resource Owner

Legacy OAuth 2.0 flow for direct credential validation

The Resource Owner grant type is a legacy OAuth 2.0 flow where the application directly receives an access token after the user's credentials (username and password) are validated by the Symantec Identity Security Platform.

> **NOTE**
> This is explicitly noted as a legacy grant type that should only be used when a legacy component specifically requires it.

Implementation

Token Endpoint

```
POST https://{{sspHost}}/{{apiPathTenant}}/oauth2/v1/token
```

Required Headers:

- **Authorization Header**
  Pass the application Client ID and secret in the request in the authorization header.
- **Content Type Header**
  ```
  content-Type: application/x-www-form-urlencoded
  ```

Sample Request

```
curl --request POST \
 --url https://<ssp-hostname>/<tenantName>/oauth2/v1/token \
 --header 'authorization: Basic <Base64 encode of Client ID:Client Secret>' \
 --header 'content-type: application/x-www-form-urlencoded' \
 --data grant_type=password \
 --data username=<userName> \
 --data scope=urn:iam:myscopes \
 --data 'password=<replace by user password>'
```

Where,

- grant_type: This value must be set to "password"
- username: The resource owner username
- password: The resource owner password
- scope: The scope of the access request

Sample Response

```
HTTP/1.1 200 OK
    Content-Type: application/json;charset=UTF-8
    Cache-Control: no-store
    Pragma: no-cache

    {
      "access_token":"2YotnFZFEjr1zCsicMWpAA",
      "id_token":"xetotnFZFEjr1zCsicMWpAA",
      "scope":"urn:iam:t.all",
      "token_type":"Bearer",
      "expires_in":3600,
      "refresh_token":"tGzv3JOkF0XG5Qx2TlKWIA"
    }
```

Authorization Server Endpoints

Learn about Authorization server endpoints, such as /jwks, /authorize, /token, /revoke, /introspect, /devicecode, /openid-configuration, /logout.

The following endpoints are the OAuth Authorization Server endpoints that are exposed by Symantec Identity Security Platform.

- Prerequisites
- Discovery Endpoint
- JSON Web Key Set (JWKS) Endpoint
- Authorize Endpoint
  - Authorize Code Flow
- Token Endpoint
- Introspect Endpoint
- UserInfo Endpoint

NOTE
Replace the text within the placeholder < > with the appropriate values in all the endpoints shown in the following table.

Endpoint	Description
https://<host>/<tenant>/.well-known/openid-configuration	Provides metadata about the authorization server
https://<host>/<tenant>/oauth2/v1/jwks	Provides applications with public keys as required to verify the signature of a JWT issued by the IDSP Authorization Service, or to encrypt a JWT sent to the Authorization server (such as encrypting Identity Token Hint).
https://<host>/<tenant>/oauth2/v1/authorize	Authenticates user identity, enabling users to authorize clients requesting access to protected resources
https://<host>/<tenant>/oauth2/v1/token	Generates access tokens and refresh tokens for a client or user
https://<host>/<tenant>/oauth2/v1/revoke	Revokes an access token or a refresh token
https://<host>/<tenant>/oauth2/v1/userinfo	Returns claims or assertions about the user authenticated using the `/authorize` flow
https://<host>/<tenant>/oauth2/v1/introspect	Returns information about a token

Endpoint	Description
https://<host>/<tenant>/oauth2/v1/devicecode	• The POST /devicecode API allows the user to create a device authorization request. The API generates the device code and the user code. • The GET /devicecode API is the device verification URL on the Authorization server which is invoked by the UI (front end "verification_uri"). This API validates the user code and initiates the user authentication flow.
https://<host>/<tenant>/oauth2/v1/logout	Terminates the user session as specified by either of the following options: • specify the logout session in the "session_state" query string parameter • if not specified in the "session_state" query string parameter, IDSP logs out the session indicated by the "sspsession" cookie. Once the session is logged out, IDSP redirects the client to a Post Logout URL if specified in the "post_logout_redirect_uri" query string paramter. If this is not specified, IDSP redirects to a default Post logout URI which is searched for in the following order: 1. App-level Post logout URL 2. Tenant Setting's postLogoutUrl 3. Application's Home URL 4. Tenant's Home URL If the client specifies the Post Logout URL query string parameter, then the URL must be authorized. This URL must be defined in one of the following places: It should either match the default Post logoutUrl, or default logoutUrl (which is configured in the application logoutUrl, or in the tenant setting logoutUrl), or any of the application's redirect URL.

Prerequisite

Install cURL to execute the samples provided in the sections below.

> **NOTE**
> A recommended way to verify the service URL is by running the service discovery curl command.

Discovery Endpoint

The discovery endpoint lets clients obtain information needed to interact with the OAuth Authorization Server, including its OAuth 2.0 endpoints.

Request

```
https://<host>/<tenant>/.well-known/openid-configuration
```

Response

```
{
"issuer": "https://<ssphost>/default/",

JSON Web Key Set (JWKS) Endpoint

A read-only JWKS service is for use by someone who develops PKI-based code to perform one of two activities:

- validate signature of received artifacts
- encrypt artifacts to be sent

The main purpose of a JWKS endpoint is to provide applications with public keys as required to verify the signature of a JWT issued by the IDSP Authorization Service, or to encrypt a JWT sent to the Authorization server (such as encrypting Identity Token Hint).

Request

```
https://<host>/<tenant>/oauth2/v1/jwks
```

Response

```

}
```

> **NOTE**
> For detailed examples of JWKS Endpoint, see here.

Authorize Endpoint

The main purpose of this endpoint is to support the Authorization Code flow. The authorization endpoint is used by the authorization server to initiate the user authentication ceremony to assert the user identity. Then, the client exchanges the

Authorization Code for the Access Token (and Identity Token if the client initially requested openid scope as part of the "/authorize" request) by invoking authorization's server Token endpoint. The client also exchanges the Authorization code for the Refresh Token, if the client initially requested "offline_access" scope as part of the "/authorize" request or as part of "/token" request.

```
https://<host>/<tenant>/oauth2/v1/authorize
```

Security consideration for clients The `/authorize` endpoint also supports *Implicit* flow for use by native apps, such as single-page apps (see Implicit Flow). However, use of the Implicit flow is not recommended. Instead, single-page apps should use Authorization Code flow with Proof Key for Code Exchange (PKCE). When public clients such as native and single-page applications request Access Tokens, there are additional security concerns since such clients cannot securely store a Client Secret or indicate a trusted callback URL. The PKCE specification (OAuth 2.0 RFC 7636) addresses this issue. Adding PKCE parameters to the Authorization Code flow enables the client to introduce a secret (Code Verifier) that can be validated by the authorization server. The client creates and sends the Code Challenge as part of the `/authorize` request to get the Authorization Code. When the client exchanges the Authorization Code for an Access Token, it includes the Code Verifier. As a result, even if attackers intercept the `/authorize` request, they will not be able to exchange it for the access token without the Code Verifier. See PKCEfor more information.

"/authorize" parameters

Parameter	Optionality	Description
client_id	Required	The Client ID for this application. This client id is used to look up allowed grants and operations, and to have the Authorization Code.
response_type	Required	• or the Authorization Code flow, specify `code`. • For the Implicit flow, specify one of the following: – `token` – `id_token` – `id_token token`
scope	Required	This is a space-delimited string containing scopes (privileges) for which you want to request authorization. You can request scopes supported by the target API (for example, `urn:iam:myscopes` or `urn:iam:t_authenticate`) as indicated in the REST API section, or any of the OpenID Connect scopes supported by the Allowed OpenID Scopes configuration parameter of the application whose client is requesting access (for example, `profile` or `email`). If initiating the OpenID flow, add `openid` to the request issuance of the Identity Token. Indicate additional OpenID scopes (client's Allowed OpenID Scopes) to authorize the client to invoke the Userinfo endpoint to request user data represented by those scopes. If initiating the Oauth or OIDC flow, add "offline_access" as part of the "/token" request to get the Refresh Token.
redirect_uri	Required	This is the URL-encoded endpoint to which the client will be sent back once the Authorization Code has been issued by the authorization server. The Authorization Code will be available in the `code` URL parameter. This URL must be specified exactly as provided in one of the values during client registration.
state	Optional	The value supplied by the client will be returned by the authorization server along with the Authorization Code.
nonce	Optional (for use with OpenID only)	This is an optional security mechanism to protect against replay attacks. This should be a strong random value associated with the internal application session. If asking for an Identity Token (in the case of OpenID Connect requests only), this value is included in the Identity Token.

Parameter	Optionality	Description
code_challenge_method	Optional (for use with PKCE only)	The method used to generate the **PKCE** challenge. The PKCE specification includes `S256` and `plain`. Use of `plain` is not recommended.
code_challenge	Optional (for use with PKCE only)	Challenge generated from the PKCE Code Verifier
state	Optional (for use with PKCE only)	This is an optional security parameter for clients to protect against certain attacks such as Cross-Site Request Forgery (CSRF, XSRF). Usually, this value is generated by cryptographically binding to some browser state such as an application cookie to detect a possible request hijacking attempt.
login_hint	Optional	This is the hint to pre-populate the user name field in the out of the box signin application.
prompt	Optional	The "prompt" property only accepts the value "login". When the "prompt" parameter is set to "login" in the "/authorize" request, users are prompted to complete the authentication process, regardless of whether they already have a valid session in the IDSP browser. This requires users to re-enter any applicable credentials to proceed with the authentication flow.
id_token_hint	Optional	The ID Token being passed as a hint about the End-User's current or past authenticated session. If the End-User identified by the ID Token is already logged in or is logged in as a result of the request (with the OP possibly evaluating other information beyond the ID Token in this decision), then the Authorization Server returns a positive response; otherwise, it MUST return an error, such as login_required. When possible, an id_token_hint SHOULD be present when prompt=none is used and an invalid_request error MAY be returned if it is not; however, the server SHOULD respond successfully when possible, even if it is not present. When validating the signature of the Identity Token Hint provided into "/authorize" API, the certificate used for validating the token signature is looked up in this order: x5t+sha256, x5t, kid+alias, and finally the issuer claim.
response_mode	Optional	This property specifies whether the authentication response to redirect_uri must be sent in the form of query parameters or encoded as HTML form values that are sent in the POST method. By default, Authorization Code Flow uses query as the response mode. To send the response in query format, you need not send this parameter in the authentication request. To send the response in encoded as HTML form values, specify form_post as the value in the authentication request.

Authorize Code Flow

The Authorization endpoint is used to obtain an Access Token on behalf of the user whose identity will be authenticated by the authorization server. Additionally, this endpoint is used by the OpenID Connect flow to acquire an Identity Token for the authenticated user by specifying `openid` as one of (or the only one) the requested scopes. The same endpoint is also used to acquire a refresh Token for the authenticated user by specifying `"offline_access"` as one of the requested scopes.

1. The client issues a front channel Authorize request with the required parameters.
2. The Authorization server redirects to the authentication flow to perform end-user authentication.

   NOTE
   Depending on the configuration, this authentication flow may redirect to an out-of-the-box *login* page or your own login app if one was configured and deployed on the application entity representing the client.

3. On successful user authentication:
   a. The Authorization server authorizes the client's requested scopes against the authorized scopes, and if valid, generates and returns the Authorization Code.

      NOTE
      If the Client is acting On-Behalf-Of, the authorization check uses the user's privileges as authorized privileges. Otherwise, the authorization check uses the intersection of client's and user's privileges as authorized privileges.

   b. The Authorization server executes a 302 Redirect to the client's registered callback URL with the Authorization Code.
4. The client invokes the backchannel Token endpoint with `grant_type=authorization_code` and includes the Authorization Code value.
5. The Token server generates and returns the Access Token. It also includes the Identity Token or the Refresh Token if the client has initially requested the `openid` scope or the "**offline_access**" scope respectively as part of invoking the Authorize endpoint.

Authorize Code Flow Examples Browser request to generate Authorization Code to be exchanged for an access token with REST API scopes only:

```
https://example.com/default/oauth2/v1/authorize?response_type=code&client_id=6cb446b9-33bf-4b97-a6e1-
e7ad389974d2&redirect_uri=&scope=uhttps://www.example.com&scope=urn:iam:myscopes&state=mystate
```

NOTE
With PKCE, the value of `code_CHALLENGE` is computed and added to the query string params (`...&code_challenge_method=S256&code_challenge=9f86d081884c7d6#39;`)

After user authentication for user "kevinlucas" is complete, the Authorization server uses a 302 Redirect to the client's redirect_uri with the Authorization Code (and State if originally provided when invoking the `/authorize` endpoint).

```
https://www.example.com/?code=66fRVqzzFdTAjmMlcirB2r1P2D0MBd&X-TRANSACTION-ID=7fd70067-d5cb-4ea6-8ea6-
c3ca4551b5cc&state=mystate
```

The client then exchanges the Authorization code for the Access Token:
Example

```
curl -k --request POST --url 'https://example.com/default/oauth2/v1/token' --header 'Content-Type:
 application/x-www-form-urlencoded' -u "6cb446b9-33bf-4b97-a6e1-e7ad389974d2:2ef66db2-1e51-4868-8c72-
bd57ce7f69dc" --data-urlencode 'grant_type=authorization_code' --data-urlencode
 'code=66fRVqzzFdTAjmMlcirB2r1P2D0MBd'
{
"access_token" : "eyJ4NXQjUzI1NiI6ImN.......",
"token_type" : "Bearer",
"expires_in" : 3600
}

"idp_type": "ldap"
}
```

NOTE
For more details on Authorization Code Flow, see here.

Token Endpoints

For details on Token endpoint, see OAuth2 Token Endpoint.

Revoke Token

For details on Revoke token, see here

Introspect Endpoint

The Introspect Endpoint lets clients verify tokens (Access Token or Refresh Token). Note that these remote calls are considered to be expensive.

```
https://<host>/<tenant>/oauth2/v1/introspect
```

NOTE
The introspection of the encrypted ID Token is not yet supported.

For maximum performance, applications should perform token validation on the client side using token validation best practices that includes at least the following:

- Validate token signature
- Validate token expiration
- Validate token audience

Click here to see Request and Response of this endpoint

```
curl -k --request POST \
--url 'https://example.com/default/oauth2/v1/introspect' \
--header 'Content-Type: application/x-www-form-urlencoded' \

NOTE

For more details on Introspect endpoint, see here.

UserInfo Endpoint

The UserInfo Endpoint gets identity information about the user. The supplied Access Token must have been generated as part of the OpenID Connect authorization flow.

```
https://<host>/<tenant>/oauth2/v1/userinfo
```

Example: Request with Access Token in the authorization header

```
curl -k --request GET \
--url 'https://example.com/default/oauth2/v1/userinfo' \
--header 'Content-Type: application/x-www-form-urlencoded' \
--header 'Authorization: Bearer eyJ4NXQjUzI1Niuk5VYTsg'

Decoded Access Token

NOTE

For more details on UserInfo Endpoint, see here.

OAuth2 Token Endpoint

The OAuth2 Token endpoint enables client applications to obtain access tokens using multiple OAuth2 grant types including client credentials, authorization code, JWT bearer, refresh token, device code, and resource owner password credentials for API authentication and authorization.

API Overview

The OAuth2 Token endpoint implements multiple OAuth 2.0 grant flows, allowing client applications to authenticate with the authorization server to obtain access tokens. This endpoint supports Client Credentials Grant, Authorization Code Grant, JWT Bearer Grant, Refresh Token Grant, Device Code Grant, and Resource Owner Password Credentials Grant flows for various authentication scenarios.

Key Functions:

- **Token Generation:** Issues JWT access tokens for authenticated client applications
- **Client Authentication:** Validates client credentials using Basic Authentication
- **Scope Authorization:** Grants specific permissions based on requested scopes and client privileges
- **Session Management:** Provides token expiration and lifecycle management

Use Cases:

- **Client Credentials:** API-to-API communication where client applications need to access protected resources
- **Authorization Code:** Web applications requiring user authorization with redirect-based flows
- **JWT Bearer:** Token exchange scenarios using existing JWT assertions (e.g., OIDC ID tokens)
- **Refresh Token:** Obtaining new access tokens using previously issued refresh tokens without user re-authentication
- **Device Code:** Input-constrained devices (smart TVs, IoT devices) that require user authorization on a separate device
- **Resource Owner Password:** Trusted applications that can securely handle user credentials (legacy systems, first-party applications)
- Backend services requiring authentication for system-level operations
- Automated processes and scheduled jobs that need API access
- Microservices authentication within a trusted environment

The returned access token is a JWT that contains client identity, granted scopes, and metadata required for subsequent API calls. This token must be included in the Authorization header of requests to protected endpoints.

Endpoint Overview

Operation Description	HTTP Method	Endpoint URL
Obtain OAuth2 access token using client credentials grant	POST	https://{{sspHost}}/{{apiPathTenant}}/oauth2

Request Parameters

Headers

Header Name	Required	Value
Content-Type	Yes	application/x-www-form-urlencoded

Authentication

There are four ways to authenticate the token endpoint:

- **Basic Authentication using client credentials in Header**:

Username: Client ID (The Client ID of the application. This client id is used to look up the allowed operations and to have the AZ Code issued.)

– **Password:** Client Secret (Required for confidential and trusted clients.)

- **Client credentials in Request Body**:
  The same client credentials can be passed in the request body instead of the header.

  NOTE

  Important: Client credential information can only be passed in one place. If credentials are duplicated in both header and body, an error is displayed.
- **Client Assertion**:
  Authentication using client assertion method. For more information, see Client Assertion.
- **MTLS (Mutual TLS)**:
  Authentication using mutual TLS certificates. For more information, see MTLS.

Request Body Parameters

Parameter	Required	Type	Grant Type	Description
grant_type	Yes	String	• client_credentials • authorization_code • jwt-bearer • refresh_token • device_code • password (Resource Owner)	These are the OA to invoke the "... /
scope	Optional	String	• client_credentials • authorization_code • jwt-bearer • refresh_token • password (Resource Owner)	This is a space-de scopes (privileges authorization. You by the target API or urn:iam:t_authe API section. Requ authorization_cod You can request f obtaining a Refres when the grant-ty or "jwt-bearer".
code	Yes	String	authorization_code	Authorization cod endpoint
code_verifier	Optional	String	• authorization_code • device_code	PKCE Code Verif Optional for grant was used with the
redirect_uri	Yes	String	authorization_code	Redirect URI that authorization requ
assertion	Yes	String	jwt-bearer	JWT assertion tok used for authentic When validating t provided into the the certificate use looked up in this c and finally the issu
refresh_token	Yes	String	refresh_token	Refresh token obt request

device_code	Yes	String	device_code	Device code obta endpoint
username	Yes	String	password (Resource Owner)	Resource owner's
password	Yes	String	password (Resource Owner)	Resource owner's

Response Format

Success Response (HTTP 200)

Field	Type	Description
access_token	String	JWT access token for API authentication
token_type	String	Token type, "Bearer"
expires_in	Integer	Token lifetime in seconds
scope	String	Space-separated list of granted scopes
id_token	String	JWT ID token (returned when openid scope
refresh_token	String	Refresh token for obtaining new access toke

Example Response:

```
{
  "access_token": "eyJ4NXQjUzI1NiI6Im1RNXJCd2tPSjF5X2toZU9Vc...",
  "id_token": "jUzyJ4NXQI1NiI6Im1RNXJCd2tPSjF5X2toZU9Vc...",
  "refresh_token": "iI6Im1RNXJCd2tPSjeyJ4NXQjUzI1NF5X2toZU9Vc...",
  "token_type": "Bearer",
  "expires_in": 3600,
  "scope": "urn:iam:t.all urn:iam:m.meclient urn:iam:t.userpasswordadmin"
}
```

Request Examples

cURL Example for client_credentials grant

```
curl -X POST "https://{{sspHost}}/<tenantName>/oauth2/v1/token" \
  -H "Content-Type: application/x-www-form-urlencoded" \
  -u "username:password" \
  -d "grant_type=client_credentials&scope=urn:iam:t.all"
```

cURL Example for authorization_code grant

```
curl --request POST \
  --url "https://{{sspHost}}/<tenantName>/oauth2/v1/token" \
  --header "authorization: Basic e3tjbGllbnRJZH19Ont7Y2xpZW50U2VjcmV0fX0=" \
  --header "content-type: application/x-www-form-urlencoded" \
  --data "grant_type=authorization_code" \
  --data "code=<code>" \
  --data "code_verifier=<enter the code verifier value>" \
  --data "redirect_uri=https://sampleapp-undefined/sample-rp/oidc/callback" \
  --data "scope=openid groups profile email"
```

cURL Example for jwt-bearer grant

```
curl --request POST \
  --url "https://{{sspHost}}/<tenantName>/oauth2/v1/token" \
  --header "authorization: Basic e3tjbGllbnRJZH19Ont7Y2xpZW50U2VjcmV0fX0=" \
  --header "content-type: application/x-www-form-urlencoded" \
  --data "grant_type=urn:ietf:params:oauth:grant-type:jwt-bearer" \
  --data "assertion=<oidcIdToken>" \
  --data "scope=openid groups profile email"
```

cURL Example for refresh_token grant

```
curl --request POST \
  --url "https://{{sspHost}}/<tenantName>/oauth2/v1/token" \
  --header "authorization: Basic e3tjbGllbnRJZH19Ont7Y2xpZW50U2VjcmV0fX0=" \
  --header "content-type: application/x-www-form-urlencoded" \
  --data "grant_type=refresh_token" \
  --data "refresh_token=<refreshToken>" \
  --data "scope=openid groups profile email offline_access urn:iam:sso:idprop"
```

cURL Example for device_code grant

```
curl --request POST \
  --url "https://{{sspHost}}/<tenantName>/oauth2/v1/token" \
  --header "authorization: Basic e3tjbGllbnRJZH19Ont7Y2xpZW50U2VjcmV0fX0=" \
  --header "content-type: application/x-www-form-urlencoded" \
  --data "grant_type=urn:ietf:params:oauth:grant-type:device_code" \
  --data "device_code=<device_code>" \
  --data "code_verifier=<enter the code verifier value>"
```

cURL Example for Resource Owner (password) grant

```
curl --request POST \
  --url "https://{{sspHost}}/<tenantName>/oauth2/v1/token" \
  --header "authorization: Basic e3tjbGllbnRJZH19Ont7Y2xpZW50U2VjcmV0fX0=" \
  --header "content-type: application/x-www-form-urlencoded" \
  --data "grant_type=password" \
  --data "scope=urn:iam:myscopes" \
  --data "username=<replace by username>" \
  --data "password=<replace by user password>"
```

Implementation Notes

NOTE

- Replace {{sspHost}} and <tenantName> with actual values in your environment
- The access token is a JWT that contains client and scope information
- Token expiration is typically 3600 seconds (1 hour)
- Use the access token in the Authorization header as "Bearer {access_token}" for subsequent API calls
- Granted scopes may differ from requested scopes based on client permissions

Client Assertion

Learn about the mandatory client validation claims in the headers and in the body of the JWT token.

Client assertion is a piece of data that verifies the client. It offers an alternate client authentication technique, one that does not need to send client secrets. Therefore, the client authentication can be done without passwords, by creating a JWT Token and signing it with the client's private key or a secret. The JWT is called client assertion in the context of client authentication. The client assertion is included in a token request as the value of the client_assertion request parameter.

Client Assertion is accepted by the "/token" and "/introspect" endpoints in Symantec Identity Security Platform. These endpoints must add the following parameters in the POST body of the "/token" and "/introspect" endpoint:

- **client_assertion = <jwt-assertion>**
- **client_assertion_type = urn:ietf:params:oauth:client-assertion-type:jwt-bearer**

The following table shows the mandatory client validation claims in the headers and in the body of the JWT token.

Mandatory JWT Headers/Claims

Header Claims	Validations
kid	Key Identifier. Used to identify the trusted third-party certificate to validate the assertion signature. The Key ID in a client assertion = Cert Alias in IDSP (/ Certs)
x5t	A unique certificate entry should exist in IDSP matching the x5t stored on the Cert resource. Lookup is based on the normal JWT validation order already in place.
alg	Identifies the specific type of JWT signing algorithm. The algorithm supported is RS256.
typ	Identifies the type of assertion. This must be JWT.

Mandatory JWT Body/Claims

Body Claims	Validations
aud	Audience(s) that this JWT Token is intended for. It is an array of strings or string values that must contain, "<token-issuer-url>" as one of the AUD values. For example, https://ssp.vlssp.bm.com:443/default/
iss	This is the Client id for the JWT assertion issued by the client.
sub	A valid client_id. **Note**: An active app should exist at the current tenant level in IDSP. This value must be the same as the client_id request param. This client id is the one in the client assertion, if the client id in params is different then the request fails.
jti	A unique identifier for the token, which can be used to prevent reuse of the token. These tokens MUST only be used once unless conditions for reuse were negotiated between the parties; any such negotiation is beyond the scope of this specification.
exp	Expiration time on or after which the JWT Token must not be accepted for processing.
nbf	Time until when JWT cannot be accepted. Its value is a JSON number representing the number of seconds from 1970-01-01T0:0:0Z as measured in UTC until the date/time.
iat	Time at which the JWT was issued. Its value is a JSON number representing the number of seconds from 1970-01-01T0:0:0Z as measured in UTC until the date/time.

Example of a JTW Client Assertion Payload

```

}
```

Configuring OAuth mTLS between Symantec Identity Security Platform Clients and Cluster

Learn how to enable and enforce OAuth mutual Transport Layer Security(mTLS) within an Symantec Identity Security Platform environment.

mTLS enhances security by authenticating clients using their client certificates when interacting with critical OAuth endpoints, **Token**, **Revoke**, and **Introspect**. It details both the deployment-level configuration using Helm charts and the application-specific enforcement through metadata attributes.

This topic includes the following sections:

- Enabling mTLS in the IDSP deployment
- Enforcing mTLS at the app level
- Sample cURL command

Enabling mTLS in the IDSP deployment

To enable Mutual TLS (mTLS) for IDSP deployment, you need to configure the Helm chart with specific flags. It is important to note that mTLS is an optional feature at the deployment level, and its enforcement can be controlled at the application level. Therefore, enabling mTLS in theIDSP deployment does not automatically mandate all clients to present a client certificate. However, if these mTLS parameters are omitted during the initial deployment and the mTLS feature is required later, a redeployment of IDSP with the necessary parameters becomes mandatory. Following redeployment, you need to configure the application metadata values to fully enable mTLS.

Helm Chart Configuration:

To enable mTLS, pass these parameters along with IDSP helm install command:

```
--set ssp.ingress.mtls.enabled=true \
--set ssp.ingress.mtls.caCertSecretName=<secret-name>
```

NOTE

- **caCertSecretName** - This is a Kubernetes secret containing a list of trusted CA certificates.

Enforcing mTLS at the app level

To mandate mTLS for a specific OAuth Application, you need to configure the following metadata attributes for that application. These attributes allow you to specify how mTLS is used for client authentication and token binding.

Metadata Property	Description	Default Value	Possible Va
urn:iam:app:**oauthAuthMethod**	To enable mTLS for the app, configure "tls_client_auth" metadata.	null/blank	• tls_clier • client_s • client_s • private_
(Optional) urn:iam:app:**oauthUseMtlsCertTokenBinding**	Indicates whether to populate the cnf (confirmation) claim in the access token or not.	false	true/false
urn:iam:app:**tlsClientAuthnMethod**	To configure the client authentication TLS method, consider one of the following values from the client certificate received: • tls_client_auth_subject_dn - Complete subject DN • tls_client_auth_san_dns - Subject Alternate Name - DNS value • tls_client_auth_san_ip - Subject Alternate Name - IP value • tls_client_auth_san_email - Subject Alternate Name - EMAIL value • tls_client_auth_san_uri - Subject Alternate Name - URI value	tls_client_auth_subject_dn	• tls_clier • tls_clier • tls_clier • tls_clier • tls_clier
urn:iam:app:**tlsClientAuthnValue**	The admin should configure the expected values for comparing with the client certificate values. At runtime, when a client attempts to authenticate through mTLS, the value based on the tlsClientAuthnMethod (for example, the full Subject DN) from the client certificate is extracted. Then, compare that extracted value to the configured "tlsClientAuthnValue" value. If they match, the client certificate is considered valid for authentication.		<expected
(Optional) urn:iam:app:**oauthRequireTlsAuth**	Configure this metadata to mandate mTLS authentication along with the other supported authentications like client secret basic/post, client assertion.	false	true/false

These metadata properties are also covered in Application Metadata Properties.

Example: The following example shows how to set the metadata attributes for an OAuth Application to enforce mTLS authentication and token binding:

```
"metadata": [
{
"name": "urn:iam:app:oauthAuthMethod",
"value": "tls_client_auth"
},
{
"name": "urn:iam:app:oauthUseMtlsCertTokenBinding",
"value": "true"
},
```

```
{
"name": "urn:iam:app:tlsClientAuthnMethod",
"value": "tls_client_auth_subject_dn"
},
{
"name": "urn:iam:app:tlsClientAuthnValue",
"value": "CN=ClientApp,OU=FN,O=XYZ,ST=AP,C=IN"
},
{
"name": "urn:iam:app:oauthRequireTlsAuth",
"value": "true"
}
]
```

Sample cURL command

The following cURL command performs an OAuth 2.0 Client Credentials Grant flow with Mutual TLS (mTLS) client authentication to obtain an access token from an endpoint:

```
curl --cert <PATH_TO_CLIENT_CERT> \
--key <PATH_TO_PRIVATEKEY> \
--request POST \
--url https://<SSP_FQDN>/default/oauth2/v1/token \
--header 'content-type: application/x-www-form-urlencoded' \
--data grant_type=client_credentials \
--data client_id=c36df799-m72f-0000-5476b-n88990h3b810
```

Where,

- **--cert <PATH_TO_CLIENT_CERT>**: This specifies the path to the client's certificate (.crt file). In an mTLS handshake, the client presents this certificate to the server for authentication.
- **--key <PATH_TO_PRIVATEKEY>:** This specifies the path to the client's private key (.key file) that corresponds to the provided public certificate.
- **--request POST**: This sets the HTTP request method to POST.
- **--url https://<SSP_FQDN>/default/oauth2/v1/token**: This is the URL of the OAuth 2.0 token endpoint to which the request is being sent. It is a secure HTTPS endpoint.
- **--header 'content-type: application/x-www-form-urlencoded'**: This sets the Content-Type HTTP header, indicating that the request body is URL-encoded form data.
- **--data grant_type=client_credentials**: This sends data in the request body, specifying the grant_type as client_credentials.
- **--data client_id=c36df799-m72f-0000-5476b-n88990h3b810**: This sends the client_id as part of the request body. This identifies the OAuth client making the request.

JSON Web Encryption (JWE)

The content outlines a secure identity/authorization system that leverages JWT encryption with configurable public keys, supporting OAuth2/OpenID Connect flows. It enables clients to encrypt tokens using specific aliases, manage certificates, and through grants such as `sts-confidential` , ensuring flexible and secure token exchange.

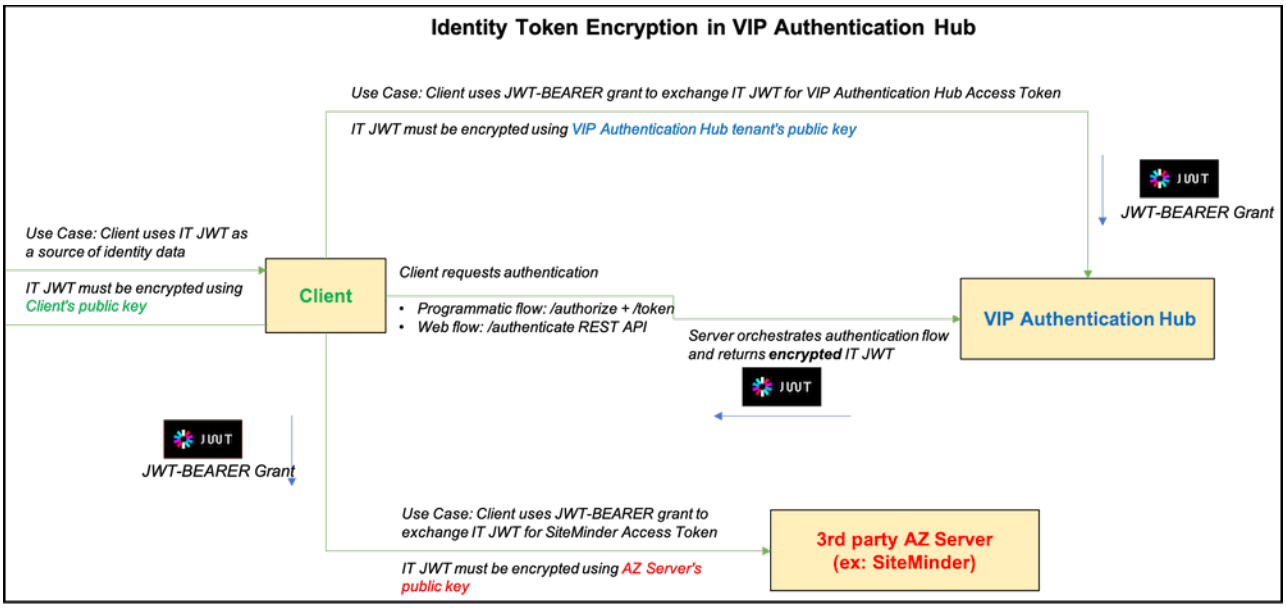
Symantec Identity Security Platform issues Identity Token (IT) for consumption by clients. Clients can use IT for a few different reasons:

- As proof of identity for client's own purposes
- Exchange IT for solution's Access Token (AT) in order to invoke solution's REST APIs
- Exchange IT for an AT from another authorization server (example: SiteMinder) that is configured to trust the issuer of the client's IT

By default IT generated by the solution is a signed JSON Web Token (JWT). JSON Web Encryption (JWE) feature can be used to encrypt IT to maintain confidentiality of IT for storage or during transmission.

Additionally, the contents of the UserInfo response to a client may be encrypted. The target of such a request is the client itself. OpenID Discovery API and JWKS API indicates availability of JWE.

Overview of JWE Support



Refer to the following JWE related topics:

- Supported Use Cases
- Global and Tenant Settings
- Keys and Certs Required
- Requesting Encrypted JWT in Authentication, Authorization Code Grant and "/userinfo" request

Supported JWE Use Cases

IT encryption is supported using the standard JWE approach to generate and/or accept encrypted Identity Token JWTs. Encryption of UserInfo JWT response is supported as well. When JWE encryption is enabled for ITs, the solution encrypts the IT using the public key of the **target** intended to receive the encrypted data (IT or userinfo response). Only the intended target meant to receive the encrypted data can decrypt it using its own private key. The configuration of the client represented by "**itEncryptionTarget"** property indicates the intended target to receive the encrypted data.

NOTE

If the client intends to use encrypted IT with multiple targets as mentioned above, then the client MUST be configured with "**itEncryptionTarget=TENANT"** in order to be able to use **sts-confidential token grant** to exchange IT encrypted by solution tenant's public key for an IT encrypted by another target's public key depending on the use case (such as client's public key or 3rd party Authorization Server public key

The following table covers supported use cases depicting the intended target of the encrypted data.

Target of the encrypted data (IT or Userinfo)	Use Case (Issue or Exchange)
Symantec Identity Security Platform	JWT-BEARER grant to exchange IT encrypted by solution tenant's public key for the solution Access Token (See JWT-Bearer grant use case)
	AZ Code grant or "/authenticate" sign-in ceremony to issue IT encrypted by solution tenant's public key
	AZ Code flow or "/authenticate" sign-in ceremony to accept IT Hint encrypted by solution tenant's public key
Client	AZ Code flow or "/authenticate" sign-in ceremony to issue IT encrypted by a client's public key (see AZ code flow grant use case)
	"/userinfo" returns JWT encrypted by client's public key (see userinfo encryption use case) **Note the following:** • Encryption of Userinfo response is independent of the **itEncryptionTarget** client property. UserInfo's JWT response is encrypted if the client is configured to request userinfo through the JWT format • The client has the option to request IT to be encrypted for a specific target by overriding application configuration during the /Authenticate request. The possible values are: – useTenantKeyForITEncryption – useUserInfoKeyForITencryption – encryptionAlias See the sections, Requesting Encrypted JWT in the Authentication flow and Requesting Encrypted JWT in AZ Code grant flow on how to pass encrypted data in the /Authenticate and /Authorize APIs.
Third-Party Authorization Server configured to trust IDSP	JWT-BEARER grant to exchange IT encrypted by a third party public key for an AT issued by that third party's Authorization Server
	AZ Code flow or "/authenticate" sign-in ceremony to issue IT encrypted by a third party's public key
Client or Third-Party Authorization Server configured to trust IDSP	**sts-confidential** grant to exchange IT encrypted by solution tenant's public key for an IT encrypted by a third party public key associated with either the client itself or another authorization server configured to accept the IT issued by the VIP Authorization Server (see STS grant use case)

Settings and Application Configurations for JWE

Learn about the tenant or global settings and application configurations that are required to enable JSON Web Encryption.

Global and Tenant Settings

Use the tenant-level properties to set the encryption algorithm and method. The following settings should be configured in the solution to enable encryption.

NOTE
Tenant Administrator can override the global settings using tenant settings.

Property Name	Property Scope	Property Description	Default Value	Comments
encryptionAlgorithm	Global (Tenant can override the setting)	This property displays the standard encryption algorithms supported by the solution. • RSA-OAEP • RSA-OAEP-256	RSA-OAEP-256	Possible values: RSA-OAEP, RSA-OAEP-256
encryptionMethod	Global (Tenant can override the setting)	This property displays the encryption methods supported by the solution. • A128CBC-HS256 • A192CBC-HS384 • A128GCM • A192GCM • A256GCM	A256GCM	Possible values: A128CBC-HS256, A192CBC-HS384, A128GCM, A192GCM, A256GCM

The relevant configuration settings are covered in Global/Tenant Settings.

Application Configuration

The following application property should be configured while creating an application in the solution:

Property Name	Description
itEncryptionTarget	Use this property to manage IT encryption. Supported values are (Case-insensitive) • NONE - IT will not be encrypted • APP - IT will be encrypted by the public key referenced by 'itEncryptionCertAlias' value. • TENANT - IT will be encrypted by solution Tenant's public key The itEncryptionTarget values that are configured through the Application can be overridden by the client. This can be done by adding additional request parameters in the following APIs: /authenticate, /authorize, /userinfo, and /token. See details below.
itEncryptionCertAlias	This property represents the alias of the encryption cert to encrypt the IT. This must be specified when 'itEncryptionTarget' is set to 'APP'.
userInfoEncryptionCertAlias	This property represents the alias of the public key to encrypt the response of the /userinfo REST API. This option is used in conjunction with the application property 'userInfoResponseFormat' and is used only when 'userInfoResponseFormat' is JWT. If the value is provided, and 'userInfoResponseFormat' is JWT - the userInfo response is signed and then encrypted, otherwise only signed.
supportedJoseHeaderParams	(Optional) This option supports comma-separated - x5t, x5t#s256, x5c Jose header parameters. If this option is left empty, then x5t and x5t#S256 are added in the JOSE Header of JWE tokens by default.

The relevant application properties are covered in Managing Applications .

Keys and Certs required for JWE

This topic describes the process of securely encrypting **Identity Tokens (ITs)** using **JWE (JSON Web Encryption).**

As JWE works using a public key of the target expected to receive the encrypted JWT, certificates have to be loaded into the solution using /Certs API prior to requesting or exchanging ITs intended to be decrypted by an entity other than the solution itself. That public key to encrypt the IT should be imported using the solution's "/Certs" REST API. Also, the certificate alias should be set up when the application is created. To encrypt the IT Token Hint received by the solution during "/authorize" flow, the third party should use the Symantec Identity Security Platform's public key. The IDSP tenant's public key is returned by the JWKS endpoint and by the "/GETSigningKey" REST API.

Requesting Encrypted JWE in various AuthN and AuthZ flows

This topic explains how to request for encrypted JWT in authentication flow, authorization code grant flow, and in "/userinfo" request. Also learn how can "sts-confidential" Token grant type be used.

Requesting Encrypted JWT in the Authentication flow

> **NOTE**
> The properties under "authContext" that is, "useUserInfoKeyForITencryption" and "useTenantKeyForITencryption" are mutually exclusive. A request with multiple properties at once results in an error response.

- When performing an authentication ceremony using programmatic REST API ("/authenticate") to acquire the IT, the client can request the IT to be encrypted by the solution tenant's public key by overriding application configuration (Application's **itEncryptionTarget** property) by passing authN context indicating use of solution tenant's public key.

```
POST /authenticate
...
"authContext": [
{
"key": "useTenantKeyForITEncryption",
"value": "true"
}
]
```

- When using authentication ceremony using programmatic REST API (/authenticate) to acquire the IT, you can force the IT to be encrypted by the certificate alias configured as 'userInfoEncryptionCertAlias' by overriding application configuration (Application's **itEncryptionTarget** property) by passing authN context indicating the use of userinfo encryption cert alias configured.

```
POST /authenticate
...
"authContext": [
{
"key": "useUserInfoKeyForITencryption",
"value": "true"
}]
```

- When using an authentication ceremony using programmatic REST API ("/authenticate") to acquire the IT, the client can request the IT to be encrypted by using a cert represented by a specific alias. This can be done by adding the "encryptionAlias" parameter into the "/authenticate" request.

```
POST /authenticate
...
"authContext": [
{
"key": "encryptionAlias",
```

```
"value":"<cert alias>"
]
```

NOTE
Pass these parameters ("useTenantKeyForITEncryption", "useUserInfoKeyForITencryption", "encryptionAlias") in the "/authenticate" call, will override the app configuration (itEncryptionTarget property) mentioned in this table.

The relevant authentication attribute details are covered in Initiate Authentication.

Requesting Encrypted JWT in AZ Code grant

- When using the AZ Code grant to obtain the solution's IT, the client can request the IT to be encrypted by the solution tenant's public key. This can be done by overwriting application configuration (**itEncryptionTarget** property) and passing the following scope in addition to other required scopes into the "/authorize" request.
  ```
  scope=urn:iam:useTenantKeyForITencryption
  ```
- When using the AZ Code grant to obtain the solution's IT, you can force the IT to be encrypted by the certificate alias configured as 'userInfoEncryptionCertAlias' by overwriting application configuration (**itEncryptionTarget** property) by passing the following scope into the /authorize request (in addition to other required scopes).
  ```
  scope=urn:iam:useUserInfoKeyForITencryption
  ```
  NOTE
  - The scopes *urn:iam:useUserInfoKeyForITencryption* and *urn:iam:useTenantKeyForITencryption* are mutually exclusive. The request with both the scopes at-a-time results in an error response.
  - Pass these parameters ("urn:iam:useTenantKeyForITencryption", "urn:iam:useUserInfoKeyForITencryption") in the "/authenticate" call to override the app configuration (Application's **itEncryptionTarget** property) mentioned in this table.
- When using the AZ Code grant to obtain the solution's IT, the client can request the IT to be encrypted by using a cert represented by a specific alias. This can be done by adding the "encryptionAlias" parameter into the "/authorize" request.
  ```
  GET /authorize?client_id=<>&scope=<>&response_type=code&redirect_uri=<value>&encryptionAlias=<value>
  ```

Requesting Encrypted JWT in /userinfo request

Configure the "userInfoEncryptionCertAlias" application property to contain the alias to a client's certificate in the certs store. Userinfo JWT response is encrypted if the alias had been provided and the application's "userInfoEndpointResponseFormat" is "jwt". Otherwise, the userinfo JWT will not be encrypted.

- When using the userinfo request to acquire the Userinfo JWT response, the client can request the userinfo to be encrypted by using a cert represented by a specific alias. This can be done by adding the "encryptionAlias" parameter into the "/userinfo" request.
  ```
  POST /userinfo
  access_token=<value>&encryptionAlias=<cert-alias-value>
  ```
  NOTE
  Pass these parameters ("encryptionAlias") in the "/userinfo" call to override the app configuration (Application's **itEncryptionTarget** property) mentioned in this table.

Using "sts-confidential" Token grant type

- Whenever a client requires an encrypted IT to be sent to multiple targets, the generated IT must be encrypted using the solution tenant's public key. After that, the sts-confidential token grant can be used to exchange that IT for an IT encrypted by the intended targets' public key. Therefore, a client can use the sts-confidential token grant to swap the IT encrypted with the solution tenant's public key for the IT encrypted by the public key of the intended target as configure by application's **itEncryptionTarget** property.

Sample Request showing sts_confidential grant type in the "/token" request:

```
POST https://${SSP_FQDN}/<tenant-name>/oauth2/v1/token

grant_type=sts_confidential&

assertion=<IT Encrypted using AH tenants key>
```

Sample Response:

```
{
"id_token": "<IT encrypted with Client's public key configured in the App>"
}
```

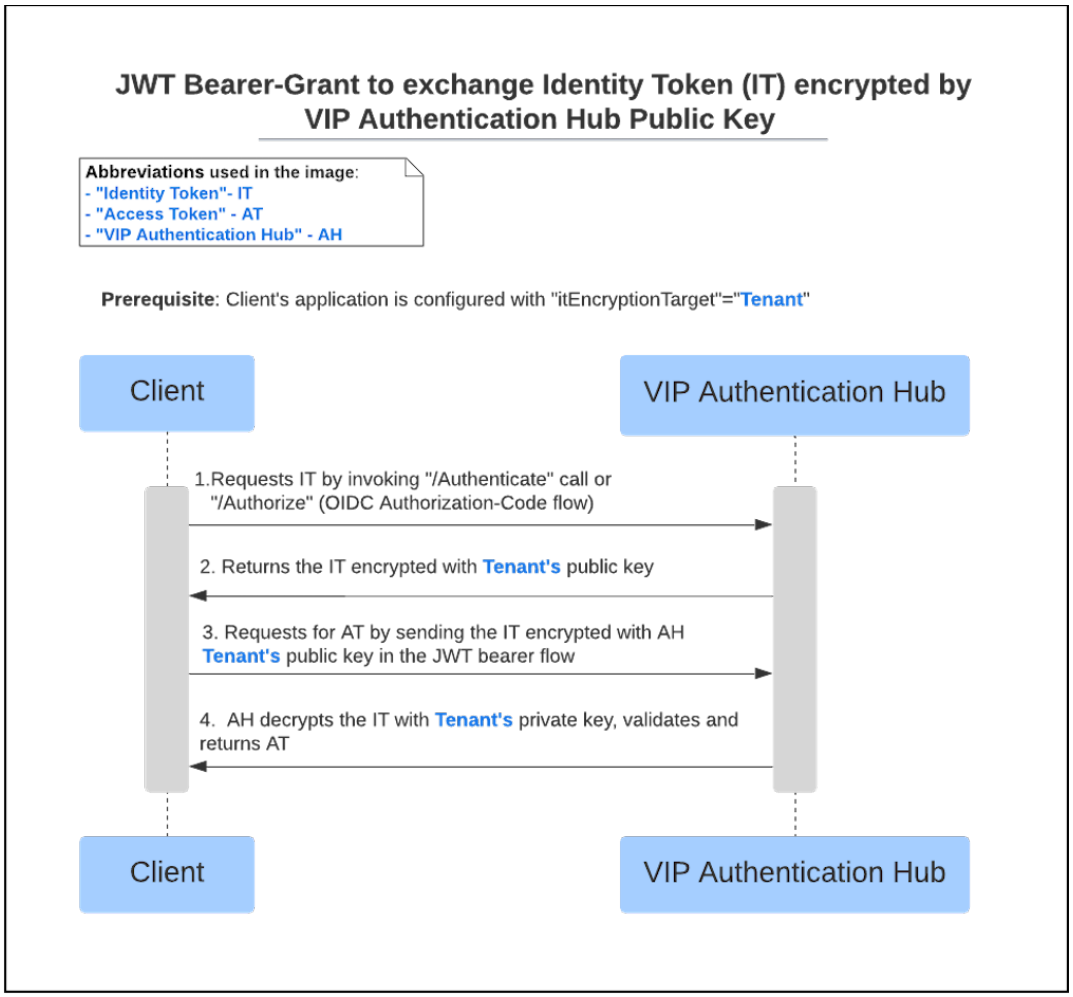
- When using the "sts-confidential" Token grant type request to encrypt the IT in the response, the client can request the token to be encrypted by using a cert represented by a specific alias. This can be done by adding the "encryptionAlias" parameter into the "/token" request.

  ```
  POST /token?grant_type=sts-confidential&assertion=<IDToken>&encryptionAlias=<cert-alias-value>
  ```

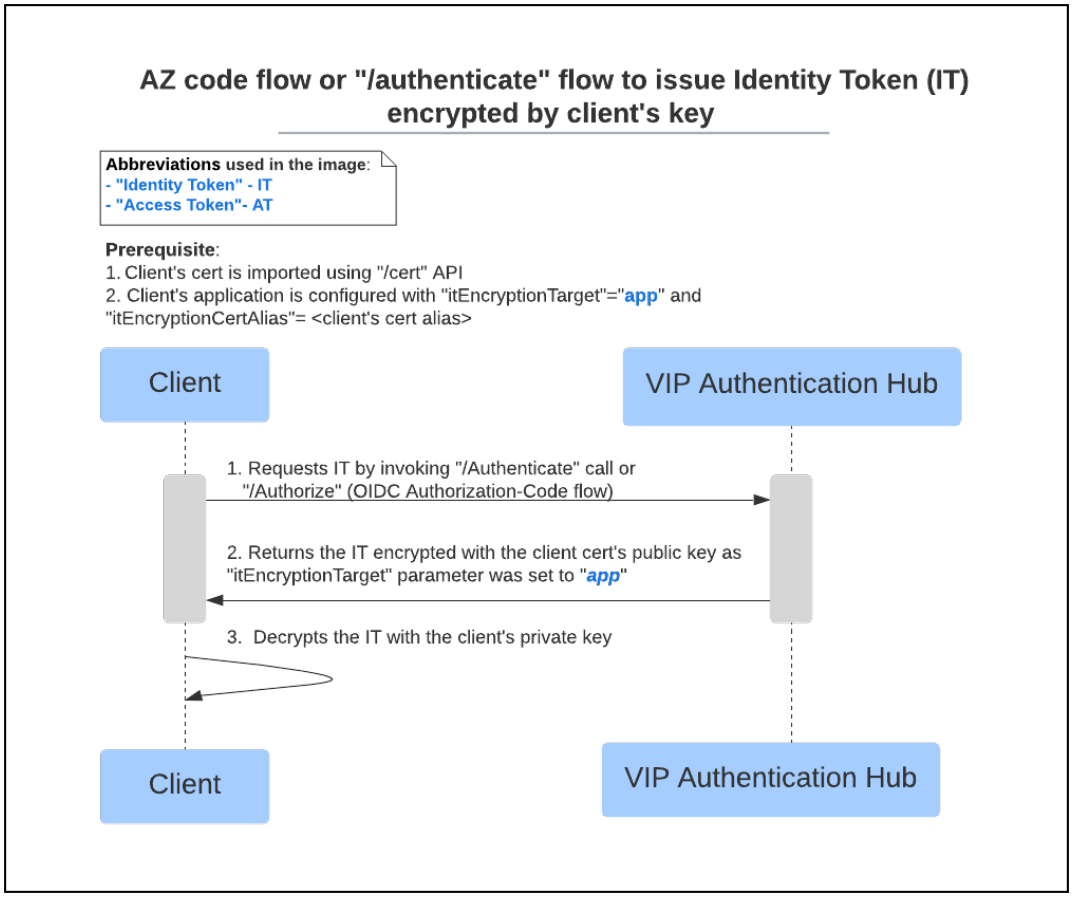
  NOTE
  Pass these parameters ("encryptionAlias") in the "/token" call to override the app configuration (Application's **itEncryptionTarget** property) mentioned in this table.

Use Cases Detailed

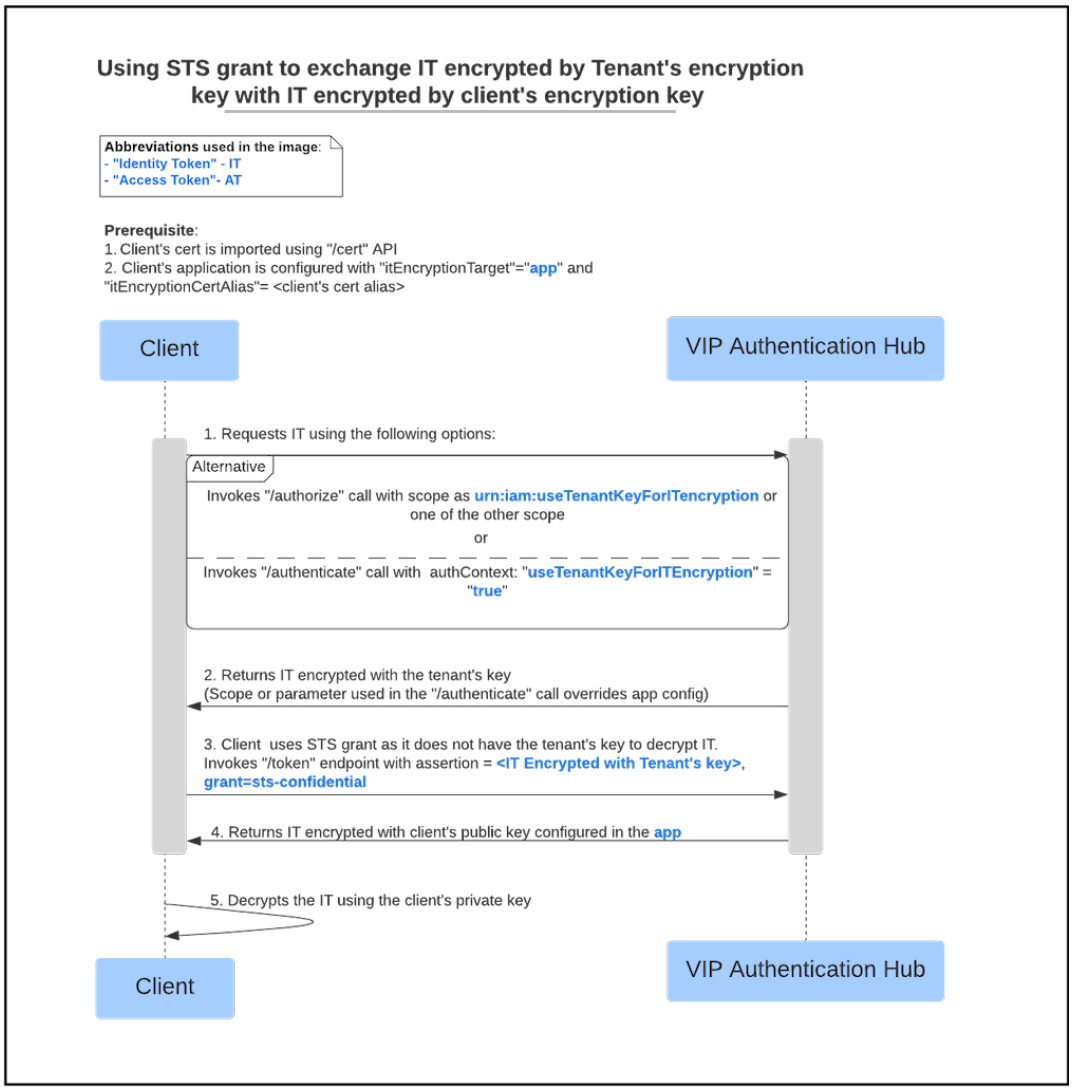
JWT-BEARER grant to exchange IT encrypted by Symantec Identity Security Platform's encryption key for the IDSP Access Token



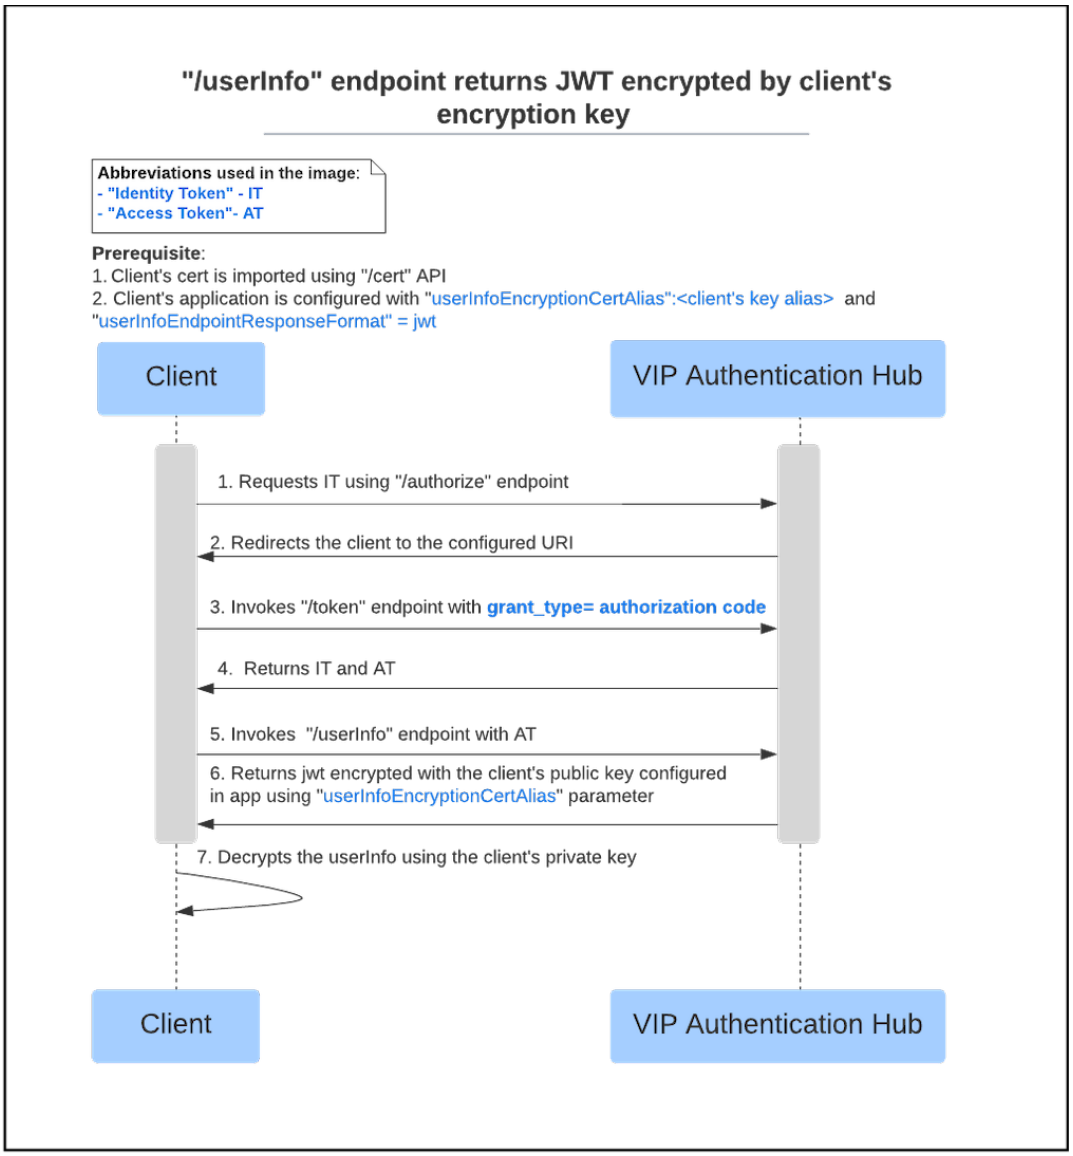
AZ Code flow or "/authenticate" sign-in ceremony to issue IT encrypted by a client's key



STS grant to exchange IT encrypted by IDSP's encryption key for an IT encrypted by a third party key associated with either the client itself or another authorization server configured to accept the IT issued by the VIP Authorization Server



"/userinfo" returns JWT encrypted by the client's encryption key (provided client is configured to request JWT)



Secure Communication for Clients Using PKCE

The communication between Authorization Endpoint and Access Token Endpoint might be compromised for public, confidential, and trusted clients. An interceptor can use the generated Authorization Code to request the tokens. To mitigate the interception attack on Authorization Code Flow for the mentioned clients, you can configure Proof Key for Code Exchange (PKCE) and secure the communication between Authorization Endpoint and Access Token Endpoint.

PKCE uses the following parameters:

- code verifier
  Defines the cryptographical random key that is generated dynamically to bind the authorization request to the token request.
- code challenge
  Defines the plain or hash value of the code verifier based on the code challenge method. The authorization server compares this value with the code verifier before generating the token.

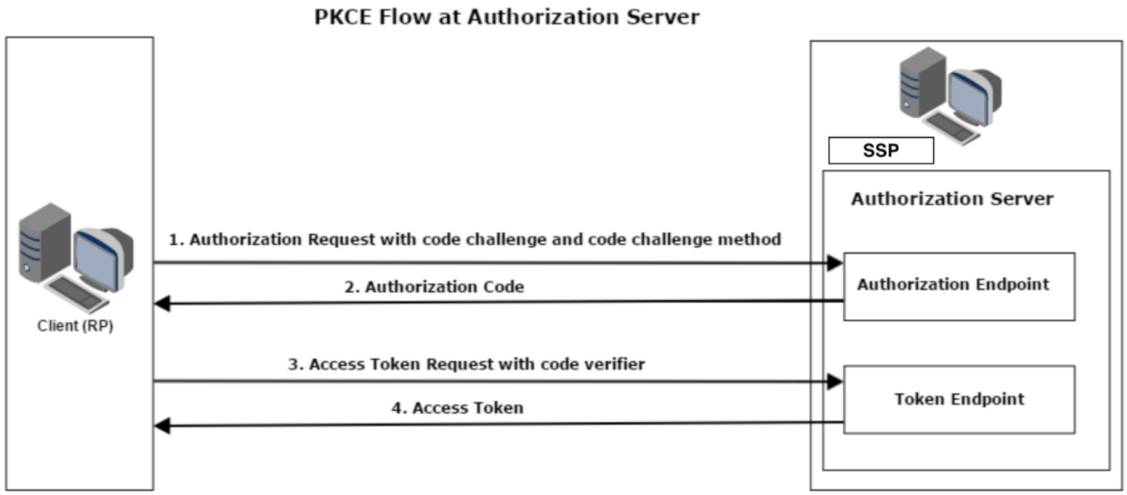
NOTE
When a code challenge is generated, characters such as '/' or '+' may appear in the challenge. For example, the code challenge may look like this-

- /iWStCpyfpd/BVlHOFtwnMgrFrmof4jGq/OQDWXQzcM
- "73l8gRjwLftklgfdXT+MdiMEjJwGPVMsyVxe16iYpk8"

In such a case, you should replace the characters '/' and '+' with '_' and '-' respectively. See PCKE RFC link for more information.

- code challenge method
  Defines how the code challenge is generated. The value is either Plain or S256. If only a code challenge is sent in the authentication request, the code challenge method defaults to Plain.

The following diagram explains the PKCE process flow:



When PKCE is enabled, the authorization server performs the following tasks:

1. The client generates a code verifier, computes the code challenge, and sends the code challenge and code challenge method with the authorization request to the Authorization Endpoint.
   ```
   https://authorization_endpoint_URL?
   response_type=code&scope=openid&client_id=clientID&state=value&redirect_uri=redirect_URL&nonce=value&code_challenge=
   S256
   ```
2. Authorization Server at Authorization Endpoint records code challenge and code challenge methods, and generates authorization code.
3. The client sends the authorization code and code verifier to the Access Token Endpoint.
4. Authorization Server at Access Token Endpoint verifies that the request contains the code verifier parameter. Then, it validates the code verifier value with the code challenge and code challenge method that was sent in the authentication request at the authorization endpoint.

Note: Example of a code

Detailed Examples of Authorization Endpoints

This section includes detailed examples of the OAuth2 Authorization Endpoints.

See the following topics:

- Supported Authorization Flows
- Discovery Profile of Provider metadata

Authorization Flows Supported

You can configure Symantec Identity Security Platform with OAuth to authenticate users and generate token for native and web applications using Authorization Code flow:

- Authorization Code Flow - returns the tokens from Token Endpoint. Use Authorization Code Flow for clients that can secure their communication with Authorization Server.

The following table differentiates how IDSP works in Authorization Code Flow and Implicit Flow:

	Authorization Code Flow	Implicit Flow
Authorization Server		
Returns Authorization Code at Authorization Endpoint	Yes	No
Returns ID token and Access Token at Authorization Endpoint	No	Yes
Returns ID token and Access Token at Access Token Endpoint	Yes	No
Authenticates Client	Yes	No
Supports PKCE with Public Clients	Yes	No
Authentication Request Parameters		
client_id	Mandatory	Mandatory
redirect_uri	Mandatory	Mandatory

response_type	Mandatory
	Must be
	`code`
		Mandatory
		Can be
		`id_token`
		or
		`id_token token`
		or
		token

scope	Mandatory One value must be `openid - to return id_token`	Mandatory One value must be openid `- to return id_token`
nonce	Optional	Mandatory
state	Optional	Optional
code_challenge & code_challenge_method	Optional	Not Applicable
Response Code		
Authorization response contains code	Yes	No
Authorization response contains access_token	No	Yes for id_token token, token No for id_token
Authorization response contains ID_token	No	Yes
ID_token contains `at_hash`	No	Yes
ID_token contains `nonce`	Yes if `nonce` was sent in the authentication request	Yes

Authentication using Authorization Code Flow

VIP Authentication Service authenticates users using Authorization Code Flow that uses *code* as the response type. Authorization Code Flow returns the tokens from Token Endpoint.

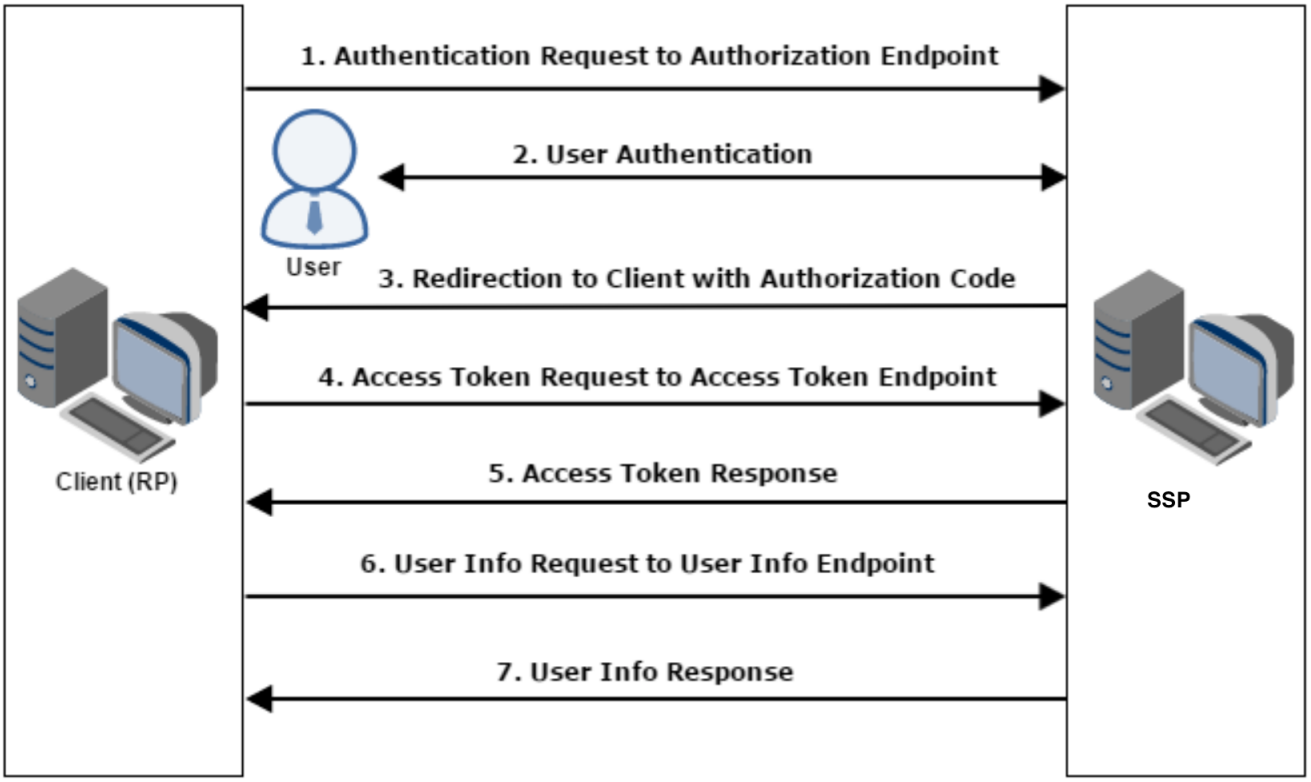
This topic includes the following sections:

- Authorization Endpoint
- Token Endpoint
- Refresh Token
- Introspection Endpoint
- UserInfo Endpoint
- JWKS Endpoint

How does Authorization Code Flow work?

The following diagram details the flow:

Figure 17: Authentication using Authorization Code Flow



The Authorization Code Flow works as follows:

1. Client sends an authentication request to Authorization Endpoint.
2. a. Authorization service redirects the user browser to a signin application indicated by the "flowUrl" application property, to perform the user authentication ceremony. If the "flowUrl" property is not specified, then a default, out-of-the-box signin application is used to orchestrate the signin flow.
   b. After the signin app has successfully completed the signin, the signin app redirects the user browser (using /AuthComplete request) back to the Authorization service, which in turn redirects to the callback URL of the application.
3. Authorization Endpoint redirects the user to the Client along with an authorization code.

4. Client sends the authorization code to Token Endpoint and requests for Access Token.
5. Token Endpoint authorizes the request and generates Access Token and ID Token. It also generates a Refresh Token, if you pass "offline_access" as one of the scopes in the "/token" request endpoint.
6. Client sends Access Token to UserInfo Endpoint.
7. UserInfo Endpoint authenticates the request and returns claims about the user

Authorization Endpoint

Authorization Endpoint handles the OAuth2/OpenId protocol part of the application's request for user authentication. It redirects to the signin application to initiate and complete the user signin ceremony, and constructs the necessary identity artifacts (Identity token) to be returned back to the requesting application.

The application is registered in Symantec Identity Security Platform as an Application with an OAuth client and other OAuth-specific artifacts required to execute an authentication request.

Supported Parameters

The authentication request supports the following parameters:

- **response_type**
  Defines the authorization processing flow that must be used. This value must be **code**.
- **scope**
  Defines the scope of the accessing request. You can specify multiple values that are separated by space. **openid** must be one of the values.
  Example: openid email phone
- **client_id**
  Defines the Client ID of the client that was registered with VIP Authentication Service.
- **state**
  (Optional) Defines an opaque value that the client uses to maintain state between the request and callback. The authorization server includes this value when redirecting the request back to the client.
- **redirect_uri**
  Specifies the URI to which the authentication response must be sent. This value must be the URI that was specified during client registration.
  The URI can begin with one of the following schemes:
  – HTTP
  – HTTPS
  – Custom URI in the *scheme* `://` format
    where *scheme* = alphabet *(alphabet|digit|+|-|.)
    Examples:

```
https://sample.ca.com/example/redirect_uri
OR
oidc.example.sso://sample.com/example/redirect_uri
```

    For Public Clients, use the HTTPS or *scheme*:// format.
- **nonce**
  (Optional) Specifies a value that associates a client session with an ID Token. The value must contain sufficient entropy to prevent attacks. VIP Authentication Service stores nonce from the authorization request and sends the same value as a standard nonce claim in ID Token.
- **code_challenge**

Defines the plain or hash value of the code verifier based on the code challenge method. Authorization Server compares this value with the code verifier before generating the token.

- **code_challenge_method**
  Defines how the code challenged is generated. The value is either **Plain** or **S256**. If only a code challenge is sent in the authentication request, the code challenge method defaults to Plain.

Supported HTTP Methods

Authorization Endpoint supports GET and POST methods.

GET

For GET, the authorization request contains an authorization endpoint URL and required query parameters in the following format:

```
 https://authorization_endpoint_URL?
response_type=code&scope=scope_value&client_id=clientID_value&state=state_value&redirect_uri=redirect_URL_value&nonce=n
 or S256 value
```

Example Request and Responses Request

Request: GET request.

```
 https://iam.example.com/<tenant-name>/oauth2/v1/authorize?response_type=code&scope=openid
%20address&client_id=c633b3f5-378d-4a22-bfa1-a0aaaa3cd799&state=UoS53-qFk0oI43icRjURWpk0OiM&redirect_uri=https
%3A%2F%2Fsample.ca.com%2Fexample%2Fredirect_uri&nonce=IkfJuXy8Sseq_8L2Fq5aH2MVUYCUV7Khm1ApnLysLmU
```

Responses

Response 1: Successful response

```
Successful response

HTTP/1.1 302 Found
Date: Thu, 08 Dec 2016 04:31:17 GMT
Server: Apache/2.4.18 (Win64) OpenSSL/1.0.2g-fips mod_jk/1.2.41

Transfer-Encoding: chunked
Response 2
```

Response 2: Invalid response:

```
 HTTP/1.1 302 Found
Location: https://sample.ca.com/example/redirect_uri?
error=invalid_request
&error_description= error
Unsupported%20response_type%20value
&state=af0ifjsldkj
```

Error Codes and Messages

Authorization Endpoint returns an error in response to an authentication request if the authentication fails or the user denies the request. When an error occurs, an error response with error, error description, and state (if included in the original request) is appended to the query string and sent to Client in redirect_uri. Authorization Endpoint displays the following errors and error descriptions:

Note:

- HTTP Status Code 302 indicates that the error code and description are sent to redirect_uri.
- HTTP Status Code 400 and HTTP Status Code 500 indicate that the error message is displayed in the web page after failing at , and that the Administrator must verify the VIP Authentication Service log and trace files.

Scenario	Error Code	Error Description	HTTP Status Code
The scope parameter is missing, or its value is empty in the authentication request	invalid_request	Missing or invalid scope	302
The value of scope is not *openid*	invalid_request	Missing or invalid scope	302
The response_type parameter is missing, or its value is empty in the authentication request	invalid_request	Missing or invalid response_type	302
The value of response_type is not *code*	unsupported_response_type	Missing or invalid response_type	302
The client_id of a disabled client is specified in the authentication request	unauthorized_client	Invalid client_id	400
The client_id parameter is missing, or its value is empty or invalid in the authentication request	invalid_request	client_id is invalid or missing	400
The redirect_uri parameter is missing or its value is empty in the authentication request, or its value is not matching with the value configured in the client configuration	invalid_request	redirect_uri is invalid or missing	400
Authorization Server configuration error	server_error	Internal Server Error	500
Authorization Code generation error	access_denied	Unauthorized user	302

Token Endpoint

Authorization Server uses the authorization code to generate access and identity tokens. . Client sends Authorization Code in a token request to Token Endpoint using **authorization_code** as the grant_type. If the client type is confidential, client must authenticate at Token Endpoint using the authentication method specified during client registration.

Token Endpoint Process

Authorization Server performs the following tasks at Token Endpoint:

1. Validates that Client uses the registered client credentials.
2. Verifies that the Authorization Code is valid and is unused.
3. Verifies that the Authorization Code was issued in response to an OpenID Connect authentication request.
4. Verifies that the **redirect_uri** parameter value is identical to the **redirect_uri** parameter value that was sent in the initial authorization request. It returns an error if the redirect_uri parameter value is not present when there is only one registered redirect_uri value.
5. If the validation is successful, it generate a successful response that includes an Access Token and ID Token . It also generates a Refresh Token if you pass "offline_access" as one of the scopes in the "/token" request endpoint.
6. If you selected the **Send User Information in ID Token** option during client registration, sends the user claims information in the ID Token.

Supported Parameters

The token request supports the following parameters:

- **grant_type**
  Specifies the code flow. This value must be **authorization_code**.
- **code**
  Specifies Authorization Code.
- **assertion**
  Specifies id_token.
- **client_assertion**
  Specifies the assertion being used to authenticate the client. Specific serialization of the assertion is defined by profile documents.
- **client_assertion_type**
  Specifies the format of the assertion as defined by the authorization server. The value is an absolute URI.
- **redirect_uri**
  (Optional) Verifies if an Authorization Code was generated for the redirect_uri defined in the initial authorization request.

Supported HTTP Methods

Token Endpoint supports the POST method.

The following is the token request format for an application that is Public:

```
POST
token_endpoint
HTTP/1.1
Host:
host_name
Content-Type: application/x-www-form-urlencoded
grant_type=authorization_code&code=
authorization_code
```

The following is the token request format for a Confidential application that uses the Basic authentication type.

```
POST
token_endpoint
HTTP/1.1
Host:
host_name
```

```
Content-Type: application/x-www-form-urlencoded
Authorization: Basic
encoded(client_id:client_secret)
grant_type=authorization_code&code=
authorization_code
```

The Client ID and Client Secret values can be specified in one of the following formats in the authorization header for a Basic client authentication:

- Base64 encoded (Client ID:Client Secret)
- Base64 encoded (URL encoded Client ID:URL encoded Client Secret)

The following is the token request format for a Confidential application that uses the POST authentication type:

```
POST
token_endpoint
HTTP/1.1
Host:
host_name
Content-Type: application/x-www-form-urlencoded
grant_type=authorization_code&code=
authorization_code
&client_id=
client_id
&client_secret=
client_secret
```

Example Requests and Responses

Request 1: Token request format for a Public Client

```
POST <tenant-name>/oauth2/v1/token HTTP/1.1
Host: iam.example.com
Content-Type: application/x-www-form-urlencoded
grant_type=authorization_code&code=SplxlOBeZQQYbYS6WxSbIA&redirect_uri=https%3A%2F%2Fsample.ca.com%2Fexample
%2Fredirect_uri
```

Request 2: Token request format for a Confidential application that uses the Basic authentication type.

```
POST <tenant-name>/oauth2/v1/token HTTP/1.1
Host: wa.example.com
Content-Type: application/x-www-form-urlencoded
Authorization: Basic czZCaGRSa3F0MzpnWDFmQmF0M2JW
grant_type=authorization_code&code=SplxlOBeZQQYbYS6WxSbIA&redirect_uri=https%3A%2F%2Fsample.ca.com%2Fexample
%2Fredirect_uri
```

Request 3: Token request format for a Confidential application that uses the POST authentication type.

```
POST <tenant-name>/oauth2/v1/token HTTP/1.1
Host: wa.example.com
Content-Type: application/x-www-form-urlencoded
grant_type=authorization_code&code=SplxlOBeZQQYbYS6WxSbIA&redirect_uri=https%3A%2F%2Fsample.ca.com%2Fexample
%2Fredirect_uri
&client_id=c633b3f5-378d-4a22-bfa1-a0aaaa3cd799
&client_secret=SplxASdfcdslOBeZQQYbYS6WxSbIA
```

Responses Response 1: Successful response

```
200 OK
Cache-Control: no-store
Content-Type: application/json; charset=UTF-8
```

```
Pragma: no-store
{
"access_token": "TkE+qlbu7dcHibOutW7QEcESdpE=",
"id_token": "yI6ICJodHRwOi8vc2Vyd....",
"expires_in": 120,
"token_type": "Bearer"
}
```

Response 2: Invalid response

```
400 Bad Request
Cache-Control: no-store
Content-Type: application/json; charset=UTF-8
Pragma: no-store
{
"error": "invalid_grant",
"error_description": "Invalid authorization code"
}
```

Error Codes and Messages Token Endpoint uses the following error codes and descriptions:

Scenario	Error Code	Error Description	HTTP Status Code
Token Endpoint received a GET request	invalid_request	GET request is not allowed	400
Token Endpoint received a POST request with the HTTP protocol	invalid_request	The request is not secure	400
The *code* request parameter is missing in the request body	invalid_request	Specify a value for Code	400
The grant_type request parameter is missing or its value is not *authorization_code*	invalid_request	Specify authorization_code as grant_type	400
Duplicate client credentials are sent with both the authorization header, and client_id and/or client_secret in the POST body	invalid_request	The request body contains both the authorization header and client_id/ client_secret	400
Authorization Code is invalid	invalid_grant	Invalid code	400
Authorization Code expired	invalid_grant	Code expired	400
The client_id configuration is missing	invalid_client	Failed to retrieve client info	401
The client authentication failed because of invalid inputs	invalid_client	Client authentication failed - (with invalid inputs)	401
The client authentication failed because authorization header was expected but received client_id and client_secret in POST body	invalid_request	Invalid client credentials	400
The redirect_uri value in the request parameter is different from the one sent in the initial request Or The redirect_uri value is modified or deleted in the client configuration during flows	invalid_grant	Invalid redirect_uri	400

Any exceptions such as failure to decrypt client_secret stored in Policy Server or failure to perform CRUD operations on session store due to connection issues	invalid_request	Internal server error	400

Refresh Token

For information, see Refresh Token.

Introspection Token Endpoint

Use the improved Introspection Endpoint using POST method in the following format to validate the received Access Token or Refresh Token, and view the scopes associated with the token:

```
POST introspection_endpoint HTTP/1.1
Host: ah_hostname
Accept: application/json
Content-Type: application/x-www-form-urlencoded
Authorization: Basic base64_encoded(client_id and client_secret)
token=token&token_type_hint=token_type
```

token

Defines the token. Enter the value of the access_token or refresh_token that you received from Token Endpoint.

(Optional) token_hint_type

Defines a hint about the token type that you want to verify. Authorization Server uses this hint in simplifying the search for the token. Enter **access_token** or **refresh_token** depending on the token value.

Client ID and Client Secret values must be sent in the authorization header:

- Base64 encoded (Client ID:Client Secret)
- Base64 encoded (URL encoded Client ID:URL encoded Client Secret)

Example Requests and Response

Request 1: Request with token and token_hint_type

```
POST /<tenant-name>/oauth2/v1/introspect  HTTP/1.1
Host: example.iam.com
Accept: application/json
Content-Type: application/x-www-form-urlencoded
Authorization: Basic czZCaGRSa3F0MzpnWDFmQmF0M2JW
token=2YotnFZFEjr1zCsicMWpAA&token_type_hint=access_token
```

Request 2: Request with only token

```
POST /<tenant-name>/oauth2/v1/introspect  HTTP/1.1
Host: example.iam.com
Accept: application/json
Content-Type: application/x-www-form-urlencoded
Authorization: Basic czZCaGRSa3F0MzpnWDFmQmF0M2JW
token=2YotnFZFEjr1zCsicMWpAA
```

Responses Response 1: Valid token response

```
HTTP/1.1 200 OK
Content-Type: application/json
{
"active": true,
"client_id": "bb8293f6-ceef-4e7a-90c8-1492e97df19f",
```

```
"token_type": "refresh_token",
"scope": "openid profile",
"sub": "cn=odicuser,dc=example,dc=com",
"exp": "86400",
"iat": "1506513918",
"iss": "https://example.iam.com"
}
```

active

Specifies the status of the token. The value true indicates that the token is valid and has not expired. The value false indicates that the token is invalid or has expired.

client_id

Identifies the client that requested the token.

token_type

Identifies the token type.

scope

Identifies the scopes that are associated with the token.

sub

Identifies the user who authorized the request.

exp

Identifies the time period in seconds in which the token expires.

iat

Identifies the time in seconds when the token was originally issued.

iss

Identifies the authorization provider that issued the token.

Response 2: Response for invalid or expired token

```
HTTP/1.1 200 OK
Content-Type: application/json
{
"active": false
}
```

Response 3: Error response

```
HTTP/1.1 400 Bad Request Content-Type:application/json;
charset=UTF-8 Cache-Control:
no-store Pragma: no-cache
{
"error":"invalid_request"
"error_description": "token is missing in the request"
}
```

Request for Access token introspection with client assertion as client credentials:

```
curl -k --request POST \
--url 'https://example.com/default/oauth2/v1/introspect' \
--header 'Content-Type: application/x-www-form-urlencoded' \
--data-urlencode 'token=eyJ4NXQjUzI1NiI6ImNJbUNYN1FyRy1BUUpkWWZ......'
--data-urlencode 'client_id=7b447d36-cac4-4a9e-b093-42f0d553d9f4' \
```

```
--data-urlencode 'client_assertion_type=urn:ietf:params:oauth:client-assertion-type:jwt-bearer' \
--data-urlencode 'client_assertion=ewogICJ4NXQjUzI1NiI6ICI4bkRSWURaUF9xcENwUz.....'

Decoded Token

  "token_type" : "Bearer"
}
```

See Client Assertion for more information. **Error Codes and Messages** The following table lists the error codes displayed:

Scenario	error_code	HTTP Status Code
• Required inputs are missing in the request • Authorization header, and Client ID and Client Secret exist in the request • Unable to get client ID from the authorization header or form parameters of the request	invalid_request	400
Client credentials are invalid	invalid_client	401
The GET request is received	invalid_request	405
Other server issues	Internal Server Error	500

UserInfo Endpoint

UserInfo Endpoint returns claims related to the authenticated user. Client sends a request to UserInfo Endpoint along with Access Token, and UserInfo Endpoint returns the claims in the Signed JWT format. VIP Authentication Service sends claims that are scoped by the token to the Client. **Supported HTTP Methods** UserInfo Endpoint supports GET and POST methods. The GET request can be of the header or query format. The POST request is of the following format:

```
POST
userinfo_endpoint
 HTTP/1.1
Host:
host_name
Content-Type: application/x-www-form-urlencoded
access_token=
access_token
```

Examples Requests and Responses

Requests

Request 1: GET request in header format.

```
GET /<tenant-name>/oauth2/v1/userinfo HTTP/1.1
Host: example.iam.com
Authorization: Bearer eyJhbGciOiJSUzI1NiIsImtpZCI6IjF
```

Request 2: GET request in query format.

```
/<tenant-name>/oauth2/v1/userinfo?access_token=eyJhbGciOiJSUzI1NiIsImtpZCI6IjF
```

Request 3: POST request

```
POST /<tenant-name>/oauth2/v1/userinfo HTTP/1.1

Host: example.iam.com
Content-Type: application/x-www-form-urlencoded
access_token=sfthwYNeo%2BvOOJses6KlKwShZF0=
```

Responses

Response 1: Successful response

```
HTTP/1.1 200 OK
Content-Type: application/jwt
eyJ4NXQjUzI1NiI6ImNJbU.........
```

Response 2: Successful response with encrypted user info

```
HTTP/1.1 200 OK
Content-Type: application/jwt
NqeGpe-gccMg4vfKjkM8FcGvnzZUN4_KSP0aAp1tOJ1zZwgjxqGByKHiOtX7Tpd
```

Response 3: Invalid response

```
HTTP/1.1 401 Unauthorized
WWW-Authenticate: error="invalid_token",
error_description="The Access Token expired"
```

Error Codes and Messages

Error codes are displayed in the following scenarios:

Scenario	Error Code	HTTP Status Code
• Access Token is not found in either form parameter or authorization header of the request • Request content type is not application/x-www-form-urlencoded • Request have more than one Access Token • Request has both authorization bearer header and access_token in the form parameters • Request contains both header and query.	invalid_request	400
The access_token value has expired, is revoked, malformed, or invalid	invalid_token	401
Other server issues	Internal Server Error	500

JSON Web Key Set Endpoint

A read-only JWKS service is for use by someone who develops PKI-based code to perform one of two activities:

- validate signature of received artifacts
- encrypt artifacts to be sent

The main purpose of a JWKS endpoint is to provide applications with public keys as required to verify the signature of a JWT issued by the IDSP Authorization Service, or to encrypt a JWT sent to the Authorization server (such as encrypting Identity Token Hint).

The following is the format of the endpoint:

When you export the metadata of a Client, this endpoint information is available in the *jwks_uri* attribute.

```
https://<tenant-name>/default/oauth2/v1/jwks
```

Example Responses

Response 1: Successful response

```
{"keys":[{"kty":"RSA","e":"AQAB","kid":"5e35223a-58b8-4f78-b8df-f92a8bae3c0b","key_ops":
["encrypt","wrapKey","verify"],"alg":"SHA256WITHRSA","n":"vemHcoWegeZvXBAurW2Im3b-

```

Response 2: Invalid response

```
{"error":"invalid_request","error_description":"Failed to retrieve Configuration information."}
```

Error Codes and Messages

The following table lists the error messages that this endpoint displays:

Scenario	Error Code	HTTP Status Code
Invalid POST request	invalid_request	405
Authorization Provider is missing in the request or is invalid, or is disabled	invalid_request	400
Other server issues	Internal Server Error	500

Discovery Profile of Provider Metadata

Use the Well-known Endpoint to dynamically retrieve OAuth provider metadata including endpoints, supported scopes, claims, and authentication methods.

You can use a Well-known Endpoint to dynamically retrieve the metadata of Symantec Identity Security Platform. A Relying Party can use this endpoint to dynamically retrieve the metadata of an Authorization Provider that is configured with a Client. The following scenarios describe how a Relying Party can use the metadata:

- OAuth Clients that display multiple authentication providers to end-users send requests to OAuth provider based on the end-user choice. Such clients can use the metadata to construct requests to specific endpoints as required.
- If a Client or mobile OAuth SDK does not have the provision to configure OAuth Client information, they can use the metadata information of endpoints, claims, and scopes to build dynamic requests to receive authorization code and tokens from Symantec Authentication Service OAuth Provider.
- If a Client does not store public certificates of Symantec Authentication Service OAuth Provider, Client can use the JWKS endpoint in the metadata to retrieve the public certificates during runtime for signature verification of ID Token.

Request Format

To retrieve the metadata, send an HTTPS GET request to the following endpoint:

```
/<tenant-name>/.well-known/openid-configuration
```

Defines the name of the client whose associated Authorization Provider metadata must be retrieved along with the following client information:

- grant_types
- response_types_supported
- response_modes_supported
- scopes_supported
- claims_supported
- code_challenge_methods_supported
- token_endpoint_auth_methods_supported

Example:

```
GET /<tenant-name>/.well-known/openid-configuration HTTP/1.1
Host: ${SSP_FQDN}
```

Response Format

The metadata response from a well-known endpoint returns a JSON document in the **application/json** content type.

The following metadata is returned for a specific Client:

Parameter	Description	Values
Issuer	Defines the issuer that generate Claims.	https://${SSP_FQDN}/<tenant-name>/
authorization_endpoint	Defines the URL of the Authorization Endpoint.	https://${SSP_FQDN}/<tenant-name>/oauth2/
token_endpoint	Defines the URL of Token Endpoint. This value is returned only if the Authorization Code Flow is selected.	https://${SSP_FQDN}/<tenant-name>/oauth2/
device_authorization_endpoint	Defines the URL of the Device Code grant. This value is returned only if the Device Used Code grant flow is selected.	https://${SSP_FQDN}/<tenant-name>//oauth2
revoke_endpoint	Defines the URL of Revoke Token Endpoint	https://${SSP_FQDN}/<tenant-name>/oauth2/

userinfo_endpoint	Defines the URL of the User Info Endpoint.	https://${SSP_FQDN}/<tenant-name>/oauth2/
introspection_endpoint	Defines the URL of Introspect Endpoint.	https://${SSP_FQDN}/<tenant-name>/oauth2/
jwks_uri	Defines the URI of JSON Web Key Set Endpoint.	https://${SSP_FQDN}/<tenant-name>/oauth2/
scopes_supported	Specifies the list of scopes that are selected for OAuth Client during client configuration in Administrative UI.	"openid", "profile", "email", "phone", "address", "groups"
claims_supported	Specifies how the Client can obtain Claims about the End-User and the Authentication event. It also defines a standard set of basic profile Claims. Pre-defined sets of Claims can be requested using specific scope values or individual Claims can be requested using the `claims` request parameter. The Claims can come directly from the OpenID Provider or from distributed sources as well.	"aud","email","email_verified","phone_number","phone_number_verified","family_name","middle_name","given_name","iat","name", "sub","address","groups","picture","nickname","preferred_username","profile","website","zoneinfo","birthdate","updated_at","sub"
response_types_supported	Specifies the list of response types that are selected for OAuth Client during client configuration in Administrative UI.	code, token, id_token, and id_token token
response_modes_supported	Specifies the list of response modes that are supported by IDSP.	Value for Authorization Code Flow, if configure Value for Implicit Flow, if configured: fragment
grant_types_supported	Specifies the list of grant types that are supported by IDSP for the specified client.	authorization_code, implicit, urn:ietf:params:oa type:jwt-bearer, client_credentials, refresh_token, urn:ietf:params:oauth:grant-typ
subject_types_supported	Specifies the list of the Subject Identifier types that are supported by IDSP	public
id_token_signing_alg_values_supported	Specifies the list of the JWS algorithms (alg values) that are supported by IDSP to sign the claims of an ID Token.	RS256
id_token_encryption_alg_values_supported	(Optional) This is a JSON array that contains a list of JWE encryption algorithms (alg values) supported by the OP for the ID Token to encode the Claims in a JWT.	"RSA-OAEP", "RSA-OAEP-256"
id_token_encryption_enc_values_supported	(Optional) This is a JSON array that contains a list of JWE encryption algorithms (enc values) supported by the OIDC for the ID Token to encode the Claims in a JWT.	"A128GCM", "A192GCM", "A256GCM", "A HS384", "A128CBC-HS256"
userinfo_signing_alg_values_supported	Specifies the list of the JWS algorithms (alg values) that are supported by IDSP to sign the claims of a UserInfo response.	RS256
userinfo_encryption_alg_values_supported	(Optional) This is a JSON array that contains a list of JWE encryption algorithms (alg values) supported by the UserInfo Endpoint to encode the Claims in a JWT.	"RSA-OAEP", "RSA-OAEP-256"
userinfo_encryption_enc_values_supported	(Optional) This is a JSON array that contains a list of JWE encryption algorithms (enc values) supported by the UserInfo Endpoint to encode the Claims in a JWT.	"A128GCM", "A192GCM", "A256GCM", "A HS384", "A128CBC-HS256"
token_endpoint_auth_methods_supported	This parameter is returned only when client type is confidential.	client_secret_basic, client_secret_post, "privat
display_values_supported	Specifies the display parameter that is supported by OP for this client.	page
code_challenge_methods_supported	Defines the supported code challenge methods.	plain, S256

NOTE

- To know the value of ${SSP_FQDN} environment variable, see Configuring IDSP Environment Variables.
- The default value for `<tenantName>` is "default".
- Replace the text {{text}} including {{}} characters with appropriate values, in all the endpoints shown in the above table.
  For example:
  `https://{{host}}/{{tenantName}}/oauth2/v1/authorize`
  should look similar to:
  `https://example.com/default/oauth2/v1/authorize`
- To know more about the scopes that are required to secure these APIs, refer to the Rest APIs and Associated Privileges section.

Sample Request and Response

Request

```
GET /<tenant-name>/.well-known/openid-configuration HTTP/1.1
Host: ${SSP_FQDN}
```

Response

```
HTTP/1.1 200 OKContent-Type: application/json
```

```

```

Error Codes

The following table lists the error codes that Symantec Authentication Service returns:

Condition	HTTP Status Code
Request URL method is not GET	405

Making the First REST API call

Learn how to make your first API call by creating the application entity to begin modeling the application integration with Symantec Identity Security Platform.

Overview

REST APIs provide a way to integrate IDSP with custom applications that support REST.

This enables you to:

- Delegate authentication management to IDSP
- Develop custom login pages for your own applications
- Fully configure IDSP to behave exactly the way your application deployment and functionality requires

NOTE
We recommend you to get familiar with the REST Architecture Style.

NOTE
Requirements for OpenShift Environment

In the OpenShift environment, when invoking tenant-specific APIs, it is mandatory to provide the "X-TENANT-NAME" header in the API request, else the API request fails with "400 BAD REQUEST" status.

Key Points:

- The tenant identified by "X-TENANT-NAME" must exist in the system
- SSL certificate must be issued for the SSP_FQDN host
- All tenant-specific API clients must include the "X-TENANT-NAME" header in their requests

For more information, see Deploying Ingress Controller on Openshift

Application Resources

Any application invoking a IDSP REST API must be represented in the solution by a dedicated \"application" resource. This resource represents the real application you are integrating with the solution. With this Application entity created, you are expected to:

- Know what REST API calls your application must invoke in order to implement the desired functionality
- Obtain security credentials (Client Id and Secret) for your application to acquire an Access Token through the OAuth2 protocol
- Use acquired Access Token to invoke the desired REST API

Once this application resource has been defined, the developer would use IDSP REST APIs to accommodate two kinds of use cases:

- **Administration** - Developers integrate with IDSP for the purpose of performing administrative tasks. For example, to manage authentication policies, configuring configuration settings, etc. These are often called IDSP Control Plane APIs.
- **Security** - Developers integrate with IDSP to request security services. For example, to have the solution perform user authentication through browser-based OpenID Connect API or programmatic /authenticate REST API. These are often called IDSP Data Plane APIs.

In this tutorial, we assume the Administration use case, and using IDSP REST API to register an application capable of performing administrative tasks such as managing Authentication Policies. The next tutorial will showcase the security use case of using IDSP APIs to authenticate your application's users.

Get Access Token to use IDSP REST APIs

Until the Admin UI is available, we use the pre-seeded Default Client to obtain an Access Token using OAuth's "Client Credential" flow.

1. Make a note of the Client's Id and Secret obtained from the Kubernetes secret representing the Default Tenant Client.
   - Client Id:
     ```
     kubectl get secret ${RELEASENAME}-ssp-secret-defaulttenantclient -n ${NAMESPACE} -o
      jsonpath="{.data.clientId}" | base64 --decode; echo
     ```
   - Client Secret:
     ```
     kubectl get secret ${RELEASENAME}-ssp-secret-defaulttenantclient -n ${NAMESPACE} -o
      jsonpath="{.data.clientSecret}" | base64 --decode; echo
     ```
2. Make a note of the ingress FQDN hosting the IDSP Service URL:
   - Ingress Host FQDN:
     ```
     kubectl get ingress -n <namespace>
     ```
3. Open a command prompt and enter the following cURL command to acquire the admin access token, substituting the ServiceIngressFQDN and clientId/clientSecret parameters:

   Token Request:
   ```
   curl -k -X POST https://<ServiceIngressFQDN>/default/oauth2/v1/token -u '<client-id>:<client-secret>' -d
    'grant_type=client_credentials&scope=urn:iam:myscopes'
   ```
   Token Response:
   ```
   {
     "access_token" : "eyJ4NXQjUzI1NiI6ImNJbUNYN1FyRy1BU......",
     "token_type" : "Bearer",
     "expires_in" : 3600
   }
   ```
   The response contains the Access Token, token_type, and expires_in. The Access Token represents your application client's requested level of access for the REST API calls it is making. This token is encoded following the JSON Web

Token (JWT) standard. To check the JWT token, copy the "access_token" and introspect its content using the jwt debugger.

Make a IDSP REST API call to create an Application Resource

Using the just acquired admin access token, the next step is to create an Application resource representing your application.

1. Copy the following example Application resource definition into "myfirstapp.json".
   Application Resource JSON

```
{
    "status": "active",
    "name": "MyFirstApp",
    "description": "My first app",
    "clientType": "CONFIDENTIAL",
    "allowedOpenIDScopes": [
        "openid",
        "email",
        "profile"
    ],
    "redirectURIs": [
        "https://www.myfirstapp.com"
    ],
    "allowedGrantTypes": [
        "client_credentials",
        "authorization_code",
        "urn:ietf:params:oauth:grant-type:jwt-bearer"
    ],
    "allowedOperations": [
        "introspect"
    ],
    "userInfoEndpointResponseFormat": "PLAIN_JSON"
}
```

2. Open a command prompt and enter the following `cURL` command to create the Application resource, substituting the ServiceIngressFQDN and AccessToken parameters:
   Application Create Request

```
curl -k -X POST https://<ServiceIngressFQDN>/default/admin/v1/Apps  -H 'Content-Type: application/json'  -
d '@myfirstapp.json'  -H 'Authorization: Bearer <AccessToken>'
```

   Application Create Response

```
{
    "status": "active",
    "name": "myfirstapp",
    "description": "My First App",
    "clientType": "CONFIDENTIAL",
    "allowedOpenIDScopes": [
        "openid",
        "profile",
        "email"
    ],
    "redirectURIs": [
        "https://www.myfirstapp.com"
    ],
    "allowedGrantTypes": [
```

```
            "authorization_code",
            "urn:ietf:params:oauth:grant-type:jwt-bearer"
        ],
        "userInfoEndpointResponseFormat": "PLAIN_JSON",
        "allowedOperations": [
            "introspect"
        ],
        "appId": "9047e9e8-aa9c-46eb-8950-24e2b6223fbe",
        "tenantId": "4764021a-9048-11ea-bb37-0242ac130002",
        "createdBy": {
            "principalType": "CLIENT",
            "principalId": "e719078f-3aa5-4433-a621-6fecd9a75ef5",
            "principalName": "defaulttenantclient"
        },
        "createdDateTime": "2020-06-01 07:37 AM UTC",
        "updatedDateTime": "2020-06-01 07:37 AM UTC",
        "secret": "393476f5-5722-42fb-a784-6251651e831e",
        "clientId": "8b109251-70d9-48e1-921c-fb35d3d91f0e"
    }
```

3. At a command prompt, enter the curl command to get all application resources, substituting the ServiceIngressFQDN and AccessToken parameters. The newly created applications should be one of them.

```
curl -k -X POST https://<ServiceIngressFQDN>/default/admin/v1/Apps -H 'Authorization: Bearer
 <AccessToken>'
```

You have successfully executed your first REST API call by creating the Application resource to begin integrating your application with IDSP. The next tutorial will demonstrate this application's integration with SSP to authenticate application users using the OpenID Connect protocol.

Integrating Sample Web App with Symantec Identity Security Platform

Learn how to integrate your web application with IDSP using REST APIs or OIDC flows to implement multi-factor authentication (MFA).

Purpose

The main aim of this topic is to help you make use of the Symantec Identity Security Platform APIs and integrate your web application with the IDSP to perform multi-factor authentication flows. You can integrate with the solution either by using the REST APIs or OIDC flow.

Includes the following sub-topics:

Sequence of Steps

This section helps you obtain a high level understanding of the sequence of steps you must take in order to use the IDSP APIs.

The solution comes with a default tenant client which can be used to perform the following tasks:

1. Obtain the default tenant client id and secret from the IDSP Kubernetes cluster.
2. Generate a default Tenant Access Token- This step helps you to generate a default tenant access token which is a prerequisite for creating an application in the solution.
3. Create an Application- This step helps you create a client in the solution.

4. Create a Policy - This step lets you perform the following:
   a. Create the Authentication policy: This step helps you create an authentication policy for the application that you have created in the previous step. The authentication policy is evaluated, when the AuthN endpoint is accessed, and on successful policy evaluation, the ID Token is presented to you.
   b. Update the Authorization policy to provide the required privileges for the newly created application. This policy is evaluated to get the Access Token.
5. Generate the client access token. This helps you initiate the authentication flow to get the user Id token.
6. Upon successfully completing the authentication flow, you obtain the User ID token.
7. Using the User ID token, generate the access token. Now, that you have obtained the User Access Token, you can invoke the appropriate IDSP APIs to implement desired functionality.

These steps have been explained in the context of the Sample Web App with the help of REST APIs in the following section.

> **NOTE**
> The APIs that you access to perform any task depends upon the privileges defined in the access token. To perform specific tasks, you should have the corresponding scopes added to the access token. See Rest APIs and Associated Privileges section for specific authorization privileges required by each API.

Exploring the REST APIs through the Sample Web App

The Sample Web App is available to help you start creating your first app. The steps are carried out using the IDSP REST APIs, which are protected with an OAuth2-based security model.

Artifact Location

You can locate the demo artifacts for the Sample Web App from the Support Portal > My Downloads (Search for IDSP in the portal and select the appropriate version number).

The Sample App works out of the box, follow the deployment instructions provided here.

Steps to Deploy the Sample App

Perform these steps to deploy the Sample App in your environment:

> **NOTE**
> In the following steps, the curl commands have used <iam.example.com> as the ingress hostname which is a dummy value. Therefore, replace <iam.example.com> with your deployment's ingress hostname. You can get this value by using this command:
> *"kubectl gets ingress -n <namespace>"*

1. Use the following command to get the default tenant client id and secret from the IDSP Kubernetes cluster:
   - `kubectl get secret ${RELEASENAME}-ssp-secret-defaulttenantclient -n ${NAMESPACE} -o jsonpath="{.data.clientId}" | base64 --decode; echo`
   - `kubectl get secret ${RELEASENAME}-ssp-secret-defaulttenantclient -n ${NAMESPACE} -o jsonpath="{.data.clientSecret}" | base64 --decode; echo`
2. Use the following API to generate the default tenant access token by passing the client Id and secret in the authorization header:
   - `https://${SSP_FQDN}/{{tenantName}}/oauth2/v1/token`

NOTE

- To know the value of ${SSP_FQDN} environment variable, see Configuring IDSP Environment Variables.
- The default value for `<tenantName>` is "default".
- Replace the text {{text}} including {{}} characters with appropriate values, in all the endpoints shown in the above table.
  For example:
  `https://{{host}}/{{tenantName}}/oauth2/v1/token`
  should look similar to:
  `https://example.com/default/oauth2/v1/token`
- To know more about the scopes that are required to secure these APIs, refer to the Rest APIs and Associated Privileges section.

Generate Access Token Request

```
curl -L -X POST 'https://iam.example.com/default/oauth2/v1/token' \
-H 'Content-Type: application/x-www-form-urlencoded' \
-H 'Authorization: Basic
 OTc1MDljMjUtNjU0Ni00NmM0LTllNGQtMTJmYmJjYTYwZjNhOjgzNGI4ZjUxLWlMC1iYmFkLTg1NDdmMzYyM2ViNA==' \
--data-urlencode 'grant_type=client_credentials' \
--data-urlencode 'scope=urn:iam:myscopes'
```

Generate Access Token Response

```
{
 "access_token": "XQjUzI1NiI6ImNJbUNYN1FyRy",
 "token_type": "Bearer",
 "expires_in": 360
}
```

Now, you have the default Tenant Client Access Token with which you can create an application.

3. Create an application using the following API:

– `https://${SSP_FQDN}/{{tenantName}}/admin/v1/Apps`

Create Application Request

```
curl -L -X POST 'https://iam.example.com/default/admin/v1/Apps' \
-H 'Content-Type: application/json' \
-H 'Authorization: Bearer Ry1BUUpkWWZ2Wlctd1BDcF' \
--data-raw '{
   "status": "active",
   "name": "Test Application",
   "description": "Default Application for Security",
   "clientType": "CONFIDENTIAL",
   "allowedOpenIDScopes": [
       "openid",
       "email",
       "profile"
   ],
   "redirectURIs": [
       "https://www.example.com"

   ],
   "allowedGrantTypes": [
       "implicit",
       "authorization_code",
       "urn:ietf:params:oauth:grant-type:jwt-bearer",
```

```
            "client_credentials"
        ],
        "allowedOperations": [
            "introspect", "onbehalfof"
        ],
        "skipIssuerAudienceForIT": true,
        "userInfoEndpointResponseFormat": "PLAIN_JSON"
    }'
```

Create Application Response

```
{
    "status": "active",
    "name": "test application",
    "description": "Default Application for Security",
    "clientType": "CONFIDENTIAL",
    "allowedOpenIDScopes": [
        "openid",
        "profile",
        "email"
    ],
    "redirectURIs": [
        "https://www.example.com",

    ]
    "allowedGrantTypes": [
        "implicit",
        "client_credentials",
        "authorization_code",
        "urn:ietf:params:oauth:grant-type:jwt-bearer"
    ],
    "userInfoEndpointResponseFormat": "PLAIN_JSON",
    "skipIssuerAudienceForIT": true,
    "allowedOperations": [
        "introspect",
        "onbehalfof"
    ],
    "appId": "a45247ea-1652-4b3b-9178-970a2caf89e5",
    "createdBy": {
        "principalType": "CLIENT",
        "principalId": "97509c25-6546-46c4-9e4d-12fbbca60f3a",
        "principalName": "defaulttenantclient"
    },
    "createdDateTime": "2020-06-11 10:37 AM UTC",
    "updatedDateTime": "2020-06-11 10:37 AM UTC",
    "secret": "b8fc0a31-2c0c-4e1f-ac3e-da298cd12819",
    "clientId": "947b2632-3283-4766-9cc9-f00a3fce6aee"
}
```

NOTE
The response payload fetches you the values for client Id, secret, and application Id for the application. Make a note of these values, as these will be used to sign in to the sample application.

4. Use the following API to create an authentication policy:
   - `https://${SSP_FQDN}/{{tenantName}}/admin/v1/AuthPolicies`

   Create Authentication Policy Request

```
curl -L -X POST 'https://iam.example.com/default/admin/v1/AuthPolicies' \
-H 'Content-Type: application/json' \
-H 'Authorization: Bearer 6ImNJbUNYN1FyRy1BUUpkWWZ2Wlctd' \
--data-raw '{
   "description": "Sample policy Record ",
   "status": "active",
   "policyName": "Sample policy with channel web",
   "apps": [
       {
           "id": "a45247ea-1652-4b3b-9178-970a2caf89e5"
       }
   ],
   "rules": [
       {
           "conditions": {
               "channel": {
                   "operator": "in",
                   "value": [
                       "web"
                   ]
               }
           },
           "result": {
               "effect": "allow",
               "obligations": [
                   "PASSWORD",
                   "OTP"
               ],
               "msg": "This policy is for login in web channel"
           }
       }
   ]
}'
```

Create Authentication Policy Response

```
{
   "policyId": "8e9de6e1-8105-40da-942e-7841332d6b5b",
   "policyName": "Sample policy with channel web",
   "description": "Sample policy Record ",
   "status": "active",
   "matchAnyApp": false,
   "apps": [
       {
           "name": "Test Application",
           "id": "a45247ea-1652-4b3b-9178-970a2caf89e5"
       }
   ],
   "rules": [
       {
           "conditions": {
               "channel": {
                   "operator": "in",
                   "value": [
```

```
                        "web"
                    ]
                }
            },
            "result": {
                "effect": "allow",
                "reAuthenticate": "false",
                "obligations": [
                    "PASSWORD",
                    "OTP"
                ],
                "msg": "This policy is for login in web channel"
            }
        }
    ],
    "createdBy": {
        "principalType": "CLIENT",
        "principalId": "97509c25-6546-46c4-9e4d-12fbbca60f3a",
        "principalName": "defaulttenantclient"
    },
    "createdDate": "2020-06-11 10:41:39"
}
```

5. Update the "AuthClient" Authorization policy with the application Id. To perform the update, we must first get all the authorization policies, and then update the "AuthClient" Authorization policy.
   a. Run the following endpoint to get the Authorization policies:

```
https://${SSP_FQDN}/{{tenantName}}/admin/v1/AuthZPolicies/{{authClientAuthorizationPolicyId}}
```

   Get all tenant Authorization Policy Request

```
curl -L -X GET 'https://iam.example.com/default/admin/v1/AuthZPolicies' \
-H 'Content-Type: application/json' \
-H 'Authorization: Bearer XQjUzI1NiI6ImNJbUNYN1FyRy1BUUpkWWZ2Wlctd1BDcFQ0WT' \
--data-raw ''
```

   Get all tenant Authorization Policy Response

```
[
   {
       "policyId": "46010fd8-93c3-4adc-9632-b0d0726cf761",
       "policyName": "TenantAdminPolicy",
       "description": "Policy for Tenant Admin",
       "status": "active",
       "matchAnyApp": false,
       "apps": [
           {
               "name": "ssp",
               "id": "3690ac36-c805-43ef-8318-627023b16d64"
           }
       ],
       "rules": [
           {
               "conditions": {
                   "principal": {
                       "clientApp": {
                           "operator": "in",
                           "value": [
```

```
                            "7328b5c9-0ece-46d7-8758-6d08a618fb9a",
                            "059bcbbc-c8b6-467d-85d0-6d15f5a5c0f7"
                        ]
                    }
                }
            },
            "result": {
                "msg": "This is Tenant Admin authorization policy",
                "privileges": [
                    "urn:iam:t.apps",
                    "urn:iam:t.authenticate",
                    "urn:iam:t.configs",
                    "urn:iam:t.ldapconfigs",
                    "urn:iam:t.users",
                    "urn:iam:t.signingkey",
                    "urn:iam:t.certs",
                    "urn:iam:t.authzpolicies",
                    "urn:iam:t.authpolicies",
                    "urn:iam:t.groups",
                    "urn:iam:t.risk",
                    "urn:iam:t.userdata"
                ]
            }
        }
    ],
    "createdDate": "2020-06-10 05:36:21",
    "updatedDate": "2020-06-10 05:36:21"
},
{
    "policyId": "dbb932c7-c926-43df-a35c-f93a71c43f4e",
    "policyName": "AuthClientPolicy",
    "description": "Policy for Authentication Client",
    "status": "active",
    "matchAnyApp": false,
    "apps": [
        {
            "name": "ssp",
            "id": "3690ac36-c805-43ef-8318-627023b16d64"
        }
    ],
    "rules": [
        {
            "conditions": {
                "principal": {
                    "clientApp": {
                        "operator": "in",
                        "value": [
                            "2d93ffc1-ac22-48f7-8f80-206535f40afb"
                        ]
                    }
                }
            },
            "result": {
```

```
                    "msg": "This policy allows clients to call authentication APIs",
                    "privileges": [
                        "urn:iam:t.authenticate"
                    ]
                }
            }
        ],
        "createdDate": "2020-06-10 05:36:21",
        "updatedDate": "2020-06-10 05:36:21"
    }
                ]
```

b. Run the following API to grant "clientApp" to the "AuthClientPolicy":

```
https://${SSP_FQDN}/{{tenantName}}/admin/v1/AdminRolesDelegator
```

Update Authorization Policy Request

```
curl --location 'example.com/default/admin/v1/AdminRolesDelegator' \
 --header 'Content-Type: application/json' \
 --header 'Authorization: Bearer eyJ4NXQ....' \
 --data '{
     "id": "3805d28b-f980-46de-a497-fad560433623",
     "principal": {
         "clientApp": {
             "operator": "in",
             "value": [
                 "a45247ea-1652-4b3b-9178-970a2caf89e5"
             ]
         }
     }
 }'
```

The following is the Authorization Policy Response:

```
{
   "id": "dbb932c7-c926-43df-a35c-f93a71c43f4e",
   "name": "AuthClientPolicy",
   "displayName": "Authentication Client",
   "description": "Perform authentication-related operations as required to implement a custom signin
 app.",
   "principal": {
       "clientApp": {
           "operator": "in",
           "value": [
               "a45247ea-1652-4b3b-9178-970a2caf89e5",
           ]
       }
   },
   "isGrantableClientOnly": true
   }
```

6. (Optional) Perform this step to configure an LDAP User Store, if you have not configured it earlier. Run the following endpoint to configure an LDAP User Store:

```
https://${SSP_FQDN}/tenantName/admin/v1/LDAPconfigs
```

NOTE

- To know the value of ${SSP_FQDN} environment variable, see Configuring IDSP Environment Variables.
- The default value for `<tenantName>` is "default".
- Replace the text {{text}} including {{}} characters with appropriate values, in all the endpoints shown in the above table.
  For example:
  `https://{{host}}/{{tenantName}}/admin/v1/LDAPconfigs`
  should look similar to:
  `https://example.com/default/admin/v1/LDAPconfigs`
- To know more about the scopes that are required to secure these APIs, refer to the Rest APIs and Associated Privileges section.

Configure LDAP User Store Request

```
curl -L -X GET 'https://iam.example.com/default/admin/v1/LDAPconfigs' \
-H 'Authorization: Bearer <token>'
```

Configure LDAP User Store Response

```
[
    {
        "tenantId": "4764021a-9048-11ea-bb37-0242ac130002",
        "configName": "TestConfig",
        "configDescription": "CA DIR k8s with default data",
        "sslEnabled": "NO",
        "certificate": null,
        "certificateAlias": null,
        "ldapQueryStart": "(&(cn=",
        "ldapQueryEnd": ")(objectClass=*))",
        "attributes": "uid,telephoneNumber,employeeType,mail,displayName,givenName,cn,sn,memberof,title",
        "objectClasses": "string",
        "groupObjectClasses": "groupOfNames",
        "hostName": "iam.example.com",
        "portNumber": "31568",
        "baseDN": "o=democorp,c=us",
        "groupBaseDN": "o=democorp,c=us",
        "userDN": "cn=DominicMAJOR,ou=Administration,ou=Corporate,o=democorp,c=US",
        "bindPassword": "/OTqCj2yPWVvhl6AjpJ/DQ==",
        "attributeMapping":
 "name=cn,family_name=sn,given_name=givenName,middle_name=givenName,nickname=displayName,preferred_username=displayN
 status=employeeType,memberof=memberof",
        "groupSearchMappingAttribute": "member",
        "useMemberOf": "yes",
        "namingAttribute": "cn",
        "passwordResetURL": "http://userPasswordResetURL",
        "createdDateTime": "2020-06-30 15:40 PM UTC",
        "updatedDateTime": "2020-06-30 15:40 PM UTC",
        "createdBy": {
            "principalType": "CLIENT",
            "principalId": "f4bcb936-769f-4377-9e76-276083d1958e",
            "principalName": "defaulttenantclient"
        },
        "ldapConfigId": "3ec2ecfa-d88b-49cd-b50b-e4dba6094a9d"
    }
]
```

7. (Optional) Perform this step to create an LDAP User Store.

   NOTE

   Check if a user store already exists. If yes, then skip this step.

Configure LDAP User Store Request

```
curl -L -X POST 'https://iam.example.com/default/admin/v1/LDAPconfigs' \
-H 'Content-Type: application/json' \
-H 'Authorization: Bearer <token>' \
--data-raw '{
    "configName": "TestConfig",
    "configDescription": "CA DIR k8s with default data",
    "sslEnabled": "NO",
    "ldapQueryStart": "(&(cn=",
    "ldapQueryEnd": ")(objectClass=*))",
    "attributes": "uid,displayName,telephoneNumber,mail,memberof",
    "objectClasses": "string",
    "hostName": "iam.example.com",
    "portNumber": "31888",
    "baseDN": "o=democorp,c=us",
    "groupBaseDN": "o=democorp,c=us",
    "groupObjectClasses": "groupOfNames",
    "groupSearchMappingAttribute": "member",
    "useMemberOf": "yes",
    "namingAttribute": "cn",
    "userDN": "cn=DominicMAJOR,ou=Administration,ou=Corporate,o=democorp,c=US",
    "bindPassword": "password",
    "attributeMapping":
 "name=cn,family_name=sn,given_name=givenName,middle_name=givenName,nickname=displayName,preferred_username=displayN
 status=employeeType,memberof=memberof",
    "passwordResetURL": "http://userPasswordResetURL"
}'
```

Configure LDAP User Store Response

```
{
    "tenantId": "4764021a-9048-11ea-bb37-0242ac130002",
    "configName": "TestConfig",
    "configDescription": "CA DIR k8s with default data",
    "sslEnabled": "NO",
    "certificate": null,
    "certificateAlias": null,
    "ldapQueryStart": "(&(cn=",
    "ldapQueryEnd": ")(objectClass=*))",
    "attributes": "uid,telephoneNumber,employeeType,mail,displayName,givenName,cn,sn,memberof,title",
    "objectClasses": "string",
    "groupObjectClasses": "groupOfNames",
    "hostName": "iam.example.com",
    "portNumber": "31888",

    }
```

Running the Sample App Locally

To run the Sample App locally, you must perform the following steps.

1. Run the following command to obtain the out of the box default tenant client id and secret from the IDSP Kubernetes cluster:
   - `kubectl get secret ${RELEASENAME}-ssp-secret-defaulttenantclient -n ${NAMESPACE} -o jsonpath="{.data.clientId}" | base64 --decode; echo`
   - `kubectl get secret ${RELEASENAME}-ssp-secret-defaulttenantclient -n ${NAMESPACE} -o jsonpath="{.data.clientSecret}" | base64 --decode; echo`
2. Navigate to the Sample Web App project folder in the Support Portal > My Downloads (Search for IDSP in the portal and select the appropriate version number) or to your locally downloaded location, access the 'env.js' file and perform the following tasks:
   a. Provide the following details of the newly created application that you have obtained in Step 1:
      a. clientId
      b. clientSecret
      c. baseServiceUrl
3. In the Sample Web App project folder update the *package.json* file as follows:
   - *"start": "ng serve -ssl -host <HOSTNAME>",*
   - For example, "ng serve --ssl --host sampleapp.example.com",
4. Add an entry in the hosts file to match the <HOSTNAME> specified in step 3 pointing to 127.0.0.1.
5. Update the IDSP allowed origins by using the tenant settings PATCH call. In this call, update the hostname that you have specified in step 3 by appending the port at the end of the code, as shown in the following request:

```
curl -L -X PATCH 'https://iam.example.com/default/admin/v1/Configs' \
-H 'Content-Type: application/json' \
-H 'Authorization: Bearer <token>' \
--data-raw '[

    {
        "name": "allowedOrigins",
        "value": "https://sampleapp.example.com:4200"
    }
]'
```

Response

```
[
    {
        "name": "persistEnrolledFactorsinIDP",
```

```
        "value": "false",
        "origin": "global"
    },
    {
        "name": "azCodeExpirySecs",
        "value": "120",
        "origin": "global"
    },
    {
        "name": "isInlineOTPEnrollmentToBePersisted",
        "value": "true",
        "origin": "global"
    },
    {
        "name": "refreshTokenExpiryDays",
        "value": "7",
        "origin": "global"
    },
    {
        "name": "pushRegTimeoutSecs",
        "value": "300",
        "origin": "global"
    },
    {
        "name": "allowedOrigins",
        "value": "https://sampleapp.example.com:4200",
        "origin": "tenant"
    },
    {
        "name": "isInlineEnrollmentAllowed",
        "value": "true",
        "origin": "global"
    },
    {
        "name": "idTokenExpirySecs",
        "value": "21600",
        "origin": "global"
    },
    {
        "name": "pushAuthTimeoutSecs",
        "value": "300",
        "origin": "global"
    },
    {
        "name": "accessTokenExpirySecs",
        "value": "3600",
        "origin": "tenant"
    },
    {
        "name": "useOriginalIdentityTokenExpiry",
        "value": "false",
        "origin": "global"
    },
```

```
    {
        "name": "inlineEnrollmentFactorsRequired",
        "value": "PASSWORD",
        "origin": "global"
    }
]
```

NOTE
Ensure that the defaulttenant client access token that you have used is valid and has not crossed the expiry time.

6. Open a command prompt, navigate to the 'sampleapp' folder and enter "npm install". This step installs all the required modules for the sample app.
7. Run "**npm run build – --prod"** to build the project.
8. Run "**npm start**".
9. Open a browser and navigate to **"https://sampleapp.example.com:4200"**. The login page of the sample app is displayed.
10. Enter your username.
11. (Optional) Click the Settings gear at the top left of the login page to provide inputs for additional parameters, such as ip address or acr values.

Building the Docker Image

Open a command prompt in the Sample App folder where the "Dockerfile" is located. Run the following commands to generate the docker image:

- docker build --no-cache -t <IMAGE NAME>
- docker tag <IMAGE NAME> < ARTIFACTORY LOCATION>/<IMAGE NAME>
- docker push <ARTIFACTORY LOCATION>/<IMAGE NAME>

Installing Sample App Helm Chart

To install the Sample App Helm Chart, run the following commands:

- `helm repo add ssp_helm_charts https://ssp_helm_charts.storage.googleapis.com`
- `helm repo update`
- `helm install <helm_release_name> -n <k8s_namespace> --set image.sampleWebapp.repository=<docker_repository_name> --set image.sampleWebapp.tag=<image_tag_version> --set featureFlags.sampleIdStore.enabled=false --set ssp.serviceUrl="https://<authHub-fqdn-hostname>/<tenant>/" --set ssp.clientId="<clientId>" --set ssp.clientSecret="<clientSecret>" --set ingress.host=<sample-app-fqdn-hostname> --set ingress.tls.host=<sample-app-fqdn-hostname> --set ingress.tls.secretName=<k8s_secretName> ssp_helm_charts/ssp-sample-app`

Internals of the Sample Application

This section discusses, for example, how the access token is created, how the transactions flow between multiple factors and the reauthentication flows, the internal workings of the sample applications.

Generating Access Token

- Access token is generated on initial page load in the browser and is stored in local storage, so the end-user does not need to generate the token multiple times.
- Access token is generated using "ngOnInit()" (line#47) method in "init.component.ts" . This method checks if there are any pre-populated values as part of "env.js" and decides which ones to use whether the environment values or the locally stored values.

Transaction Flows Between the Multi-Factors

- After successful response from each api's, a call is made to "**displayservices.ts"** which has "**routeActions()"**(line#69). Based on the "nextaction" which is part of api response the flow is routed to the respective component. See examples below:
- Example explaining the flow to id store authentication:
  - {"flowState":<FLOWSTATE>,"nextaction":"PASSWORD_AUTH","currentFactors":["PASSWORD"]} – As the next action in this example is pointing to "PASSWORD_AUTH" we route this transaction to "ldap.component.ts" (line#88).
- Example explaining the flow to otp authentication:
  - {"flowState":"<FLOWSTATE>","credentials":[{"credId":"e6240c61-c0d0-4933-8566-f31cab4becaa","tenantId":"100","userId":"8c49025d-4a60-458a-9335-f94486687029","credType":"email","credValue":"su*******@broadcom.com ["OTP","FIDO"]} –As the next action in this example is pointing to "OTP_SELECTION" we route this transaction to "sotp.component.ts"(line#108)

Generating Device Signature for Device Risk Analysis

- All of this happens when the login page is loaded for the first time in the browser. An asynchronous call is sent to the "**fingerprint2.getpromise()"**(line#93) from **"ngOnInit()"**(line#47) in **"init.component.ts"** and will store this device signature in one of our local variables called **"fingerPrintDna"** which is will passed in the initial authenticate api call.

Re-authentication Flow

- Re-authentication happens in two services calls as to demo the usecases in multiple scenarios. One deals with **"StepUp"** which happens in **"welcome.component.ts"** and other scenarios in **"header.component.ts".**
- For more in-depth information we can go to individual methods like **"forceReauthWealth"** (line#21)**,"forceReauthCommercial"** (line#78),**"forceReauthBiz"**(line#52)

Token Display on the Welcome Page

- After successful authentication at the end of transaction **"id token"** is generated as part of successful response.
- Example: {"flowState": "<FLOWSTATE>","nextaction": "AUTH_ALLOWED","data": {"message": "Password authentication is successful for user example"},"deviceID": "<DEVICEID>","id_token": "<IDTOKEN>"}
- With this id token a "**user access token"** is generated via **"getUserAccessToken"**(line#46) in **"init.service.ts"**

FIDO Self-Registration

- With the above generated user access token fido self-registration is progressed via **"onRegister ()"**(line#80) in **"fidoreg.component.ts".**

Integrating Sample Mobile App with Symantec Identity Security Platform

Integrating Sample Mobile App with Symantec Identity Security Platform. Learn how to integrate the sample mobile application with IDSP APIs for multi-factor authentication, reauthentication, and risk flows.

The Sample Mobile application discusses how to set up a demo environment and test the various multi-factor authentication flows offered by the solution.

> **NOTE**
> The Sample Mobile application is not intended to be published to production and as such does not concern itself with the best practices, such as data modeling, design patterns, and so on. The primary aim of the Sample Mobile application is to address the recommended approach to integrate with IDSP

Sequence of Steps

This section lets you obtain a high-level understanding of the sequence of steps you must take to integrate the SampleMobile application with the IDSP APIs.

To set up your sample mobile application, perform the following steps:

1. Obtain the default tenant client id and secret from the IDSP Kubernetes cluster.
2. Generate a default Tenant Access Token- This step helps you to generate a default tenant access token which is a prerequisite for creating an application in the solution.
3. Create an Application- This step helps you create a client in the solution.
4. Create a Policy - This step lets you perform the following:
   a. Create the Authentication policy: This step helps you create an authentication policy for the application that you have created in the previous step. The authentication policy is evaluated, when the AuthN endpoint is accessed, and on successful policy evaluation, the ID Token is presented to you.
   b. Update the Authorization policy to provide the required privileges for the newly created application. This policy is evaluated to get the Access Token.
5. Generate the client access token. This helps you initiate the authentication flow to get the user Id token.
6. Upon successfully completing the authentication flow, you obtain the User ID token.
7. Using the User ID token, generate the access token. Now, that you have obtained the User Access Token, you can invoke the appropriate IDSP APIs to implement desired functionality.

These steps have been explained in the context of REST APIs in the following section.

Configuration Steps

> **NOTE**
> In the following steps, the curl commands have used <iam.example.com> as the ingress hostname which is a dummy value. Therefore, replace <iam.example.com> with your deployment's ingress hostname. You can get this value by using this command:
> *"kubectl gets ingress -n <namespace>"*

1. Use the following command to get the default tenant client id and secret from the IDSP Kubernetes cluster:
   - `kubectl get secret ${RELEASENAME}-ssp-secret-defaulttenantclient -n ${NAMESPACE} -o jsonpath="{.data.clientId}" | base64 --decode; echo`
   - `kubectl get secret ${RELEASENAME}-ssp-secret-defaulttenantclient -n ${NAMESPACE} -o jsonpath="{.data.clientSecret}" | base64 --decode; echo`
2. Use the following API to generate the default tenant access token by passing the client Id and secret in the authorization header:
   - `https://${SSP_FQDN}/{{tenantName}}/oauth2/v1/token`

NOTE

- To know the value of ${SSP_FQDN} environment variable, see Configuring IDSP Environment Variables.
- The default value for `<tenantName>` is "default".
- Replace the text {{text}} including {{}} characters with appropriate values, in all the endpoints shown in the above table.
  For example:
  `https://{{host}}/{{tenantName}}/oauth2/v1/token`
  should look similar to:
  `https://example.com/default/oauth2/v1/token`
- To know more about the scopes that are required to secure these APIs, refer to the Rest APIs and Associated Privileges section.

Generate Access Token Request

```
curl -L -X POST 'https://iam.example.com/default/oauth2/v1/token' \
-H 'Content-Type: application/x-www-form-urlencoded' \
-H 'Authorization: Basic
 OTc1MDljMjUtNjU0Ni00NmM0LTllNGQtMTJmYmJjYTYwZjNhOjgzNGI4ZjUxLWlMC1iYmFkLTg1NDdmMzYyM2ViNA==' \
--data-urlencode 'grant_type=client_credentials' \
--data-urlencode 'scope=urn:iam:myscopes'
```

Generate Access Token Response

```
{
 "access_token": "XQjUzI1NiI6ImNJbUNYN1FyRy",
 "token_type": "Bearer",
 "expires_in": 360
}
```

Now, you have the default Tenant Client Access Token with which you can create an application.

3. Create an application using the following API:

– `https://${SSP_FQDN}/{{tenantName}}/admin/v1/Apps`

Create Application Request

```
curl -L -X POST 'https://iam.example.com/default/admin/v1/Apps' \
-H 'Content-Type: application/json' \
-H 'Authorization: Bearer Ry1BUUpkWWZ2Wlctd1BDcF' \
--data-raw '{
   "status": "active",
   "name": "Test Application",
   "description": "Default Application for Security",
   "clientType": "CONFIDENTIAL",
   "allowedOpenIDScopes": [
       "openid",
       "email",
       "profile"
   ],
   "redirectURIs": [
       "https://www.example.com"

   ],
   "allowedGrantTypes": [
       "implicit",
       "authorization_code",
       "urn:ietf:params:oauth:grant-type:jwt-bearer",
```

```
            "client_credentials"
        ],
        "allowedOperations": [
            "introspect", "onbehalfof"
        ],
        "skipIssuerAudienceForIT": true,
        "userInfoEndpointResponseFormat": "PLAIN_JSON"
    }'
```

Create Application Response

```
{
    "status": "active",
    "name": "test application",
    "description": "Default Application for Security",
    "clientType": "CONFIDENTIAL",
    "allowedOpenIDScopes": [
        "openid",
        "profile",
        "email"
    ],
    "redirectURIs": [
        "https://www.example.com",

    ]
    "allowedGrantTypes": [
        "implicit",
        "client_credentials",
        "authorization_code",
        "urn:ietf:params:oauth:grant-type:jwt-bearer"
    ],
    "userInfoEndpointResponseFormat": "PLAIN_JSON",
    "skipIssuerAudienceForIT": true,
    "allowedOperations": [
        "introspect",
        "onbehalfof"
    ],
    "appId": "a45247ea-1652-4b3b-9178-970a2caf89e5",
    "createdBy": {
        "principalType": "CLIENT",
        "principalId": "97509c25-6546-46c4-9e4d-12fbbca60f3a",
        "principalName": "defaulttenantclient"
    },
    "createdDateTime": "2020-06-11 10:37 AM UTC",
    "updatedDateTime": "2020-06-11 10:37 AM UTC",
    "secret": "b8fc0a31-2c0c-4e1f-ac3e-da298cd12819",
    "clientId": "947b2632-3283-4766-9cc9-f00a3fce6aee"
}
```

NOTE
The response payload fetches you the values for client Id, secret, and application Id for the application. Make a note of these values, as these will be used to sign in to the sample application.

4. Use the following API to create an authentication policy:
   - `https://${SSP_FQDN}/{{tenantName}}/admin/v1/AuthPolicies`

   Create Authentication Policy Request

```
curl -L -X POST 'https://iam.example.com/default/admin/v1/AuthPolicies' \
-H 'Content-Type: application/json' \
-H 'Authorization: Bearer 6ImNJbUNYN1FyRy1BUUpkWWZ2Wlctd' \
--data-raw '{
   "description": "Sample policy Record ",
   "status": "active",
   "policyName": "Sample policy with channel web",
   "apps": [
       {
           "id": "a45247ea-1652-4b3b-9178-970a2caf89e5"
       }
   ],
   "rules": [
       {
           "conditions": {
               "channel": {
                   "operator": "in",
                   "value": [
                       "web"
                   ]
               }
           },
           "result": {
               "effect": "allow",
               "obligations": [
                   "PASSWORD",
                   "OTP"
               ],
               "msg": "This policy is for login in web channel"
           }
       }
   ]
}'
```

Create Authentication Policy Response

```
{
   "policyId": "8e9de6e1-8105-40da-942e-7841332d6b5b",
   "policyName": "Sample policy with channel web",
   "description": "Sample policy Record ",
   "status": "active",
   "matchAnyApp": false,
   "apps": [
       {
           "name": "Test Application",
           "id": "a45247ea-1652-4b3b-9178-970a2caf89e5"
       }
   ],
   "rules": [
       {
           "conditions": {
               "channel": {
                   "operator": "in",
                   "value": [
```

```
                        "web"
                    ]
                }
            },
            "result": {
                "effect": "allow",
                "reAuthenticate": "false",
                "obligations": [
                    "PASSWORD",
                    "OTP"
                ],
                "msg": "This policy is for login in web channel"
            }
        }
    ],
    "createdBy": {
        "principalType": "CLIENT",
        "principalId": "97509c25-6546-46c4-9e4d-12fbbca60f3a",
        "principalName": "defaulttenantclient"
    },
    "createdDate": "2020-06-11 10:41:39"
}
```

5. Update the "AuthClient" Authorization policy with the application Id. To perform the update, we must first get all the authorization policies, and then update the "AuthClient" Authorization policy.
   a. Run the following endpoint to get the Authorization policies:

```
https://${SSP_FQDN}/{{tenantName}}/admin/v1/AuthZPolicies/{{authClientAuthorizationPolicyId}}
```

   Get all tenant Authorization Policy Request

```
curl -L -X GET 'https://iam.example.com/default/admin/v1/AuthZPolicies' \
-H 'Content-Type: application/json' \
-H 'Authorization: Bearer XQjUzI1NiI6ImNJbUNYN1FyRy1BUUpkWWZ2Wlctd1BDcFQ0WT' \
--data-raw ''
```

   Get all tenant Authorization Policy Response

```
[
   {
       "policyId": "46010fd8-93c3-4adc-9632-b0d0726cf761",
       "policyName": "TenantAdminPolicy",
       "description": "Policy for Tenant Admin",
       "status": "active",
       "matchAnyApp": false,
       "apps": [
           {
               "name": "ssp",
               "id": "3690ac36-c805-43ef-8318-627023b16d64"
           }
       ],
       "rules": [
           {
               "conditions": {
                   "principal": {
                       "clientApp": {
                           "operator": "in",
                           "value": [
```

```
                            "7328b5c9-0ece-46d7-8758-6d08a618fb9a",
                            "059bcbbc-c8b6-467d-85d0-6d15f5a5c0f7"
                        ]
                    }
                }
            },
            "result": {
                "msg": "This is Tenant Admin authorization policy",
                "privileges": [
                    "urn:iam:t.apps",
                    "urn:iam:t.authenticate",

    "status": "active",
    "matchAnyApp": false,
    "apps": [
        {
            "name": "ssp",
            "id": "3690ac36-c805-43ef-8318-627023b16d64"
        }
    ],
    "rules": [
        {
            "conditions": {
                "principal": {
                    "clientApp": {
                        "operator": "in",
                        "value": [
                            "2d93ffc1-ac22-48f7-8f80-206535f40afb"
                        ]
                    }
                }
            },
            "result": {
```

```
                    "msg": "This policy allows clients to call authentication APIs",
                    "privileges": [
                        "urn:iam:t.authenticate"
                    ]
                }
            }
        ],
        "createdDate": "2020-06-10 05:36:21",
        "updatedDate": "2020-06-10 05:36:21"
    }
                ]
```

b. Run the following API to grant "clientApp" to the "AuthClientPolicy":

```
https://${SSP_FQDN}/{{tenantName}}/admin/v1/AdminRolesDelegator
```

Update Authorization Policy Request

```
curl --location 'example.com/default/admin/v1/AdminRolesDelegator' \
 --header 'Content-Type: application/json' \
 --header 'Authorization: Bearer eyJ4NXQ....' \
 --data '{
     "id": "3805d28b-f980-46de-a497-fad560433623",
     "principal": {
         "clientApp": {
             "operator": "in",
             "value": [
                 "a45247ea-1652-4b3b-9178-970a2caf89e5"
             ]
         }
     }
 }'
```

The following is the Authorization Policy Response:

```
{
   "id": "dbb932c7-c926-43df-a35c-f93a71c43f4e",
   "name": "AuthClientPolicy",
   "displayName": "Authentication Client",
   "description": "Perform authentication-related operations as required to implement a custom signin
 app.",
   "principal": {
       "clientApp": {
           "operator": "in",
           "value": [
               "a45247ea-1652-4b3b-9178-970a2caf89e5",
           ]
       }
   },
   "isGrantableClientOnly": true
   }
```

6. (Optional) Perform this step to configure an LDAP User Store, if you have not configured it earlier. Run the following endpoint to configure an LDAP User Store:

```
https://${SSP_FQDN}/tenantName/admin/v1/LDAPconfigs
```

NOTE

- To know the value of ${SSP_FQDN} environment variable, see Configuring IDSP Environment Variables.
- The default value for `<tenantName>` is "default".
- Replace the text {{text}} including {{}} characters with appropriate values, in all the endpoints shown in the above table.
  For example:
  `https://{{host}}/{{tenantName}}/admin/v1/LDAPconfigs`
  should look similar to:
  `https://example.com/default/admin/v1/LDAPconfigs`
- To know more about the scopes that are required to secure these APIs, refer to the Rest APIs and Associated Privileges section.

Configure LDAP User Store Request

```
curl -L -X GET 'https://iam.example.com/default/admin/v1/LDAPconfigs' \
-H 'Authorization: Bearer <token>'
```

Configure LDAP User Store Response

```
[
    {
        "tenantId": "4764021a-9048-11ea-bb37-0242ac130002",
        "configName": "TestConfig",
        "configDescription": "CA DIR k8s with default data",
        "sslEnabled": "NO",
        "certificate": null,
        "certificateAlias": null,
        "ldapQueryStart": "(&(cn=",
        "ldapQueryEnd": ")(objectClass=*))",
        "attributes": "uid,telephoneNumber,employeeType,mail,displayName,givenName,cn,sn,memberof,title",
        "objectClasses": "string",
        "groupObjectClasses": "groupOfNames",
        "hostName": "iam.example.com",
        "portNumber": "31568",
        "baseDN": "o=democorp,c=us",
        "groupBaseDN": "o=democorp,c=us",
        "userDN": "cn=DominicMAJOR,ou=Administration,ou=Corporate,o=democorp,c=US",
        "bindPassword": "/OTqCj2yPWVvhl6AjpJ/DQ==",
        "attributeMapping":
 "name=cn,family_name=sn,given_name=givenName,middle_name=givenName,nickname=displayName,preferred_username=displayN
 status=employeeType,memberof=memberof",
        "groupSearchMappingAttribute": "member",
        "useMemberOf": "yes",
        "namingAttribute": "cn",
        "passwordResetURL": "http://userPasswordResetURL",
        "createdDateTime": "2020-06-30 15:40 PM UTC",
        "updatedDateTime": "2020-06-30 15:40 PM UTC",
        "createdBy": {
            "principalType": "CLIENT",
            "principalId": "f4bcb936-769f-4377-9e76-276083d1958e",
            "principalName": "defaulttenantclient"
        },
        "ldapConfigId": "3ec2ecfa-d88b-49cd-b50b-e4dba6094a9d"
    }
]
```

7. (Optional) Perform this step to create an LDAP User Store.

   NOTE

   Check if a user store already exists. If yes, then skip this step.

Configure LDAP User Store Request

```
curl -L -X POST 'https://iam.example.com/default/admin/v1/LDAPconfigs' \
-H 'Content-Type: application/json' \
-H 'Authorization: Bearer <token>' \
--data-raw '{
    "configName": "TestConfig",
    "configDescription": "CA DIR k8s with default data",
    "sslEnabled": "NO",
    "ldapQueryStart": "(&(cn=",
    "ldapQueryEnd": ")(objectClass=*))",
    "attributes": "uid,displayName,telephoneNumber,mail,memberof",
    "objectClasses": "string",
    "hostName": "iam.example.com",
    "portNumber": "31888",
    "baseDN": "o=democorp,c=us",
    "groupBaseDN": "o=democorp,c=us",
    "groupObjectClasses": "groupOfNames",
    "groupSearchMappingAttribute": "member",
    "useMemberOf": "yes",
    "namingAttribute": "cn",
    "userDN": "cn=DominicMAJOR,ou=Administration,ou=Corporate,o=democorp,c=US",
    "bindPassword": "password",
    "attributeMapping":
 "name=cn,family_name=sn,given_name=givenName,middle_name=givenName,nickname=displayName,preferred_username=displayN
 status=employeeType,memberof=memberof",
    "passwordResetURL": "http://userPasswordResetURL"
}'
```

Configure LDAP User Store Response

```
{
    "tenantId": "4764021a-9048-11ea-bb37-0242ac130002",
    "configName": "TestConfig",
    "configDescription": "CA DIR k8s with default data",
    "sslEnabled": "NO",
    "certificate": null,
    "certificateAlias": null,
    "ldapQueryStart": "(&(cn=",
    "ldapQueryEnd": ")(objectClass=*))",
    "attributes": "uid,telephoneNumber,employeeType,mail,displayName,givenName,cn,sn,memberof,title",

Steps to Build and Install Sample Mobile Application

Learn about the steps to install the Sample Mobile application (also known as Hedmoral Technologies app) to perform authentication flows in Symantec Identity Security Platform.

The Mobile client application is available for users to perform EMAILOTP, SMSOTP, FIDO, and Password authentication flows.

> **NOTE**
> The Mobile application does not support Push and Mobile OTP flows.

This topic includes the following:

- Prerequisites
- Latest Builds
- Installing the Mobile Application Using APK File

Prerequisites

To be able to run the latest Hedmoral Mobile Application (version 12.0), ensure that you have met the following prerequisites:

- Android Studio "2025.1.4" or later
- Android Gradle Plugin 8.13.2

Downloading and Building

Follow these steps to download the latest code and build the Mobile Authentication application.

1. Navigate to the Support Portal > My Downloads.
2. In the package, look for **IDSP_4.0-Android-Release-Package-v3.0.3.zip** and unzip it in a local directory in your machine.
3. Unzip the **"hedmoral-sample-app.zip"** source code in the same directory as the previous step.
4. Use the following commands to build the application. Ensure to set the ANDROID_HOME environment before building the sample app:

   ```
   $ cd hedmoral-sample-app
   $ ./gradlew build
   ```

   The output displays a message similar to the following:

   ```
   BUILD SUCCESSFUL in 14s
   59 actionable tasks: 58 executed, 1 up-to-date
   ```
5. After the build is successfully deployed, you can find the APK debug & release file in the following location:

- The "hedmoraltechnologies-debug.apk" output file is available in the following location:
  ```
  $ cd hedmoraltechnologies/build/outputs/apk/debug
  ```
- The "hedmoraltechnologies-release.apk" output file is available in the following location:
  ```
  $ cd hedmoraltechnologies/build/outputs/apk/release
  ```

Installing the Mobile Application Using APK File

Follow these steps:

1. Copy the Android Package Kit, "APK" file from the "hedmoral-sample-app-apk-files" folder to your mobile device.
2. On your device, go to Menu Settings Security and check the **Menu** > **Settings** > **Security "Allow installation of apps from unknown sources"** option.
3. Tap the "APK" file and then click "INSTALL". The app begins installing on your device.
4. Look for the "Hedmoral Technologies" app in the Menu.

Now you can start testing the Mobile use cases described here using the IDSP app.

Using the Sample Mobile Application

This topic includes the following:

Using the Sample Mobile application

Follow these steps to use the Sample Mobile application:

1. Open the Installed Application.
2. Click the gear icon available on the bottom right corner.
   This opens the Application Configuration UI.
3. Enter the following inn the UI:
   `Endpoint Host Name, Client ID & Client Secret`
4. Save the Application Configuration.
   You are automatically navigated to the MainActivity where you must enter your Username to initiate the Authentication.

Flow Controller in Mobile Application

The following flow states take care of user factors registration and authentication based on a configured Authentication Policy.

PolicyController.java

State	Description
INIT0	Generates Access Token to invoke the "/authenticate" API. For this API Endpoint Host, Client ID & Client Secret is picked from Preferences which the user enters by launching the **ApplicationSettings** Activity.
INIT	Calls "/authenticate" API to evaluate.
FACTOR_SELECTION	Opens UI for Factor Selection where user can select (PASSWORD, EMAILOTP, SMSOTP, FIDO, etc) factors for authentication (**FactorSelectionActivity**)
FACTOR_SELECTED_BY_USER	Factor selected by the user
PASSWORD_AUTH	Opens UI for User to enter password (**LDAPPassword**)

LDAP_AUTHENTICATION	Initiates the LDAP Authentication
EMAIL_OTP_REGISTER	This activity opens only when the user does not have EMAIL configured and EMAIL_OTP Factor is not available yet. Opens UI for user to register EMAIL_OTP Factor (EMAIL_OTP_REGISTER).
EMAIL_OTP_REGISTER_2	Initiates the EMAIL_OTP Factor registration API
EMAIL_OTP_SELECTION	Multiple registered email addresses are shown as masked text, where the user can select one of them to receive EMAIL_OTP (**EMAILOTPSelection**)
EMAIL_OTP_GENERATE	Generates EMAIL_OTP and sends EMAIL_OTP to EMAIL
EMAIL_OTP_AUTH	Opens UI to enter EMAIL_OTP received by User (EMAIL_OTP Collection)
EMAIL_OTP_VERIFY	Initiates EMAIL_OTP Authentication
SMS_OTP_REGISTER	This activity opens only when the user does not have SMS configured and SMS_OTP Factor is not available yet. Opens UI for user to register SMS_OTP Factor (SMS_OTP_Register).
SMS_OTP_REGISTER_2	Initiates the SMS_OTP Factor registration API
SMS_OTP_SELECTION	Multiple registered mobile numbers are shown as masked text, where the user can select one of them to receive SMS_OTP (SMSOTPSelection).
SMS_OTP_GENERATE	Generates SMS_OTP and sends SMS_OTP as SMS
SMS_OTP_AUTH	Opens UI to enter SMS_OTP received by user (SMS_OTP Collection)
SMS_OTP_VERIFY	Initiates SMS_OTP Authentication
FIDO_REGISTER_GENERATE_CHALLENGE	Opens UI to enter Device Identifier in case the user does not have FIDO Factor available (**FIDODeviceNameCollection**).
FIDO_REGISTER_GENERATE_CHALLENGE_2	Initiates FIDO Registration SDK API which in turn initiates the Android OS FIDO Registration Activity.
FIDO_AUTH_GENERATE_CHALLENGE	Opens FIDO Authentication Waiting screen and initiates the Android OS FIDO Authentication (**FIDOAuthenticationActivity**).
AUTH_FAILURE	Indicates that User Authentication was not successful and then takes the user back to MainActivity or ProtectedActivity based on whether a user wants to perform authentication or reauthentication respectively.
AUTH_ALLOWED	Opens ProtectedActivity which is the User Protected Dashboard and stores the user ID Token in Preferences from where the user can try initiating the reauthentication flow by selecting any of the following action: 1. Investment Banking 2. Business Banking 3. Wealth Banking 4. Commercial Banking

Implementing Registration of Multiple FIDO Credentials

This topic describes how to handle the registration of multiple FIDO credentials in different devices in Symantec Identity Security Platform.

Use Case

If you already have a FIDO credential registered for a device (such as Chrome on Windows), and you attempt to register a new credential for a different device (such as an Android phone, an iOS phone, or a MAC), a credential registration error is returned by the authenticator.

For both, iOS and Android FIDO SDKs, the mobile SDK returns the error, **FAILURE_FIDO_CREDENTIAL_NOT_FOUND: 909**, and the web client /browser returns a generic error message, for example- Google Chrome returns, **"DOMException: The operation either timed out or was not allowed. See: https://www.w3.org/TR/webauthn-2/#sctn-privacy-considerations-client."**, when the FIDO credential that was passed to the authenticator (device/browser) is not present on the device. This error code signifies that the FIDO Authenticator was unable to locate the credential.

In this case, the client application can be designed to provide a choice to the user to register the new FIDO credential on the new device.

Follow this step to implement such a flow at the mobile/web application side:

When the error message is displayed, the client app should check for the **'isInlineEnrollmentAllowed'** attribute configuration that is set in the IDSP's ***".../factor/v1/FIDOAuthChallengeGenerator"*** server API response. This may result in the following:

- if the **"isInlineEnrollmentAllowed"**="**true**", the client application can render the option to register a new FIDO credential. Therefore, if the user decides to register a new credential, the client app must invoke the IDSP's ***".../auth/v1/SelectedFactor"*** server API with the following payload:

  ```
  { "action": "restorelastaction",  "registerFido" : true }
  ```

  This initiates the FIDO credential registration flow. This step is followed by next actions, where the client application must invoke IDSP's ***".../factor/v1/FIDORegChallengeGenerator"*** API and ***".../factor/v1/FIDORegChallengeVerifier"*** server APIs to register the new credential.
- if the **"isInlineEnrollmentAllowed"="false",** the client app cannot register a new FIDO credential and must display the proper option to proceed.

NOTE

- Every client type returns different error messages and codes.
- For more details about error messages from mobile SDK, refer to the FIDO SDK (iOS) Error Codes.

- Security Key and Biometric (FIDO) Authenticator.

Integrating Custom Web Applications with Symantec Identity Security Platform

This section describes the process of using Symantec Identity Security Platform to provide authentication for a custom web application, using the OpenID Connect protocol. It covers the required artifacts and sequence of calls between the application and IDSP in order to demonstrate the OpenID Connect flow.

The OpenID Connect (OIDC) protocol is a lightweight REST/JSON based identity protocol built on top of the OAuth 2.0 protocol. It is important to understand that OpenID Connect is mainly a user authentication mechanism enabling use of identity to be decoupled from the management of identity, while OAuth2 itself is a delegated authorization mechanism. Since user authentication is necessary to support the delegated authorization, the OAuth2 specification was overloaded to satisfy user authentication use cases. Using OpenID Connect is a modern and straightforward way for an application to delegate user authentication to a common authentication service that also doubles up as a lightweight identity profile service completing its OpenID Connect responsibilities.

NOTE
Access Tokens and Identity Tokens generated by flows mentioned in this document can be examined using the jwt debugger.

Overview

The application is expected to integrate with OpenID Connect using the OpenID Connect Authorization Code flow. Note that to perform the actual OpenID Connect flow, numerous libraries exist for different platforms/languages to assist developers with the uptake.

The Authorize endpoint is used to initiate OpenID Connect flow to authenticate the user identity and acquire Identity and Access tokens.

1. Application makes a browser call to IDSP's Authorize endpoint with the required parameters, specifying "openid" as one of the requested scopes (or as the only scope), and providing the "callback URL" for IDSP to invoke after the authentication flow completes. Presence of the "openid" scope instructs IDSP to begin the OpenID Connect flow.
2. IDSP authorizes application's request for requested scopes and begins the user authentication ceremony
3. IDSP redirects user's browser to the sign in page. This can be IDSP's built-in sign in page, or this can be the application's own custom login page. For this example we use the built-in sign in page
4. The sign in page orchestrates the user authentication ceremony to obtain from the user all the credentials required by applicable authentication policies in effect for the requesting application, specific user identity, and other contextual information.
5. Upon successful authentication, IDSP generates an authorization code and redirect user's browser to the callback URL specified in step 1, appending the code to the redirect URL.
6. Application makes a REST call to IDSP's Token endpoint with grant_type=authorization_code and Authorization Code value
7. IDSP authenticates application's client credentials, supplied authorization code, and returns a JSON document containing the JWT-based Identity Token and Access Token
8. Application uses IDSP's public signing certificate to validate, among other validations, the Identity Token containing claims about the authenticated identity. The exact validation flow is specified by the OpenID Connect specification.
9. If required, application makes a REST call to IDSP's Userinfo endpoint to request user profile data authorized by the Access Token.
10. This completes the OpenID Connect flow. The application now has the user's identity and profile information and can map the identity to, or create a profile for, local application identity.

Configuring IDSP

To get the OpenID Connect flow working, we use IDSP REST APIs to pre-create required artifacts to ensure the example works end to end. It is assumed these steps have not been done in the IDSP environment.

Step1: Generate access token to make REST API calls

1. Use the following command to get the default tenant client id and secret from IDSP's K8S cluster. Alternatively use the id/secret of the OpenID Connect capable client as provided to you. *Obtain Admin Client's ID and Secret*

```
kubectl get secret ${RELEASENAME}-ssp-secret-defaulttenantclient -n ${NAMESPACE} -o
 jsonpath="{.data.clientId}" | base64 --decode; echo
kubectl get secret ${RELEASENAME}-ssp-secret-defaulttenantclient -n ${NAMESPACE} -o
 jsonpath="{.data.clientSecret}" | base64 --decode; echo
```

2. Generate an access token by calling IDSP's Token endpoint using <clientId> and <clientSecret> from the previous step.
   Request payload

```
curl -k -u '<clientId>:<clientSecret>' \
   --request POST --url 'https://iam.example.com/default/oauth2/v1/token' \
   --header 'Content-Type: application/x-www-form-urlencoded' \
   --data-urlencode 'grant_type=client_credentials' \
          --data-urlencode 'scope=urn:iam:myscopes'
```

   Response payload

```
"access_token": "eyJ4NXQjUzI1NiI6ImNJbUNYN1........",
```

```
        "token_type": "Bearer",
        "expires_in": 3600
      }
```

Step 2 - Create LDAP ID Store Configuration for Sample ID Store

In the sample OpenID Connect flow, users being authenticated are expected to be located in an identity store. Invoke a IDSP REST API to create the ID Store configuration representing IDSP's Sample ID Store, replacing <AccessToken> with the value of the generated access token. Make sure to replace the hostName and PortNumber with your sample directory's FQDN host and port.

Create LDAP Configuration Request

```
curl -k --request POST --url 'https://iam.example.com/default/admin/v1/LDAPconfigs' \
   --header 'Content-Type: application/json' \
   --header 'Authorization: Bearer eyJ4NXQjUzI1NiI6ImNJbUNYN1........' \
   --data-raw '{
       "configName": "SampleIDStore",
       "configDescription": "SampleIDStore CA Dir",
       "sslEnabled": "no",
       "ldapQueryStart": "(&(cn=",
       "ldapQueryEnd": ")(objectClass=*))",
       "attributes":
 "employeeType,telephoneNumber,mail,displayName,givenName,name,company,cn,sn,memberof,title,l",
       "objectClasses": "inetorgperson",
       "hostName": "iam.example.com",
       "portNumber": "31888",
       "baseDN": "o=democorp,c=us",
       "groupBaseDN": "o=democorp,c=us",
       "groupObjectClasses": "groupOfNames",
       "groupSearchMappingAttribute": "member",
       "useMemberOf": "yes",
       "namingAttribute": "cn",
       "userDN": "cn=DominicMAJOR,ou=Administration,ou=Corporate,o=democorp,c=US",
       "bindPassword": "password",
       "attributeMapping": "status=employeeType, name=cn, family_name=sn, given_name=givenName,
 middle_name=givenName, nickname=displayName, preferred_username=displayName,
 profile=title,email=mail,phone_number=telephoneNumber, user_universalid=cn,memberof=memberof",
       "passwordResetURL": "http://userPasswordResetURL"
        }
```

Create LDAP Configuration Response

```
{
     "tenantId": "4764021a-9048-11ea-bb37-0242ac130002",
     "configName": "SampleIDStore",
     "configDescription": "SampleIDStore CA Dir",
     "sslEnabled": "no",
     "certificate": null,
     "certificateAlias": null,
     "ldapQueryStart": "(&(cn=",
     "ldapQueryEnd": ")(objectClass=*))",
     "attributes":
 "employeeType,telephoneNumber,mail,displayName,givenName,name,company,cn,sn,memberof,title,l",
     "objectClasses": "inetorgperson",
     "groupObjectClasses": "groupOfNames",
     "hostName": "iam.example.com",
```

```
    "portNumber": "31888",
    "baseDN": "o=democorp,c=us",
    "groupBaseDN": "o=democorp,c=us",
    "userDN": "cn=DominicMAJOR,ou=Administration,ou=Corporate,o=democorp,c=US",
    "bindPassword": "/OTqCj2yPWVvhl6AjpJ/DQ==",
    "attributeMapping": "status=employeeType, name=cn, family_name=sn, given_name=givenName,
 middle_name=givenName, nickname=displayName, preferred_username=displayName,
 profile=title,email=mail,phone_number=telephoneNumber, user_universalid=cn,memberof=memberof",
    "groupSearchMappingAttribute": "member",
    "useMemberOf": "yes",
    "namingAttribute": "cn",
    "passwordResetURL": "http://userPasswordResetURL",
    "createdDateTime": "2020-06-23 18:52 PM UTC",
    "updatedDateTime": "2020-06-23 18:52 PM UTC",
    "createdBy": {
      "principalType": "CLIENT",
      "principalId": "6f0f804b-38ec-4e91-aac9-f112ffc849ce",
      "principalName": "defaulttenantclient"
    },
    "ldapConfigId": "cdd13ae4-b9ab-4296-ae2f-4a17e7c2b7e5"
  }
```

Step 3 - Create Application Resource

This application requests OpenID Connect authentication for users residing in the sample id store. Invoke the IDSP REST API to create the Application Resource, replacing <AccessToken> in the Authorization header with the access token thats has beed generated in Step 1. Make sure to replace the hostName and PortNumber with your sample directory's FQDN host and port.

The response payload brings back the appId, clientId, and clientSecret for the newly created application.

- Make a note of the returned AppID as it will be used in the Authentication Policy to "secure the app" by Password-based authentication.
- Make a note of returned clientID and ClientSecret as these will be used to execute the OpenID Connect flow.

Create Application Request

```
curl -k --request POST --url 'https://iam.example.com/default/admin/v1/Apps' \
--header 'Content-Type: application/json' \
--header 'Authorization: Bearer eyJ4NXQjUzI1N........' \
--data-raw '{
"status": "active",
"name": "OIDC App",
"description": "App using OpenID Connect AZ Code flow",
"clientType": "CONFIDENTIAL",
"allowedOpenIDScopes": [
"openid",
"email",
"profile"
],
"redirectURIs": [
"https://www.example.com/azcode"
],
"allowedGrantTypes": [
"implicit",
"authorization_code"
```

```
],
"allowedOperations": [
"introspect",
"onbehalfof"
],
"skipIssuerAudienceForIT": false,
"userInfoEndpointResponseFormat": "PLAIN_JSON"
}'
```

Create Application Response

```
{
  "status": "active",
  "name": "oidc app",
  "description": "App using OpenID Connect AZ Code flow",
  "clientType": "CONFIDENTIAL",
  "allowedOpenIDScopes": [
    "openid",
    "profile",
    "email"
  ],
  "redirectURIs": [
    "https://www.example.com/azcode"
  ],
  "allowedGrantTypes": [
    "implicit",
    "authorization_code"
  ],
  "userInfoEndpointResponseFormat": "PLAIN_JSON",
  "skipIssuerAudienceForIT": false,
  "allowedOperations": [
    "introspect",
    "onbehalfof"
  ],
  "appId": "5211485d-4013-4136-9f4e-4abc4b928d81",
  "createdBy": {
    "principalType": "CLIENT",
    "principalId": "6f0f804b-38ec-4e91-aac9-f112ffc849ce",
    "principalName": "defaulttenantclient"
  },
  "createdDateTime": "2020-06-23 21:26 PM UTC",
  "updatedDateTime": "2020-06-23 21:26 PM UTC",
  "secret": "0989bcba-fba9-477b-9841-194b0f7147e4",
  "clientId": "a85a9a21-7d37-4afe-9c9c-ee19174fb66b"
}
```

Step 4 - Create Authentication Policy

Applicable authentication policies drives the specific credentials a user has to present in order to get authenticated.

Invoke the IDSP REST API to create the Authentication Policy, replacing <AccessToken> in the Authorization header with the access token generated in Step 1. Also, replace the "id" in the "apps" section with the "appId" of the Application Resource created in Step 3.

Create Authentication Policy Request

```
curl -k --request POST --url 'https://iam.example.com/default/admin/v1/AuthPolicies' \
```

```
--header 'Content-Type: application/json' \
--header 'Authorization: Bearer eyJ4NXQjUzI1NiI6I......' \
--data-raw '{
  "description": "Test Authentication Policy for OpenID Connect App",
  "status": "active",
  "policyName": "Test Authentication policy for OIDC",
  "apps": [
    {
      "id": "5211485d-4013-4136-9f4e-4abc4b928d81"
    }
  ],
  "rules": [
    {
      "conditions": {
        "principal": {
          "group": {
            "operator": "in",
            "value": [
              "Admin"
            ]
          },
          "user": {
            "operator": "in",
            "value": [
              "Malbail"
            ]
          }
        },
        "action": {
          "operator": "in",
          "value": [
            "authenticate"
          ]
        },
        "channel": {
          "operator": "in",
          "value": [
            "web"
          ]
        }
      },
      "result": {
        "effect": "allow",
        "obligations": [
          "PASSWORD"
        ],
        "msg": "This authentication policy is for signin via web channel"
      }
    }
  ]
}'
```

Create Authentication Policy Response

```
{
```

```
"policyId": "8306992b-54fe-44a3-9118-465eb5e0bc93",
"policyName": "Test Authentication policy for OIDC",
"description": "Test Authentication Policy for OpenID Connect App",
"status": "active",
"matchAnyApp": false,
"apps": [
  {
    "name": "OIDC App",
    "id": "5211485d-4013-4136-9f4e-4abc4b928d81"
  }
],
"rules": [
  {
    "conditions": {
      "principal": {
        "group": {
          "operator": "in",
          "value": [
            "Admin"
          ]
        },
        "user": {
          "operator": "in",
          "value": [
            "Malbail"
          ]
        }
      },
      "action": {
        "operator": "in",
        "value": [
          "authenticate"
        ]
      },
      "channel": {
        "operator": "in",
        "value": [
          "web"
        ]
      }
    },
    "result": {
      "effect": "allow",
      "reAuthenticate": "false",
      "obligations": [
        "PASSWORD"
      ],
      "msg": "This authentication policy is for signin via web channel"
    }
  }
],

  "principalType": "CLIENT",
```

```
    "principalId": "6f0f804b-38ec-4e91-aac9-f112ffc849ce",
    "principalName": "defaulttenantclient"
  },
  "createdDate": "2020-06-23 21:49:58"
}
```

Authenticating the User

Now that we have the setup completed, we can look at the details of the OpenID Connect flow. There are three main steps involved and the first is to send the user to the OpenID Connect Provider for authentication. This is done by redirecting the client browser to IDSP OpenID Connect's Authorize endpoint and passing parameters, as defined below. Note that this redirect can be accomplished in a number of different ways: the user can explicitly click a link on the app homepage to start the login flow, or the app could use an intercepting session filter to generate an automatic redirect when it detects that the browser does not have a valid application session.

The Authorize endpoint is used by IDSP to initiate the user authentication ceremony to assert the user identity. The main purpose of this endpoint is to support the Authorization Code flow. After that the client exchanges the Authorization Code for the Identity Token and Access Token by invoking the authorization's server Token endpoint.

Security Considerations for Public Clients

When public clients such as native and single-page applications request user authentication, there are additional security concerns related to the fact that such clients cannot securely hold a secret or indicate a trusted callback URL. Proof Key for Code Exchange (PKCE) as OAuth 2.0 RFC 7636 addresses this issue.

Adding PKCE parameters to the Authorization Code flow enables the client to introduce a secret (Code Verifier) that can be validated by the authorization server. The client creates and sends Code Challenge as part of the /authorize request to get the Authorization Code. When the client exchanges the Authorization Code for an Access Token, it includes the Code Verifier. This ensures that even if the attacker intercepts the /authorize request, they will not be able to exchange is for the access token without the Code Verifier.

OpenID Connect Parameters

The following table displays the OIDC parameters.

Parameter	Optionality	Description
client_id	Required	The Client ID for this application. This client id is used to lookup allowed grants and operations, and to have the Authorization Code.
response_type	Required	For Authorization Code flow, this must be specified as "code".
scope	Required	For OpenID Connect flow, add "openid" to request issuance of Identity Token. Indicate additional OpenID scopes (Client's Allowed OpenID Scopes such as *profile* or *email*) to authorize the client to invoke the Userinfo endpoint to request user data represented by those scopes.
redirect_uri	Required	This is the URL-encoded endpoint to which the client will be sent back once the Authorization Code has been issued by the authorization server. The Authorization Code is available in the *code* URL parameter. This URL must be specified exactly as provided in one of the values during client registration.

Parameter	Optionality	Description
state	Optional	This is an optional security parameter for the client to protect against certain attacks such as Cross-Site Request Forgery (CSRF, XSRF). Usually this value is generated by cryptographically binding to some browser state such as an application cookie to detect a possible request hijacking attempt. The value supplied by the client will be returned by the authorization server along with the Authorization Code.
nonce	Optional (OpenID only)	This is an optional security mechanism to protect against replay attacks. This should be a strong **random** value associated with the internal application session. For OpenID Connect flows, this value is included in the Identity Token.
code_challenge_method	Optional (For use with PKCE only)	Method used to generate the **PKCE** challenge The PKCE spec includes `S256` and `plain`. Use of *plain* is not recommended.
code_challenge	Optional (For use with PKCE only)	Generated challenge from the **PKCE** Code Verifier

Step 1 - Obtaining Authorization Code

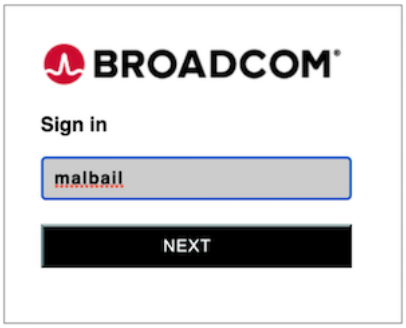
Application executes a browser request to generate an Authorization Code to be exchanged for OpenID Connect's Identity Token and Access Token in the next step. Here, the application uses its clientID that was established during creation of the Application Resource.

Create Authentication Policy Response

```
https://iam.example.com/default/oauth2/v1/authorize?response_type=code&client_id=a85a9a21-7d37-4afe-9c9c-
ee19174fb66b&redirect_uri=https://www.example.com/azcode&scope=openid%20email&state=mystate&nonce=mynonce
```

> **NOTE**
> *If PKCE was used, code_challenge would have been computed and added to the query string params: ...&code_challenge_method=S256&code_challenge=9f86d081884c7d659a2feaa0c55ad.....'*

User browser is redirected to the built-in signin page. We use user "malbail" expected to be a member of "admin" group as maintained in IDSP's sample id store.



After the authentication flow for user "malbail" completes, IDSP will redirect to client's redirect_uri with Authorization Code, and State if originally provided when invoking the Authorize endpoint.

```
https://www.myapp.com/azcode/?code=7riOHCJohHZK5Fs1C6jNHf3FuQdZWf&state=mystate&X-TRANSACTION-
ID=66d19fce-60fe-4ba7-a4a8-b48dfbf53814
```

Step 2 - Exchanging Authorization Code for Tokens

The client then exchanges the Authorization Code for Identity Token and Identity Token. Before the application does that, it should examine the received "state" parameter value redirect to make sure it matches the one specified in the previous steps when redirecting to the Authorize endpoint. Then, application extracts the received code parameter and passes it to IDSP through the REST API call to IDSP's Token endpoint. This back-channel call guards against the potential "man in the middle" threat that exists in browser redirects. Here, the application uses its clientID and clientSecret that was established during creation of the Application resource.

Token Request

```
curl -k --request POST --url 'https://iam.example.com/default/oauth2/v1/token' --header 'Content-
Type: application/x-www-form-urlencoded' -u "a85a9a21-7d37-4afe-9c9c-ee19174fb66b:0989bcba-
fba9-477b-9841-194b0f7147e4" --data-urlencode 'grant_type=authorization_code' --data-urlencode
 'code=7riOHCJohHZK5Fs1C6jNHf3FuQdZWf'
```

Token Response

```
{
  "access_token" : "eyJ4NXQjUzI1NiI6ImNJb......",
  "token_type" : "Bearer",
  "expires_in" : 3600,
  "id_token" : "eyJ4NXQjUzI1NiI6ImNJbUNYN1......"
}

    "https://iam.example.com/default/"
  ],
  "nbf": 1592949250
}
```

Step 3 - Validating Identity Token

Before the Identity Token can be used, it must be validated as per the OpenID Connect specification, validating the signature, expiration, and audience.

To support signature validation, your application needs to acquire IDSP's signing certificate from IDSP and pass that into the library you will be using to perform JWT validation. There are different ways of using such libraries, but almost every approach requires getting the signer's certificate. In IDSP, this can be done using the JWKS endpoint (curl -k https://iam.example.com/default/oauth2/v1/jwks). There are best practices for obtaining, caching, and using public keys to accommodate expected and unexpected server-side certificate rollovers. The actual validation of the Identity Token is beyond the scope of this document.

> **NOTE**
> If the "nonce" value was used, the application must validate that the nonce in the Identity Token matches the nonce passed into IDSP's Authorize flow.

Step 4 - Acquiring User Info

Finally, the application invokes IDSP's Userinfo endpoint to request information about the user, using the Access Token generated in the previous step.

> **NOTE**
> Another way to specify the access token is via form variable instead of the authorization header: --data-urlencode 'access_token=<token>'

The application can use this data to create a local user profile. It can also perform "just in time" creation of the user if so required.

UserInfo Request

```
curl -k --request GET \
--url 'https://iam.example.com/default/oauth2/v1/userinfo' \
--header 'Content-Type: application/x-www-form-urlencoded' \
--header 'Authorization: Bearer eyJ4NXQjUzI1NiI6ImNJbUNYN1.......'
```

Response below assumes the application has been configured to receive JSON from the Userinfo endpoint.

> **NOTE**
> *To see the email value get returned for user 'malbail', first update the sample id store's entry for 'malbail' with the email value.*

UserInfo Response

```
 {
   "aud":"6cb446b9-33bf-4b97-a6e1-e7ad389974d2",
   "sub":"5aee7c64-a5e1-4899-aad3-51e1f569c292",
   "iss":"https://iam.example.com/default/",
   "email":"mal.bail@DEMOCORP.com"
}
```

Troubleshooting API Errors

To identify log messages related to your application's API call processing, include the "X-CLIENT-TRANSACTION-ID" request header in your API calls. This header's value should be unique to your application and will appear in all log messages generated by the API calls. By using the same value in your application log messages, you can correlate them with the IDSP logs. See also Using Logs to Troubleshoot Operational Errors .

Working with ACR

Working with ACR

The Authentication Context Class Reference (ACR) is a parameter used during authentication to indicate the context in which the authentication takes place. During the creation of an authentication policy in Symantec Identity Security Platform, authentication policy rules can be associated with ACR values to trigger required authentication flows.

This topic includes the following sections:

Using ACR in Authentication Policy

The ACR parameter can be used as a condition in the Authentication policy. The parameter 'acr' is a list of strings, for example:

```
"acr": {
    "operator": "in",
    "value": ["urn:iam:acr:aal:aal2", "urn:iam:acr:aal:aal1"]
}
```

The policy containing the 'acr' rule condition only gets triggered when an incoming authentication request with 'acr' is sent by the client. The incoming 'acr' is then evaluated with the 'acr's' that are specified in the policy. If multiple 'acr's' are specified in the policy rule, then the first 'acr' from the list will be picked for evaluation, and if these values match, then the user is presented with the obligations that are defined in the authentication policy rule. The rest of the 'acr's" will not be evaluated, as a match was already found. However, during evaluation, if the first 'acr' did not match, then the next value in the list will be picked for evaluation. The evaluation process continues until an "acr" match is found.

If the policy evaluation results in a mismatch of 'acr' values, authentication is denied to the user.

Example of a rule containing "ACR" condition

```
{
  "policyName": "ACR Based Policy",
  "description": "Policy with rules based on the ACR condition",
  "status": "active",
  "apps": [
    {
      "id": "059bcbbc-c8b6-467d-85d0-6d15f5a5c0f7"
    }
  ],
  "rules": [
    {
      "conditions": {
        "principal": {
          "user": {
            "operator": "in",
            "value": [
              "user1",
              "user2"
            ]
          }
        },
        "action": {
          "operator": "in",
          "value": [
            "authenticate"
          ]
        },
        "channel": {
           "operator": "in",
           "value": [
                 "web"
           ]
        },
        "acr": {
          "operator": "in",
          "value": [
            "urn:iam:acr:aal:aal1"
          ]
        }
      },
      "result": {
        "effect": "allow",
        "obligations": [
          "PWD:1"
        ],
        "msg": "AAL1 level policy rule"
      }
    },
    {
      "conditions": {
        "principal": {
          "group": {
```

```
          "operator": "in",
          "value": [
            "Administrators"
          ]
        }
      },
      "action": {
        "operator": "in",
        "value": [
          "authenticate"
        ]
      },
      "acr": {
        "operator": "in",
        "value": [
          "urn:iam:acr:aal:aal1"
        ]
      }
    },
    "result": {
      "effect": "allow",
      "obligations": [
        "PWD:1", "FIDO:2"
      ],
      "msg": "AAL1 level policy rule with an administrator user."
    }
  },
  {
    "conditions": {
      "principal": {
        "user": {
          "operator": "in",
          "value": [
            "user1",
            "user2"
          ]
        }
      },
      "action": {
        "operator": "in",
        "value": [
          "authenticate"
        ]
      },
      "acr": {
        "operator": "in",
        "value": [
          "urn:iam:acr:aal:aal3"
        ]
      }
    },
    "result": {
      "effect": "allow",
```

```
        "obligations": [
          "PWD:1", "FIDO:2"
        ],
        "msg": "AAL3 level policy rule"
      }
    }
  ]
}
```

NOTE
To define multiple conditions in an ACR policy, ensure that all those conditions such as 'action' or 'channel' are included in the ACR rule.

When ACR is introduced in a policy, the key-value pair must be passed in the "/authenticate" and "/authorize" calls.

Indicating desired ACR in the '/authentication' call

The 'acrValues' value should be passed in the POST /authenticate call. You can pass multiple 'acrValues' .

This is a sample 'acr' request payload for a /authenticate call:

```
{
  "subject": "malbail",
  "ipaddress": "172.##.#.##",
  "action": "authenticate",
  "acrValues": ["urn:iam:acr:aal:aal2", "urn:iam:acr:aal:aal1"]
}
```

NOTE
When you must add multiple 'acrValues', specify the list of strings in the /authenticate call.

Indicating desired ACR in the OIDC '/authorize' call

The 'acr_values' must be passed along with other query parameters, in the GET /authorize call.

This is a sample 'acr' request payload for an /authorize call:

```
https://test.example.net/default/oauth2/v1/authorize?scope=openid&
                                                client_id=322b2331-e336-46eb-885a-4beaa78784a7&
                                                response_type=id_token token&
                                                redirect_uri=https://www.example.com&
                                                acr_values=urn:iam:acr:aal:aal2 urn:iam:acr:aal:aal1
```

NOTE
If you must specify multiple 'acr values,' the /authorize call only accepts space-separated values.

Results in the ID Token

Once the authentication is successful and you have generated the ID token, the specific "acr" value used during authentication will be contained in the ID token. However, if you did not specify any "acr" values during authentication, then the "acr" value in the ID token will be one of the following based on the authentication factor performed by the user:

- urn:iam:acr:aal3 (If you validated using FIDO or SECURITYKEY as one of the factors)
- urn:iam:acr:aal2 (If you validated using PUSH or OTP as one of the factors)
- urn:iam:acr:aal1 otherwise

Custom Web App with Identity Token Hint

Configure Symantec Identity Security Platform to delegate authentication to a custom web application using a custom flow URL.

IDSP supports different user Multi-factor Authentication (MFA) mechanisms. You can use the MFA mechanisms that are provided by IDSP or if you have your own ways to perform MFA, IDSP can delegate authentication to your configured custom web app using OIDC protocol. If you intend to use your own custom web app to perform authentication, you must design your own authentication policy. IDSP policies will not be applicable to determine the authentication factors.

Follow these steps to integrate your custom web app with IDSP to use its Open ID Connect capabilities:

1. Configure the Application:
   a. Use this API to configure your application:
      `https://${SSP_FQDN}/{{tenantName}}/admin/v1/App`

      NOTE

      - To know the value of ${SSP_FQDN} environment variable, see Configuring IDSP Environment Variables.
      - The default value for `<tenantName>` is "default".
      - Replace the text {{text}} including {{}} characters with appropriate values, in all the endpoints shown in the above table.
        For example:
        `https://{{host}}/{{tenantName}}/admin/v1/App`
        should look similar to:
        `https://example.com/default/admin/v1/App`
      - To know more about the scopes that are required to secure these APIs, refer to the Rest APIs and Associated Privileges section.

   b. Set the "flowURL": The flowURL is your custom web app sign-in URL.
   c. Set the following application parameters:
      - "delegatedAuthentication":"true"- This property specifies whether the configured flow URL application is built with IDSP APIs or not. The default value is false.
      - "autoPostToFlowURL":"true"- This property specifies whether the data should be redirected or posted into the flowURL. The default value is false.

        NOTE
        Configuring this parameter is optional as it depends on whether the custom sign-in URL accepts a POST or a GET request.

      The relevant configuration settings are covered in Application.
2. Configure CORS Origin:
   a. Configure the AllowedOrigins of your custom web app, using the `PATCH "/admin/v1/Configs"` API. See Settings page to know about allowedOrigins setting and see Applications to check the steps to update allowedOrigins setting.
3. Import Certificate:
   a. Add the public certification for the JWT signature verification. The JWT is obtained by IDSP following a successful user authentication at the third party. See Managing Certs for more info on adding certificates.

Integration Between IDSP and Custom Web App

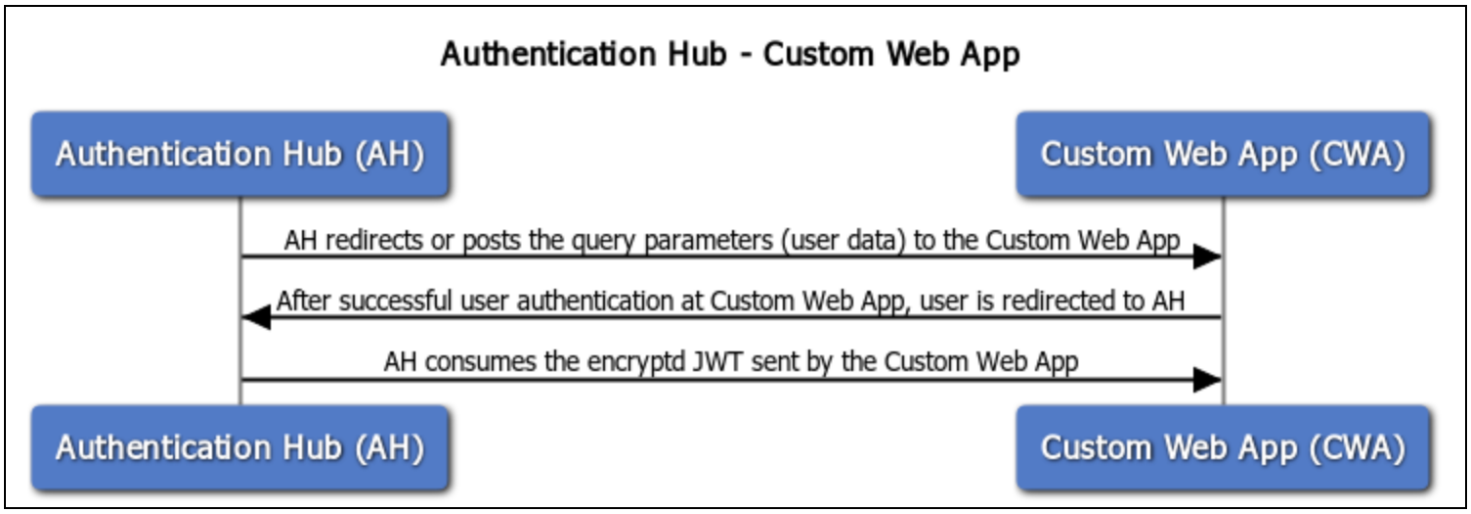
When the Custom Web App interacts with the IDSP to use the open ID connect feature of IDSP, information is exchanged between the two entities. IDSP sends.

The following use case describes the integration between Custom SMS Provider and IDSP.

List of participants and what they represent:

- IDSP- This is the solution which delegates authentication to the third party.
- Custom web App- This is the third party where the authentication takes place.

Figure 18: Custom Web App with ID Token Hint



Flow Description:

1. IDSP redirects or posts the query parameters (user data) to the Custom Web App endpoint.

   NOTE
   IDSP generates a new 'x-flow-state' and 'id_token_hint' (optional). ID Token Hint is generated only when IDSP receives request for a partial delegation from the relying party. ID Token Hint is signed by the private key of IDSP.
2. After user authentication, the user is redirected to IDSP.

   NOTE
   A custom Web App displays the required SignIn actions in the UI. After successful user authentication, the Custom Web App generates required information in the JWT, encrypts it with the public key of IDSP.
3. IDSP consumes the encrypted JWT sent by the Custom Web App.

   NOTE
   At the backend, the encrypted JWT is decrypted using the private key of IDSP. The JWT information is retrieved, flow state details are updated in the cache, and it is used as needed.

   Following successful authentication, the flow of obtaining tokens can be accomplished by invoking the token endpoints and user information endpoints. See Authorization Server Endpoints.

Data sent to the Custom Web App

IDSP sends the following query parameters to the Custom Web Application in the form of an ID token:

Parameter Name	Value	Mandatory Fields
x-flow-state		Yes
x-service-baseurl	<IDSP Issuer URL>	Yes
x-callback-url	<IDSP Issuer URL>**/oauth2/v1/authcomplete**	Yes
id_token_hint		Optional. Only if received from the relying party.

X-CLIENT-TRANSACTION-ID		Optional. Only if received from the relying party.
x-app-id	IDSP application Id	Yes
ui_locales	UI Locale information that is received from the relying party.	Optional. Only if received from the relying party.
signinExpMins	The number of minutes before the active sign-in flow expires.	Optional.

Data sent to the IDSP

The Custom Web Application sends the following parameters to the IDSP using the POST /oauth2/vi/authcomplete API:

Parameter Name	Value	Mandatory Fields
x-flow-state	Received from IDSP	Yes
userContext	Encrypted JWT	Yes
X-CLIENT-TRANSACTION-ID	Received from IDSP	Optional. Only if received from the relying party.

User Context Claims sent to IDSP

IDSP expects the following userContext claims in the JWT sent by the Custom Web App:

Claim Name	Claim Description	Data Type	Full Delegation Mandatory/ Optional	Partial Delegation
user_loginid	User login identifier	String	Yes	**Not available in VIPLogin**
user_loginidattrmappingname	User attribute name in the user store that is mapped to the user login id.	String	Yes	
user_universalid	User universal id mapped in the store	String	Yes	
user_riskscore	The user risk score, if any	Number	Optional	
user_dn	User DN	String	Yes	
amr	Authentication methods used for the user authentication Standard AMR	Array	Yes	Yes
sid	User Session id, if any	String	Optional	Yes
email	User Email	String	Yes	
phone_number	User Phone Number	String	Yes	
auth_time	The time at which the user authentication is complete.	Epoch Time	Yes	Yes
idp_name	User Store Name	String	Yes	
idp_guid	User Store GUID	String	Yes	
idp_type	User Store Type	String	Yes	
x-flow-state	x-flow-state received for the check	String	Yes	Yes

Standard attributes exp, nbf, iss, azp, etc.			Yes	Yes
error	Error code as per OIDC spec		Yes, if there is a failure scenario.	Yes, if there is a failure scenario.
error_description	Error Message		Yes, if there is a failure scenario.	Yes, if there is a failure scenario.

Integrating with Custom Service Provider Interface (SPI)

Overview of authentication delegation using custom flow URLs in Symantec Identity Security Platform.

By delegating authentication to an external web app, you can implement bespoke identity verification steps while maintaining Symantec Identity Security Platform as the primary orchestrator.

This topic includes the following:

- Custom Provider Support
- Custom Provider SPI
- Steps to Integrate SPI
- Open API Spec
- Custom Provider APIs
- Examples of Custom Provider APIs
- List of attributes and their descriptions used in the Custom Provider API request
- Security Method Types
- Custom Provider API Error Codes
- Sharing IDSP context with SPI

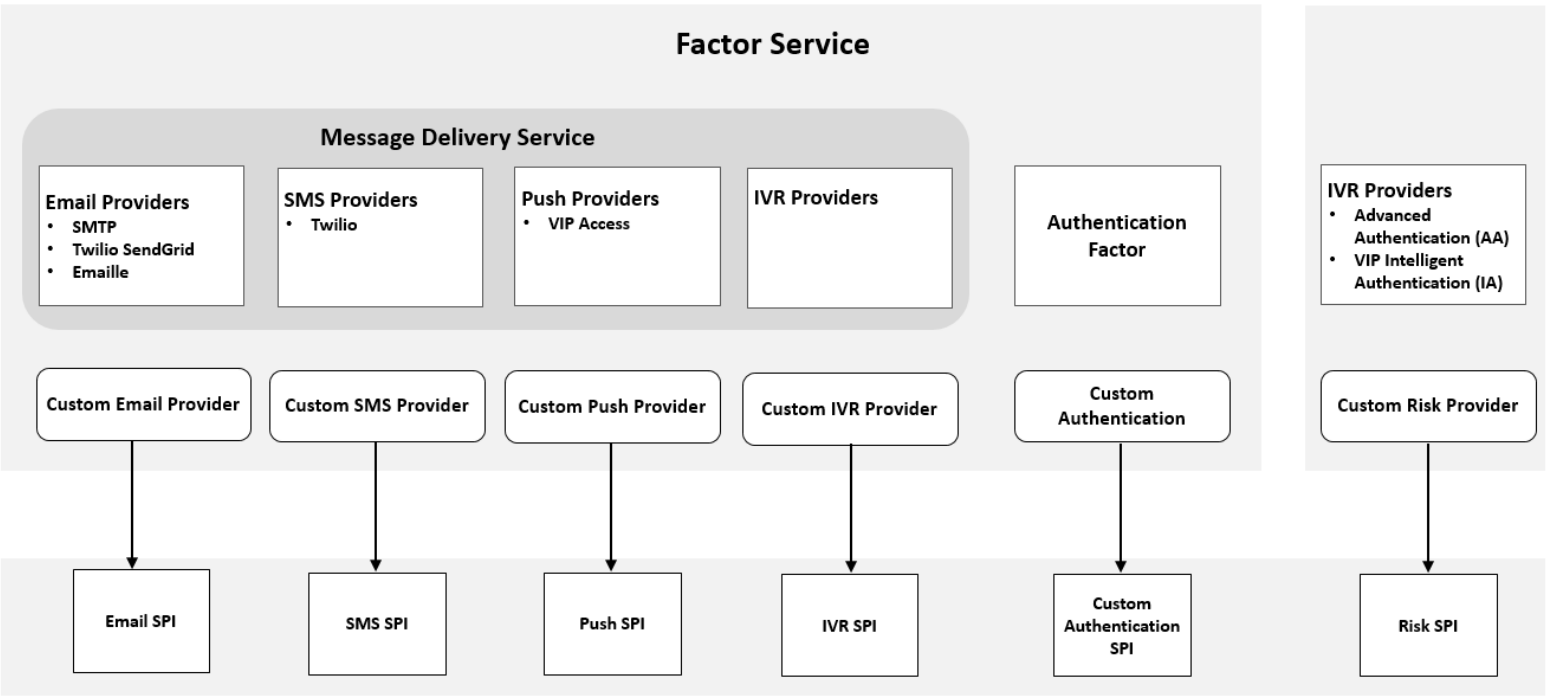
Custom Provider Support

Symantec Identity Security Platform extends Custom Provider support using Service Provider Interface (SPI) to its customers. This feature can be used by the customers to leverage their existing investment in message delivery infrastructure and risk engines with our solution. The Custom SPI support is extended to message delivery channels that include SMS, EMAIL, PUSH, and IVR.

IDSP exposes an SPI for each of the supported custom operations in the solution. The SPI uses an Open API spec and expects the customers to implement it as a separate web service that runs in their environment. The customer should implement the APIs that are defined by the solution for each service to enable the solution's custom SPI to communicate with the customer's service provider.

Custom Provider Support Using SPI for all supported services

The solution exposes a separate Service Provider Interface for each operation. Each interface can be implemented, deployed, and configured with the solution separately as shown in the following diagram:



Each message delivery service and the risk service has its own SPI that is exposed to the customer by the IDSP. Using this Open API specification, the customers can implement their custom provider as a REST service in their own environment.

Steps to Integrate with Custom SPI

The three steps that the Customers have to perform to integrate with the SPI are:

1. Develop their custom service based on the Open API Spec provided by IDSP.
2. Create a custom provider in IDSP using the Provider endpoint- https://<SSP_FQDN>/<tenantName>/admin/v1/CustomProviders
3. Specify the configuration settings in IDSP.

Common Open API Spec for all Custom Providers (Yaml File)

Click IDSP SPI Spec to view the consolidated Open API specification YAML file for Custom SPI.

Custom Provider APIs

The following table lists the Custom Provider endpoint URLs that are available for the admin to invoke and perform CRUD (create, retrieve, update, and delete) operations on all the custom providers that are added to the solution. These operations can be performed by both, Tenant and System admins.

For sample request and response payloads of all these URLs, refer to Custom Provider Swagger content.

Operation Description	Operation Type	Endpoint URLs
Creating a new Custom Provider	POST	https://${SSP_FQDN}/<tenantName>/admin/v1/CustomProviders
Retrieving Custom Provider based on Provider Id	GET	https://${SSP_FQDN}/<tenantName>/admin/v1/CustomProviders/<providerId>

Updating Custom Providers based on Provider Id	PUT	https://${SSP_FQDN}/<tenantName>/admin/v1/CustomProviders/<providerId>
Retrieving all Custom Providers	GET	https://${SSP_FQDN}/<tenantName>/admin/v1/CustomProviders
Deleting a specific Custom Provider based on Provider Id	DELETE	https://${SSP_FQDN}/<tenantName>/admin/v1/CustomProviders/<providerId> To forcefully delete a custom provider, including those currently in use, see Resource Deletion in IDSP.

NOTE

- To know the value of ${SSP_FQDN} environment variable, see Configuring IDSP Environment Variables.
- The default value for `<tenantName>` is "default".
- Replace the text {{text}} including {{}} characters with appropriate values, in all the endpoints shown in the above table.
  For example:
  `https://{{host}}/{{tenantName}}/admin/v1/CustomProviders`
  should look similar to:
  `https://example.com/default/admin/v1/CustomProviders`
- To know more about the scopes that are required to secure these APIs, refer to the Rest APIs and Associated Privileges section.

Samples of POST and PUT call for Custom Providers

Sample of Custom Provider POST call with "securityMethod" as apikey

The following is a sample that shows the request payload of Custom Provider POST call with **securityMethod-apiKey**.

```
{
"providerName": "customRiskProvider",
"version": "1.0",
"apiKey": "6fd06fd82aceb78b0bbbe3990b865f96ea",
"url": "https://localhost:8091",
"securityMethod": "apikey",
"certAlias": "<certificateAlias>",
"ignoreSSLValidation": false,
"providerHeaders": [
   {
       "name": "clientId",
       "value": "8289-b1e8817a3fec"
   }
],
"providerProperties": [
   {
       "name": "app",
       "value": "test"
   },
   {
       "name": "region",
       "value": "us-west"
   }
]
}
```

The value in the "providerHeaders" and "providerProperties" attributes of the Custom Providers config can contain dynamic environment variables. When used, these variables are substituted with their corresponding value in runtime. See Dynamic Environment Variable Substitution.

Sample of Custom Provider POST call with "securityMethod" as basic

The following is a sample that shows the request payload of Custom Provider POST call with **securityMethod-basic**.

```
{
"providerName": "customRiskProvider",
"version": "1.0",
"clientId": "<clientId>",
"clientSecretAlias": "<clientSecretAlias>",
"url": "https://localhost:8091",
"securityMethod": "basic",
"certAlias": "<certificateAlias>",
"ignoreSSLValidation": false,

"providerHeaders": [
   {
       "name": "clientId",
       "value": "8289-b1e8817a3fec"
   }
],
"providerProperties": [
   {
       "name": "app",
       "value": "test"
   },
   {
       "name": "region",
       "value": "us-west"
   }
]
}
```

NOTE
In the case of "securityMethod" as “basic”, the userid is passed through the clientId, and the password is passed through the clientSecretAlias.

Sample of Custom Provider POST call with "securityMethod" as oauth

The following is a sample that shows the request payload of Custom Provider POST call with **securityMethod-oauth**.

```
{
"providerName": "customRiskProvider",
"version": "1.0",
"url": "https://localhost:8091",
"certAlias": "<certificateAlias>",
"ignoreSSLValidation": false,
"clientId": "clientId",
"clientSecretAlias": "clientSecretAlias",
"oauthScopes": "scopes",
"securityMethod": "oauth",
"sslMode": "VERIFY_CA",
"oauthTokenUrl": "http://<hostname>/<tenantName>/oauth2/v1/token",
"oauthTokenIgnoreSslValidation": true,
```

```
"providerHeaders": [
   {
       "name": "clientId",
       "value": "8289-b1e8817a3fec"
   }
],
"providerProperties": [
   {
       "name": "app",
       "value": "test"
   },
   {
       "name": "region",
       "value": "us-west"
   }
],
"oauthResourceInAzRequest": "none",
"oauthTokenCertificateAlias": "",
"oauthTokenRequestCtxBase64": "",
"oauthTokenSslMode": "VERIFY_CA",
"oauthTokenReadTimeoutMillis": "10000",
"oauthTokenConnectTimeoutMillis": "10000",
"skewTimeSecs": "0"
}
```

Sample of Custom Provider POST call with "securityMethod" as oauthassertion

The following is a sample that shows the request payload of Custom Provider POST call with **securityMethod-oauthassertion**.

```
{
"providerName": "customRiskProvider",
"version": "1.0",
"url": "https://localhost:8091",
"certAlias": "<certificateAlias>",
"ignoreSSLValidation": false,
"skipUserStrikeCountIncrement": false,
"clientId": "<clientId>",
"clientSecretAlias": "<clientSecretAlias>",
"oauthScopes": "<scopes>",
"sslMode": "VERIFY_CA",
"securityMethod": "oauthassertion",
"oauthTokenUrl": "http://<hostname>/<tenantName>/oauth2/v1/token",
"oauthAssertionAud": "http://<hostname>/<tenantName>/",
"oauthResourceInAzRequest": "none",
"oauthTokenIgnoreSslValidation": true,
"oauthAssertionKidType": "x5t",
"providerHeaders": [
   {
       "name": "clientId",
       "value": "8289-b1e8817a3fec"
   }
],
"providerProperties": [
   {
```

```
        "name": "app",
        "value": "test"
    },
    {
        "name": "region",
        "value": "us-west"
    }
],
"oauthTokenCertificateAlias": "",
"oauthTokenRequestCtxBase64": "",
"oauthTokenSslMode": "VERIFY_CA",
"oauthTokenReadTimeoutMillis": "10000",
"oauthTokenConnectTimeoutMillis": "10000",
"skewTimeSecs": "0"
}
```

List of attributes and their descriptions used in the Custom Provider API request

Table 82: Custom Provider attributes and their descriptions

Attribute Name	Mandatory Fields	Description
providerName	Yes	Specify the name of the custom provider to be used.
version	Yes	Specify if any particular version of the provider must be picked.
apiKey	No	This is a unique passphrase or key that is used by Custom Provid identify the calling application. The value of the "securityMethod" for this model is - "securityMethod":"apikey" In the case of the "securityMethod" property as "apikey", the IDSP checks for the value of the "apiKey" property. If the property value empty, then the apiKey value should be added using the Secrets (/admin/v1/Secrets/) and the name of the created secret should b provided in the clientSecretAlias parameter.
url	Yes	The location where the provider is hosted.
certAlias	No	This is the name of the certificate alias pointing to IDSP's certifica The certificate should be added using the https://<SSP_F <tenantName>/admin/v1/Certs API. This attribute should be provided if "ignoreSSLValidation" is set to
sslMode	No	This indicates whether SSL validation should be performed or ign the "sslMode" is enabled, it should validate the server's identity. Possible Values are - "VERIFY_CA", "VERIFY_IDENTITY". If the "sslMode" is not indicated, it defaults to ""VERIFY_CA".
ignoreSSLValidation	No	This boolean indicates if the SSL validation is to be ignored or no The default is set to "false".

spiReadTimeoutMillis	No	This is the value of time in milliseconds that will be used on waitin read data. However, the value of spiReadTimeoutMillis property will be contr the configuration set at the ingress controller when the value of "c timeout" set in the ingress is less than the value of "spiReadTime set in the SPI. For example: If the "spiReadTimeoutMillis" is set to 120000 millis (2mins) in the SPI configuration and the read-timeout is set to 60 in the ingress controller, then the ingress controller timeout takes precedence over the spiReadTimeoutMillis value. The default value is 60000 and it allows a value greater than 0.
spiConnectTimeoutMillis	No	This is the value of time in milliseconds that will be used in makin initial connection. However, the value of spiConnectTimeoutMillis will be controlled by the configuration set at the ingress controller the value of "connect-timeout" set in the ingress is less than the v "spiConnectTimeoutMillis" set in the SPI. For example: If the "spiConnectTimeoutMillis" is set to 120000 milliseconds (2 mins) in the SPI configuration and the connect-tim is set to 60 seconds in the ingress controller, then the ingress con timeout takes precedence over the spiConnectTimeoutMillis value The default value is 60000.
providerHeaders	No	These are key-value pairs set as part of the header while invoking endpoint. Whenever the securityMethod="apikey", the header value passed the **providerHeaders** is considered. However, in the case of the 3 security methods (basic, OAuth, oauthassertion) the value of th **requestCtxBase64** is considered and the value of the providerHe ignored.
providerProperties		These are key-value pairs that contain additional information that required by the provider to perform its functions. This needs to be while invoking the SPI endpoint.
clientId	No	Client Id is used to connect to the SPI host. This is mandatory, if "*securityMethod*" is "OAuth" or "oauthassertion" or "basic". • For securityMethod="basic" - clientId corresponds to the User • For securityMethod="OAuth" or "oauthassertion" - clientId corresponds to the Oauth2 clientId

clientSecretAlias	No	Alias to a secret of the type as required by "*securityMethod*" prop The secret is expected to contain client authentication details req connect to the SPI - apiKey, basic, OAuth, oauthassertion. • In the case of the "securityMethod" property as "apikey", the I checks for the value of the "apiKey" property. If the property v empty, then the apiKey value should be added using the Secr (/admin/v1/Secrets/) and the name of the created secret shou provided in the clientSecretAlias parameter. See Managing Se • In the case of the "securityMethod" property as "basic", the pa should be added using the Secrets API (/admin/v1/Secrets/) a name of the created secret should be provided in the clientSe parameter. • In the case of "securityMethod" property as "OAuth", the clien should be added using the Secrets API(/admin/v1/Secrets/) a name of the created secret should be provided in the clientSe parameter. • In the case of "securityMethod" property as "oauthassertion", secret of type RSAKEY must be created containing the RSA private key to sign the assertion using the keys API(/admin/v1 Keys/) and the name of the created RSAKEY should be provi the clientSecretAlias parameter. • In the case of "securityMethod" as "oauthassertion", the "clientSecretAlias" property is required when "oauthAssertionKidType" is "secret" or "skid". Refer to the "oauthAssertionKidType" property mentioned in this table for on when "clientSecretAlias" is required.
requestCtxBase64	No	This is a 64 Bit encoded string of the Context map in key-value pa used to execute when invoking SPI endpoints - such as sending s headers. This parameter can be used as a substitute property for providerH
oauthScopes	No	Space delimited, optional OAuth scopes to request the access tol
securityMethod	Yes	Type of security method to be used to connect. Values are "basic "OAuth", "oauthassertion", and "apikey". The default value is "apil For more information about the securityMethods and its associate mandatory properties that are required while creating a Custom P see securityMethod Required Properties.
oauthTokenUrl	No	URL for the Token generation. This is mandatory if "*securityMeth* "OAuth" or "oauthassertion".

oauthResourceInAzRequestCsv	No	Represents the RFC8707 resource indicator for OAuth STS requ comma-separated values (csv) format. These are the request par that enable a client to explicitly signal to an authorization server a the identity of the protected resource(s) to which it is requesting a based on oauthResourceInAzRequest parameter value. Whenev oauthResourceInAzRequest is configured as "all", the values are in the csv format as given in the example. Possible values are "none", "all" and "base".
oauthResourceInAzRequest	No	Represents whether to add RFC8707 resource indicator for OAut request. When oauthResourceInAzRequest is configured as "all", resource values given in oauthResourceInAzRequestCsv are pas during the OAuth STS request. Possible values are "none", "all" and "base"
oauthAssertionKidType	No	Used when the "securityMethod" is set to "oauthassertion". It indi how to establish the kid of the signed assertion. Possible Values: skid, x5t, secret If "oauthAssertionKidType" is "secret", then the "kid" value of the assertion is populated from the "kid" value of the rsakey secret id by “clientSecretAlias". If "oauthAssertionKidType" is "skid", then the "kid" value of the as is populated from the "skid" value of the certificate stored in the rs secret identified by clientSecretAlias. If clientSecretAlias is not pr the signing key of the tenant is used. If "oauthAssertionKidType" is "x5t", then the "kid" value of the ass populated from the x5t value of the certificate stored in the rsakey identified by clientSecretAlias. If clientSecretAlias is not provided, signing key of the tenant is used.
oauthAssertionAud		When using "*securityMethod*" as "oauthassertion", this attribute in the audience to inject into the assertion. If this attribute is not spe the value of the oauthTokenUrl will be injected.
oauthTokenIgnoreSslValidation	Yes	This attribute indicates if the SSL validation should be ignored or default is set to "false".
oauthTokenSslMode	No	This attribute indicates if the SSL validation should be enabled. Possible Values are - "VERIFY_CA", "VERIFY_IDENTITY". If the "sslMode" is not indicated, it defaults to "VERIFY_CA".
oauthTokenCertificateAlias	No	This is the name of the certificate alias pointing to IDSP's "/Certs" This attribute should be provided if "ignoreSSLValidation" is set to false. The certificate or certificate chain pointed to by the alias sh added using the "/Certs" API.
oauthTokenRequestCtxBase64	No	This is a base64 encoded string of the Context map in key-value
oauthTokenReadTimeoutMillis	No	This is the value of time in milliseconds that will be used on waitin read the data.
oauthTokenConnectTimeoutMillis	No	This is the value of time in milliseconds that will be used in makin initial connection.

skewTimeSecs	No	When using securityMethod="oauthassertion", this property is hel cases when the target STS has no capability to adjust time comp for skew time. In that case, an integer "skewTimeSecs" (could be or negative) is used to offset the "exp" and "nbf" claims. In case o securityMethod as "oauthassertion", the clientassertion expiry = 6 1000 miliseconds (10 mins) + skewTimeSecs x1000 miliseconds. Here,10 minutes is the constant value.
skipUserStrikeCountIncrement	No	This boolean setting determines whether the strikeCount update s be skipped during a custom authentication failure for the user. If s true, a failed login attempt does not increase the strikeCount in th record, which means the user does not get closer to being locked The default is set to "false".

Sample Response of a Custom Provider POST Call

The following sample shows the **response of a Custom Provider POST call**. The response returns a ***providerId*** that must be used in the subsequent API calls to perform GET/PUT or DELETE operations.

```
{
"providerName": "customRiskProvider",
"version": "1.0",
"apiKey": "gJuDj15N8iLeQa08kuX20gD0nID4jsXo/XEDdCyjieHBLd+R7SE+ZpPgwBXl1CWw",
"certAlias": "",
"url": "http://localhost:8091",
"providerHeaders": [
   {
       "name": "clientId",
       "value": "8289-b1e8817a3fec"
   }
],
"providerProperties": [
   {
       "name": "app",
       "value": "test"
   },
   {
       "name": "region",
       "value": "us-west"
   }
],
"updatedBy": {
   "principalType": "CLIENT",
   "principalId": "1fc0e655-b5a1-4cb5-9251-5828d9769029",
   "principalName": "defaulttenantclient"
},
"updatedDateTime": "2021-12-01 05:46 AM UTC",
"origin": "tenant",
"ignoreSSLValidation": true,
"providerId": "8b59cf35-61db-45fc-8744-6eef9f02876b",
"sslMode": "VERIFY_CA",
"requestCtxBase64": "",
"clientId": "c801e8ee-b581-4365-aa1a-9c61a8bc7012",
"clientSecretAlias": "samplealias",
```

```
"oauthScopes": "test",
"securityMethod": "apiKey",
"oauthTokenUrl": "http://oauth:8091",
"oauthResourceInAzRequest": "none",
"oauthAssertionKidType": "",
"oauthAssertionAud": "",
"oauthTokenIgnoreSslValidation": true,
"oauthTokenSslMode": "VERIFY_CA",
"oauthTokenCertificateAlias": "",
"oauthTokenRequestCtxBase64": "d06fd82a90b865f96eadfdsf",
"oauthTokenReadTimeoutMillis": "10000",
"oauthTokenConnectTimeoutMillis": "10000",
"skewTimeSecs": "10"
 }
```

Sample request of a Custom Provider PUT call

The following sample shows the **request of a Custom Provider PUT call**:

```
{
"version": "1.0",
"apiKey": "6fd06fd82aceb78b0bbbe3990b865f96ea",
"url": "https://localhost:8091",
"securityMethod": "apikey",
"certAlias": "<certificateAlias>",
"ignoreSSLValidation": false,

"providerHeaders": [
   {
       "name": "clientId",
       "value": "8289-b1e8817a3fec"
   }
],
"providerProperties": [
   {
       "name": "app",
       "value": "test"
   },
   {
       "name": "region",
       "value": "us-west"
   }
]
}
```

Sample response of a Custom Provider PUT call

The following sample shows the **response of a Custom Provider PUT call**:

```
{
   "providerName": "customRiskProvider",
   "version": "1.0",
   "apiKey": "9nlsomQ4CZkz4jOOHT/3cQ==",
   "certAlias": "spiip",
   "url": "https://localhost:8094/",
```

```
    "providerHeaders": [
        {
            "name": "clientId",
            "value": "8289-b1e8817a3fec"
        }
    ],
    "providerProperties": [
        {

```

securityMethod Types and Associated Mandatory Properties

The following table lists the securityMethods and their associated mandatory properties that are required while creating a Custom Provider:

Table 83: securityMethod Types and its Associated Mandatory Properties

securityMethod Type	Required Properties for the securityMethod Type	Notes
apikey	apikey or clientSecretAlias	The apiKey value must be added using the Secrets API (/admin/v1/Secrets/) and the name of the created secret must be provided in the clientSecretAlias property. See Managing Secrets.
basic	clientId (username), clientSecretAlias (Password)	The password must be added using the Secrets API(/admin/v1/Secrets/) and the name of the created secret must be provided in the clientSecretAlias property.
OAuth	clientId (clientId), clientSecretAlias (secret), oauthTokenUrl, oauthScopes	The client secret must be added using the Secrets API(/admin/v1/Secrets/) and the name of the created secret must be provided in the clientSecretAlias property. The header key-value pair that is associated with the OAuth TokenServer can be passed through the oauthTokenRequestCtxBase64 property.
oauthassertion	clientId (clientId), clientSecretAlias (key), oauthTokenUrl, oauthScopes, oauthAssertionAud, oauthAssertionKidType(secret)	In the case of oauthAssertionKidType as secret, the signature details must be added using the keys API(/admin/v1/Keys/) and the name of the created key must be provided in the clientSecretAlias parameter. The clientSecretAlias property is required when oauthAssertionKidType is secret or skid. The header key-value pair that is associated with the OAuth TokenServer can be passed through the oauthTokenRequestCtxBase64 property.

Custom Provider API Error Codes

The following table lists the error codes that the Custom Provider API returns:

Table 84: Error Codes for Custom Provider API

Error Codes	Error Messages
8800049	Invalid configuration ({0})
8800050	Length of parameter ({0}) more than expected
8800051	Invalid configuration - missing required configuration parameter(s) ({0})
8800052	Provided certificate Alias is not valid
8800053	Provided the secret alias is not valid
8800054	Provided secret Alias is not having the required type 'rsakey' in the secrets store
8800055	Internal Server Error

Sharing IDSP Context with SPI

IDSP sends the current operational state as the context in each SPI call. The following table lists the supported key-value pairs of the IDSP context that is shared in the **ahContext** request parameter in a SPI call:

Reserved Key	Description	Example
x-ssp-base-uri	Specifies the base URL of the IDSP deployment.	https://ssp.ssp10.bm.com
x-ssp-issuer-url	Specifies the logical tenant-specific issuer that signs the IDSP tokens.	https://ssp.ssp10.bm.com/default
x-SSP_FQDN	Specifies the FQDN of the host that is assigned to the IDSP service.	ssp.ssp10.bm.com
x-ssp-path	Specifies the tenant-specific component of the IDSP URL.	/default
clientTxnId	Specifies the request ID as indicated by a client that is making a request to IDSP.	myClientTxnID
txnId	Specifies the unique transaction ID that is asserted by IDSP for every received request.	<guid>
tname	Specifies the name of the tenant that receives a request.	default
tid	Specifies the ID of the tenant that receives a request.	<guid>
clientIp	Specifies the IP address of the client that is making a request.	10.76.13.107
clientTid	Specifies the ID of the tenant that owns the client, which is making a request.	<guid>
clientId	Specifies the ID of the client that is making a request.	<guid>
userIp	Specifies the IP address of the user on whose behalf a client is making a request.	1.1.1.2
reauthIsRequest	Specifies that re-authentication was requested by a client that is making a request.	false
reauthIsPolicy	Specifies that re-authentication was requested by an evaluated policy.	false
reauthAmrNames	In case of re-authentication, specifies the AMR values from an ID Token.	"OTP","PWD","FIDO","MYAUTH"
completedAmrNames	Specifies the AMR values of the completed authentication factors.	"OTP","MYAUTH"
locale	Specifies the current locale as indicated by the server.	en-US
userId	Specifies the internal ID of the user being authenticated.	<guid>
userDN	Specifies the DN of the user being authenticated.	cn=bob, ou=org, o=acme, dc=com

userLoginId	Specifies the login ID of the user being authenticated.	bob
userUniversalId	Specifies the universal ID of the user being authenticated.	12345
userStatusCode	In case of ID store status encoding = "Siteminder", specifies the user's "disabled state" as encoded per SiteMinder's convention.	"Disabled flag" bitmask. For information, see this SiteMinder Knowledge Base article.
userStatusEncoding	Specifies the type of the ID store status encoding, as configured for the ID store that contains the user who isbeing authenticated.	Siteminder, oud, cadir, etc.
userIdTokenPresent	Specifies whether an ID Token was provided during the initiation of the authentication flow.	true
userIdToken	Specifies the JSON string that contains the ID Token as provided during the initiation of the authentication flow.	false
hideAuthFailureReason	Specifies whether an authentication failure reason must be returned.	true
idpUserGuid	Specifies the unique ID of the user as maintained in the ID store or provided in an ID Token.	Usually a <guid>
idpType	Specifies the type of the identity provider that is used to assert the identity being disambiguated. In ZFP mode with SiteMinder integration, this may contain different types such as "siteminder".	LDAP or SCIM
idpName	Specifies the name of the identity provider that is used to assert the identity being disambiguated.	Name of the ID store or as provided via ZFP token
idpGuid	Specifies the ID of the identity provider that is used to assert the identity being disambiguated.	ID of the ID store or as provided via a ZFP token
providerName	Specifies the name of the custom provider that is implementing the current SPI.	MyCustomProvider
providerId	Specifies the ID of the custom provider that is implementing the current SPI.	<guid>
appId	Specifies the ID of the application on whose behalf the user is being authenticated.	MyApp

Integrating with External Risk Provider

Learn how the Symantec Identity Security Platform Custom Service Provider Interface (SPI) integrates with a custom risk provider for risk-based authentication.

This topic includes the following:

- Custom Provider Overview
- Implementing the APIs
- API Specification
- Open API Schema - (Swagger Content)
- Supported Use Cases

Custom Provider Overview

The IDSP Custom Service Provider Interface (SPI) allows the solution to be integrated with a custom risk provider for risk-based authentication. The SPI uses an Open API spec and expects customers to implement it as a separate web service that runs in their environment. The customer should implement a set of APIs that are defined by the solution to enable the solution's custom SPI to communicate with the customer's risk provider. These APIs have been explained in the subsequent section.

Implementing the APIs

The following APIs should be implemented by the customer to integrate their risk provider with the solution's custom SPI:

- **UserRiskScoreEvaluator** - This API request is used to evaluate the user risk and return a risk profile (which includes risk score and risk advice) apart from additional risk profile details which may be required for post user evaluation. For example, a device tag. The use of risk profile differs based on the configuration that is set for the parameters, **riskProviderPrePrimaryAuth** and **riskProviderPrimaryAuthSuccess** in the global/tenant settings. See Settings for more information.
- **PostUserRiskScoreEvaluator** - This API request is used to update the risk context for a user whose risk has been evaluated as part of the /UserRiskScoreEvaluator API. If the UserRiskScoreEvaluator returns risk advice of stepup or allow, this API is invoked.

The API request and response templates are based on the standard Open API spec that IDSP expects the customers to provide during the integration process. These specifications have been explained in the subsequent sections.

API Specification

The API request and response templates are explained below.

UserRiskScoreEvaluator API Specification

UserRiskScoreEvaluator API Specification	
API Name	UserRiskScoreEvaluator
API URL	*https://<CustomProviderHost>/UserRiskScoreEvaluator*
API OPERATION	*POST*
AUTHORIZATION	*<API Key shared by the custom risk provider>*
API RESPONSE CODE	*200 Success, 400 Failures, 500 Server Errors*

Request Payload includes the following parameters:

Parameter	Type	Mandatory (Yes/No)	Description
X-API-KEY	Header	No	API key used to invoke the custom risk provider.
subject	string	Yes	Unique identifier of the user.

Parameter	Type	Mandatory (Yes/No)	Description
clientContext	array of key-value pairs	Yes	Client context parameters received as part of the "/auth/v1/authenticate" call will be passed here by the client. Example: transactionIdentifier, appid `{ "subject": "<userLoginid>", "channel": "web", "ipAddress": "10.10.123.124", "action":"authenticate", "rememberMe" : true, "device": { "signature": { "iaAuthData": "_v02MyUgNGgYOi88OTk0....." } }, "clientContext": [{ "key": "transactionIdentifier", "value": "540715af-96f2-4b86-b89f-ca0e8ae93f40" }] }`
ahContext	array of key-value pairs	No	Contains the IDSP context parameters. For information, see the *Sharing IDSP Context with SPI* section in Integrating with Custom SPI.
providerContext	array of key-value pairs	No	Parameters that are configured as part of the custom risk provider.

Sample Request of "/UserRiskScoreEvaluator" API:

```
{
"subject": "nbruce",
"clientContext": [
{
"key": "transactionIdentifier",
"value": "gga323a24"
}
],
"ahContext": [
{
"key": "clientTxnId",
"value": "cd2f1e6e-c356-49ae-a5b8-c10bf571a9a0"
},
{
"key": "txnId",
"value": "txn-id-hd26se23"
}
],
"providerContext": [
{
```

```
"key": "instanceId",
"value": "brazil-instance-1"
}
]
}
```

Response Payload should include the following parameters:

Parameter	Type	Mandatory (Yes/No)	Description
subject	string	Yes	Unique identifier of the user.
riskScore	int	Yes	Risk score returned by the risk service.
riskReason	string	No	Reason for the risk score and risk advice.
riskFactors	array of strings	No	An array of risk factors that resulted in the risk score by the risk service.
riskAdvice	string	Yes	This attribute provides the risk advice which results in one of the following: • ALLOW - Ignores the remaining obligations and allows the user to continue the transaction. • DENY - User is denied from performing any further transactions. • STEPUP - Continues the authentication flow with the remaining obligations that are defined in the policy.
msg	string	Yes	If the status of the transaction is successful, returns "Risk evaluation success". If the status of the transaction is a failure, return the reason for the failure.
riskEvalContext	array of key-value pairs	No	All the parameters that must be returned as part of the post evaluate risk call should be sent in this field (example: transactionid, deviceid)

Sample Response of "/UserRiskScoreEvaluator" API:

```
{
"subject": "nbruce",
"riskScore": 55,
"riskReason": "Registered device not detected. Possibly shared remembered device",
"riskFactors": [
"Device Recognition"
],
"riskAdvice": "deny",
"msg": "Risk evaluation success",
"riskEvalContext": [
{
"key": "transactionId",
"value": "txnId-6hdds733"
},
{
"key": "deviceId",
"value": "device-hdyn235sd"
```

```
}
]
}
```

PostUserRiskScoreEvaluator API Specification

PostUserRiskScoreEvaluator API Specification	
API Name	PostUserRiskScoreEvaluator
API URL	*https://<CustomProviderHost>/PostUserRiskScoreEvaluator*
API OPERATION	*POST*
AUTHORIZATION	*<API Key shared by the custom risk provider>*
API RESPONSE CODE	*200 Success, 400 Failures, 500 Server Errors*

Request Payload includes the following parameters:

Parameter	Type	Mandatory (Yes/No)	Description
X-API-KEY	Header	No	API key used to invoke the custom risk provider.
subject	string	Yes	Unique identifier of the user.
authStatus	string	Yes	Status of the authentication (possible values - success/ failure).
riskEvalContext	array of key-value pairs	No	Add the parameters that are returned as part of the *UserRiskScoreEvaluator* call in this field (example: transactionid, deviceid). Add only the parameters and not the entire payload as part of this field.
ahContext	array of key-value pairs	No	Contains the IDSP context parameters. For information, see the *Sharing IDSP Context with SPI* section in Integrating with Custom SPI.
providerContext	array of key-value pairs	No	All the providerContext received in the "/ UserRiskScoreEvaluator" call will be returned back in the post risk eval

Sample Request of "/PostUserRiskScoreEvaluator" API:

```
{
"subject": "nbruce",
"authStatus": "success",
"riskEvalContext": [
{
"key": "transactionId",
"value": "txnId-6hdds733"
},
{
"key": "deviceId",
"value": "device-hdyn235sd"
}
],
"ahContext": [
{
"key": "clientTxnId",
```

```
"value": "cd2f1e6e-c356-49ae-a5b8-c10bf571a9a0"
},
{
"key": "txnId",
"value": "txn-id-hd26se23"
},
{
"key": "isTrustedDevice",
"value": "true"
}
],
"providerContext": [
{
"key": "instanceId",
"value": "brazil-instance-1"
}
]
}
```

Response Payload should include the following parameters:

Parameter	Type	Mandatory (Yes/No)	Description
subject	string	Yes	Unique identifier of the user.
msg	string	No	If the status is successful, returns ”Post Risk evaluation successful”. If the status is a failure, return the reason for the failure.
clientRespContext	array of key-value pairs	No	All the client response context that must be returned to the client as part of the successful authentication response should be returned in this field.

Sample Response of "/PostUserRiskScoreEvaluator" API:

```
{
"subject": "nbruce",
"msg": "Post risk evaluation success",
"clientRespContext": [
{
"key": "deviceId",
"value": "device-hdyn235sd"
}
]
}
```

API Schema - (Swagger Content)

To view the sample representation of the API schema, see the **Common Open API Spec for all Custom Providers - (Swagger Content)** section in Integrating with Custom SPI.

Supported Use Cases

The following diagrams show different scenarios of integration between Custom Risk Provider and IDSP.

Use Case: 1

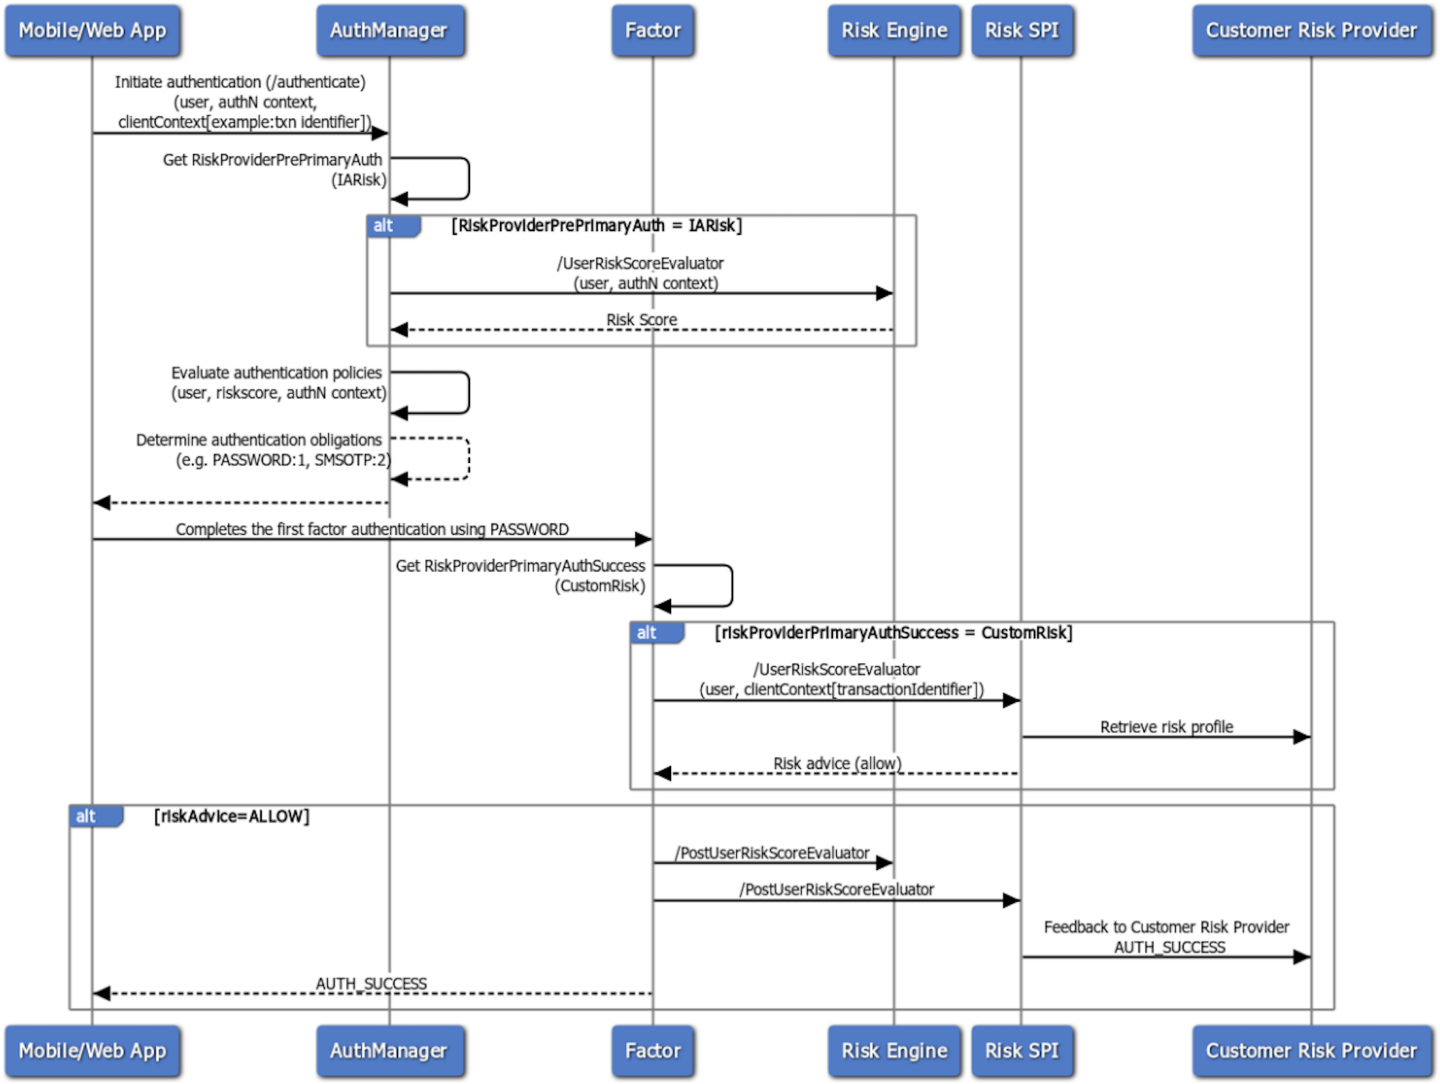
This use case assumes that the customer has configured the global setting parameters for risk-based authentication as follows:

- riskProviderPrePrimaryAuth = IARISK
- riskProviderPrimaryAuthSuccess = CustomRisk

> **NOTE**
>
> "IARISK", is the name of an internal risk provider.
>
> "CustomRisk" is the name of the customer risk provider.
>
> To know more about the global setting parameters, see Settings.

List of participants and what they represent:

- **Application (Mobile/Web App):** Represents the application that calls the solution APIs to acquire the identity token and complete the authentication flow.
- **IDSP Microservices:**
  - **AuthManager:** Initiates the authentication flow when a client invokes the **/auth/v1/authenticate** API.
  - **Factor:** Exposes the APIs to perform user authentication using different factors/obligations (PASSWORD, SMSOTP, EMAILOTP, Biometrics, PUSH, and so on) identified by the policy engine.
  - **Risk Engine:** Represents an internal risk engine that exposes the APIs to evaluate the risk score for a user transaction.
  - **Risk SPI:** Represents a wrapper (implemented by the customer) that the solution uses to call the customer risk provider.
  - **Customer Risk Provider:** Represents the customer risk provider API that is used to evaluate the risk advice for a user transaction.



Flow Description:

1. The client app invokes the **/auth/v1/authenticate** API to initiate the authentication flow.

   NOTE
   In certain cases, a client app may have to send additional parameters that may be mandatorily required by the custom risk to function. These parameters (example, transaction Id, and so on) can be passed through the **clientContext** in the **/auth/v1/authenticate** API call. See the following reference sample:

```
{
    "subject": "<userLoginid>",
    "channel": "web",
    "ipAddress": "10.10.123.124",
    "action":"authenticate",
    "rememberMe" : true,
    "device": {
        "signature": {
            "iaAuthData": "_v02MyUgNGgYOi88OTk0........."
        }
    },
```

```
            "clientContext": [
                {
                    "key": "transactionIdentifier",
                    "value": "540715af-96f2-4b86-b89f-ca0e8ae93f40"
                }
            ]
        }
```

2. Internally, the **/auth/v1/authenticate** API performs the following actions:
   a. Retrieves the configured risk provider from the global setting - **riskProviderPrePrimaryAuth.** The supported values are **IARISK, AARisk, CustomRisk** or **None.** In this flow, **IARISK** is assumed to be configured.
   b. The AuthManager invokes the **/iarisk/v1/UserRiskScoreEvaluator** API to evaluate the risk score.
   c. Upon getting the risk score, AuthManager internally communicates with the policy engine to evaluate the configured policy rules for the client app and determines the authentication obligations. In the flow, it is assumed that the obligations returned are PASSWORD:1 and SMSOTP:2. The AuthManager communicates the authentication challenges to the client.
3. The client invokes the **/factor/v1/PasswordAuthenticator** API to successfully complete authentication for the first factor, PASSWORD:1.
4. After the authentication is successful, and before authenticating the second factor, the PasswordAuthenticator API checks the configured value of the global setting - **riskProviderPrimaryAuthSuccess.** This property defines the risk provider that has been configured to perform risk evaluation post the primary authentication is successful. The supported values are **CustomRisk** or **None.** In this flow, **CustomRisk** is assumed to be configured.

   NOTE
   If the **riskProviderPrimaryAuthSuccess (secondary risk)** parameter is set to custom, the solution analyzes the risk and uses the ***risk advice*** to assess the next steps in the flow. The risk score returned by the custom risk engine is ignored.
5. The **PasswordAuthenticator** API invokes the **<CustomProviderHost>/UserRiskScoreEvaluator** API to evaluate the risk advice. Based on the evaluation, the Risk SPI returns either of the following advice:
   – **ALLOW:** The solution skips the remaining authentication factors, completes the authentication flow, and marks it as AUTH_ALLOWED.
   – **DENY:** The solution skips the remaining authentication factors, completes the authentication flow, and marks it as AUTH_DENIED.
   – **STEPUP:** The solution continues to challenge the user with the remaining authentication factors.
6. Assume that the **<CustomProviderHost>/UserRiskScoreEvaluator** API returns the risk advice as ALLOW in the response payload.

```
{
   "subject": "nbruce",
   "riskScore": 5,
   "riskReason": "Registered device detected",
   "riskFactors": [
   "Device Recognition"
       ],
   "riskAdvice": "allow",
   "msg": "Risk evaluation success",
   "riskEvalContext": [
     {
       "key": "transactionId",
       "value": "txnId-6hdds733"
     },
     {
       "key": "deviceId",
       "value": "device-hdyn235sd"
```

```
        }
      ]
  }
```

7. The PasswordAuthenticator API invokes the **/PostUserRiskScoreEvaluator** API individually to the Risk Engine and Risk SPI to inform about the authentication status. The Risk SPI in return sends the feedback about the authentication status to the Customer Risk Provider.
8. The PasswordAuthenticator API returns AUTH_SUCCESS to the client, thereby completing the authentication flow.

Use Case: 2

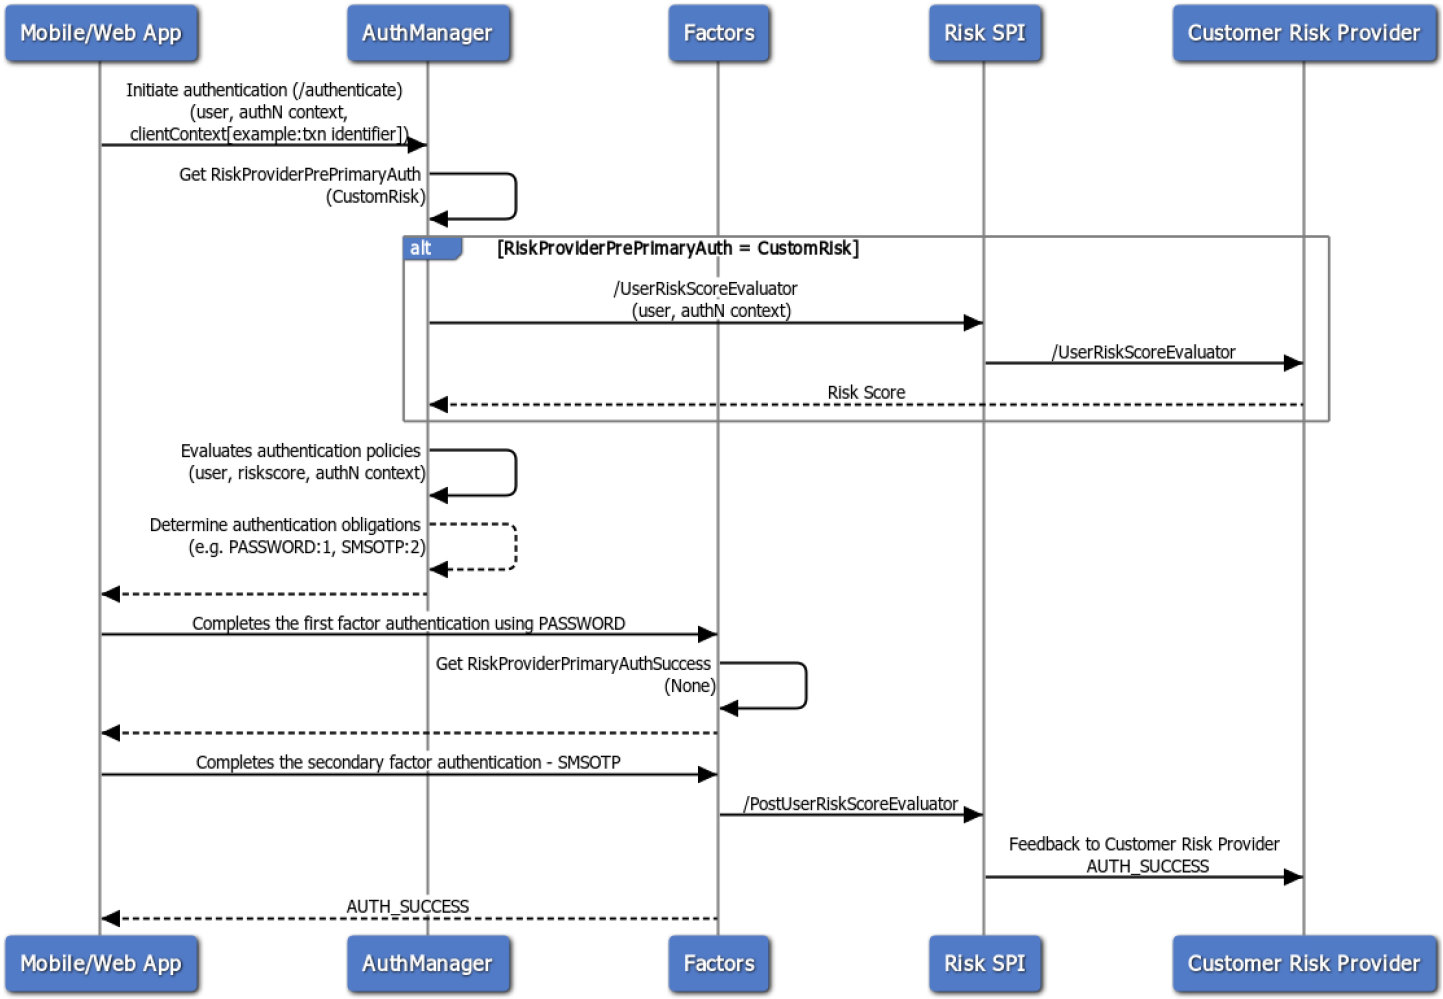
This use case assumes that the customer has configured the global setting parameters for risk-based authentication as follows:

- riskProviderPrePrimaryAuth = CustomRisk
- riskProviderPrimaryAuthSuccess = None

> **NOTE**
> "CustomRisk" is the name of the customer risk provider. To know more about the global setting parameters, see Settings.

List of participants and what they represent:

- **Application (Mobile/Web App):** Represents the application that calls the solution APIs to acquire the identity token and complete the authentication flow.
- **IDSP Microservices:**
  - **AuthManager:** Initiates the authentication flow when a client invokes the **/auth/v1/authenticate** API.
  - **Factor:** Exposes the APIs to perform user authentication using different factors/obligations (PASSWORD, SMSOTP, EMAILOTP, Biometrics, PUSH, and so on) identified by the policy engine.
  - **Risk SPI:** Represents a wrapper (implemented by the customer) that the solution uses to call the customer risk provider.
  - **Customer Risk Provider:** Represents the customer risk provider API that is used to evaluate the risk advice for a user transaction.



Flow Description:

1. The client app invokes the **/auth/v1/authenticate** API to initiate the authentication flow.

   NOTE
   In certain cases, a client app may have to send additional parameters that may be mandatorily required by the custom risk to function. These parameters (example, transaction Id, and so on) can be passed through the **clientContext** in the **/auth/v1/authenticate** API call. See the following reference sample:

```
{
    "subject": "<userLoginid>",
    "channel": "web",
    "ipAddress": "10.10.123.124",
    "action":"authenticate",
    "rememberMe" : true,
    "device": {
        "signature": {
            "iaAuthData": "_v02MyUgNGgYOi88OTk0........."
        }
    },
     "clientContext": [
        {
            "key": "transactionIdentifier",
```

```
                    "value": "540715af-96f2-4b86-b89f-ca0e8ae93f40"
                }
            ]
        }
```

2. Internally, the **/auth/v1/authenticate** API performs the following actions:
   a. Retrieves the configured risk provider from the global setting - **riskProviderPrePrimaryAuth.** The supported values are **IARISK, AARisk, CustomRisk** or **None.** In this flow, **CustomRisk** is assumed to be configured.
   b. The AuthManager invokes the **<CustomProviderHost>/UserRiskScoreEvaluation** API to evaluate the risk score. The API call passes through the Risk SPI to the Custom Risk Provider. Risk evaluation results in the risk score and risk advice.

      NOTE
      In a scenario where **riskProviderPrePrimaryAuth** is set to **CustomRisk,** only the risk score is considered for the policy evaluation and the risk advice is ignored.

   c. Upon getting the risk score, AuthManager internally communicates with the policy engine to evaluate the configured policy rules for the client app and determines the authentication obligations. In the flow, it is assumed that the obligations returned are PASSWORD:1 and SMSOTP:2. The AuthManager communicates the authentication challenges to the client.
3. The client invokes the **/factor/v1/PasswordAuthenticator** API to successfully complete authentication for the first factor, PASSWORD:1.
4. After the authentication is successful, and before authenticating the second factor, the PasswordAuthenticator API checks the configured value of the global setting - **riskProviderPrimaryAuthSuccess.** This property defines the risk provider that has been configured to perform risk evaluation post the primary authentication is successful. The supported values are **CustomRisk** or **None.** In this flow, **None** is assumed to be configured.
5. The client is challenged with the remaining obligation - SMSOTP:2. The client successfully completes the Multi-factor authentication (MFA).
6. On MFA completion, the PasswordAuthenticator API invokes the **/PostUserRiskScoreEvaluator** API to the Risk SPI to inform about the authentication status. The Risk SPI in return sends the feedback about the authentication status to the Customer Risk Provider.
7. The PasswordAuthenticator API returns AUTH_SUCCESS to the client, thereby completing the authentication flow.

Use Case: 3

This use case assumes that the customer has configured the global setting parameters for risk-based authentication as follows:

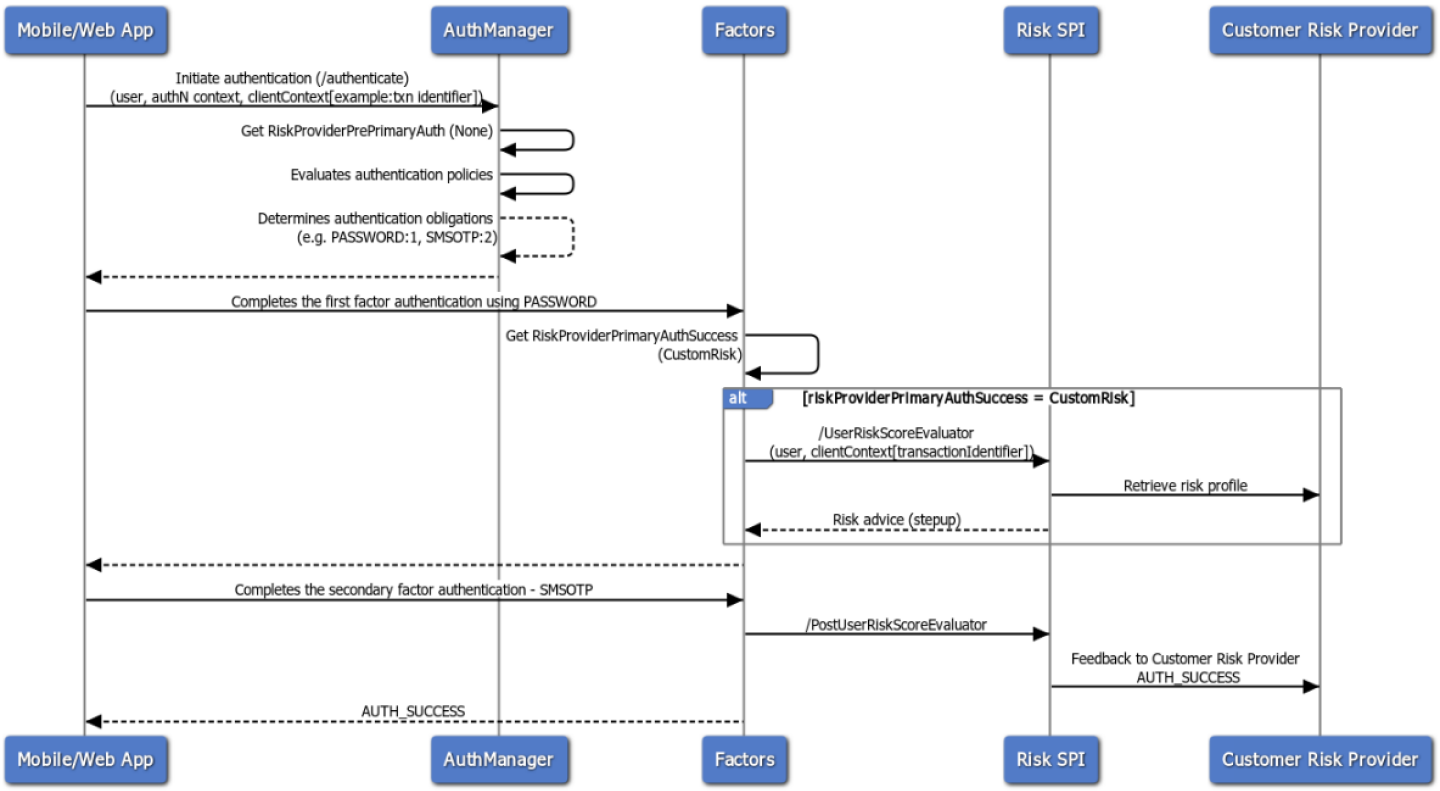
- riskProviderPrePrimaryAuth = None
- riskProviderPrimaryAuthSuccess = CustomRisk

NOTE
"CustomRisk" is the name of the customer risk provider. To know more about the global setting parameters, see Settings.

List of participants and what they represent:

- **Application (Mobile/Web App):** Represents the application that calls the solution APIs to acquire the identity token and complete the authentication flow.
- **IDSP Microservices:**

- **AuthManager:** Initiates the authentication flow when a client invokes the **/auth/v1/authenticate** API.
- **Factor:** Exposes the APIs to perform user authentication using different factors/obligations (PASSWORD, SMSOTP, EMAILOTP, Biometrics, PUSH, and so on) identified by the policy engine.
- **Risk SPI:** Represents a wrapper (implemented by the customer) that the solution uses to call the customer risk provider.
- **Customer Risk Provider:** Represents the customer risk provider API that is used to evaluate the risk advice for a user transaction.



Flow Description:

1. The client app invokes the **/auth/v1/authenticate** API to initiate the authentication flow.

   NOTE
   In certain cases, a client app may have to send additional parameters that may be mandatorily required by the custom risk to function. These parameters (example, transaction Id, and so on) can be passed through the **clientContext** in the **/auth/v1/authenticate** API call. See the following reference sample:

```
{
    "subject": "<userLoginid>",
    "channel": "web",
    "ipAddress": "10.10.123.124",
    "action":"authenticate",
    "rememberMe" : true,
    "device": {
        "signature": {
            "iaAuthData": "_v02MyUgNGgYOi88OTk0........."
        }
    },
     "clientContext": [
```

```
                {
                    "key": "transactionIdentifier",
                    "value": "540715af-96f2-4b86-b89f-ca0e8ae93f40"
                }
            ]
        }
```

2. Internally, the **/auth/v1/authenticate** API performs the following actions:
   a. Retrieves the configured risk provider from the global setting - **riskProviderPrePrimaryAuth.** The supported values are **IARISK, AARisk, CustomRisk** or **None.** In this flow, **None** is assumed to be configured.
   b. AuthManager invokes the Policy Engine to evaluate the configured policy rules, without any riskscore for the client app, and determines the authentication obligations. In this flow, it is assumed that the obligations returned are PASSWORD:1, and SMSOTP:2.
3. The client invokes the **/factor/v1/PasswordAuthenticator** API to successfully complete authentication for the first factor, PASSWORD:1.
4. After the authentication is successful, and before authenticating the second factor, the PasswordAuthenticator API checks the configured value of the global setting - **riskProviderPrimaryAuthSuccess.** This property defines the risk provider that has been configured to perform risk evaluation post the primary authentication is successful. The supported values are **CustomRisk** or **None.** In this flow, **CustomRisk** is assumed to be configured.

   NOTE
   If the **riskProviderPrimaryAuthSuccess (secondary risk)** parameter is set to custom, the solution analyzes the risk and uses the ***risk advice*** to assess the next steps in the flow. The risk score returned by the custom risk engine is ignored.
5. The **PasswordAuthenticator** API invokes the **<CustomProviderHost>/UserRiskScoreEvaluator** API to evaluate the risk advice. Based on the evaluation, the Risk SPI returns either of the following advice:
   - **ALLOW:** The solution skips the remaining authentication factors, completes the authentication flow, and marks it as AUTH_ALLOWED.
   - **DENY:** The solution skips the remaining authentication factors, completes the authentication flow, and marks it as AUTH_DENIED.
   - **STEPUP:** The solution continues to challenge the user with the remaining authentication factors.
6. Assume that the **<CustomProviderHost>/UserRiskScoreEvaluator** API returns the risk advice as STEPUP in the response payload.

```
{
  "subject": "nbruce",
  "riskScore": 65,
  "riskReason": "Unknown device",
  "riskFactors": [
  "Device Recognition"
    ],
  "riskAdvice": "stepup",
  "msg": "Risk evaluation success",
  "riskEvalContext": [
    {
      "key": "transactionId",
      "value": "txnId-6hdds733"
    },
    {
      "key": "deviceId",
      "value": "device-hdyn235sd"
    }
  ]
}
```

7. The **PasswordAuthenticator** API invokes the **/factor/v1/OTPGenerator** API to initiate MFA using SMSOTP.
8. The client is challenged with the obligation - SMSOTP. The client successfully completes the Multi-factor authentication (MFA).
9. On completing the authentication, the Factor API (/factor/v1/OTPVerifier) invokes the **<CustomProviderHost>/PostUserRiskScoreEvaluator** API to the Risk SPI. The Risk SPI internally invokes the Customer Risk Provider to inform about the AUTH_SUCCESS status. The Custom Risk Provider sends the response details to Risk SPI > Factor API, for example, device Id.
10. The Factor API returns AUTH_SUCCESS to the client app, thereby completing the authentication flow.

- Custom Risk Provider APIs

Integrating with External SMS Provider

Integrate Symantec Identity Security Platform with external SMS providers for multi-factor authentication using the Custom Service Provider Interface (SPI).

The Custom SPI utilizes an OpenAPI specification, requiring you to host a compliant web service within your own environment. To enable communication between Symantec Identity Security Platform and your SMS provider, you must implement the specific API endpoints defined in the following sections.

This topic includes the following:

- Custom Provider Overview
- Steps to Integrate with Custom SMS SPI
- Implementing the API
- API Schema - (Swagger Content)
- Creating a SMS Provider
- Configuring Settings in IDSP
- SMS Use Case

Custom Provider Overview

The Symantec Identity Security Platform Custom Service Provider Interface (SPI) enables integration with third-party SMS providers for multi-factor authentication. This SPI is based on an OpenAPI specification and requires a custom web service hosted within your environment. To establish communication, you must implement the API endpoints and configure the system settings as defined in this documentation.

Steps to Integrate with Custom SMS SPI

The three steps that the Customers have to perform to integrate with the SMS SPI are:

1. Develop the custom SMS service based on the SMS-Open API Spec provided by IDSP.
2. Create an SMS Custom Provider in IDSP using the Provider endpoint- https://${SSP_FQDN}/{{tenantName}}/admin/v1/CustomProviders
3. Specify the configuration settings in IDSP.

These steps have been described in the subsequent sections.

Implementing the API

The following API should be implemented by the customer to integrate their SMS provider with the solution's custom SPI:

- "**SMSMessageSender**" - This API request is used to send the SMS to the customers.

The API request and response templates are based on the standard Open API spec that IDSP expects the customers to provide during the integration process. These specifications have been explained in the subsequent sections.

SMSMessageSender API Specification

SMSMessageSender API Specification	
API Name	SMSMessageSender
API URL	*https://<CustomProviderHost>/**SMSMessageSender***
API OPERATION	*POST*
AUTHORIZATION	*<<API Key shared by the custom SMS provider>>*
API RESPONSE CODE	*200 Success, 400 Failures, 500 Server Errors*

Request Payload includes the following parameters:

Parameter	Type	Mandatory (Yes/No)	Description
X-API-KEY	Header	No	API key used to invoke the custom SMS provider
subject	string	Yes	Unique identifier of the user
phoneNumber	string	Yes	Phone number to which SMS must be delivered
otp	string	Yes	OTP value that must be delivered
otpValidityInSecs	Integer	Yes	Validity of the OTP in seconds
message	string	Yes	The status message that must be delivered through the SMS

clientContext	an array of key-value pairs	Yes	Client context parameters received as part of the "/auth/v1/authenticate" call will be passed here by the client. Example: transactionIdentifier, appid, etc.
			`{`
			`"subject": "{{userLoginid}}",`
			`"channel": "web",`
			`"ipAddress": "10.10.123.124",`
			`"action":"authenticate",`
			`"rememberMe" : true,`
			`"device": {`
			`"signature": {`
			`"iaAuthData": "_v02MyUgNGgYOi88OTk0....."`
			`}`
			`},`
			`"clientContext": [`
			`{`
			`"key": "transactionIdentifier",`
			`"value": "540715af-96f2-4b86-b89f-ca0e8ae93f40"`
			`}`
			`]`
			`}`

ahContext	an array of key-value pairs	No	Contains the IDSP context parameters. For information, see the *Sharing IDSP Context with SPI* section in Integrating with Custom SPI.

Parameter	Type	Mandatory (Yes/No)	Description
providerContext	array of key-value pairs	No	Parameters configured as part of the custom sms provider

Sample Request of "/SMSMessageSender" API:

```
{
  "subject": "nbruce",
  "phoneNumber": 13242342341,
  "otp": 783242,
  "otpValidityInSecs": 300,
  "message": "783242 is your One-Time Password to login. The OTP is valid upto 10 minutes.",
  "clientContext": [
    {
      "key": "transactionIdentifier",
      "value": "540715af-96f2-4b86-b89f-ca0e8ae93f40"
    }
  ],
  "ahContext": [
    {
      "key": "clientTxnId",
      "value": "cd2f1e6e-c356-49ae-a5b8-c10bf571a9a0"
    },
    {
      "key": "txnId",
      "value": "txn-id-hd26se23"
    }
  ],
  "providerContext": [
    {
      "key": "instanceId",
      "value": "brazil-instance-1"
    }
  ]
}
```

Response Payload should include the following parameters:

Parameter	Type	Mandatory (Yes/No)	Description
status	string	Yes	This parameter returns the message delivery status as either a "success" or a "failure".
msg	string	Yes	This parameter returns a status message reflecting the delivery outcome. It returns specific messages based on success or failure instances. For example: • In case of failure, it may return a message such as "INTERNAL ERROR". • In case of success, it may return a message like "Message delivered successfully via SMS".

Parameter	Type	Mandatory (Yes/No)	Description
clientRespContext	an array of key-value pairs	No	This parameter returns all the client response context that must be returned by the SPI client as part of the successful authentication response.

Sample Response of "/SMSMessageSender" API:

```
{
   "status": "success",
   "msg": "Message delivered successfully via SMS",
   "clientRespContext": [
    {
      "key": "transactionId",
      "value": "txnId-6hdds733"
    },
    {
      "key": "deviceId",
      "value": "device-hdyn235sd"
    }
  ]
}
```

API Schema - (Swagger Content)

To view the sample representation of the API schema, see the **Common Open API Spec for all Custom Providers - (Swagger Content)** section in Integrating with Custom SPI.

Creating an SMS Custom Provider

- Create an SMS custom provider in IDSP using the Provider endpoint-
  `https://${SSP_FQDN}/{{tenantName}}/admin/v1/CustomProviders`

  NOTE

  - To know the value of ${SSP_FQDN} environment variable, see Configuring IDSP Environment Variables.
  - The default value for `<tenantName>` is "default".
  - Replace the text {{text}} including {{}} characters with appropriate values, in all the endpoints shown in the above table.
    For example:
    `https://{{host}}/{{tenantName}}/admin/v1/CustomProviders`
    should look similar to:
    `https://example.com/default/admin/v1/CustomProviders`
  - To know more about the scopes that are required to secure these APIs, refer to the Rest APIs and Associated Privileges section.

  NOTE
  To refer to the Custom Provider APIs which can be used to perform CRUD operations in IDSP, see here.

Configuring the Global/Tenant Setting attribute

- Configure the global/tenant setting, ***smsProviderToBeUsed*** in IDSP to set a custom SPI provider as the SMS provider. The default value is "Twilio". See Settings for more information.

SMS Use Case

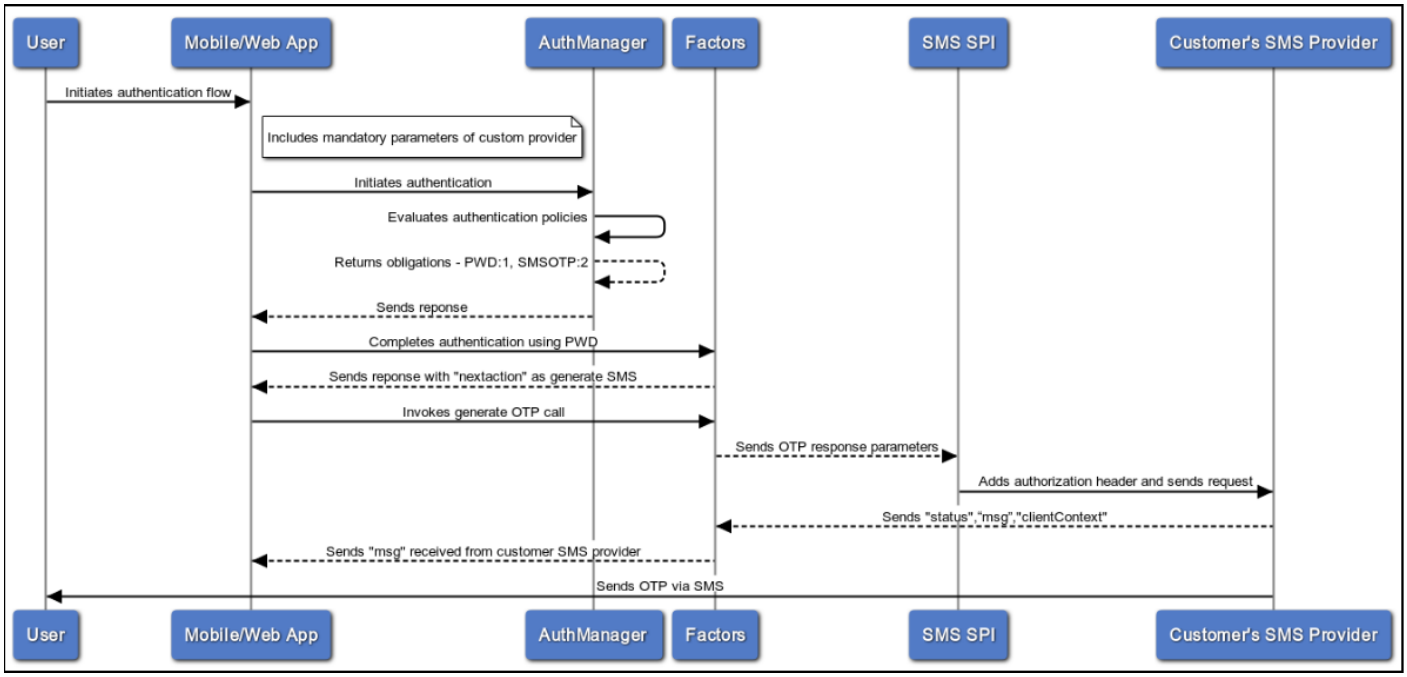
The following use case describes the integration between Custom SMS Provider and IDSP.

It is assumed that the customer has configured the following global/tenant setting parameter:

- "smsProviderToBeUsed"

List of participants and what they represent:

- User- User who initiates the authentication flow.
- Application (Mobile/Web App): This is the application that calls the solution's APIs to acquire the identity token and complete the authentication flow.
- IDSP microservices:
  - AuthManager- This is the ***"/auth/v1/authenticate"*** API used to initiate the authentication flow.
  - Factors- This is the ***"/factor/v1/OTPGenerator"*** API used to generate the otp.
  - SMS SPI- This is the SMS module in the IDSP used to call the custom SMS provider.
  - Customer's SMS Provider- This is the customer's implementation of SMS Provider API which is used to deliver SMS to the end user's phone number.



Flow Description:

1. The User initiates the Authentication Flow.
2. The client app invokes the "auth/v1/authenticate" API to initiate the Authentication flow. The request includes parameters such as user, authN context, clientContext [example:txn identifier].

   NOTE
   In certain cases, a client app may have to send additional parameters that may be mandatorily required by the custom SMS provider to function. These parameters, for example, transaction Id, etc. can be passed through the "***clientContext***" in the "/auth/v1/authenticate" call. See the following reference sample:

```
{
    "subject": "{{userLoginid}}",
    "channel": "web",
    "ipAddress": "10.10.123.124",
```

```
            "action":"authenticate",
            "rememberMe" : true,
            "device": {
                "signature": {
                    "iaAuthData": "_v02MyUgNGgYOi88OTk0........."
                }
            },
             "clientContext": [
                {
                    "key": "transactionIdentifier",
                    "value": "540715af-96f2-4b86-b89f-ca0e8ae93f40"
                }
            ]
        }
```

3. Internally, the "/auth/v1/authenticate" API does the following:
   - Checks whether the global/tenant settings parameter, "smsProviderToBeUsed" is configured in the IDSP. In this flow, we have assumed that the setting is configured to a custom SMS provider.
   - AuthManager communicates with the Policy Engine to evaluate the configured policy rules for the client app and determines the authentication obligations. Also, sends a response to the client app. In the flow, it is assumed that the obligations returned are PWD:1 and SMSOTP:2.
4. The client successfully completes the first-factor authentication, PWD:1.
5. The client is challenged with the remaining obligation, that is SMSOTP:2.
6. The Factor API sends response to the client app with "nextaction" as generate SMSOTP.
7. The client app invokes the "/factor/v1/OTPGenerator" API to generate the SMSOTP.
8. The Factor API sends SMSOTP details, including otp, otpValidity, message, clientContext, providerContext and so on, to the SMS SPI.
9. The SMS SPI adds an Authorization header (API Key) and sends the SMSOTP details to the Customer's SPI provider.
10. The Customer's SMS Provider in return sends the SMS delivery response to the Factors service. The response includes transaction status and message. It also sends the OTP through SMS to the end customer’s mobile number.
11. The Factor API sends "msg" received from the customer's SMS provider to the client app.

Integrating with External Email Provider

Integrate Symantec Identity Security Platform with a custom email provider for email-based authentication using the Custom Service Provider Interface (SPI).

The Custom SPI is based on an OpenAPI specification and requires a separate web service hosted within your infrastructure. To enable communication between Symantec Identity Security Platform and your email provider, you must implement the required API endpoints and configure the settings defined in this section.

This topic includes the following:

- Custom Provider Overview
- Steps to Integrate with Custom Email SPI
- Implementing the APIs
- API Schema - (Swagger Content)
- Creating an Email Provider
- Configuring Settings in IDSP
- Email Use Case

Custom Provider Overview

The Symantec Identity Security Platform Custom Service Provider Interface (SPI) allows the solution to be integrated with a custom Email provider for Email-based authentication. The SPI uses an Open API spec and expects the customers to implement it as a separate web service that runs in their environment. The customer should implement the API, and should configure the required settings that are defined by the solution, to enable the solution's custom SPI to communicate with the customer's email provider. The API and Configuration settings have been explained in the subsequent sections.

Steps to Integrate with Custom Email SPI

The three steps that the Customers have to perform to integrate with the Email SPI are:

1. Develop the custom Email service based on the Email-Open API Spec provided by IDSP.
2. Create an Email Custom Provider in IDSP using the Provider endpoint- https://${SSP_FQDN}/{{tenantName}}/admin/v1/CustomProviders
3. Specify the configuration settings in IDSP.

These steps have been described in the subsequent sections.

Implementing the API

The following API should be implemented by the customer to integrate their Email provider with the solution's custom SPI:

- "**EmailMessageSender**" - This API request is used to send the Email to the customers.

The API request and response templates are based on the standard Open API spec that IDSP expects the customers to provide during the integration process. These specifications have been explained in the subsequent sections.

EmailMessageSender API Specification

EmailMessageSender API Specification	
API Name	EmailMessageSender
API URL	*https://<CustomProviderHost>/**EmailMessageSender***
API OPERATION	*POST*
AUTHORIZATION	*<<API Key shared by the custom Email provider>>*
API RESPONSE CODE	*200 Success, 400 Failures, 500 Server Errors*

Request Payload includes the following parameters:

Parameter	Type	Mandatory (Yes/No)	Description
X-API-KEY	Header	No	API key used to invoke the custom Email provider
subject	string	Yes	Unique identifier of the user
email	string	Yes	Email Address to which email must be delivered
otp	string	Yes	OTP value that must be delivered
emailSubject	string	Yes	Subject of the email to be delivered
otpValidityInSecs	Integer	Yes	Validity of the OTP in seconds
message	string	Yes	The status message that must be delivered through the email

Parameter	Type	Mandatory (Yes/No)	Description
clientContext	an array of key-value pairs	No	Client context parameters received as part of the "/auth/v1/authenticate" call will be passed here by the client. Example: transactionIdentifier, appid, etc. `{ "subject": "{{userLoginid}}", "channel": "web", "ipAddress": "10.10.123.124", "action":"authenticate", "rememberMe" : true, "device": { "signature": { "iaAuthData": "_v02MyUgNGgYOi88OTk0........." } }, "clientContext": [{ "key": "transactionIdentifier", "value": "540715af-96f2-4b86-b89f-ca0e8ae93f40" }] }`
ahContext	an array of key-value pairs	No	Contains the IDSP context parameters. For information, see the *Sharing IDSP Context with SPI* section in Integrating with Custom SPI.
providerContext	array of key-value pairs	No	Parameters configured as part of the custom Email provider

Sample Request of "/EmailMessageSender" API:

```
{
  "subject": "nbruce",
  "email": "nina.bruce@example.com",
  "emailSubject": "One-Time Password",
  "otp" : "657841"
  "otpValidityInSecs": 300,
  "message": "657841 is your One-Time Password to login. The OTP is valid upto 10 minutes.",
  "clientContext": [
    {
      "key": "transactionIdentifier",
      "value": "540715af-96f2-4b86-b89f-ca0e8ae93f40"
    }
  ],
  "ahContext": [
    {
      "key": "clientTxnId",
      "value": "cd2f1e6e-c356-49ae-a5b8-c10bf571a9a0"
    },
    {
      "key": "txnId",
```

```
      "value": "txn-id-hd26se23"
    }
  ],
  "providerContext": [
    {
      "key": "instanceId",
      "value": "brazil-instance-1"
    }
  ]
}
```

Response Payload should include the following parameters:

Parameter	Type	Mandatory (Yes/No)	Description
status	string	Yes	This parameter returns the message delivery status as either a "success" or a "failure".
msg	string	Yes	This parameter returns a status message reflecting the delivery outcome. It returns specific messages based on success or failure instances.
clientRespContext	an array of key-value pairs	No	All the client response context that must be returned to the client as part of the successful authentication response should be returned in this field.

Sample Response of "/EmailMessageSender" API:

```
{
   "status": "success",
   "msg": "Message delivered successfully via Email",
   "clientRespContext": [
    {
      "key": "transactionId",
      "value": "txnId-6hdds733"
    },
    {
      "key": "deviceId",
      "value": "device-hdyn235sd"
    }
  ]
}
```

API Schema - (Swagger Content)

To view the sample representation of the API schema, see the **Common Open API Spec for all Custom Providers - (Swagger Content)** section in Integrating with Custom SPI.

Creating an Email Custom Provider

- Create an Email custom provider in IDSP using the Provider endpoint-
  `https://${SSP_FQDN}/{{tenantName}}/admin/v1/CustomProviders`

NOTE

- To know the value of ${SSP_FQDN} environment variable, see Configuring IDSP Environment Variables.
- The default value for `<tenantName>` is "default".
- Replace the text {{text}} including {{}} characters with appropriate values, in all the endpoints shown in the above table.
  For example:
  `https://{{host}}/{{tenantName}}/admin/v1/CustomProviders`
  should look similar to:
  `https://example.com/default/admin/v1/CustomProviders`
- To know more about the scopes that are required to secure these APIs, refer to the Rest APIs and Associated Privileges section.

NOTE
To refer to the Custom Provider APIs which can be used to perform CRUD operations in IDSP, see here.

Configuring the Global/Tenant Setting attribute

- Configure the global/tenant setting, ***emailProviderToBeUsed*** in IDSP to set a custom SPI Provider as the Email provider. The default value is "SMTP". See Settings for more information.

Email Use Case

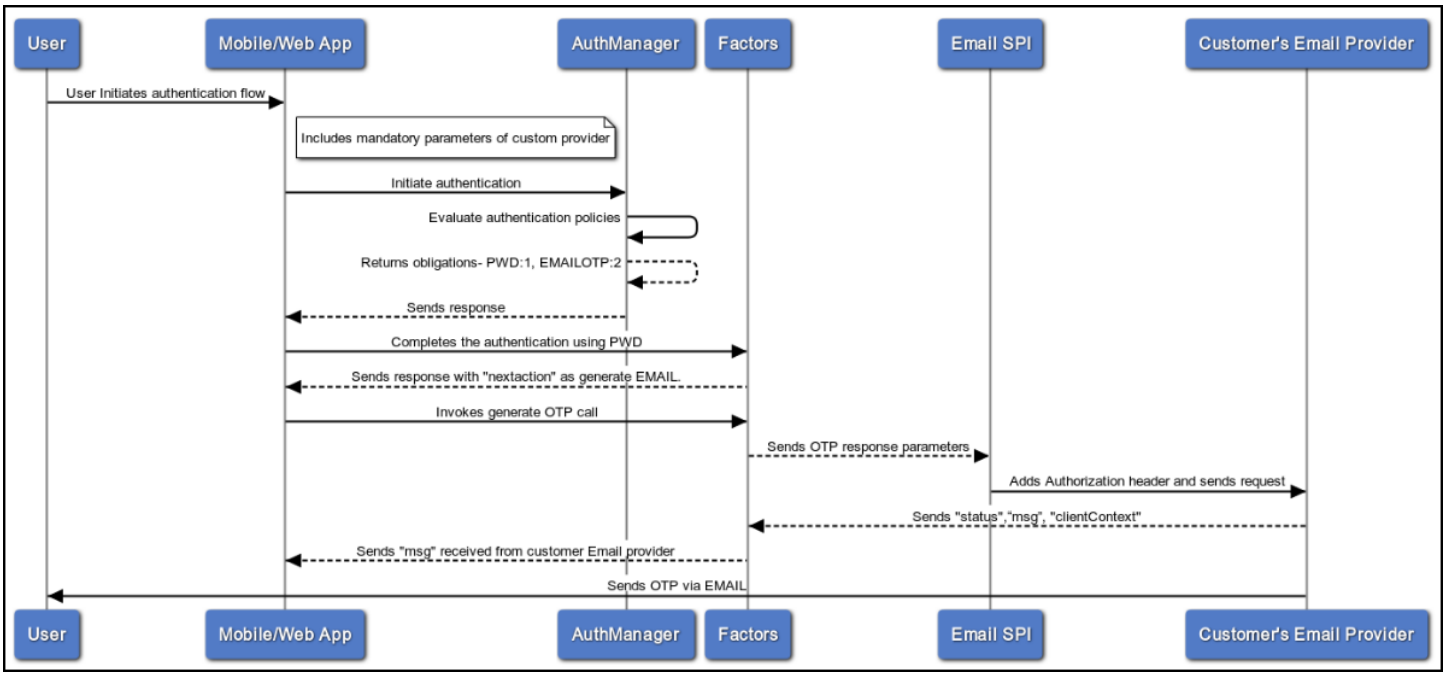
The following use case describes the integration between Custom Email Provider and IDSP.

It is assumed that the customer has configured the following global/tenant setting parameter:

- "emailProviderToBeUsed"

List of participants and what they represent:

- User- User who initiates the authentication flow.
- Application (Mobile/Web App): This is the application that calls the solution's APIs to acquire the identity token and complete the authentication flow.
- IDSP microservices:
  - AuthManager- This is the ***"/auth/v1/authenticate"*** API used to initiate the authentication flow.
  - Factor- This is the ***"/factor/v1/OTPGenerator"*** API used to generate the EMAIL.
  - Email SPI- This is the email wrapper used by the solution to call the custom email provider.
  - Customer's Email Provider- This is the customer's implementation of Email Provider API which is used to deliver email to the end user's email Id.



Flow Description:

1. The User initiates the Authentication Flow.
2. The client app invokes the "auth/v1/authenticate" API to initiate the Authentication flow. The request includes parameters such as user, authN context, clientContext [example:txn identifier].

   NOTE

   In certain cases, a client app may have to send additional parameters that may be mandatorily required by the custom Email provider to function. These parameters, for example, transaction Id, etc can be passed through the "***clientContext***" in the "/auth/v1/authenticate" call. See the following reference sample:

```
{
    "subject": "{{userLoginid}}",
    "channel": "web",
    "ipAddress": "10.10.123.124",
    "action":"authenticate",
    "rememberMe" : true,
    "device": {
        "signature": {
            "iaAuthData": "_v02MyUgNGgYOi88OTk0........."
        }
    },
     "clientContext": [
        {
            "key": "transactionIdentifier",
            "value": "540715af-96f2-4b86-b89f-ca0e8ae93f40"
        }
    ]
}
```

3. Internally, the "/auth/v1/authenticate" API does the following:

  - Checks whether the global/tenant settings parameter, "emailProviderToBeUsed" is configured in the IDSP. In this flow, we have assumed that the setting is configured to a custom email provider.
  - AuthManager communicates with the Policy Engine to evaluate the configured policy rules for the client app and determines the authentication obligations. Also, sends a response to the client app. In the flow, it is assumed that the obligations returned are PWD:1, and EMAILOTP:2.
4. The client successfully completes the first-factor authentication, PWD:1.
5. The client is challenged with the remaining obligation, that is EMAILOTP:2.
6. The Factors API sends a response to the app with "nextaction" as generate EMAILOTP.
7. The Client app invokes the "/factor/v1/OTPGenerator" API to generate the EMAILOTP.
8. The Factor API sends EMAILOTP details, including email, emailSubject, otp, otpValidity, clientContext, providerContext, and so on, to the EMAIL SPI.
9. The Email SPI adds an Authorization header (API Key) and sends the EMAILOTP details to the Customer's SPI provider.
10. The Customer's Email Provider in return sends the Email delivery response to the Factors service. The response includes transaction status and message. It also sends the OTP through email to the end customer’s email Id.
11. The Factor API sends "msg" received from customer's Email provider to the client app.

- Email OTP Authentication

Integrating with External Push Provider

Integrate Symantec Identity Security Platform with a custom push provider to send authentication notifications to mobile devices using the Custom Service Provider Interface (SPI).

This topic includes the following:

- Custom Provider Overview
- Implementing the SPIs
- Steps to Integrate with Custom Push SPI
- API Schema - (Swagger Content)
- Creating a Push Provider
- Configuring Settings in IDSP
- Push Use Case

Custom Provider Overview

The Custom SPI utilizes an OpenAPI specification and requires a separate web service hosted within your infrastructure. To enable communication between Symantec Identity Security Platform and your push provider, you must implement the SPI endpoints and configure the system settings detailed in the following sections.

Steps to Integrate with Custom Push SPI

The three steps that the Customers have to perform to integrate with the Push SPI are:

1. Develop the Custom Push Service based on the Push-Open API Spec provided by IDSP.
2. Create a Push Custom Provider in IDSP using the Provider endpoint-

```
https://${SSP_FQDN}/{{tenantName}}/admin/v1/CustomProviders
```

NOTE

- To know the value of ${SSP_FQDN} environment variable, see Configuring IDSP Environment Variables.
- The default value for `<tenantName>` is "default".
- Replace the text {{text}} including {{}} characters with appropriate values, in all the endpoints shown in the above table.
  For example:
  `https://{{host}}/{{tenantName}}/admin/v1/CustomProviders`
  should look similar to:
  `https://example.com/default/admin/v1/CustomProviders`
- To know more about the scopes that are required to secure these APIs, refer to the Rest APIs and Associated Privileges section.

3. Specify the configuration settings in IDSP.

These steps have been described in the subsequent sections.

Implementing the SPIs

The following SPI should be implemented by the customer to integrate their Push provider with the solution's custom SPI:

- "**PushMessageSender**" - This SPI request is used to send push notifications to the customers.
- "**PushStatus**" - This SPI request is used to check the status of push authentication at the Push SPI provider service.

The SPI request and response templates are based on the standard Open API spec that IDSP expects the customers to provide during the integration process. The SPI specifications have been explained in the subsequent sections.

PushMessageSender SPI Specification

PushMessageSender SPI Specification	
API Name	PushMessageSender
API URL	*https://<CustomProviderHost>/**PushMessageSender***
API OPERATION	*POST*
AUTHORIZATION	*<<SPI Key shared by the custom Push provider>>*
API RESPONSE CODE	*200 Success, 400 Failures, 500 Server Errors*

Request Payload includes the following parameters:

Parameter	Type	Mandatory (Yes/No)	Description
X-API-KEY	Header	No	API key used to invoke the custom Push provider
subject	string	Yes	Unique identifier of the user
deviceIdentifier	string	Yes	Device Identifier of the device to which a Push notification must be sent. For example, FCM registration token for a device.
title	string	Yes	Title of Push notification
msg	string	Yes	The message that must be delivered through the Push notification

Parameter	Type	Mandatory (Yes/No)	Description
clientContext	an array of key-value pairs	Yes	Client context parameters received as part of the "/auth/v1/authenticate" call will be passed here by the client. Example: transactionIdentifier, appid, etc. `{ "subject": "{{userLoginid}}", "channel": "web", "ipAddress": "10.10.123.124", "action":"authenticate", "rememberMe" : true, "device": { "signature": { "iaAuthData": "_v02MyUgNGgYOi88OTk0........." } }, "clientContext": [{ "key": "transactionIdentifier", "value": "540715af-96f2-4b86-b89f-ca0e8ae93f40" }] }`
ahContext	an array of key-value pairs	No	Contains the IDSP context parameters. For information, see the *Sharing IDSP Context with SPI* section in Integrating with Custom SPI.
providerContext	array of key-value pairs	No	Parameters configured as part of the custom Push provider

Sample Request of "/PushMessageSender" SPI:

```
{
  "subject": "nbruce",
  "deviceIdentifier": "DEVID-01-002",
  "title": "Push Authentication",
  "msg": "Please approve your transaction",
  "clientContext": [
    {
      "key": "transactionIdentifier",
      "value": "540715af-96f2-4b86-b89f-ca0e8ae93f40"
    }
  ],
  "ahContext": [
    {
      "key": "clientTxnId",
      "value": "cd2f1e6e-c356-49ae-a5b8-c10bf571a9a0"
    },
    {
      "key": "txnId",
      "value": "txn-id-hd26se23"
    }
```

```
  ],
  "providerContext": [
    {
      "key": "instanceId",
      "value": "brazil-instance-1"
    }
  ]
}
```

Response Payload should include the following parameters:

Parameter	Type	Mandatory (Yes/No)	Description
status	string	Yes	This parameter returns the message delivery status as either of the followig: "INITIATED", "AUTHENTICATED", "REJECTED", "IN_PROGRESS", "TIMED_OUT"
msg	string	Yes	This parameter returns a status message reflecting the delivery outcome. For example: In case of success, it may return a message like "Message delivered successfully via Push".
pushContext	an array of key-value pairs	No	The keys in the 'pushContext' element are returned by your PushMessageSender SPI implementation and consumed by your PushStatus SPI implementation. It is upto your implementation to construct and name these keys as you see fit. Note that whatever lookup you have implemented in your PushStatus custom SPI to track previously sent PUSH request, that lookup uses the data from and only from, 'pushContext' that is being passed into your custom PushStatus SPI. Your custom PushStatus SPI must not rely on any other identifiers. All the push context key-value pairs are returned by your SPI client as part of the Push authentication response. For example, pushRequestId, customDeviceId

Sample Response of "/PushMessageSender" SPI:

```
{
   "status": "success",
   "msg": "Message delivered successfully via Push",
   "pushContext": [
    {
      "key": "pushRequestId",
      "value": "12345"
    },
    {
      "key": "customDeviceId",
      "value": "device-hdyn235sd"
    }
  ]
}
```

PushStatus SPI Specification

This SPI request is used to check the status of Push authentication at the Push SPI provider service.

PushStatus SPI Specification	
API Name	PushStatus
API URL	*https://<CustomProviderHost>/**PushStatus***
API OPERATION	*POST*
AUTHORIZATION	*<<SPI Key shared by the custom Push provider>>*
API RESPONSE CODE	*200 Success, 400 Failures, 500 Server Errors*

Request Payload includes the following parameters:

Parameter	Type	Mandatory (Yes/No)	Description
X-API-KEY	Header	No	API key used to invoke the custom Push provider
subject	string	Yes	Unique identifier of the user
pushContext	an array of key-value pairs	Yes	PushContext is returned by the /PushMessageSender SPI that contains push-specific context attributes. Example: pushRequestId, customDeviceId
ahContext	an array of key-value pairs	No	Contains the IDSP context parameters. For information, see the *Sharing IDSP Context with SPI* section in Integrating with Custom SPI.
providerContext	array of key-value pairs	No	Parameters configured as part of the custom push provider SPI.

Sample Request of "/PushStatus" SPI:

```
{
  "subject": "nbruce",
  "pushContext": [
    {
      "key": "pushRequestId",
      "value": "12345"
    },
    {
      "key": "customDeviceId",
      "value": "device-hdyn235sd"
    }
  ],
  "ahContext": [
    {
      "key": "clientTxnId",
      "value": "cd2f1e6e-c356-49ae-a5b8-c10bf571a9a0"
    },
    {
      "key": "txnId",
      "value": "txn-id-hd26se23"
    }
  ],
  "providerContext": [
```

```
    {
      "key": "instanceId",
      "value": "brazil-instance-1"
    }
  ]
}
```

Response Payload should include the following parameters:

Parameter	Type	Mandatory (Yes/No)	Description
status	string	Yes	This parameter returns the message delivery status as either of the followig: "INITIATED", "AUTHENTICATED", "REJECTED", "IN_PROGRESS", "TIMED_OUT"
msg	string	Yes	This parameter returns a status message reflecting the delivery outcome. For example: 'Approved'
clientRespContext	an array of key-value pairs	No	All the push context key-value pairs must be returned by the SPI client as part of the Push authentication response. For example, transactionId.

Sample Response of "/PushStatus" SPI:

```
{
  "status": "success",
  "msg": "Message delivered successfully via Push",
  "clientRespContext": [
    {
      "key": "pushRequestId",
      "value": "12345"
    },
    {
      "key": "customDeviceId",
      "value": "device-hdyn235sd"
    }
  ]
}
```

Possible PushStatus responses

Message	Status	Description
Approved	success	If push is approved by end-used, this particular message and status will be returned by Push SPI end-point.
Denied	success	If push is denied by end-used, this particular message and status will be returned by Push SPI end-point.
Inprogress	success	If the end-used has not taken any action on the Push notification, this particular message and status will be returned.
Timeout	success	If the Push notification got timed out, this particular message and status will be returned.

Message	Status	Description
Any error message	failure	In case, any other error takes place at the Push SPI end-point, the error message and status as 'failure' will be returned.

API Schema - (Swagger Content)

To view the sample representation of the API schema, see the **Common Open API Spec for all Custom Providers - (Swagger Content)** section in Integrating with Custom SPI.

Creating a Push Custom Provider

- Create a Push custom provider in IDSP using the Provider endpoint-
  `https://${SSP_FQDN}/{{tenantName}}/admin/v1/CustomProviders`

  NOTE
  To refer to the Custom Provider SPIs that can be used to perform CRUD operations in IDSP, see here.

Configuring the Global/Tenant Setting attribute

- Configure the global/tenant setting, ***pushProviderToBeUsed*** i n IDSP to set a custom SPI Provider as the Push provider. The default value is "VIP". See Settings for more information.

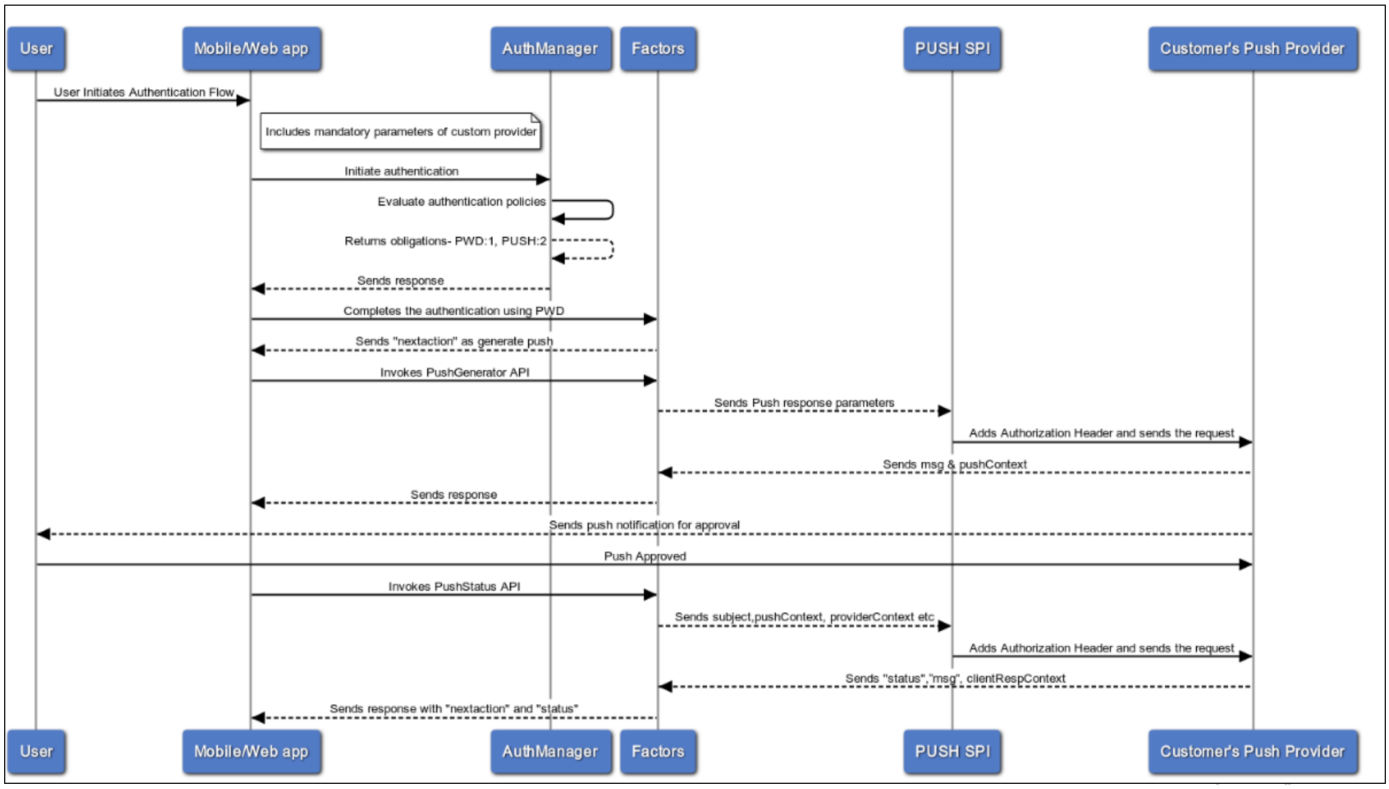
Push Use Case

The following use case describes the integration between Custom Push Provider and IDSP. It is assumed that the customer has configured the following global/tenant setting parameter:

- "pushProviderToBeUsed"

List of participants and what they represent:

- User- One who initiates the authentication flow.
- Application (Mobile/Web App): This is the application that calls the solution's APIs to acquire the identity token and complete the authentication flow.
- IDSP microservices:
  - AuthManager- This is the ***"/auth/v1/authenticate"*** API used to initiate the authentication flow.
  - Factor- This is the ***"/factor/v1/PushGenerator"*** API used to generate the PUSH.
  - PUSH SPI- This is the push wrapper used by the solution to call the custom push provider.
  - Customer's PUSH Provider- This is the customer's implementation of PUSH Provider SPI which is used to deliver push to the end user's phone number.



Flow Description:

1. The User initiates the Authentication Flow.
2. The client app invokes the "auth/v1/authenticate" API to initiate the Authentication flow. The request includes parameters such as user, authN context, clientContext [example:txn identifier].

   NOTE

   In certain cases, a client app may have to send additional parameters that may be mandatorily required by the custom Push provider to function. These parameters, for example, transaction Id, etc can be passed through the "***clientContext***" in the "/auth/v1/authenticate" call. See the following reference sample:

```
{
    "subject": "{{userLoginid}}",
    "channel": "web",
    "ipAddress": "10.10.123.124",
    "action":"authenticate",
    "rememberMe" : true,
    "device": {
        "signature": {
            "iaAuthData": "_v02MyUgNGgYOi88OTk0........."
        }
    },
     "clientContext": [
        {
            "key": "transactionIdentifier",
            "value": "540715af-96f2-4b86-b89f-ca0e8ae93f40"
        }
    ]
}
```

3. Internally, the "/auth/v1/authenticate" API does the following:
   – Checks whether the global/tenant settings parameter, "pushProviderToBeUsed" is configured in the IDSP. In this flow, we have assumed that the setting is configured to a custom push provider.
   – AuthManager communicates with the Policy Engine to evaluate the configured policy rules for the client app and determines the authentication obligations and sends the response to the client app. In the flow, it is assumed that the obligations returned are PWD:1, and PUSH:2.
4. The client successfully completes the first-factor authentication, PWD:1.
5. The Factor API challenges the client with the remaining obligation, that is PUSH:2. Sends the response to the client app with "nextaction" as generate PUSH.
6. The client app invokes the "/factor/v1/PushGenerator" API to generate the PUSH.
7. The Factors API sends the subject, title, pushMsg, deviceIdentifier, providerContext, and so on, to the Push SPI.
8. The PUSH SPI adds an Authorization header (API Key) and sends the PUSH details to the Customer's SPI provider.
9. The Customer's PUSH Provider in return sends success, Message delivery successful, pushContext to the factors and also sends the push notification for approval to user.
10. The user approves the push and sends the response back to the custom provider.
11. The client app invokes the "/factor/v1/PushStatus" SPI to check the status of the push authentication. The Factors API sends subject, pushContext, providerContext, and so on, to the PUSH SPI.
12. The PUSH SPI adds an Authorization header (API Key) and sends the pushContext details to the Customer's SPI provider.
13. The custom push provider sends "status"="success",“msg”: "Approved”, clientRespContext [example:txn identifier] back to the factors.
14. The Factors API sends back the response with "nextaction" as "AUTH_ALLOWED" and "status" as "AUTHENTICATED" to the client app.

Integrating with External IVR Provider

Integrate Symantec Identity Security Platform with a custom IVR provider to deliver voice-based authentication to mobile devices using the Custom Service Provider Interface (SPI).

This topic includes the following:

- Custom Provider Overview
- Steps to Integrate with Custom IVR SPI
- Implementing the APIs
- API Schema - (Swagger Content)
- Creating a IVR Provider
- Configuring Settings in IDSP
- IVR Use Case

Custom Provider Overview

The Custom SPI is based on an OpenAPI specification and requires a separate web service hosted within your infrastructure. To enable communication between Symantec Identity Security Platform and your IVR provider, you must implement the required API endpoints and configure the system settings detailed in the following sections.

NOTE

- IDSP does not have a built-in provider for IVR.
- The Sample Applications (Mobile & Web) and the Signin UI have not been updated to support IVR.
- If a user has already registered a phone number with IDSP for SMS OTP, the IVR service will utilize that phone number to deliver IVR OTP. The user is requested for inline registration if there is no phone number registered.

Steps to Integrate with Custom IVR SPI

The three steps that the Customers have to perform to integrate with the IVR SPI are:

1. Develop the custom IVR service based on the IVR-Open API Spec provided by IDSP.
2. Create an IVR Custom Provider in IDSP using the Provider endpoint-
   `https://${SSP_FQDN}/{{tenantName}}/admin/v1/CustomProviders`

   NOTE

   - To know the value of ${SSP_FQDN} environment variable, see Configuring IDSP Environment Variables.
   - The default value for `<tenantName>` is "default".
   - Replace the text {{text}} including {{}} characters with appropriate values, in all the endpoints shown in the above table.
     For example:
     `https://{{host}}/{{tenantName}}/admin/v1/CustomProviders`
     should look similar to:
     `https://example.com/default/admin/v1/CustomProviders`
   - To know more about the scopes that are required to secure these APIs, refer to the Rest APIs and Associated Privileges section.
3. Specify the configuration settings in IDSP.

These steps have been described in the subsequent sections.

Implementing the API

The following APIs should be implemented by the customer to integrate their IVR provider with the solution's custom SPI:

- "**IVRMessageSender**" - This API request is used to send the SMS to the custom IVR provider that sends a voice message to the customer's phone.

The API request and response templates are based on the standard Open API spec that IDSP expects the customers to provide during the integration process. The API specifications have been explained in the subsequent sections.

IVRMessageSender API Specification

IVRMessageSender API Specification	
API Name	IVRMessageSender
API URL	*https://<CustomProviderHost>/**IVRMessageSender***
API OPERATION	*POST*
AUTHORIZATION	*<<API Key shared by the custom IVR provider>>*
API RESPONSE CODE	*200 Success, 400 Failures, 500 Server Errors*

Request Payload includes the following parameters:

Parameter	Type	Mandatory (Yes/No)	Description
X-API-KEY	Header	No	API key used to invoke the custom IVR provider
subject	string	Yes	Unique identifier of the user
phoneNumber	string	Yes	Phone number to which the voice SMS must be delivered
otp	string	Yes	otp value that must be delivered
otpValidityInSecs	Integer	Yes	Validity of the OTP in seconds
message	string	Yes	Status message that must be delivered via voice SMS

clientContext	an array of key-value pairs	Yes	Client context parameters received as part of the "/auth/v1/authenticate" call will be passed here by the client. Example: transactionIdentifier, appid, etc.
			`{`
			`"subject": "{{userLoginid}}",`
			`"channel": "web",`
			`"ipAddress": "10.10.123.124",`
			`"action":"authenticate",`
			`"rememberMe" : true,`
			`"device": {`
			`"signature": {`
			`"iaAuthData": "_v02MyUgNGgYOi88OTk0....."`
			`}`
			`},`
			`"clientContext": [`
			`{`
			`"key": "transactionIdentifier",`
			`"value": "540715af-96f2-4b86-b89f-ca0e8ae93f40"`
			`}`
			`]`
			`}`

ahContext	an array of key-value pairs	No	Contains the IDSP context parameters. For information, see the *Sharing IDSP Context with SPI* section in Integrating with Custom SPI.
providerContext	array of key-value pairs	No	Parameters configured as part of the custom IVR provider

Sample Request of "/IVRMessageSender" API:

```
{
  "subject": "nbruce",
  "phoneNumber": 13242342341,
  "otp": 783242,
  "otpValidityInSecs": 300,
  "message": "783242 is your One-Time Password to login. The OTP is valid upto 10 minutes.",
  "clientContext": [
    {
      "key": "transactionIdentifier",
```

```
      "value": "540715af-96f2-4b86-b89f-ca0e8ae93f40"
    }
  ],
  "ahContext": [
    {
      "key": "clientTxnId",
      "value": "cd2f1e6e-c356-49ae-a5b8-c10bf571a9a0"
    },
    {
      "key": "txnId",
      "value": "txn-id-hd26se23"
    }
  ],
  "providerContext": [
    {
      "key": "instanceId",
      "value": "brazil-instance-1"
    }
  ]
}
```

Response Payload should include the following parameters:

Parameter	Type	Mandatory (Yes/No)	Description
status	string	Yes	This parameter returns the voice message delivery status as either a "success" or a "failure".
msg	string	Yes	This parameter returns a status message reflecting the delivery outcome. It returns specific messages based on success or failure instances.
clientRespContext	an array of key-value pairs	No	All the IVR context key-value pairs must be returned by the SPI client as part of the IVR authentication response. For example, transactionId.

Sample Response of "/IVRMessageSender" API:

```
{
  "status": "success",
  "msg": "Message delivered successfully via IVR",
  "clientRespContext": [
    {
      "key": "transactionId",
      "value": "txnId-6hdds733"
    },
    {
      "key": "deviceId",
      "value": "device-hdyn235sd"
    }
  ]
}
```

API Schema - (Swagger Content)

To view the sample representation of the API schema, see the **Common Open API Spec for all Custom Providers - (Swagger Content)** section in Integrating with Custom SPI.

Creating an IVR Custom Provider

- Create an IVR custom provider in IDSP using the Provider endpoint-

  ```
  https://${SSP_FQDN}/{{tenantName}}/admin/v1/CustomProviders
  ```

  NOTE
  To refer to the Custom Provider APIs that can be used to perform CRUD operations in IDSP, see here.

Configuring the Global/Tenant Setting attribute

- Configure the global/tenant setting, ***ivrProviderToBeUsed*** in IDSP to set a custom SPI Provider as the IVR provider. See Settings for more information. Default value is "**none**".

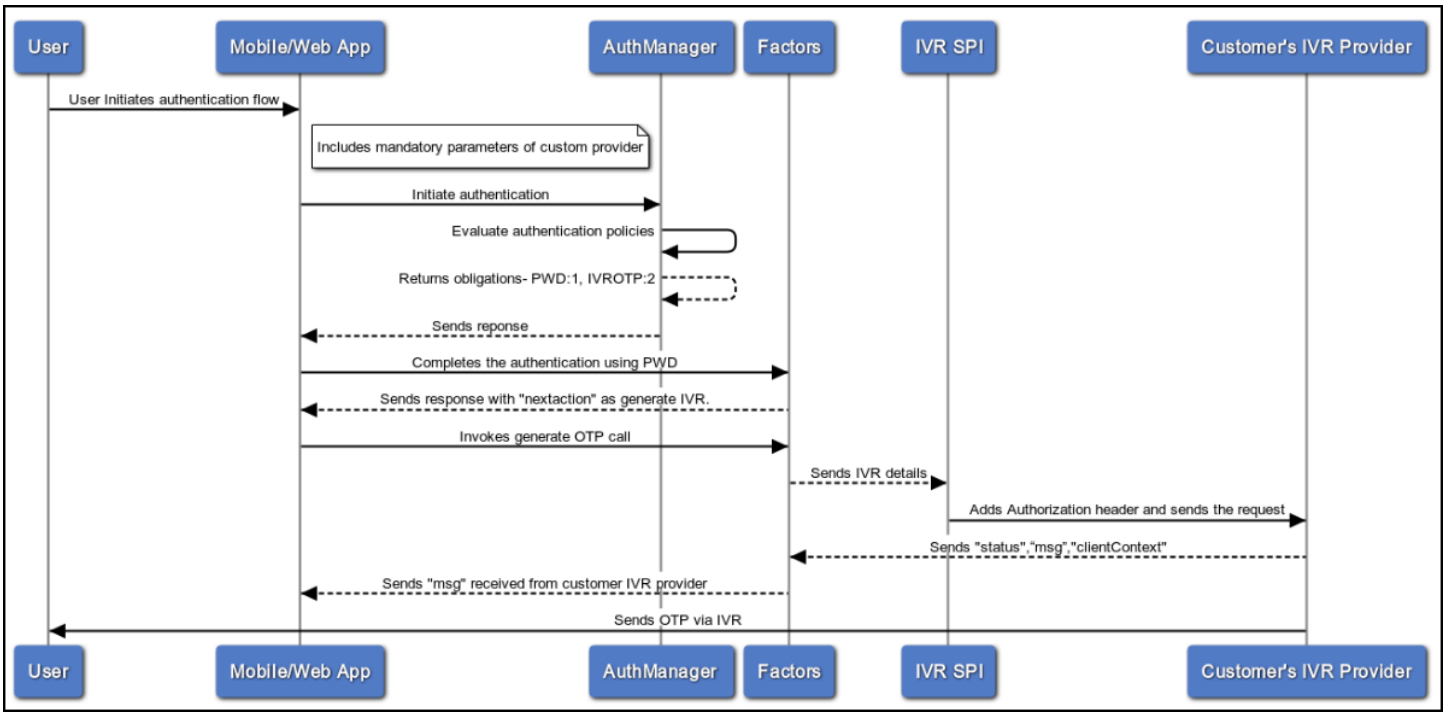
IVR Use Case

The following use case describes the integration between Custom IVR Provider and IDSP. It is assumed that the customer has configured the following global/tenant setting parameter:

- "ivrProviderToBeUsed"

List of participants and what they represent:

- User- User who initiates the authentication flow.
- Application (Mobile/Web App): This is the application that calls the solution's APIs to acquire the identity token and complete the authentication flow.
- IDSP microservices:
  - AuthManager- This is the ***"/auth/v1/authenticate"*** API used to initiate the authentication flow.
  - Factor- This is the ***"/factor/v1/OTPGenerator"*** API used to generate the IVR.
  - IVR SPI- This is the IVR module in IDSP used to call the custom ivr provider in customer's environment.
  - Customer's IVR Provider- This is the customer's implementation of IVR Provider API which is used to deliver ivr to the end user's phone number.



Flow Description:

1. The User initiates the Authentication Flow.
2. The client app invokes the "auth/v1/authenticate" API to initiate the Authentication flow. The request includes parameters such as user, authN context, clientContext [example:txn identifier].

   NOTE

   In certain cases, a client app may have to send additional parameters that may be mandatorily required by the custom IVR provider to function. These parameters, for example, transaction Id, etc. can be passed through the "***clientContext***" in the "/auth/v1/authenticate" call. See the following reference sample:

```
{
    "subject": "{{userLoginid}}",
    "channel": "web",
    "ipAddress": "10.10.123.124",
    "action":"authenticate",
    "rememberMe" : true,
    "device": {
        "signature": {
            "iaAuthData": "_v02MyUgNGgYOi88OTk0........."
        }
    },
     "clientContext": [
        {
            "key": "transactionIdentifier",
            "value": "540715af-96f2-4b86-b89f-ca0e8ae93f40"
        }
    ]
}
```

3. Internally, the "/auth/v1/authenticate" API does the following:

   - Checks whether the global/tenant settings parameter, "ivrProviderToBeUsed" is configured in the IDSP. In this flow, we have assumed that the setting is configured to a custom ivr provider.
   - AuthManager communicates with the Policy Engine to evaluate the configured policy rules for the client app and determines the authentication obligations. Also, send a response to the client app. In the flow, it is assumed that the obligations returned are PWD:1, and IVROTP:2.
4. The client successfully completes the first-factor authentication, PWD:1.
5. The client is challenged with the remaining obligation, that is IVROTP:2.
6. The Factor API sends the response to the client app with "nextaction" as generate IVROTP.
7. The Client app invokes the "/factor/v1/OTPGenerator" API to generate the IVROTP. IDSP sends the IVROTP to the IVR SPI.
8. The Factor API sends IVROTP details, including subject, phoneNumber, otp, message, otpValidity, clientContext, providerContext, and so on, to the IVR SPI.
9. The IVR SPI adds an Authorization header (API Key) and sends the IVROTP details to the Customer's SPI provider.
10. The Customer's IVR Provider in return sends the ivr delivery response to the Factors service. The response includes transaction status and message. It also sends the IVR OTP through phone to the end customer’s phone number.
11. The Factor API sends "msg" received from customer's IVR provider to the client app.

- IVR OTP Authentication

Integrating with Custom Authentication Factor

Configure and implement custom authentication factors within Symantec Identity Security Platform policies to meet specialized security and business requirements.

Consider using a custom authentication factor in the following scenarios:

- When a password is hashed in a specific way.
- When implementing a custom challenge/response mechanism with a custom SignIn Client that uses a unique data set.
- To address any other specialized business requirements.

To implement this, develop a Custom SPI that integrates with the standard SignIn UI via the Custom Authenticator API. IDSP also supports fully custom SignIn clients, allowing the custom factor to function as a standalone requirement or as part of a multi-factor authentication policy.

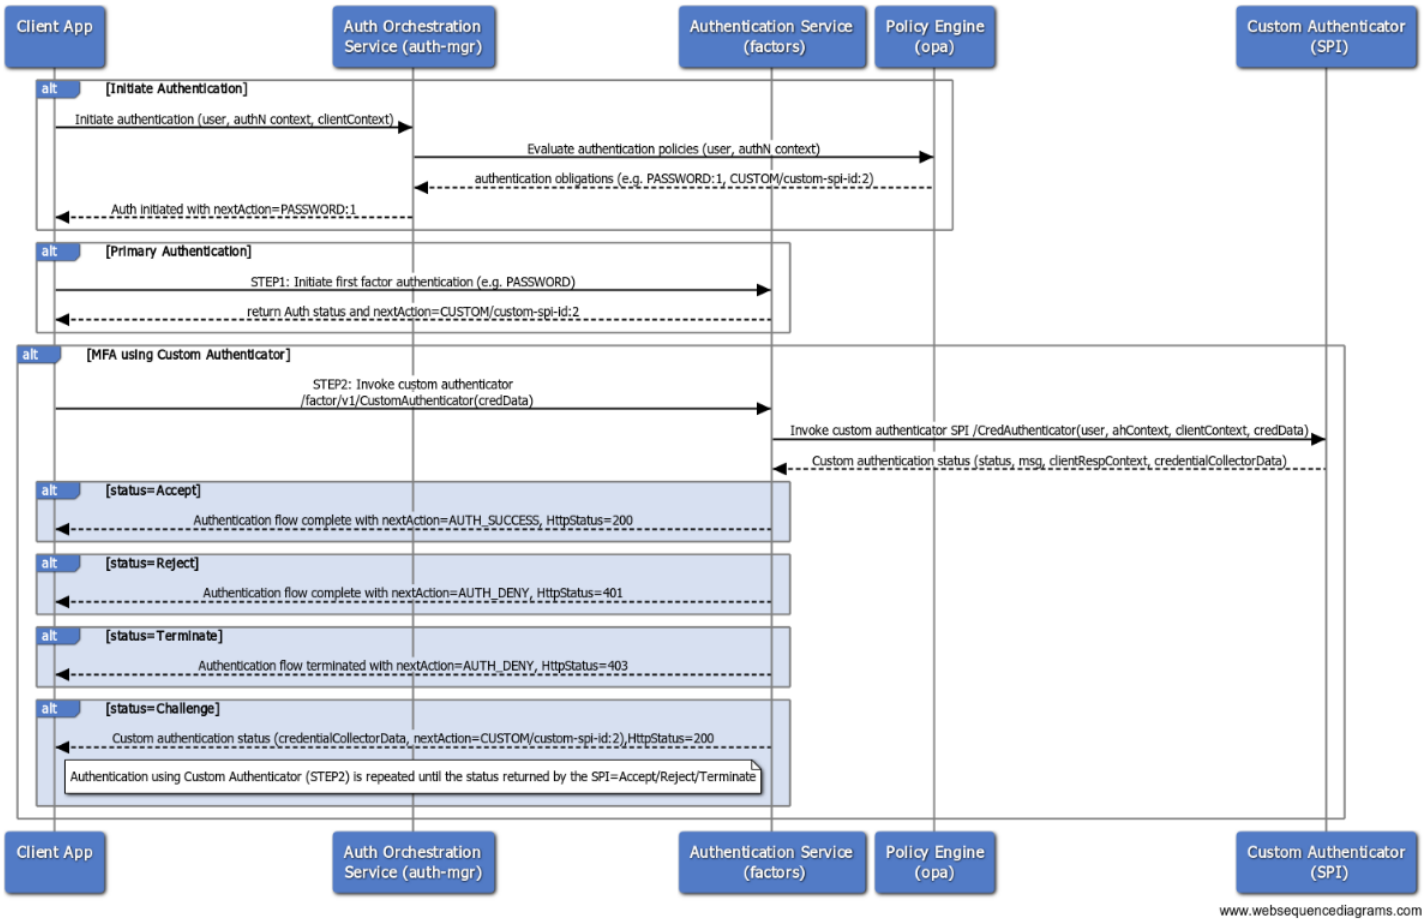
- For information about developing a custom SPI, see Integrating with Custom SPI.
- For information about a SignIn Client, see SignIn User Interface (UI).

This topic covers the following sections:

- Authentication Flow of a Custom Authentication Factor
- Configuration to Support a Custom Authentication Factor
- API Specification
- SPI Specification

Authentication Flow of a Custom Authentication Factor

The following sequence diagram explains the authentication flow between a Client and the Custom Authentication Factor API:



The following process explains the workflow between the Client and the Custom Authentication Factor API when a custom authentication factor is used:

1. The Client invokes `https://${SSP_FQDN}/{{tenantName}}/auth/v1/authenticate`.

   NOTE

   - To know the value of ${SSP_FQDN} environment variable, see Configuring IDSP Environment Variables.
   - The default value for `<tenantName>` is "default".
   - Replace the text {{text}} including {{}} characters with appropriate values, in all the endpoints shown in the above table.

     For example:

     `https://{{host}}/{{tenantName}}/auth/v1/authenticate`

     should look similar to:

     `https://example.com/default/auth/v1/authenticate`
   - To know more about the scopes that are required to secure these APIs, refer to the Rest APIs and Associated Privileges section.
2. IDSP evaluates the authentication policy with an optional risk SPI.
3. IDSP constructs a flow state with specific factors to execute, such as F1, F2, and F3, where F2 is a custom authentication factor and CUSTOM_AUTH is its obligation.
4. The Client invokes the /CustomAuthenticator API with the "first time" directive in OperationalContext, an optional parameter in the request.

This step begins the interaction with the custom SPI that is represented by the custom provider, which is associated with the custom authentication factor. The interaction continues until the API indicates AUTH_ALLOW or AUTH_DENY.

5. The custom SPI returns challenge directive for the Client to display.
6. The Client invokes the /CustomAuthenticator API with the response directive in the CredData context of the request.
7. The custom SPI returns Accept/Reject/Challenge/Terminate as the status as per the custom SPI implementation.
   - **Accept**: Indicates that the custom SPI has successfully authenticated the user. IDSP advances the authentication flow as per authentication policy.
   - **Challenge**: Indicates that the custom SPI requests a challenge. IDSP does not proceed to the next authentication factor or complete the flow. The Client challenges again with "credData" as returned by the Custom SPI. This "challenge" does not impact the flow state as asserted by IDSP and does not impact the next authentication factor if there is one. Any state to be passed to the custom SPI is done by the client using dedicated Credential Data.
   - **Reject**: Indicates that the custom SPI has rejected credentials and expects the Client to redo the operation. IDSP increments the user lock strike count, and does not advance the authentication flow.
   - **Terminate**: Indicates that the custom SPI has failed to authenticate the user. IDSP fails the authentication flow.

For more information about the flow, see Examples of Using a Custom Authentication Factor.

> **NOTE**
> The OperationalContext of the custom SPI may include the cookie/header directives to be processed by IDSP when returning the API response.

Configuration to Support a Custom Authentication Factor

The following configurations are required to use a custom authentication factor:

Authentication Policy

Configure the authentication policy to use the `CUSTOM/<custom-provider-guid>:<factor-level>` obligation.

Example: CUSTOM/MyCustomAuthProvider:2

A custom provider is resolved in the resource tenancy first. If it is not found, then it is resolved in the system tenancy.

Custom Provider - providerProperties

A custom provider uses the providerProperties key-value pairs to define a provider-specific behavior. There are two property types:

- **Custom**: All custom properties are published into the providerContext of the SPI request and are consumed by the custom SPI.
- **Well-known**: All well-known properties begin with the **spi.** prefix, representing the directives to be performed by IDSP when sending requests to and receiving responses from the custom SPI.

The following table lists the providerProperties that must be configured to support the use of a custom authentication factor:

Type	providerContext	Description
Custom	**key**: <custom-key> **value**: <custom-value>	Publishes a custom key-value pair into the ProviderContext of the custom SPI. The value in a key-value pair supports dynamic substitution using the ${keyword} notation. For information, see Dynamic Environment Substitution.

Well-known	**key**: spi.discover.capabilities **value**: CSV list of capabilities	Specifies the capabilities that are supported by the custom provider using multiple, comma-delimited placeholders. This enables IDSP to recognize the configured Custom Provider as having custom authentication capabilities, for example: • **customauthenticator**: Specifies that the custom SPI supports a custom authentication factor that is accessible through the "/CustomAuthenticator" runtime flow.
Well-known	**key**: spi.auth.factor.flowid **value**: N/A	Identifies the flow to be performed by the SignIn Client. If this property is defined, this flowid is communicated to the SignIn Client when a custom authentication factor is to be invoked the first time. • Prior to the first invocation of the custom SPI, if no such property exists, the flowid comes from ProviderContext to be passed into the custom SPI. The SignIn Client is expected to pass this value into the custom SPI via OperationalContext of the request from the custom SPI. • On subsequent flows within the same custom authentication factor, the value is derived from OperationalContext that is returned by the custom SPI.

Well-known	**key**: spi.auth.factor.amr **value**: <amr-value>	Represents one or more AMR values (in CSV format) of the custom authentication factor. These AMR values are to be associated with the custom provider. You can enter multiple comma-delimited values from the following list: • PWD: Password style authentication • OTP: One time code (SMS, EMAIL, IVR) • FIDO: Passwordless • HWK: Hardware Key (Yubikey) • MOTP: Mobile one time code • PUSH: Mobile push • POP: SiteMinder X509 integration use case • SWK: N/A • WIA: SiteMinder IWA/Kerberos integration use case • <custom>: A custom AMR value If multiple instances of this key are provided, the last one takes precedence. If this key is specified by ProviderContext and also returned by the OperationalContext of the custom SPI, then the value from the OperationalContext takes precedence.
Well-known	**key**: spi.request.header.proxy **value**: <*header-name*>	Identifies the header name in an API request that must be included as an HTTP header in the request of the custom SPI.
Well-known	**key**: spi.request.cookie.proxy **value**: <*cookie-name*>	Identifies the cookie name in an API request that must be included as an HTTP cookie in the request of the custom SPI.
Well-known	**key**: spi.response.header.proxy **value**: <*header-name*>	Identifies the header name in the response of the custom SPI that must be included as an HTTP header in an API request.
Well-known	**key**: spi.response.cookie.proxy **value**: <*cookie-name*>	Identifies the cookie name in the response of the custom SPI that must be included as an HTTP cookie in an API request.

Custom Provider - providerHeaders

A custom provider uses providerHeaders in a key-value pair format to define provider-specific headers to be sent to the custom SPI. Similar to "providerProperties", the headers definitions also supports dynamic substitution using the ${keyword} notation. For information, see Dynamic Environment Variable Substitution.

API Specification

API Name	**CustomAuthenticator**
API URL	https://${SSP_FQDN}/<tenant-name>/factor/v1/CustomAuthenticator

API OPERATION	POST
AUTHORIZATION	Client-Access-Token
API RESPONSE CODE	• 200 Success (Allow or Challenge) • 401 Unauthorized (Reject) • 403 Forbidden (Terminate) • 400 Bad Request (API/SPI error) • 500 Internal Server Error (API/SPI error)

Note: A custom SPI that expects to plug and play with IDSP's out-of-the-box SignIn UI SignIn Client must support the challenge/response directives as documented.

API Request

The API request to a custom provider can contain cookies, headers, standard headers, and regular x-flow-state header along with the following properties:

Property	Type	Mandatory?	Description		
operationalContext	Array of key-value pairs	Yes	Specifies the optional directives as hints to a custom SPI.		
			Key	**Value**	**Description**
			(Optional) spi.auth.factor.flowid	<string>	Client submits a flowid for the custom SPI to execute. Custom provider uses the same property to let the Client know the flowid to start with. Subsequent invocations of the custom SPI return next flowid for the Client to request.
			spi.auth.factor.firsttime	true/false	Client submits this flag for the custom SPI to know that it is being invoked for the first time. Custom SPI supporting such behavior would respond back with the challenge (in credData) for the Client to challenge the user with. **Note:** • Custom SPI that expects to plug and play with the out-of-the-box SignIn UI/ custom SignIn Client must support this.

			<custom-key>	<string>	Any custom key and related value the Client considers to be as an operational input to the custom SPI.
credData	Array of key-value pairs	Yes	Specifies the credential data to be validated by the custom authenticator SPI using the challenge/response approach.		
			Key	**Value**	**Description**
			<custom-key>	<string>	Specifies the custom data to be exchanged between the custom SPI and out-of-the-box SignIn UI/custom SignIn Client.
			spi.auth.factor.request	<string>	Indicates the credential exchange between the default IDSP SignIn Client and the custom SPI in the future, IDSP SignIn Client has a support for the Custom Authenticator API.

API Response

The API response from a custom provider can contain cookies, headers, regular flow state response that includes the following "data" and "additional" properties:

Property under "data"	**Type**	**Description**		
status	String	Indicates the status of the custom authentication as given by the SPI. Supported values are Accept, Reject, Challenge, or Terminate.		
clientRespContext	Array of key-value pairs	Specifies the additional context data that must be returned to the Client by the SPI, at the end of the authentication by the custom authentication factor.		
credData	Array of key-value pairs	Specifies the credential data to be validated by the Custom Authenticator API.		
		Key	**Value**	**Description**
		<custom-key>	<string>	Represents the custom data to be exchanged between the custom SPI and out-of-the-box SignIn UI/custom SignIn Client.

		spi.auth.factor.challenge	<string>	Represents the credential exchange (Challenge, Reject) between the default custom SPI and the IDSP SignIn Client in the future, when IDSP SignIn Client supports the Custom Authenticator API.
		spi.auth.factor.response	<string>	Represents the credential exchange (Accept, Terminate) between the default custom SPI and the IDSP SignIn Client in the future, when IDSP SignIn Client supports the Custom Authenticator API.

Property under "additional"	Type	Description
isCustom	String	If set to **true**, indicates that the current factor is **CUSTOM**.
customProvider	String	Specifies the name of the custom provider.
(Optional) customFlowId	String	Specifies the flowid returned by the custom SPI.

For more information about these properties, see Examples of Using a Custom Authentication Factor.

SPI Specification

SPI Name	CustomAuthenticator
SPI URL	https://<CustomProviderHost>/CustomAuthenticator
SPI OPERATION	POST
AUTHORIZATION	As per the SPI security model: • OAuth Client Assertion • OAuth ClientId & Secret • ApiKey • Basic Auth
SPI RESPONSE CODE	200 Success, 400 Failure, 500 Server Error

When the request comes to the IDSP endpoint that is hosted on the "signin domain", IDSP proxies cookies and/or headers to and from the custom SPI as per the configuration of the custom provider. If the custom authentication factor specifies that a cookie named "mycookie" must be acquired from the request and passed into the Custom Authenticator SPI, then the actual invocation of the custom SPI includes the cookie and/or header in the custom SPI request's **ahContext**. If the response from the SPI indicates that a cookie and/or header must be set on the way back, the response from the factors API includes the native cookie and/or header as indicated. For the details, see the sample response payload of the SPI.

SPI Request

The SPI request to a custom provider can contain cookies and headers that are requested by SPI, along with the following parameters:

Parameter	Type	Mandatory	Description
subject	String	Yes	Specifies the unique identifier of the user representing **user_loginid** semantics as configured in the ID store config resource.
clientContext	Array of key-value pairs	Yes	Specifies that the Client context parameters that are received as part of the programmatic/authenticate or web/authorized (IT) flows are passed here as key-value pairs, which are understood by client. Example: transactionIdentifier, appid.
ahContext	Array of key-value pairs	Yes	Contains the IDSP context parameters. For information, see the *Sharing IDSP Context with SPI* section in Integrating with Custom SPI.
providerContext	Array of key-value pairs	Yes	Specifies the custom provider-specific configuration. For information, see Integrating with Custom SPI.
operationalContext	Array of key-value pairs	Yes	Specifies the optional directives to be processed by SPI. For information, see OperationalContext in the API Request section. In addition to the directives passed by the Client into the Custom Authenticator API, the following directive is added by IDSP:
			Key / **Value**
			spi.auth.factor.amr / Represents the AMR values as specified by the custom authenticator provider.
metadataContext	Array of key-value pairs	Yes	Specifies the metadata of the application that is requesting authentication.
credData	Array of key-value pairs	Yes	Specifies the credential data that is required by the custom SPI to process authentication.

SPI Response

The SPI response from a custom provider can contain cookies and headers that are requested by SPI's response, along with the following parameters:

Parameter	Type	Description
msg	String	Specifies the message to be logged.
status	String	Specifies the status of the custom authentication. The supported values are Accept, Reject, Challenge, or Terminate.
credData	Array of key-value pairs	Specifies the data to be collected by SignIn Client, which is required by the Credential Authenticator SPI, as key-value pairs.
clientRespContext	Array of key-value pairs	Specifies the additional context data to be returned to SignIn Client by the SPI at the end of the authentication by the custom authentication factor.
operationalContext	Array of key-value pairs	Specifies the optional directives that are indicated by the SPI to be processed by IDSP. The following directives are processed:
		Key / **Value**

		spi.response.header.proxy	Represents the name of the header present in the SPI response to proxy to the API response as an http header.
		spi.response.cookie.proxy	Represents the name of the cookie present in the SPI response to proxy to the API response as an http header.
		spi.auth.factor.flowid	Represents the "flow id" as a hint to the signin client to know what specific flow to perform.
		spi.auth.factor.amr	Represents the "amr" value of the custom authentication, returned after the user has successfully completed authentication. If this value is provided by the SPI, it overwrites the value that is configured on the custom provider.

For more information about the flow, see Examples of Using a Custom Authentication Factor.

Examples of Using a Custom Authentication Factor

Explore detailed implementation examples of Custom Service Provider Interfaces (SPI) within Symantec Identity Security Platform, including runtime interaction models, state management, and multi-factor authentication workflows.

The following examples illustrate use of custom SPI under few different conditions and configurations. The example uses an out of the box **Sample Demo** custom SPI that is deployed by the **Sample App** chart in the same cluster where Symantec Identity Security Platform is deployed. IDSP accesses this custom SPI using an internal service name as configured in the custom provider representing the SPI, using no functional security. In a real deployment, a custom SPI is accessed on its published URL that is protected by one of the supported security methods.

The examples demonstrate:

- Runtime interaction model depicting SignIn Client → IDSP → SPI workflow model and the use of runtime semantics, such as:
  - "First Time" and "FlowID" state management
  - Out of the box Challenge/Response interaction
- Propagation of headers and cookies as per directives that are configured in the custom provider or as instructed by SPI's OperationalContext.
- Propagation of providerContext and providerHeaders as configured in the custom provider.
- Dynamic substitution of custom providerHeader and providerContext directives using data from Identity Profile, ID Token, and Application Metadata.
- Propagation of ClientContext and CredData Context.

This topic covers the following sections:

- Using Provider Helper API to get Authentication Providers Information
- Example 1: Admin client using custom SPI to obtain access token for an administrator
- Example 2: Multi-factor flow with different custom SPIs to complete OpenID Connect authentication flow

Using Provider Helper API to get Authentication Providers Information

To view the different custom providers, use the Provider Helper API.

Request and response formats of the ProviderHelper API in the following format:

Request

```
GET https://${SSP_FQDN}/{{apiPathTenant}}/admin/v1/ProviderHelper
```

NOTE

- To know the value of ${SSP_FQDN} environment variable, see Configuring IDSP Environment Variables.
- The default value for `<tenantName>` is "default".
- Replace the text {{text}} including {{}} characters with appropriate values, in all the endpoints shown in the above table.
  For example:
  `https://{{host}}/{{tenantName}}/admin/v1/ProviderHelper`
  should look similar to:
  `https://example.com/default/admin/v1/ProviderHelper`
- To know more about the scopes that are required to secure these APIs, refer to the Rest APIs and Associated Privileges section.

Response

```

Example 1: Admin client using custom SPI to obtain an access token for an administrator

This example demonstrates a simple custom SPI setup that authenticates an administrator using an out of the box **Sample Demo** custom SPI. It extends the "Acquire Admin Token" example in IDSP's out of the box postman collection under "Tenant Admin Operations" to obtain an Access Token. Normally, the authentication step requires a single ID store password, however, for this example, the authentication flow is updated to require an ID store password or a custom factor that is implemented by out of the box Sample SPI Demo provider.

Step 1: Create a custom provider definition for "MyCustomAuthProvider"

This provider uses the out of the box Sample Demo custom provider that is deployed by Sample App chart.

 \
--data-raw '{
   "factor": "CUSTOM/2db88c50-93a9-4618-ad64-23b9291811cb"
}'
```

Response

```
{
   "flowState":
 "TWJZZzkzNW12ZGwwOHRhK3BFL2dDTXR5dDY4MTFVZmxqTWNZU0hCblpkamcxUzFPT21lSkRnQzRhQWpMaWg4S2pFNFNzSHVnOWxrVCtMV3RGY2t2UDBle
   "nextaction": "CUSTOM_AUTH",
   "currentFactors": [
       "PASSWORD",
       "CUSTOM/2db88c50-93a9-4618-ad64-23b9291811cb"
   ],
   "additional": {
       "currentFactorLevel": 1,
       "isCustom": true,
       "isCustomFirstTime": true,
       "customProvider": "2db88c50-93a9-4618-ad64-23b9291811cb"
   }
}
```

Step 5: Authenticate using custom SPI

Note that this example does not use the Challenge/Response workflow. The Client invokes the custom SPI (as per Sample Demo SPI semantics), instructing it to "accept" without actually challenging for credentials. A real custom SPI would request and authenticate credentials using the client/SPI workflow as covered above.

Request

```
curl --location --request POST 'https://example.com/default/factor/v1/CustomAuthenticator' \
--header 'Content-Type: application/json' \
--header 'X-Flow-State:
 TWJZZzkzNW12ZGwwOHRhK3BFL2dDTXR5dDY4MTFVZmxqTWNZU0hCblpkamcxUzFPT21lSkRnQzRhQWpMaWg4S2pFNFNzSHVnOWxrVCtMV3RGY2t2UDBleC
 \
--header 'Authorization: Bearer
 eyJ4NXQjUzI1NiI6InY1ckluZElocS1peXdRdTMxcTF3Vm9idEQ1YVRTckFyNmloa2d3WmJQeU0iLCJ4NXQiOiJZbExTMDdlWG5ZRVU1TVgxQlpMTDd0UG
xbG9Fq6IWxYUEVkPVXKWhKbusXyhyqLWyPfgsRQ_Adx3I2NFNAHM9P3YZpX4JLHICwrjKUQ2cIkPDrtZI_8pl9UERdy7gQasvnd8kk2R8AKrCEvPrUP7aAK
 \
--header 'Cookie: cookie-by-spi=sample-cookie-by-spi' \
--data-raw '{
   "operationalContext": [
   ],
   "credData": [
       {
           "key": "spi.auth.factor.response",
           "value": "accept"
       }
   ]
}'
```

SPI Request to the Custom SPI

Output from the Sample Demo Custom SPI provider "MyCustomAuthProvider" showing the SPI request.

Notice substitutions that are made by IDSP as per providerContext and header configuration in the custom provider "MyCustomAuthProvider". As this authentication request did not include an ID Token, the "${idToken.user_riskscore}" got removed from the headers sent to the SPI. If the authentication request did include '"id_token_hint" : "<existingIdToken>" (as defined in provider configuration) in the payload, the header would have been sent with the proper value.

```

}
```

Example 2: Multi-factor flow with different custom SPIs to complete the OpenID Connect authentication flow

This example demonstrates use of custom SPI to implement multi-step authentication flow using an out of the box Sample Demo custom SPI deployed by the Sample App chart to the same cluster running IDSP. This example extends AZ Code flow under "OAuth and OpenId Connect" postman section to leverage custom SPI authentication using a more complete flow. Unlike the previous example, this example does not show the creation of entities that are required to support the runtime flow, but rather shows those entities as already existing.

Step 1: Create an application

Notice the use of custom claims and metadata.

```

Step 3: Create a custom SPI

Notice the use of directives in ProviderProperties in configurations for both "customSampleProvider2" and "customSampleProvider3", and correlate the use of those directives to runtime flows.

```

```
   "oauthTokenConnectTimeoutMillis": "10000",
   "skewTimeSecs": "0"
}
```

Step 4: Relying Party initiates OpenID Connect flow

Request

```
curl --location --request GET 'https://example.com/default/oauth2/v1/authorize?scope=openid
 offline_access&client_id=a940539a-dd10-4e21-b765-e9b54dc2037d&response_type=code&redirect_uri=https://
www.example.com' \
--header 'X-CLIENT-TRANSACTION-ID: MyClientTxnId' \
--header 'Cookie: cookie-by-spi=sample-cookie-by-spi'
```

Response

```
Redirect to Location: https://example.com/default/ui/v1/signin/?x-flow-
state=T3ZkbFJicXYxVENMRFJtdmEwaWNRTkQ1bkNJeGs0RHBxRlQ4cWhJZFlLemIrVjZGTEFjV0I5V2JjejBsZFhnQVh0R0JydjIyOWg0S2wzN3pIYUw3M
service-baseurl=https://example.com/default
```

Step 5: SignIn Client acquires Access Token

Request

```
curl --location --request POST 'https://example.com/default/oauth2/v1/token' \
--header 'Content-Type: application/x-www-form-urlencoded' \
--header 'Authorization: Basic
 YTk0MDUzOWEtZGQxMC00ZTIxLWI3NjUtZTliNTRkYzIwMzdkOmNkNzNhYTUzLTZkM2EtNDYwYS05NTE4LTYyMTY5Y2Y2ZjA2NQ==' \
--header 'Cookie: cookie-by-spi=sample-cookie-by-spi' \
--data-urlencode 'grant_type=client_credentials' \
--data-urlencode 'scope=urn:iam:myscopes'
```

Response

```
{
   "access_token":
 "eyJ4NXQjUzI1NiI6InY1ckluZElocS1peXdRdTMxcTF3Vm9idEQ1YVRTckFyNmloa2d3WmJQeU0iLCJ4NXQiOiJZbExTMDdlWG5ZRVU1TVgxQlpMTDd0U

Integrating with Custom Password Authenticator

Implement the Custom Password Authenticator SPI to integrate your existing password authentication infrastructure with IDSP as a hosted web service.

This topic covers the following sections:

- Custom Password Authentication Overview
- Steps to Integrate with Custom Password Authenticator SPI
- API Schema - (Swagger Content)
- Configuration to Support Custom Password Authentication
  - Configuring the Custom Provider - providerProperties
  - Updating Authentication (AuthN)Policy
- IDSP Password Authentication API Specification
- SPI Specification to be Used by the Customer
- Use Case: Custom Password Authentication Flow

Custom Password Authentication Overview

The IDSP Custom Password Authenticator enables integration with your existing password authentication infrastructure through a Service Provider Interface (SPI). To use this functionality, you must implement the SPI as a web service within your environment. Your implementation must adhere to the IDSP API specification to ensure seamless communication between the solution and your custom authentication service.

Steps to Integrate with Custom Password Authenticator SPI

You have to perform the following steps to integrate with the Custom Password Authenticator SPI:

1. Develop the Custom Password Authentication service based on the Password Authentication-Open API Schema - (Swagger Content) provided by IDSP.
2. Create a Custom Password Authentication Custom Provider in IDSP using the Provider endpoint- `https://${SSP_FQDN}/{{tenantName}}/admin/v1/CustomProviders`
3. Update the Authentication Policy with the custom provider Id in IDSP.

NOTE

- To know the value of ${SSP_FQDN} environment variable, see Configuring IDSP Environment Variables.
- The default value for `<tenantName>` is "default".
- Replace the text {{text}} including {{}} characters with appropriate values, in all the endpoints shown in the above table.
  For example:
  `https://{{host}}/{{tenantName}}/admin/v1/CustomProviders`
  should look similar to:
  `https://example.com/default/admin/v1/CustomProviders`
- To know more about the scopes that are required to secure these APIs, refer to the Rest APIs and Associated Privileges section.

These steps have been described in the subsequent sections.

API Schema - (Swagger Content)

To view the sample representation of the API schema, see the **Common Open API Spec for all Custom Providers - (Swagger Content)** section in Integrating with Custom SPI.

Configurations to support Custom Password Authentication in IDSP

Creating a Custom Password Authentication Custom Provider

- Create a custom password provider in IDSP to use your current password authentication infrastructure using the following API:

```
POST https://${SSP_FQDN}/{{tenantName}}/admin/v1/CustomProviders
```

NOTE
To refer to the Custom Provider APIs which can be used to perform CRUD operations in IDSP, see here.

Configuring the Custom Provider - providerProperties

Custom Provider - providerProperties

A custom provider uses the providerProperties key-value pairs to define a provider-specific behavior. There are two property types:

- **Custom**: All custom properties are published into the providerContext of the SPI request and are consumed by the custom SPI.
- **Well-known**: All well-known properties begin with the **spi.** prefix, representing the directives to be performed by IDSP when sending requests to and receiving responses from the custom SPI.

The following table lists the providerProperties that must be configured to support the use of a custom authentication factor:

Type	providerContext	Description
Custom	**key**: <custom-key> **value**: <custom-value>	Publishes a custom key-value pair into the ProviderContext of the custom SPI. The value in a key-value pair supports dynamic substitution using the ${keyword} notation. For information, see Dynamic Environment Substitution.

Well-known	**key**: spi.discover.capabilities **value**: CSV list of capabilities	Specifies the capabilities that are supported by the custom provider using multiple, comma-delimited placeholders. This enables IDSP to recognize the configured Custom Provider as having custom authentication capabilities, for example: • **custompasswordauthenticator**: Specifies that the custom SPI supports a custom password authentication factor that is accessible via "/CustomPasswordAuthenticator" runtime flow.
Well-known	**key**: spi.auth.factor.amr **value**: <amr-value>	Represents one or more AMR values (in CSV format) of the custom authentication factor. These AMR values are to be associated with the custom provider. You can enter multiple comma-delimited values from the following list: • PWD: Password style authentication • OTP: One time code (SMS, EMAIL, IVR) • FIDO: Passwordless • HWK: Hardware Key (Yubikey) • MOTP: Mobile one time code • PUSH: Mobile push • POP: SiteMinder X509 integration use case • SWK: N/A • WIA: SiteMinder IWA/Kerberos integration use case • <custom>: A custom AMR value If multiple instances of this key are provided, the last one takes precedence. If this key is specified by ProviderContext, and also returned by the OperationalContext of the custom SPI, then the value from the OperationalContext takes precedence.

Custom Provider - providerHeaders

A custom provider uses providerHeaders in a key-value pair format to define provider-specific headers to be sent to the custom SPI. Similar to "providerProperties", the headers definitions also supports dynamic substitution using the ${keyword} notation. For information, see Dynamic Environment Variable Substitution.

Updating the Authentication Policy

To support the implementation of Custom Password Authenticator, you must update the IDSP Authentication Policy.

Perform the following PATCH call to update the Authentication Policy to add a custom provider:

```
PATCH https://${SSP_FQDN}/{{tenantName}}/admin/v1/AuthPolicies/{{policyId}}
```

Sample Patch payload:

```
{
```

```
    "Operations": [
        {
            "op": "replace",
            "path": "/rules/[id eq \"1c722537-aaa2-4d62-a476-147e693c097a\"]/result/obligations/0",
            "value": "PASSWORD/{custom}2db88c50-93a9-4618-ad64-23b9291811cb"
        }
    ]
}
```

Where, the "**value**" field holds the PASSWORD/{custom} custom provider id which was returned when creating a Custom Provider in IDSP.

IDSP Password Authentication API Specification

For Password Authentication API specification, see Password Authentication API Specification .

SPI Specification to be Used by the Customer

The following SPI specification should be used:

SPI Name	CustomPasswordAuthenticator
SPI URL	https://<CustomProviderHost>/CustomPasswordAuthenticator
SPI OPERATION	POST
AUTHORIZATION	As per the SPI security model: • OAuth Client Assertion • OAuth ClientID and Secret • ApiKey • Basic Auth
SPI RESPONSE CODE	200 Success, 400 Failure, 500 Server Error

SPI Request:
The SPI request to a custom provider can contain cookies and headers that are requested by SPI, along with the following parameters:

Parameter	Type	Mandatory	Description
subject	String	Yes	Specifies the unique identifier of the user representing **user_loginid** semantics as configured in the ID store config resource.

clientContext	Array of key-value pairs	Yes	Specifies that the Client context parameters that are received as part of the ".../auth/v1/ authenticate" or web/authorized (IT) flows are passed here as key-value pairs, which are understood by client. Example: transactionIdentifier, appid. `{ "subject": "<userLoginid>", "channel": "web", "ipAddress": "10.10.123.124", "action":"authenticate", "rememberMe" : true, "device": { "signature": { "iaAuthData": "_v02MyUgNGgYOi88OTk0..... } }, "clientContext": [{ "key": "transactionIdentifier", "value": "540715af-96f2-4b86-b89f-ca0e8ae93f40" }] }`
ahContext	Array of key-value pairs	Yes	Contains the IDSP context parameters. For information, see the *Sharing IDSP Context with SPI* section in Integrating with Custom SPI.

providerContext	Array of key-value pairs	Yes	Specifies the custom provider-specific configuration. For information, see Integrating with Custom SPI. • Provider should be configured with "spi.discover.capabilities" key containing "custompasswordd value. This enables Admin UI to recognize configured custom provider as supporting a PASSWORD policy obligation. • Custom Password Provider can be configured with "spi.auth.factor.amr" key containing Authentication Method Reference (AMR) values (in CSV format) to be associated with the custom authentication provider. – Multiple comma-delimited values can be provided. – If multiple instances of this key are provided, the last one takes precedent. – If this key is specified by both ProviderContext, and returned by SPI's OperationalContext, then the value from the OperationalContext takes precedent.
operationalContext	Array of key-value pairs	Yes	Specifies the optional directives to be processed by SPI: **Key** spi.auth.factor.amr
metadataContext	Array of key-value pairs	Yes	Specifies the metadata of the application that is requesting authentication.

credData	Array of key-value pairs	Yes	Specifies the credential data that is required by the custom SPI to process authentication. "spi.auth.factor.password" key carries the password value.

SPI Response

The SPI response from a custom provider can contain cookies and headers that are requested by SPI's response, along with the following parameters:

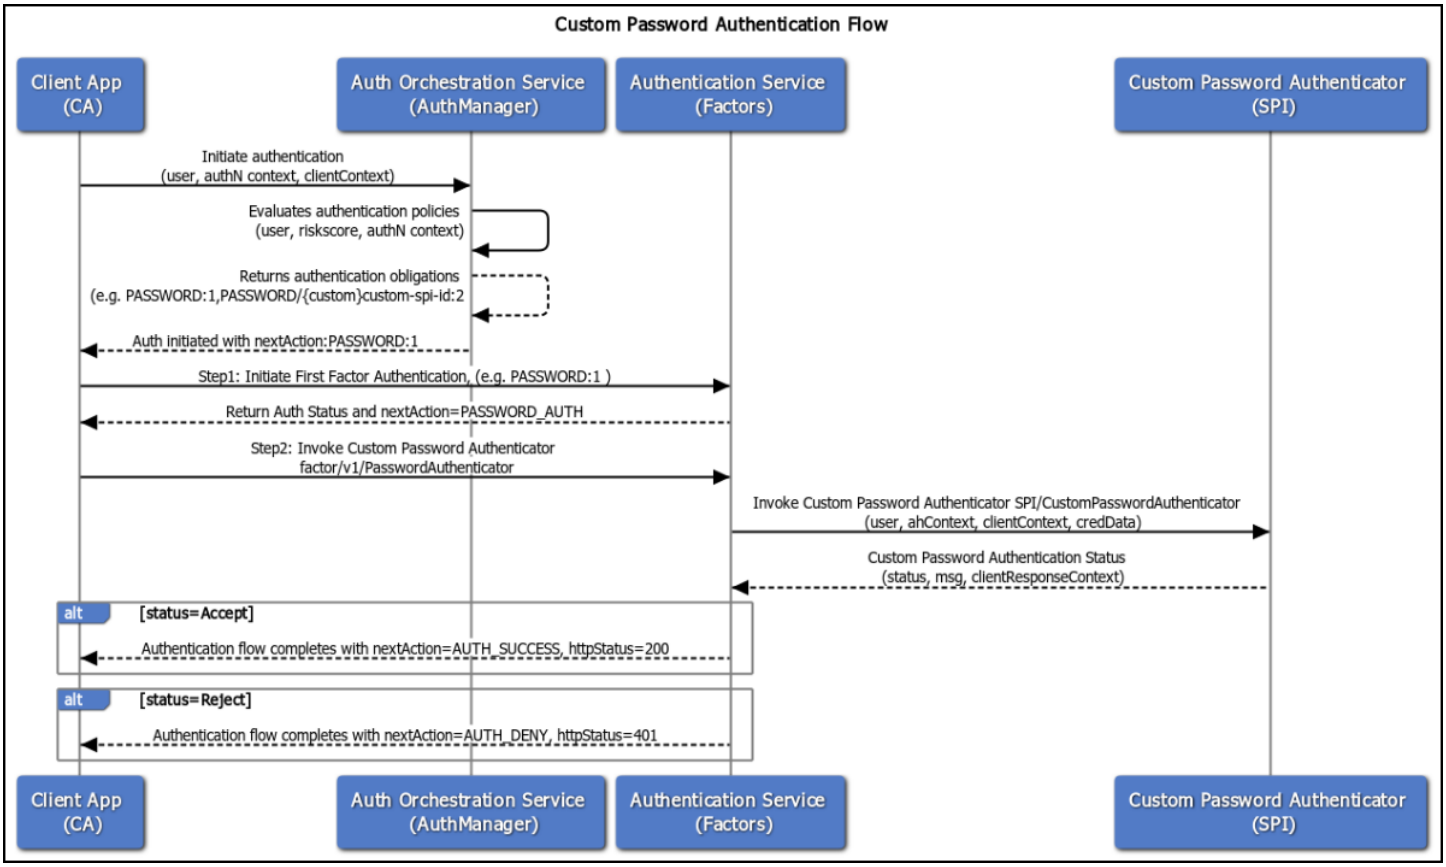
Parameter	Type	Description	
msg	String	Specifies the message to be sent back to IDSP to be logged in the operational log.	
status	String	Specifies the status of the custom password authentication. The supported values are Accept| Reject. All other values are treated as Reject. In case of Reject, additional data should be provided via directives in clientRespContext.	
clientRespContext	Array of key-value pairs	Specifies the response data to be returned by the SPI to satisfy the contract expected by ".../factors/v1/PasswordAuthenticator" API:	
		Key	**Value**
		spi.auth.factor.password.message	Contains the message IDSP to return to the signin client in case of successful and failed authentication.
		spi.auth.factor.password.errorcode	Contains the error code IDSP to return to the signin client when authentication fails.
		spi.auth.factor.password.reseturl	Contains the password reset URL IDSP to return to the signin client.
operationalContext	Array of key-value pairs	Specifies the optional directives that are indicated by the SPI to be processed by IDSP. The following directives are processed:	
		Key	**Value**
		spi.auth.factor.amr	Represents the "amr" value of the custom password authentication, returned after the user has successfully completed authentication. If this value is provided by the SPI, it overwrites the value that is configured on the custom provider.

Use Case: Custom Password Authentication Flow

List of participants and what they represent:

- Client App (CA) (Web App): This is the application that calls the solution's APIs to acquire the identity token and complete the authentication flow.
- IDSP microservices:
  - Auth Orchestration Service (AuthManager)- This is the ***"/auth/v1/authenticate"*** API used to initiate the authentication flow.
  - Authentication Service (Factors)- This is the ***"/factor/v1/PasswordAuthenticator"*** API used to authenticate an identity using a password.
  - Customer's Password Authentication Service Provider Interface (SPI)- This is the customer's implementation of Password Authentication Service Provider Interface (SPI) which will be used to perform the Password Authentication flow.

The following sequence diagram explains the authentication workflow between a Client and a Customers Password Authenticator SPI:



Flow Description:

1. The Client invokes `https://${SSP_FQDN}/{{tenantName}}/auth/v1/authenticate` API to initiate the Authentication flow. The request includes parameters such as user, authN context, clientContext [example:txn identifier].
2. Internally, the ".../auth/v1/authenticate" API communicates with the Policy Engine to evaluate the configured policy rules for the client app and determines the authentication obligations. Also, sends a response to the client app. In the flow, it is assumed that the obligations returned are PASSWORD: 1, PASSWORD/{custom} -custom_spi_Id: 2.
3. The client successfully completes the first-factor authentication, PASSWORD: 1.
4. The client is challenged with the remaining obligation that is PASSWORD/{custom} -custom_spi_Id: 2 this is the custom password authenticator.
5. The ".../factor/v1/PasswordAuthenticator sends a response to the client app with "nextaction" as PASSWORD_AUTH.

6. The Client invokes the "...factor/v1/PasswordAuthenticator" API. The Factor API sends details including user, ahContext, clientContext, credData to the Custom Password Authenticator SPI.
   This step begins the interaction with the custom SPI that is represented by the custom provider, which is associated with the custom password authentication factor. The interaction continues until the API indicates AUTH_ALLOW or AUTH_DENY.
7. The custom SPI returns authentication status that includes, status, msg, clientResponseContext to the Factor API.
8. The factor API sends "msg" received from customer's password authenticator to the client app.
9. The custom Password authenticator SPI returns Accept/Reject as the status as per the custom SPI implementation.
   - **Accept**: Indicates that the custom SPI has successfully authenticated the user. IDSP advances the authentication flow as per authentication policy.
   - **Reject**: Indicates that the custom SPI has rejected credentials and expects the Client to redo the operation. IDSP increments the user lock strike count, and does not advance the authentication flow.

Integrating with Custom Claims Provider

Populate custom claims in SAML assertions and OIDC tokens by implementing and configuring a Custom Claim Service Provider Interface (SPI).

This topic covers the following sections:

- Custom Claims Provider Overview
- Steps to Integrate with Custom Claims SPI
- SPI specification to be used by the customer
- Creating a Custom Claims Provider
  - Configuring - providerProperties
  - Configuring - headerProperties
- Configurations to Support Custom Claims
  - Application Configuration
  - Tenant Settings Configuration
- Sample Custom Claims Provider
- Custom Claims SPI Examples

Custom Claims Provider Overview

To deliver custom identity data, you can build a Custom Claim SPI provider and host it as a web service in your environment. These providers can be applied at the tenant level for global use or at the application level for specific requirements. Note that while tenant-level providers serve as a default, an application-specific configuration takes precedence; only one provider can be active for a single application at any time.

Steps to Integrate with Custom Claims SPI

Perform the following steps to integrate the Custom Claims SPI with IDSP:

1. Develop the Custom Claims service based on the Open API specification that is made available to you in YAML format and can be downloaded. Click this link to download the IDSP SPI Spec.yml.
2. Create a Custom Claims Provider in IDSP using the Provider endpoint- `https://${SSP_FQDN}/{{tenantName}}/admin/v1/CustomProviders`

   NOTE

   - To know the value of ${SSP_FQDN} environment variable, see Configuring IDSP Environment Variables.
   - The default value for `<tenantName>` is "default".
   - Replace the text {{text}} including {{}} characters with appropriate values, in all the endpoints shown in the above table.

For example:
`https://{{host}}/{{tenantName}}/admin/v1/CustomProviders`
should look similar to:
`https://example.com/default/admin/v1/CustomProviders`

- To know more about the scopes that are required to secure these APIs, refer to the Rest APIs and Associated Privileges section.

3. Update the tenant or the application level configuration in IDSP.

These steps have been described in detail in the subsequent sections.

SPI specification to be implemented by customer

While building the Custom Claim SPI, the implementation should follow the specified SPI specification:

SPI Name	**CustomClaimGetter**
SPI URL	https://<CustomProviderHost>:<port>/CustomClaimGetter
SPI OPERATION	POST
AUTHORIZATION	As per the SPI security model: • OAuth Client Assertion • OAuth ClientID and Secret • ApiKey • Basic Auth
SPI RESPONSE CODE	200 Success, 400 Failure, 500 Server Error

SPI Request:
The SPI request to a custom provider can contain cookies and headers that are requested by SPI, along with the following parameters:

Parameter	**Type**	**Mandatory**	**Description**
subject	String	Yes	Specifies the unique identifier of the user representing **user_loginid** semantics as configured in the ID store config resource.
clientContext	Array of key-value pairs	No	Not Used.
ahContext	Array of key-value pairs	Yes	Contains the IDSP context parameters. For information, see the *Sharing IDSP Context with SPI* section in Integrating with Custom SPI.

providerContext	Array of key-value pairs	Yes	Specifies the custom provider-specific configuration. For information, see Integrating with Custom SPI. • Provider should be configured with "spi.discover.capabilities" key containing "customclaim value. This enables Admin UI to recognize configured custom provider as supporting custom claims. • Custom Claims Provider can be configured with "spi.customclaim.token.types " key containing a combination of these values: ***it***, ***userat***, ***clientat***, ***userinfo***, samlassertion values (in CSV format) to be associated with the custom claims provider.
metadataContext	Array of key-value pairs	Yes	Specifies the metadata of the application that is requesting authentication.
tokenType	String	Yes	The type of token being issued corresponds to the values defined for "spi.customclaim.token.types".
rawType	String	Yes	Indicates that the raw data can be represented either in XML or JSON format.

SPI Response

The SPI response from a custom provider can contain cookies and headers that are requested by SPI's response, along with the following parameters:

Parameter	Type	Description
msg	String	Specifies the message to be sent back to IDSP to be logged in the operational log.
status	String	Specifies the status of the custom claims. The supported values are: success| failure.
clientRespContext	Array of key-value pairs	Not Used
claimsListMva	Array of key-value pairs	MVA (Multiple-Valued Attribute) claims. Each claim in the array can have multiple values.
claimsListSva	Array of key-value pairs	SVA (Single-Valued Attribute) claims.
claimsListRaw	List of values	Raw XML or JSON claims, depending on the value of request's rawType.
claimsListRawNs	Array of key-value pairs	For XML claims, specifies additional XML namespaces to be added to the SAML response.

Creating a Custom Claims Provider

After you have implemented the SPI, create a Custom Claim Provider in IDSP.

Creating a Custom Claims Provider

- Create a custom claims provider in IDSP using the following API:

```
POST https://${SSP_FQDN}/{{tenantName}}/admin/v1/CustomProviders
```

Custom Provider- Sample Request Payload

```
{
    "providerName": "customRiskProvider",
    "version": "1.0",
    "apiKey": "6fd06fd82aceb78b0bbbe3990b865f96ea",
    "securityMethod": "apikey",
    "url": "https://example:xxxx",
   "providerHeaders": [
        {
            "name": "clientId",
            "value": "8289-b1e8817a3fec"
        }
    ],
    "providerProperties": [
        {
            "name": "app",
            "value": "test"
        },
        {
            "name": "region",
            "value": "us-west"
        }
    ]
}
```

Custom Provider - Sample Response Payload

The response generates a providerId for the custom Claim.

```
{
        "providerName": "customRiskProvider",
        "version": "1.0",
        "apiKey": "McbVn0nLba2e1vPFSw0hDtkvR0cGSLj3h1RgDNwQHTEL6gA8s8Xy4MKJ5lpP6iQU",
        "certAlias": "",
        "url": "http://example:xxxx",
        "providerHeaders": [
            {
                "name": "clientId",
                "value": "8289-b1e8817a3fec"
            }
        ],
        "providerProperties": [
            {
                "name": "app",
                "value": "test"
            },
            {
                "name": "region",
                "value": "us-west"
            }
        ],
        "createdBy": {
            "principalType": "CLIENT",
            "principalId": "c2d28f2c-4f4a-4557-9ba7-0248052e9a60",
            "principalName": "DefaultTenantClient"
        },
        "createdDateTime": "2024-04-11 10:26 AM UTC",
        "origin": "tenant",
        "ignoreSSLValidation": false,
        "providerId": "2cebd036-8ebe-4fe9-8752-5d6ca7ec5c12",
        "sslMode": "VERIFY_CA",
        "spiReadTimeoutMillis": "60000",
        "spiConnectTimeoutMillis": "60000",
        "requestCtxBase64": "",
        "clientId": "",
        "clientSecretAlias": "",
        "oauthScopes": "",
        "securityMethod": "apikey",
        "oauthTokenUrl": "",
        "oauthDiscoveryUrl": "",
        "oauthResourceInAzRequest": "none",
        "oauthAssertionKidType": "",
        "oauthAssertionAud": "",
        "oauthTokenIgnoreSslValidation": false,
        "oauthTokenSslMode": "VERIFY_CA",
        "oauthTokenCertificateAlias": "",
        "oauthTokenRequestCtxBase64": "",
        "oauthTokenReadTimeoutMillis": "30000",
        "oauthTokenConnectTimeoutMillis": "30000",
        "skewTimeSecs": "0"
```

```
}
```

NOTE
To refer to the Custom Provider APIs which can be used to perform CRUD operations in IDSP, see here.

Configuring Custom Provider - providerProperties

A custom provider uses the providerProperties key-value pairs to define a provider-specific behavior. There are two property types:

- **Custom**: All custom properties are published into the providerContext of the SPI request and are consumed by the custom SPI.
- **Well-known**: All well-known properties begin with the **spi.** prefix, representing the directives to be performed by IDSP when sending requests to and receiving responses from the custom SPI.

The following table lists the providerProperties that must be configured to support the use of custom claims:

<table>
<tr><th>Type</th><th>providerContext</th><th>Description</th></tr>
<tr><td>Custom</td><td>key: <custom-key>
value: <custom-value></td><td>Publishes a custom key-value pair into the ProviderContext of the custom SPI. The value in a key-value pair supports dynamic substitution using the ${keyword} notation. For information, see Dynamic Environment Substitution.</td></tr>
<tr><td>Well-known</td><td>key: spi.description
value: provider description</td><td>This value contains the description of the provider.</td></tr>
<tr><td>Well-known</td><td>key: spi.discover.capabilities
value: CSV list of capabilities</td><td>Specifies the capabilities that are supported by the custom provider using multiple, comma-delimited placeholders.
This enables Admin UI to recognize configured custom provider as supporting custom claims.
<table>
<tr><th>Capability</th><th>Description</th></tr>
<tr><td>customclaim</td><td>SPI supports a custom claim getter exposed through the "/CustomClaimGetter" API.</td></tr>
</table>
</td></tr>
<tr><td>Well-known</td><td>key: spi.customclaim.token.types
value: CSV list of token types</td><td>Informs the token generator of which token types should retrieve claims from the custom claims SPI provider.
The following CSV lists indicate the supported token types
• IT (OIDC id token)
• USERAT (OIDC user access token)
• CLIENTAT (OIDC client-only access token)
• USERINFO (OIDC user info)
• SAMLASSERTION (SAML User Assertion)</td></tr>
</table>

Well-known	**key**: spi.customclaim.cache.enabled **value**: true | false	Cache is disabled if this property is not defined or contains a value other than "true." Caching results from a custom claim SPI provider that is done based on <AppId>-<TokenType> leverages distributed cluster-wide Hazelcast cache.

Configuring Custom Provider - headerProperties

A custom provider uses providerHeaders in a key-value pair format to define provider-specific headers to be sent to the custom SPI. Similar to "providerProperties", the headers definitions also supports dynamic substitution using the ${keyword} notation. For information, see Dynamic Environment Variable Substitution.

Configuring Application/Tenant settings to support Custom Claims

After creating the CustomProvider in IDSP, you are required to configure custom claim related property either at the tenant level or at the application level.

- When configured at the ***tenant level*** (property name- **customClaimProviderToBeUsed**), this update is applied universally to all applications within the specified tenant.
- When configured at the ***application level*** (property name- **customClaimProviderToUse**) overrides the configuration at the tenant level for that particular application, when the token gets generated.

Application Configuration to support Custom Claims

You can configure the application property in IDSP to set a custom claim SPI Provider either using the Admin Console or by invoking the Application API.

- ***Configuring the "custom claim provider" application property using the Admin Console***:
  Follow these steps:
  a. Login to the Admin Console.
  b. Navigate to **Applications** > **General**.
  c. Under the "***Additional Configuration"*** section, configure the "***Custom Claim Provider"*** property.
  The **Claim Provider** configuration is also covered in the Admin Console - Claim Provider setting.
- ***Configuring the "customClaimProviderToUse" application property by invoking the Application API endpoint***.
  Follow this step:
  a. Invoke the following API:

```
POST https://${SSP_FQDN}/{{apiPathTenant}}/admin/v1/Apps
```

Sample Application Request payload

The value of the "***customClaimProviderToUse***" property is a GUID of the "providerId" that can be found in the response of the ".../admin/v1/CustomProviders" API. In this sample, look for the application property, "customClaimProviderToUse": "2cebd036-8ebe-4fe9-8752-5d6ca7ec5c12" in the request.

```
{
        "status": "active",
        "name": "DemoClient",
        "description": "Demo client to perform tenant level operations for demo purpose.",
        "clientType": "TRUSTED",
        "allowedOpenIDScopes": [
            "urn:iam:at:groups",
            "address",
            "urn:iam:it:groups",
            "openid",
```

```
        "profile",
        "urn:iam:scim:core",

            "postLogoutUrl": "https://democlient/postlogouturl",
            "isSamlApp": true,
            "isOidcApp": true,
            "isLauncherApp": true,
            "requireAccessControl": "false"
        }
```

The **customClaimProviderToUse** configuration is also covered in the Applications API.

Tenant Configuration to support Custom Claims

Configure the tenant setting in IDSP to set a custom claim SPI Provider using the IDSP ".../admin/v1/Configs" API, or using the Admin Console.

- ***Configuring the "custom claim provider"setting using the Admin Console***:
  Follow this step:
  a. Login to the Admin Console.
  b. Navigate to the **Settings** > **Service Configuration**.
  c. Under the "***Risk and Custom Service Provider Settings"*** section, configure the "***Claim Provider"*** property.
  The **Claim Provider** tenant setting information is also covered in the Admin Console - Claim Provider setting.
- ***Configuring the "customClaimProviderToBeUsed" tenant setting by invoking the Config API endpoint***.
  Follow this step:
  a. Invoke the following API:
  ```
  PATCH https://${SSP_FQDN}/{{apiPathTenant}}/admin/v1/Configs
  ```
  Sample Apps Request payload: The value of this property is a GUID of the "providerId" that can be found in the response of the ".../admin/v1/CustomProviders" API.
  ```
  {
     "name": "customClaimProviderToBeUsed",
     "value": "<GUID_of_the_providerId>"
  }
  ```
  The **customClaimProviderToBeUsed** configuration is also covered in Settings.

Creating a Sample Custom Claim Provider

The following IDSP Custom Provider API is used to create the Sample Provider:

```
POST https://${SSP_FQDN}/{{tenantName}}/admin/v1/CustomProviders
```

NOTE

- The custom claims SPI is invoked for various token types, including it, userat, clientat, userinfo, and samlassertion. This is specified by the "***spi.customclaim.token.types***" property under the "***providerProperties***," which defines the token types for which custom claims are generated.
- The presence of the "***spi.discover.capabilities***" property under the "***providerProperties***" signifies that this is a custom claim SPI.
- The URL specified by the ***"url": "https://<custom-provider-URL>"*** property in the example must be accessible from the IDSP (SSP) pod.
- Provider's Header and Property configurations show examples of dynamically substituted expressions using appMetadata, idProfile, and userGroups contexts.

```

Discovery of User Groups by Applications

Learn how applications can discover information about user groups using different approaches.

The following approaches can be used to search for User Groups information by an application:

- Obtaining user groups information by application in the "/oauth/v1/userinfo" API response (OIDC flow)
- Obtaining user groups information by application in Access Token or Identity Token
- Obtaining user groups information by application by configuring the "Custom Claims" property in the application
- Obtaining user groups information by application using the Admin API or SCIM API

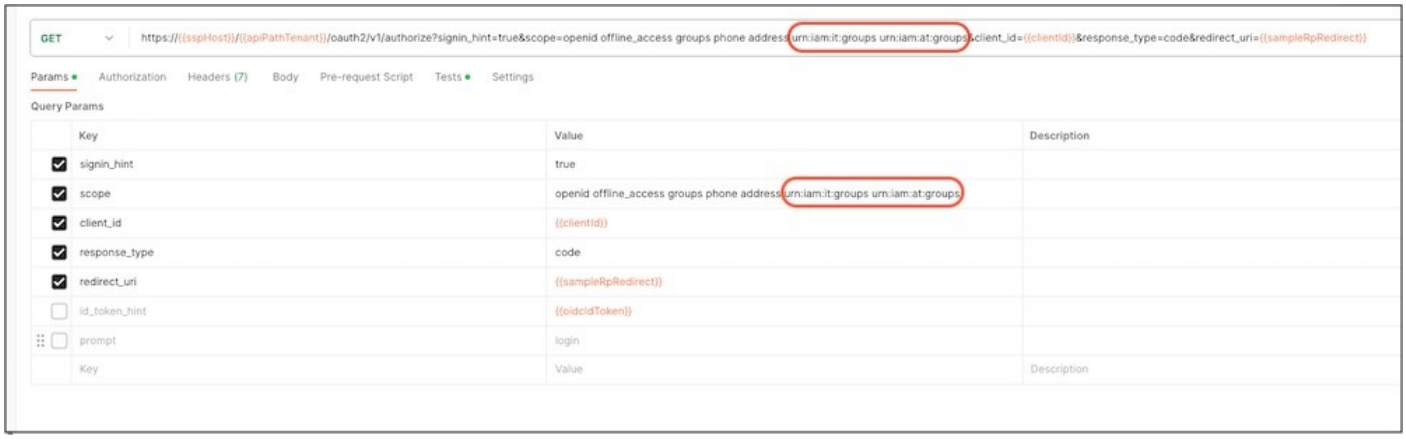
Obtaining user groups information in the "/oauth/v1/userinfo" API response using OIDC flow

This section describes the steps that are required to perform when an application wants to obtain user groups information using the "/oauth/v1/userinfo" API.

You can authorize the application to access a user's groups through the "/oauth2/v1/userinfo" API by modifying the application configuration to incorporate the "groups" scope within the "Allowed Open Id scopes" section. Once this scope is granted, the application can request the "groups" scope, and using the Access Token with that scope, invoke the "/userinfo" API. The response from the "/userinfo" API will include the user's group information. See Userinfo API.

1. From the Admin Console UI, if you want the application to be able to request the "groups" scope, you must perform the following steps:
   a. Navigate to **Applications**, select the app to which you want to configure to obtain user's groups information.
   b. Select the **User Groups (groups)** scope under the **Allowed Open ID Scopes** section as shown in the following image:

2. The following image shows how you can request "groups" scope in the Authorization Code Request using the Postman.



The application invokes the "/oauth2/v1/userinfo" API using an access token containing the "groups" scope, and receives the following userinfo response:

```
{
    "sub": "admin",
    "idp_name": "internal",
    "address": "this is formatted address",
    "user_loginid": "admin",
    "idp_guid": "internal",
```

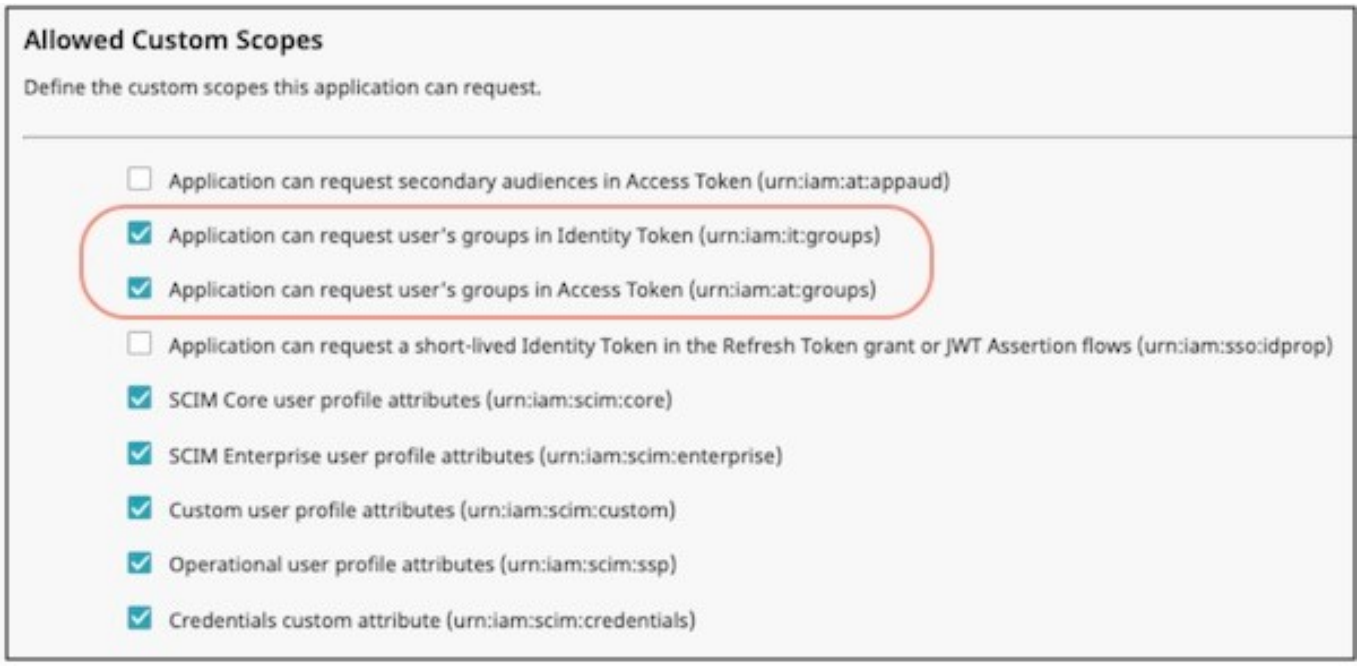
```
    "iss": "https://myssp.example.com/default",
    "groups": [
        "Admin",
        "MyGroup"
    ],
    "phone_number_verified": "true",
    "user_guid": "4ed30eec-3c1f-4eeb-b4e8-cdb52c2ee01f",
    "given_name": "Admin",
    "user_subattrmappingname": "user_loginid",
    "aud": "f35fa6ae-2fa8-4d67-8d45-a4218563f82a",
    "user_zfp": "false",
    "user_loginidattrmappingname": "user_loginid",
    "address_verified": "false",
    "phone_number": "1-617-584-9860",
    "family_name": "Admin",
    "idp_type": "internal"
}
```

Obtaining user groups information by application tokens

This section outlines the necessary steps for an application to obtain user groups information through the application tokens, Access and/or Identity token.

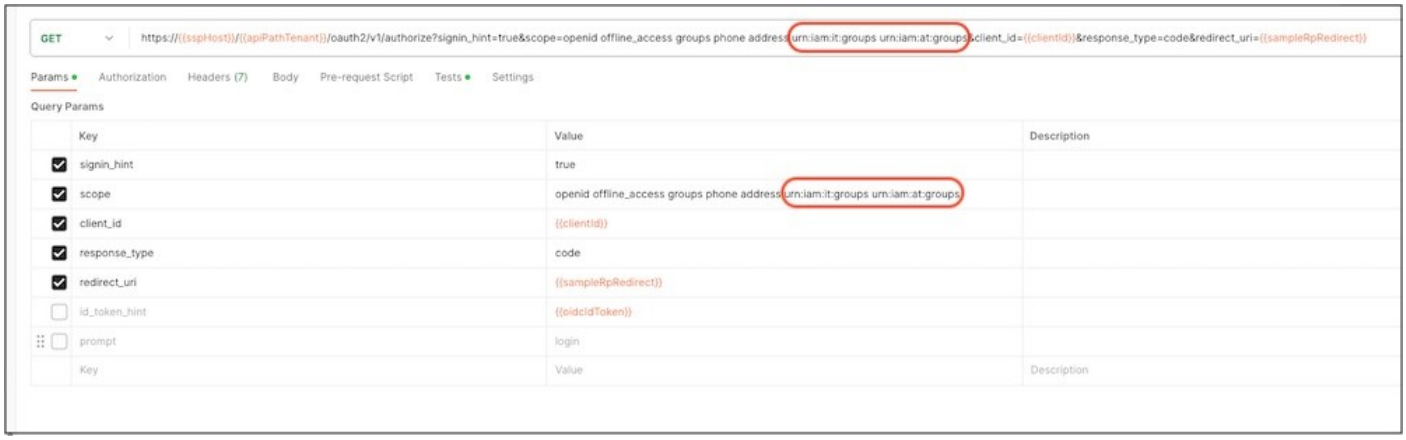
You can authorize the application to obtain user groups information by specifying the "urn:iam:it:groups" and/or "urn:iam:at:groups" scopes in the Identity token and/or Access Token accordingly.

1. To allow these scopes to be used by the application, in the Admin Console UI, perform the following steps:
   a. Navigate to **Applications**, select the app to which you want to configure to obtain user's groups information.
   b. Open the application, navigate to the OAuth/OpenID tab, and under the **Allowed Custom Scopes** section, select the "urn:iam:it:groups" and/or "urn:iam:at:groups" scopes as highlighted in the following image:



2. The application invokes the "/authorize" API requesting for "urn:iam:it:groups" and/or "urn:iam:at:groups" scopes. The user groups are returned in the Identity Token or Access Token respectively.

The following image shows how you can request "groups" scope in the Authorization Code Request using the Postman.



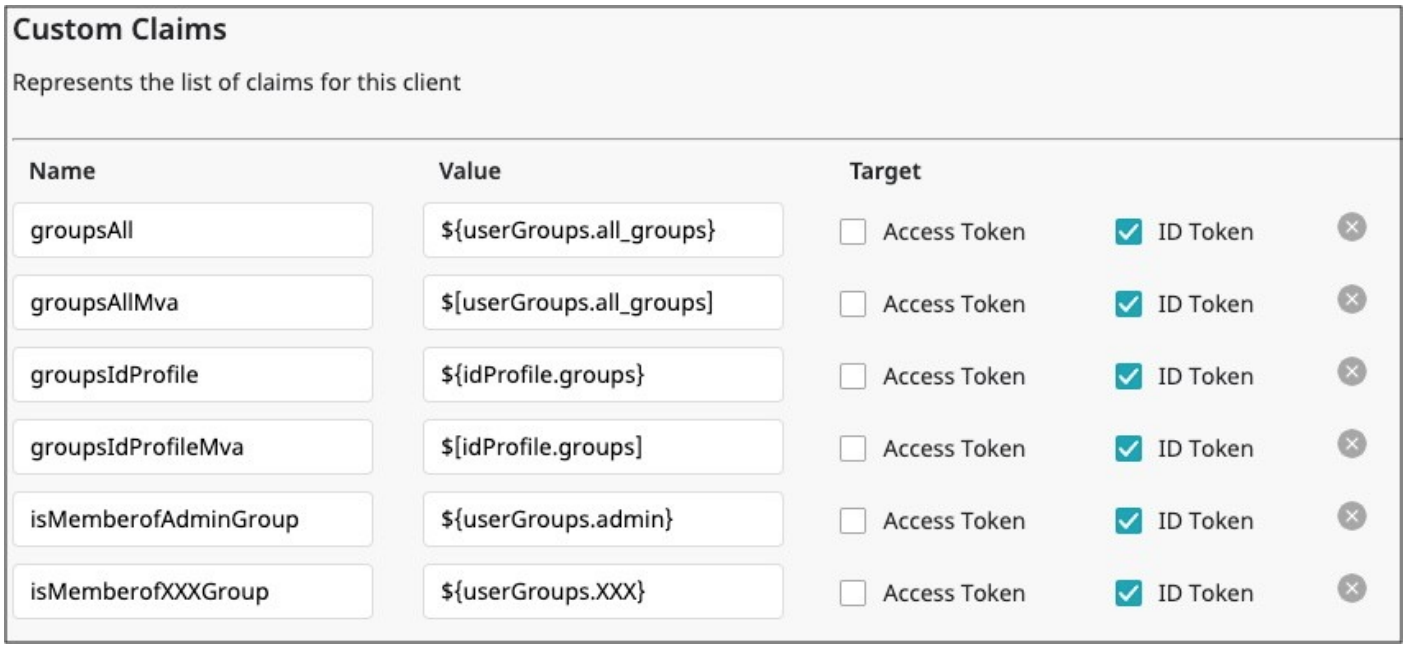
The following example displays the additional user's group information that gets added to the token.

```
"hasgroups": true,
"groups": [
  "MyGroup",
  "Admin"
]
```

Obtaining user's groups information by defining "Custom Claims" in the application

This section outlines the different options in which "Custom Claims" can be configured to contain user's groups information in the application's Access and/or Identity token.

1. In **Applications**, select the app to which you want to configure to obtain user's groups information.
2. In the "Custom Claims" section, create a custom claim with any of the following values as shown in the following image:
   - $[userGroups.all_groups] or $[userGroups.all_groups] - This will be replaced with a list of user's groups.
   - ${userProfile.groups} or $[userProfile.groups] - This will be replaced with a comma separated value (csv) containing the user's groups.



NOTE
Alternatively, you can create a custom claim that indicates whether the user is a member of a specific group by using ${userGroups.<groupname>} value which sets the claim value to true or false accordingly.

Obtaining user's groups information by using the Admin API or SCIM API

This section outlines the APIs that can be used by an application to obtain user's groups information.

- Obtain the Authorized adminAccessToken from the "/authorize" API and use the following API to request user's profile that will include user groups.

  `https://${SSP_FQDN}/<apiPathTenant>/idstore/v1/Users/<userLoginName>`

  NOTE

  - To know the value of ${SSP_FQDN} environment variable, see Configuring IDSP Environment Variables.
  - The default value for `<tenantName>` is "default".
  - Replace the text {{text}} including {{}} characters with appropriate values, in all the endpoints shown in the above table.
    For example:
    `https://{{host}}/{{tenantName}}/idstore/v1/Users/<userLoginName>`
    should look similar to:
    `https://example.com/default/idstore/v1/Users/<userLoginName>`
  - To know more about the scopes that are required to secure these APIs, refer to the Rest APIs and Associated Privileges section.
- Use the Authorized adminAccessToken obtained from the following APIs to discover user groups by apps.

  `https://${SSP_FQDN}/<apiPathTenant>/scim2/v1/Users?filter=userName=<userLoginid>?attributes=groups (az=adminAccessToken)`

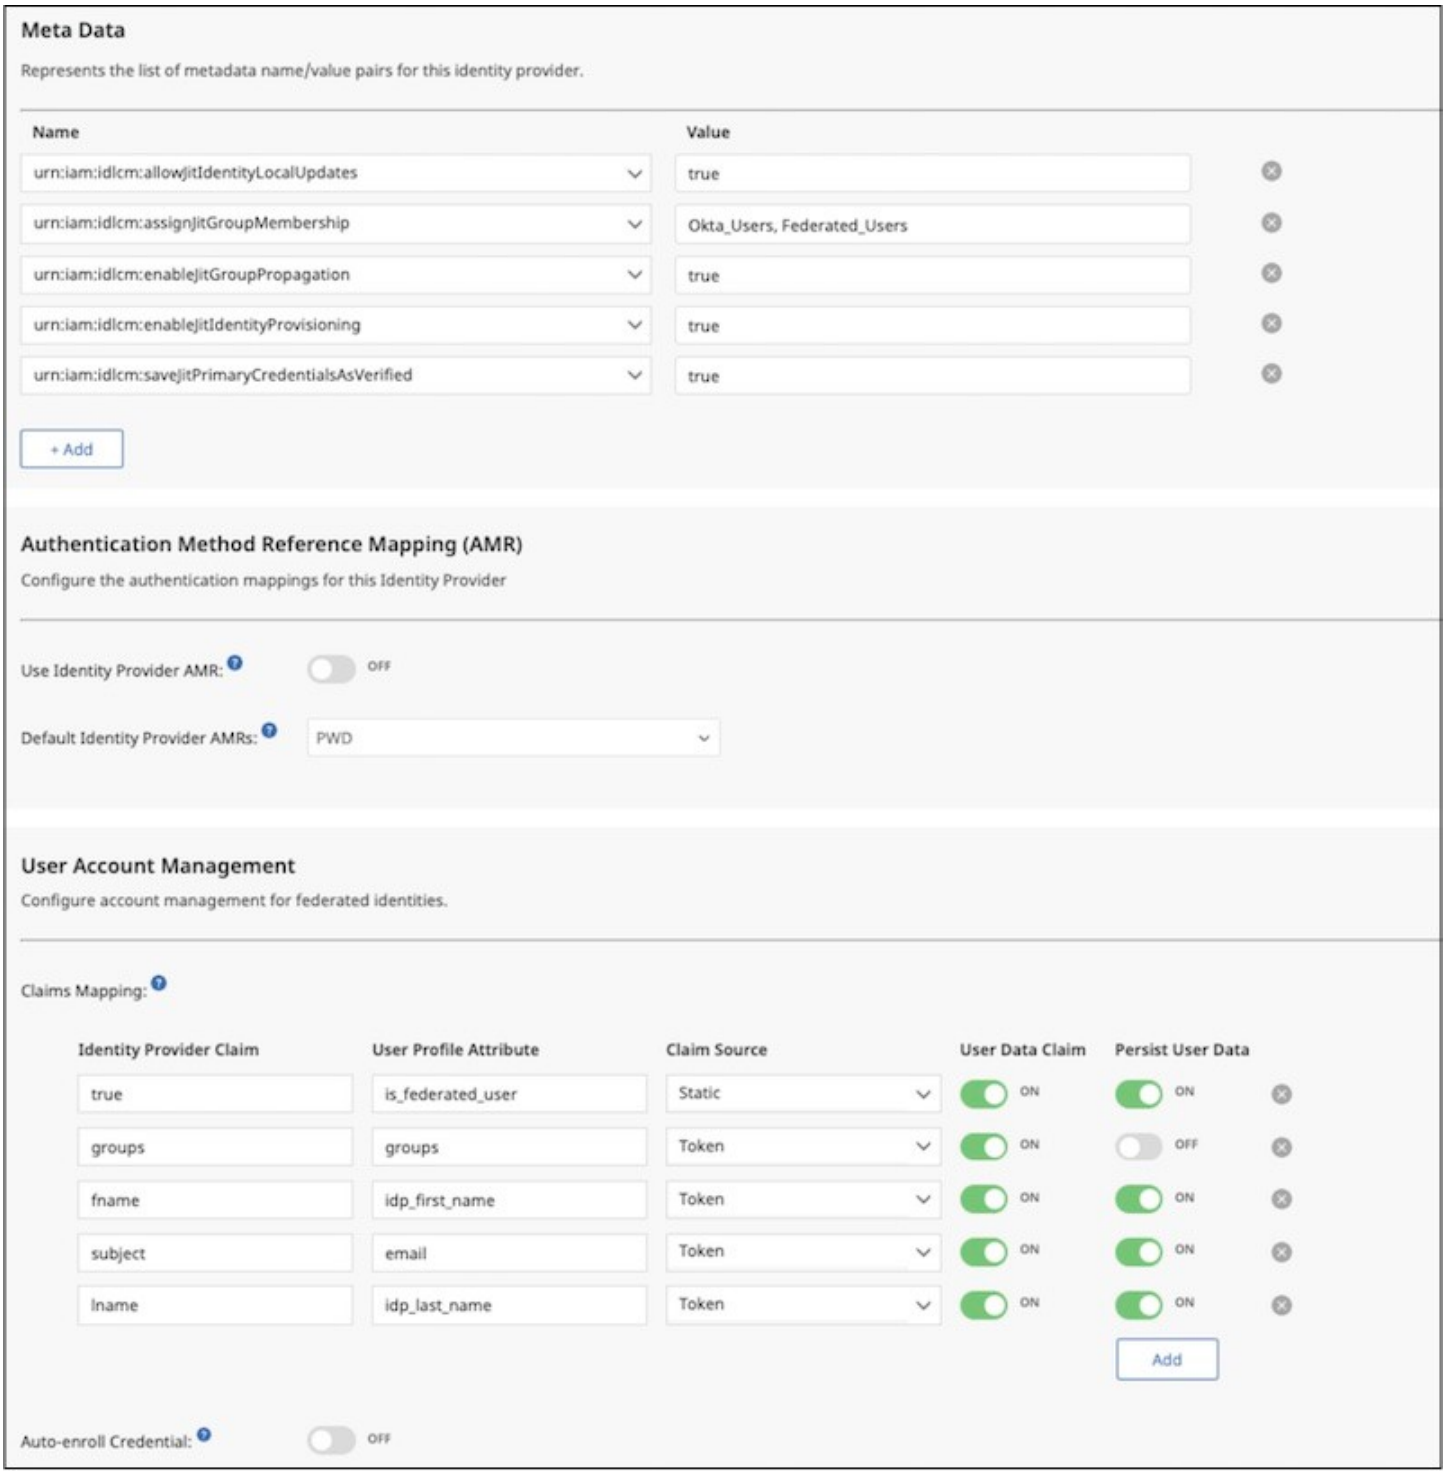
  `https://${SSP_FQDN}/<apiPathTenant>/scim2/v1/Users/?<userId>?attributes=groups (az=adminAccessToken)`

  For more information on these APIs, see ID Store APIs and Managing Users in the Identity Service.

IDP Flow

If a third-party Identity Provider (IDP) is set up to include groups in the user assertion, the Symantec Identity Security Platform IDP configuration allows mapping these groups from the incoming user assertion, referred to as the Identity Provider Claim "groups" in the following image to the universally recognized User Profile Attribute "groups." This attribute is populated by every IDP interaction during the signin ceremony.

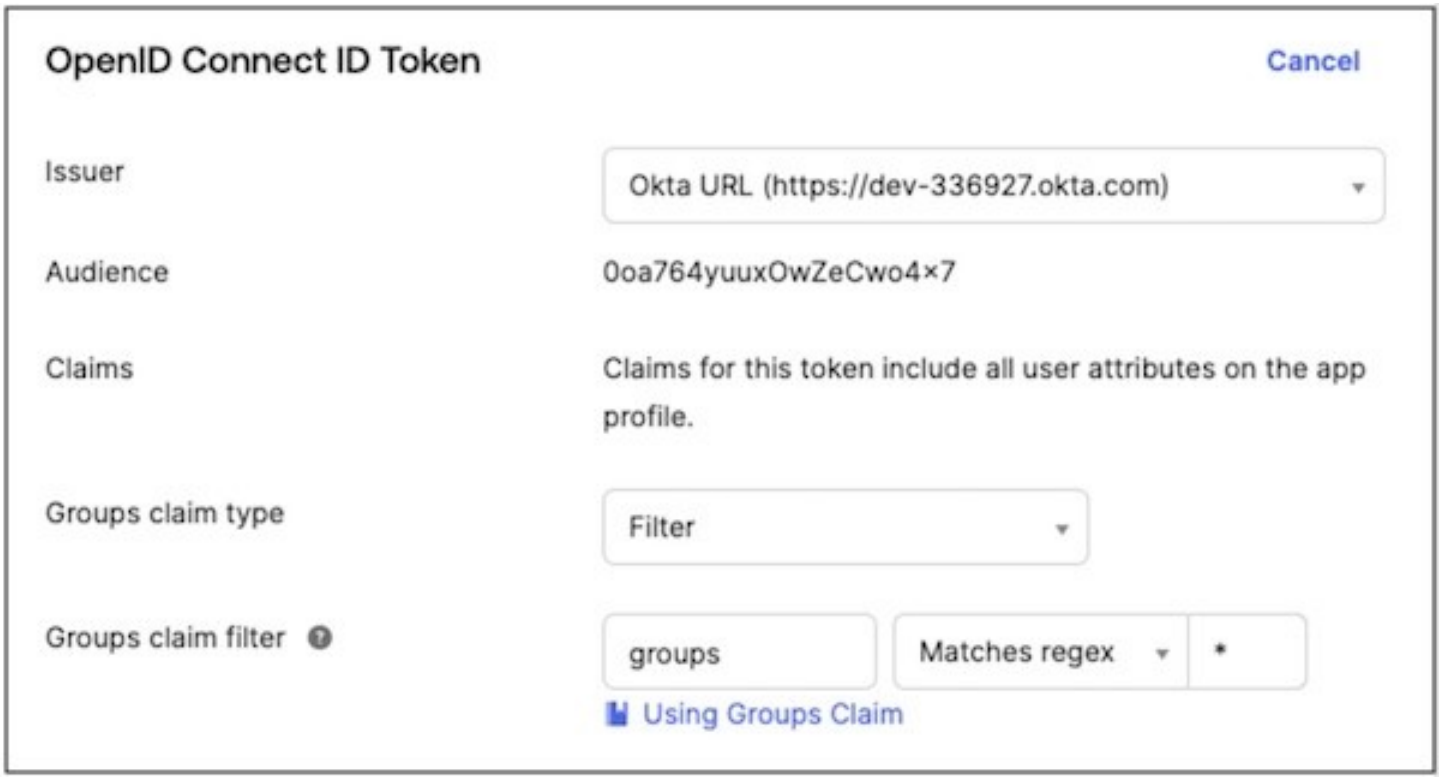
In non Zero-Footprint (ZFP) flows, user groups from the identity assertion are appended to the list of user groups retrieved from the identity store. Refer to each third-party IDP to know how to configure groups to return user groups in the identity assertion.



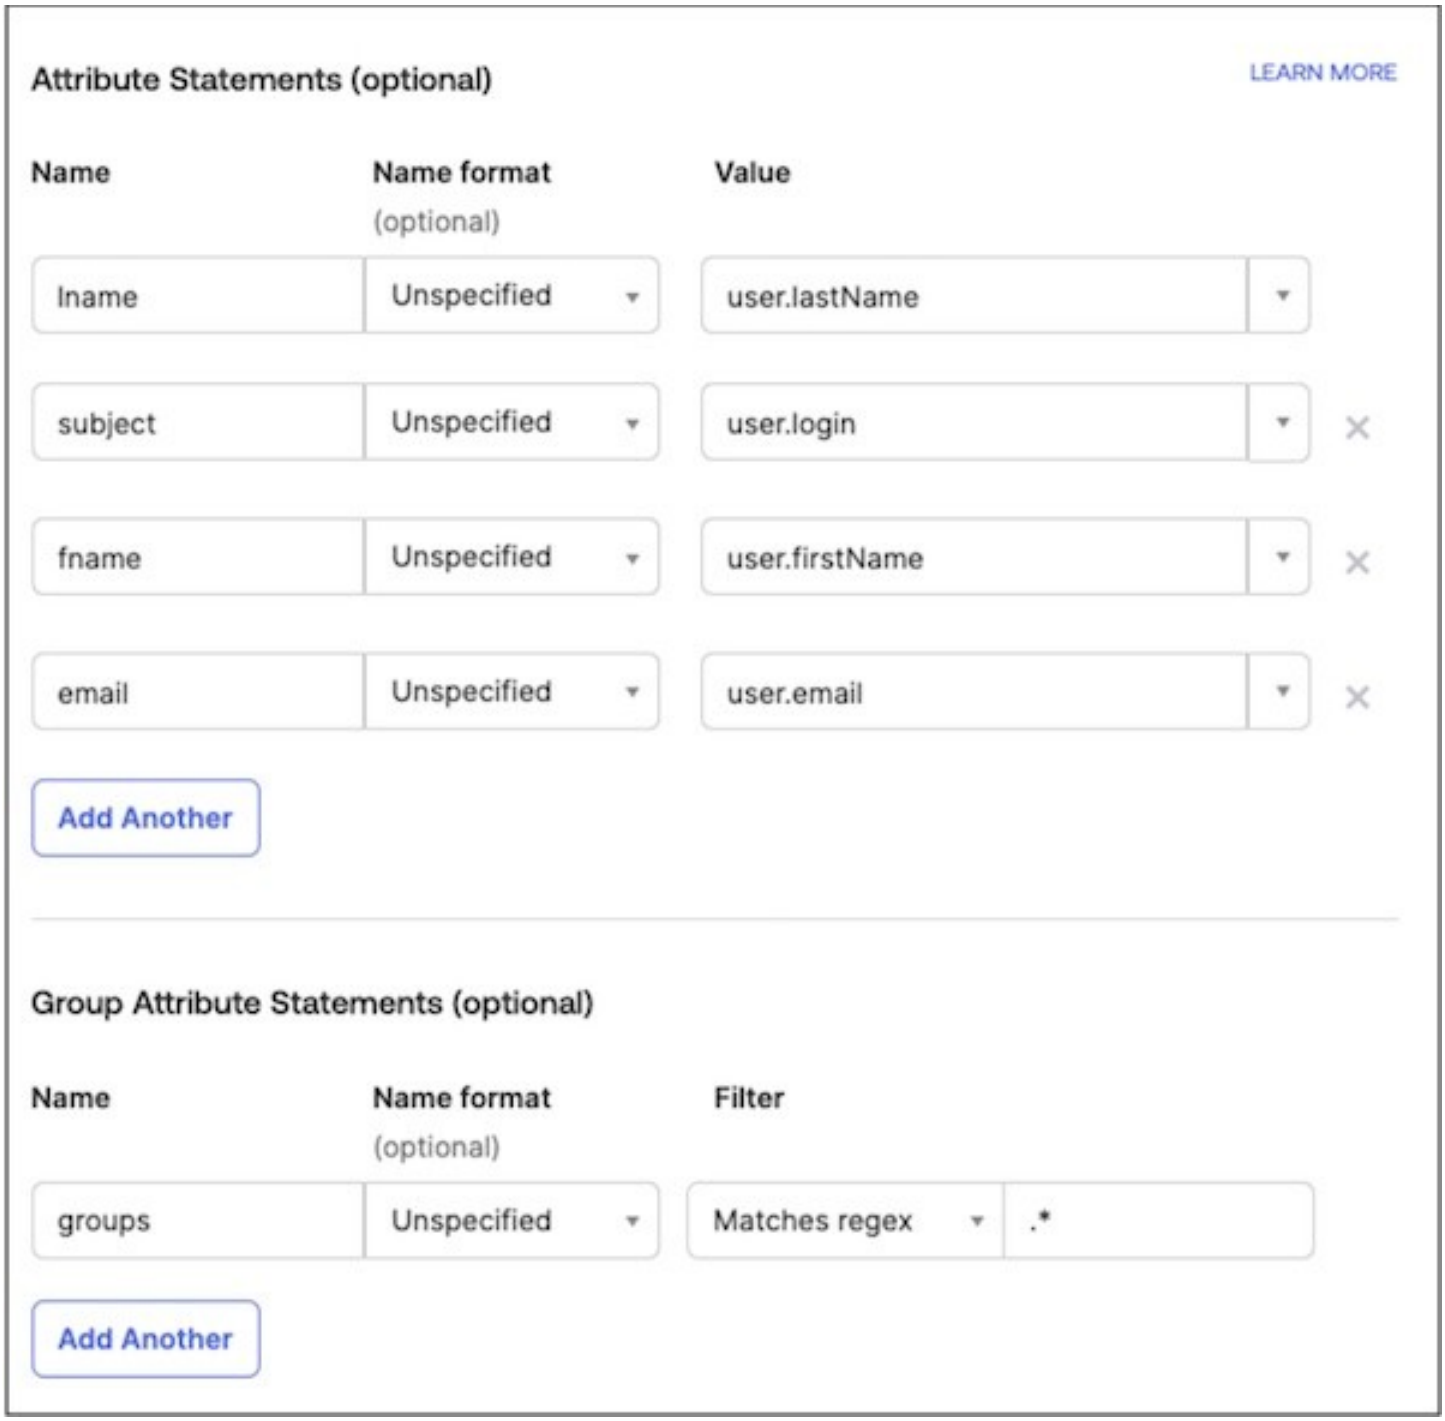
Configuring Third-Party IDP's to include user's groups in the user assertion

The following examples show how different IDP configurations include user's groups information in the user assertion.

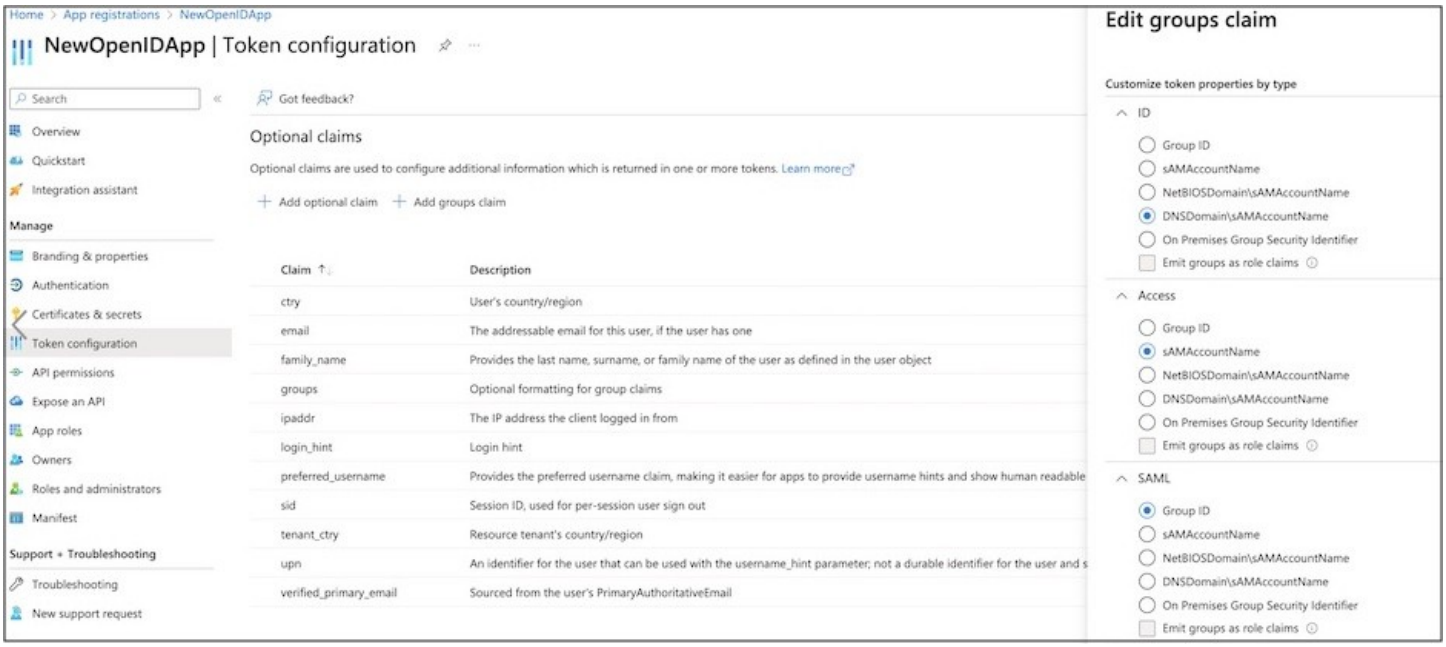
Example of OKTA IDP OpenID Configuration UI that shows how user's groups claims can be configured.



Example of OKTA IDP SAML Configuration UI that shows how user's groups claims can be configured.



Example of Azure Configuration UI that shows how user's groups claims can be configured.



Resource Server Application Flow

Resource Servers host protected resources. This topic covers the provisioning of client applications, the setup of resource server applications, and the definition of associated authentication and authorization policies, roles, and scopes, including the OIDC (OpenID Connect) flow.

Resource Servers are essential components in an OAuth 2.0 and OpenID Connect ecosystem, responsible for hosting protected resources and responding to authenticated requests from client applications. Proper management of Resource Server Applications involves defining their scopes, roles, and access policies to ensure secure and controlled access to sensitive data and functionalities. This topic provides a detailed walkthrough of this functionality.

This topic includes the following sections to secure a Resource Server using Symantec Identity Security Platform :

- Aquire Access Token
- Client App Provisioning
- Resource Server Provisioning
- Client App Flow Using Resource Server
- OIDC Flow using Resource Server

Tenant Setting Configuration

Configure this tenant setting, "**persistUserConsentGivenForResourceApps**" to true, if the consent given by the user during the authorization flow for the resource apps needs to be persisted. By default, this setting is set to **false**. This setting is also covered in the See Managing Settings page.

Get Access Token

- Acquire Client-only Access Token by using the "/token" API:

  ```
  POST https://{{sspHost}}/{{apiPathTenant}}/oauth2/v1/token
  ```

  Acquire Client-only Access Token- Response

  Response:

  ```
  {
  ```

```
"access_token": "eyJ4NXQjUzI1NiI6I.....",
"token_type": "Bearer",
"expires_in": 3600,
"scope": "urn:iam:t.authpolicies urn:iam:t.authzpolicies urn:iam:t.adminroles"
}
```

Client App Provisioning

1. **Create a client app named "acmehr"**:
   This step involves registering a new client application named "acmehr" with the authorization server. Client applications are entities that request access to protected resources on behalf of a user or themselves.

   ```
   POST https://{{sspHost}}/{{apiPathTenant}}/admin/v1/Apps
   ```

   Create a client app- Response

   Request:

   ```
   {
     "status": "active",
     "name": "acmehr",
     "description": "Client Application to access HR Resource server",
     "clientType": "CONFIDENTIAL",
     "allowedOpenIDScopes": [
       "openid",
       "email",
       "profile",
       "urn:iam:sso:idprop"
     ],
     "redirectURIs": [
       "https://www.example.com"
     ],

```

2. **Perform a GET of the "AuthClientPolicy" AuthZ Policy details**:

This step retrieves the details of a specific Authorization Policy named "AuthClientPolicy". This particular policy is designed to enable client applications to perform authentication-related operations.

```
GET https://{{sspHost}}/{{apiPathTenant}}/admin/v1/AuthZPolicies/f5a82a07-b87b-4557-9967-87cccaefeec2
```

Perform a GET of the "AuthClientPolicy" AuthZ Policy- Response

Response:

```
{
  "policyId": "f5a82a07-b87b-4557-9967-87cccaefeec2",
  "policyName": "AuthClientPolicy",
  "description": "Perform authentication-related operations as required to implement a custom signin app",

        "principal": {
          "clientApp": {
            "operator": "in",
            "value": [
              "$DEMO_CLIENT_APP_ID"
            ]
          }
        }
      },
      "result": {
        "effect": "grant",
        "msg": "This policy allows clients to call authentication APIs",
        "privileges": [
          "$AUTHCLIENT_PRIVILEGES"
        ]
      }
    }
  ],
  "adminscope.criteria": [],
  "adminscope.managedby": [],
  "createdDate": "2025-10-15 06:05 AM UTC",
  "updatedBy": {
    "principalType": "USER",
    "principalId": "ff337dec-d588-4564-b147-d1cccb3e4a73",
    "principalName": "internaluser"
  },
  "updatedDate": "2025-11-03 07:22 AM UTC",
  "preventedOperations": "Delete,Update"
```

```
}
```

3. **Grant the "AuthClientPolicy" role to the already created client app** (acmehr - id:c95ae9c1-eca0-42e3-afa7-bba019aa82c0).
   The "AuthClientPolicy" is granted to the "acmehr" client application. This action effectively assigns the privileges defined within the "AuthClientPolicy" to the "acmehr" app, allowing it to execute authentication-related operations. The request uses the "authZPolicyID" to identify the policy and "ClientAppId" to specify the recipient client application.

   ```
   POST https://{{sspHost}}/{{apiPathTenant}}/admin/v1/AdminRolesDelegator
   ```

   Grant the "AuthClientPolicy" role- Request and Response

   Request:

   ```
   {
     "id": "f5a82a07-b87b-4557-9967-87cccaefeec2",
     "principal": {
       "clientApp": {
         "operator": "in",
         "value": [
           "c95ae9c1-eca0-42e3-afa7-bba019aa82c0"
         ]
       }
     }
   }
   ```

   Where,

   - id = This is the "AuthClientPolicy" authorization PolicyID
   - ClientApp value = This is the client app (acmehr app id) already created in step1.

   Response:

   ```
   {
     "id": "f5a82a07-b87b-4557-9967-87cccaefeec2",
     "name": "AuthClientPolicy",
     "displayName": "Authentication Client",
     "description": "Perform authentication-related operations as required to implement a custom signin app",
     "principal": {
       "clientApp": {
         "operator": "in",
         "value": [
           "c95ae9c1-eca0-42e3-afa7-bba019aa82c0",
           "$DEMO_CLIENT_APP_ID"
         ]
       }
     },
     "isGrantableClientOnly": true,
     "isSubdelegatable": false,
     "privileges": [
       "$AUTHCLIENT_PRIVILEGES"
     ]
   }
   ```

4. **Create a authentication Policy for the Client App**:
   This step creates an Authentication Policy specifically for the "acmehr" client application. This policy defines rules that, under certain conditions (for example, a specific user attempting to "authenticate"), will result in a granted effect with required obligations (for example, "PASSWORD:1" for single-factor password authentication).

   ```
   POST https://{{sspHost}}/{{apiPathTenant}}/admin/v1/AuthPolicies
   ```

Create a authentication Policy for the Client App- Request and Response

Request:

```
{
  "description": "Authentication policy for acmehr",
  "status": "active",
  "policyName": "AuthNPolicy for acmehr",
  "apps": [
    {
      "id": "c95ae9c1-eca0-42e3-afa7-bba019aa82c0"
    }
  ],
  "rules": [
    {
      "conditions": {
        "principal": {
          "user": {
            "operator": "in",
            "value": [
              "malbail"
            ]
          }
        },
        "action": {
          "operator": "in",
          "value": [
            "authenticate"
          ]
        }
      },
      "result": {
        "effect": "allow",
        "obligations": [
          "PASSWORD:1"
        ],
        "msg": "AuthNPolicy rule for acmehr"
      }
    }
  ]
}
```

Where,

- "description" and "policyName" has the client app name, which is "acmehr" in this example.
- "apps" id = client app Id (acmehr app id)

Response:

```
{
  "policyId": "f543eac3-d0f3-4a7d-b965-f47599fcebd6",
  "policyName": "AuthNPolicy for acmehr",
  "description": "Authentication policy for acmehr",
  "status": "active",
  "matchAnyApp": false,
  "apps": [
    {
```

```
        "name": "acmehr",
        "id": "c95ae9c1-eca0-42e3-afa7-bba019aa82c0"
      }
    ],
    "rules": [
      {
        "id": "d732df16-f896-482f-8b9a-ed0ad9c061ce",
        "conditions": {
          "principal": {
            "user": {
              "operator": "in",
              "value": [
                "malbail"
              ]
            }
          },
          "action": {
            "operator": "in",
            "value": [
              "authenticate"
            ]
          }
        },
        "result": {
          "effect": "allow",
          "reAuthenticate": "false",
          "obligations": [
            "PASSWORD:1"
          ],
          "msg": "AuthNPolicy rule for acmehr"
        }
      }
    ],
    "adminscope.criteria": [],
    "adminscope.managedby": [],
    "createdBy": {
      "principalType": "CLIENT",

      "principalName": "DefaultTenantClient"
    },
    "createdDate": "2025-11-03 09:47 AM UTC",
    "policySubType": "userDefined"
  }
```

Client Provisioning steps end here. Next section describes Resource Server App provisioning.

Resource Server Provisioning

NOTE

- An authorization policy (AppRole) can include only single resource server app. It is not recommended to have multiple resource server apps associated to a single authorization policy.

  Example:

  ```
  "apps": [
  ```

```
 {
  "id": "{{rsAppId}}"
 }
]
```

- When configuring an application role for a resource server, verify that the resource server application is the sole entry under 'apps'. The out-of-the-box SSP application should not be included along with the resource server application.
- Only resource server applications can be assigned to application roles; normal applications are not supported.
- Application group is supported in Authentication policy, Risk policy and IDP Discovery policy. It is not supported in Authorization policy.

1. **Create a Resource Server App** (HR)
   This step involves registering the "HR" application as a Resource Server. A Resource Server hosts protected resources and accepts and responds to protected resource requests using access tokens.
   Key attributes for a Resource Server include the following:
   For all other attribute descriptions, see Description of Application Attributes (OIDC and SAML attributes).

   - **name**: The name of the Resource Server application (example, "HR").
   - **resScope**: A unique URI that identifies the Resource Server within the authorization server's domain (e.g., "urn:rs:hr"). This scope is used to request access to resources protected by this server.
   - **description**: A clear description of the Resource Server's function.
   - **isResourceServerApp**: Set to `true` to designate this application as a Resource Server. This enables specific behaviors and configurations related to resource protection.
   - **primaryAudience**: The primary audience for access tokens issued for this Resource Server (e.g., "https://hr.com"). Access tokens with this audience are intended for this Resource Server.
   - **resourceServerScopes**: A list of scopes defined by the Resource Server, along with their descriptions and whether consent is required. These scopes represent specific permissions that client applications can request to access the Resource Server's protected resources.
     - **promote**: A scope to manage promotions within a department.
     - **hire**: A scope to manage hiring processes within a department.
     - **transfer**: A scope to manage transfers in and out of a department.
   - **consentTermsAndConditionsUrl**: The URL for the terms and conditions that users must agree to before granting consent to the client application.
   - **consentPrivacyPolicyUrl**: The URL for the privacy policy that users can review before granting consent to the client application.

   ```
   POST https://{{sspHost}}/{{apiPathTenant}}/admin/v1/Apps
   ```

   Create a a Resource Server App- Request and Response

   Request:

   ```

  "isLauncherApp": false,
  "requireAccessControl": null,
  "isResourceServerApp": true
}
```

2. **Create a Role (Hire and Transfer) for the Resource Server App**

   This step creates an Authorization Policy named "HRHireAndTransfer". In the context of a Resource Server, an Authorization Policy acts as a role that defines a set of privileges that can be granted to a principal (user, client app, or group). This specific policy grants the "hire" and "transfer" privileges, allowing entities assigned this role to perform hiring and transfer-related operations on the HR Resource Server.

   ```
   POST https://{{sspHost}}/{{apiPathTenant}}/admin/v1/AuthZPolicies
   ```

   Create a Role (Hire and Transfer) for the Resource Server App- Request and Response

   Request:

   ```
   {
     "policyName": "HRHireAndTransfer",
     "description": "HR role for hire and transfer privilege",
     "displayName": "HR role for hire and transfer privilege",
     "status": "active",
     "isGrantableClientOnly": false,
     "isSubdelegatable": true,
     "matchAnyApp": false,
     "apps": [
       {
         "id": "25d25465-db50-44ec-b9ea-5c9b2ef2f8ff"
       }
     ],
     "rules": [
       {
         "conditions": {
           "principal": {
             "clientApp": {
               "operator": "in",
               "value": [
                 "c95ae9c1-eca0-42e3-afa7-bba019aa82c0"
               ]
             },
             "user": {
               "operator": "in",
               "value": [
                 "malbail"
               ]
             }
           }
         },
         "result": {
           "effect": "grant",
           "msg": "HR role for hire and transfer privilege",
           "privileges": [
   ```

```
          "hire",
          "transfer"
        ]
      }
    }
  ]
}
```

Where,

- apps Id = This is the value of the resource app (HR) created in step 1 (25d25465-db50-44ec-b9ea-5c9b2ef2f8ff)
- Under rules, the client app value = acmehr client app id, and user =malbail.

Response:

```
{
  "policyId": "6b53393e-d906-45ca-a531-2e7c0daa0c90",

    "createdBy": {
      "principalType": "CLIENT",
      "principalId": "ae9964b4-44fa-4976-8557-4097bbfbb9b5",
      "principalName": "DefaultTenantClient"
    },
    "createdDate": "2025-11-03 09:59 AM UTC"
  }
```

3. **Create Promote role for the Resource Server App**:

   Similar to the previous step, this creates another Authorization Policy named "HRPromote". This policy defines the "promote" privilege, enabling principals with this role to manage promotions within the HR department. These roles are critical for implementing fine-grained access control to the Resource Server's functionalities.

   ```
   POST https://{{sspHost}}/{{apiPathTenant}}/admin/v1/AuthZPolicies
   ```

   Create Promote role for the Resource Server App- Request and Response

   Request:

   ```
   {
     "policyName": "HRPromote",
     "description": "HR promote role",
     "displayName": "HR promote role",
     "status": "active",
     "isGrantableClientOnly": false,
     "isSubdelegatable": true,
     "matchAnyApp": false,
     "apps": [
       {
         "id": "25d25465-db50-44ec-b9ea-5c9b2ef2f8ff"
       }
     ],
     "rules": [
       {
         "conditions": {
           "principal": {
             "clientApp": {
               "operator": "in",
               "value": [
                 "c95ae9c1-eca0-42e3-afa7-bba019aa82c0"
               ]
             },
             "user": {
               "operator": "in",
               "value": [
                 "malbail"
               ]
             }
           }
         },
         "result": {
   ```

```
        "effect": "grant",
        "msg": "HR promote role",
        "privileges": [
          "promote"
        ]
      }
    }
  ]
}
```

Where,

- apps Id = This is the value of the resource app (HR) created in step 1 (25d25465-db50-44ec-b9ea-5c9b2ef2f8ff)
- Under rules, the client app value = acmehr client app id, and user = malbail.

Response:

```
{
  "policyId": "0d701ed6-eab4-44bf-8132-5cf1c1042d40",
  "policyName": "HRPromote",
  "description": "HR promote role",
  "status": "active",
  "isGrantableClientOnly": false,
  "isSubdelegatable": true,
  "displayName": "HR promote role",
  "matchAnyApp": false,
  "apps": [
    {
      "name": "HR",
      "id": "25d25465-db50-44ec-b9ea-5c9b2ef2f8ff"
    }
  ],
  "rules": [
    {
      "id": "bda17ffe-eec9-454b-9cf1-79031a15c8b8",
      "conditions": {
        "principal": {
          "user": {
            "operator": "in",
            "value": [
              "malbail"
            ]
          },
          "clientApp": {
            "operator": "in",
            "value": [
              "c95ae9c1-eca0-42e3-afa7-bba019aa82c0"
            ]
          }
        }
      },
      "result": {
        "effect": "grant",
        "msg": "HR promote role",
        "privileges": [
```

```
            "promote"
          ]
        }
      }
    ],
    "adminscope.criteria": [],
    "adminscope.managedby": [],
    "createdBy": {
      "principalType": "CLIENT",
      "principalId": "ae9964b4-44fa-4976-8557-4097bbfbb9b5",
      "principalName": "DefaultTenantClient"
    },
    "createdDate": "2025-11-03 10:08 AM UTC"
  }
```

4. **Grant (Hire and Transfer) role to the Client App**

   This action delegates the "HRHireAndTransfer" role to the client application (acmehr) and/or specific users. By granting this role, the client application (and/or user) is authorized to request and receive access tokens with the "hire" and "transfer" scopes, allowing them to interact with the HR Resource Server's protected resources that correspond to these privileges.

   ```
   POST https://{{sspHost}}/{{apiPathTenant}}/admin/v1/AppRolesDelegator
   ```

   Grant (Hire and Transfer) role to the Client App- Request and Response

   Request:

   ```
   {
     "id": "6b53393e-d906-45ca-a531-2e7c0daa0c90",
     "principal": {
       "clientApp": {
         "operator": "in",
         "value": [
           "c95ae9c1-eca0-42e3-afa7-bba019aa82c0"
         ]
       },
       "user": {
         "operator": "in",
         "value": [
           "malbail"
         ]
       }
     }
   }
   ```

   Where,

   - id= This is the "hireandtransfer" PolicyId
   - Under rules, the client app value = acmehr client app id, and user = malbail.

   Response:

   ```
   {
    "id": "6b53393e-d906-45ca-a531-2e7c0daa0c90",
    "name": "HRHireAndTransfer",
    "displayName": "HR role for hire and transfer privilege",
    "description": "HR role for hire and transfer privilege",
    "principal": {
   ```

```
    "user": {
      "operator": "in",
      "value": [
        "malbail"
      ]
    },
    "clientApp": {
      "operator": "in",
      "value": [
        "c95ae9c1-eca0-42e3-afa7-bba019aa82c0"
      ]
    }
  },
  "isGrantableClientOnly": false,
  "isSubdelegatable": true,
  "privileges": [
    "hire",
    "transfer"
  ]
}
```

5. **Grant (Promote) role to the Client App**

   This step grants the "HRPromote" role to the client application (acmehr) and/or specific users. This authorizes the client application (and/or user) to request and use access tokens that include the "promote" scope, thereby enabling access to promotion-related functionalities on the HR Resource Server.

   ```
   POST https://{{sspHost}}/{{apiPathTenant}}/admin/v1/AppRolesDelegator
   ```

   Grant (Promote) role to the Client App- Request and Response

   Request:

   ```
   {
     "id": "0d701ed6-eab4-44bf-8132-5cf1c1042d40",
     "principal": {
       "clientApp": {
         "operator": "in",
         "value": [
           "c95ae9c1-eca0-42e3-afa7-bba019aa82c0"
         ]
       },
       "user": {
         "operator": "in",
         "value": [
           "malbail"
         ]
       }
     }
   }
   ```

   Where,

   - id= This is the "Promote" PolicyId
   - Under rules, the client app value = acmehr client app id, and user = malbail.

   Response:

   ```
   {
   ```

```
  "id": "0d701ed6-eab4-44bf-8132-5cf1c1042d40",
  "name": "HRPromote",
  "displayName": "HR promote role",
  "description": "HR promote role",
  "principal": {
    "user": {
      "operator": "in",
      "value": [
        "malbail"
      ]
    },
    "clientApp": {
      "operator": "in",
      "value": [
        "c95ae9c1-eca0-42e3-afa7-bba019aa82c0"
      ]
    }
  },
  "isGrantableClientOnly": false,
  "isSubdelegatable": true,
  "privileges": [
    "promote"
  ]
}
```

6. **(Optional) Create an Access Policy for the Resource App**:
   This is the Authentication Policy created for the HR Resource Server, named "Access Policy for HR". This policy defines the access rules for the Resource Server. It specifies that any principal possessing either the "hireandtransferPolicyId" or "promotePolicyId" app roles is allowed to "access" the HR Resource Server. This policy acts as a gatekeeper, ensuring that only clients with the appropriate roles can interact with the HR resources.

   ```
   POST https://{{sspHost}}/{{apiPathTenant}}/admin/v1/AuthPolicies
   ```

   Create an Access Policy for the Resource App- Request and Response

   Request:

   ```
   {
     "description": "Access policy for HR ",
     "status": "active",
     "policyName": "Access Policy for HR",
     "apps": [
       {
         "id": "{{rsAppId}}"
       }
     ],
     "rules": [
       {
         "conditions": {
           "principal": {
             "appRole": {
               "operator": "in",
               "value": [
                 "6b53393e-d906-45ca-a531-2e7c0daa0c90",
                 "0d701ed6-eab4-44bf-8132-5cf1c1042d40"
               ]
   ```

```
          }
        },
        "action": {
          "operator": "in",
          "value": [
            "access"
          ]
        }
      },
      "result": {
        "effect": "allow",
        "msg": "Access rule for HR"
      }
    }
  ]
}
```

Where,

- "description" and "policyName"= This is the value of the resource app (HR in this example)
- "id"= This is the resource app id.
- Under rules, app role value= "hireandtransfer" policy Id and promote policy Id.

Response:

```
{
  "policyId": "fadbc766-642c-4f5e-ad28-f4f40614db2f",
  "policyName": "Access Policy for HR",
  "description": "Access policy for HR ",
  "status": "active",
  "matchAnyApp": false,
  "apps": [
    {
      "name": "HR",
      "id": "25d25465-db50-44ec-b9ea-5c9b2ef2f8ff"
    }
  ],
  "rules": [
    {
      "id": "c5b755a1-477e-4a3d-ae1c-ed19df025597",
      "conditions": {
        "principal": {
          "appRole": {
            "operator": "in",
            "value": [
              "6b53393e-d906-45ca-a531-2e7c0daa0c90",
              "0d701ed6-eab4-44bf-8132-5cf1c1042d40"
            ]
          }
        },
        "action": {
          "operator": "in",
          "value": [
            "access"
          ]
```

```
            }
          },
          "result": {
            "effect": "allow",
            "reAuthenticate": "false",
            "msg": "Access rule for HR"
          }
        }
      ],
      "adminscope.criteria": [],
      "adminscope.managedby": [],
      "createdBy": {
        "principalType": "CLIENT",
        "principalId": "ae9964b4-44fa-4976-8557-4097bbfbb9b5",
        "principalName": "DefaultTenantClient"
      },
      "createdDate": "2025-11-03 10:26 AM UTC",
      "policySubType": "userDefined"
    }
```

Client App Flow Using Resource Server

This section describes the client application's interaction with the Resource Server after all provisioning and policy configurations are in place. The client application acquires an access token with the necessary scopes to access the protected resources.

```
POST https://{{sspHost}}/{{apiPathTenant}}/oauth2/v1/token
```

This is a request to the OAuth 2.0 token endpoint to obtain an access token. The client application typically sends its credentials and requests specific scopes (for example, "promote", "transfer", "hire") that it needs to access the Resource Server's functionalities.

Client App Flow Using Resource Server- Request and Response

Response:

```
{
"access_token": "eyJ4NXQjUzI1NiI6IjdvcXZva2tnSkZ0dWd0....",
"token_type": "Bearer",
"expires_in": 3600,
"scope": "promote transfer hire"
}
```

Where,

- access_token - "eyJ4NXQjUzI1NiI6IjdvcXZva2tnSkZ0dWd0...." - The JWT (JSON Web Token) that grants access to protected resources on the Resource Server.
- token_type: "Bearer" - Indicates the type of token issued. "Bearer" means the token should be included in the Authorization header as "Bearer <access_token>" when making requests to protected resources.
- expires_in: 3600 - The lifetime of the access token in seconds. In this case, 3600 seconds (1 hour) indicates when the token will expire and need to be renewed.
- Scope: "promote transfer hire" - These scopes indicate that the issued access token grants the client application permissions for the "promote", "transfer", and "hire" operations on the Resource Server. These are the specific privileges that the client application can exercise.

Decoded Response:

```
{
```

```
"client_tid": "181b8f45-e1dc-45cf-8d5b-7811b6c4f19b",

}
```

OIDC Flow using Resource Server

These steps outlines the OpenID Connect (OIDC) flow, detailing the steps required to acquire an Access Token (AT) and Identity Token (IT) when interacting with a resource server.

1. **Initiate Authorization Request**
   This is the initial request made to the authorization server to begin the OIDC flow. The client application requests authorization from the user, specifying its identity and the resource server it intends to access.
   ```
   POST https://{{sspHost}}/{{apiPathTenant}}/oauth2/v1/authorize?signin_hint=true
   ```
   Where, pass the query parameter, `signin_hint=true` in the authorization URL. This parameter instructs the authorization server to immediately present the sign-in interface to the user.
   Initiate Authorization - Request and Response
   In the request, specify the following request body parameters:

Key	Value
client_id	Identifies the client application provisioned in the system (For example, acmehr).
resource	Specifies the identifier of the resource server - urn:rs:type:appid:25d25465-db50-44ec-b9ea-5c9b2ef2f8ff
response_type	Specifies the OAuth 2.0 flow type being used. Must be set to code for Authorization Code flow. For example: "response_type=code"
redirect_URI	URL where the authorization server will redirect the user after authentication. This URL should match the redirect URIs registered for the client application. For example: "redirect_URI=https://www.example.com"

code_challenge	Base64-URL encoded SHA256 hash of the code verifier for Proof Key for Code Exchange (PKCE). Example: "code_challenge=A6xnQhbz4Vx2HuGl4lXwZ5U2I8iziLRFnhP5eNfIRvQ"
code_challenge_method	Specifies the method used to generate the code challenge. It should be S256 (SHA256 hashing method) when using PKCE. Example: code_challenge_method=S256
scope	List of permissions being requested from the resource server. These scopes must match scopes defined in the resource server application. Example: "scope=promote hire transfer"

Response:

```
https://<sspHost>/default/ui/v1/signin/?x-flow-state=UHh4OTdkQ3BWUmNySkxub2FKbHc0dHl6WklyUytBRFZm....
```

The authorization server responds with a redirect URI that includes the following parameters, crucial for continuing the authentication flow:

- redirect Uri - The URL to which the user's browser should be redirected.
- x-flow-state - A unique identifier representing the current state of the authentication flow.
- x-service-baseurl - The base URL for subsequent service interactions.

2. **Initial Token Request (Client Credentials Flow)**

This step involves invoking the token endpoint. This initial call is made to the token endpoint to obtain an Access Token using client credentials.

```
POST https://{{sspHost}}/{{apiPathTenant}}/oauth2/v1/token
```

Initial Token Request - Request and Response

Request:

- Under "Auth" headers > Basic Auth - provide the client app id and password.
- Under "Body" parameters > - provide grant_type=client_credentials, and scope=urn:iam:myscopes

Response:

```
{
"access_token": "eyJ4NXQjUzI1NiI6IjdvcXZva2tnSkZ0dWd0TEhyem....",
"token_type": "Bearer",
"expires_in": 3600,
"scope": "urn:iam:t.authenticate urn:iam:m.meclient"
}
```

Where,

- access_token: The JWT (JSON Web Token) that grants access to protected resources.
- token_type: "Bearer" - Indicates the type of token issued. "Bearer" means the token should be included in the Authorization header as "Bearer <access_token>" when making requests to protected resources.
- expires_in: 3600 - The lifetime of the access token in seconds. In this case, 3600 seconds (1 hour) indicates when the token will expire and need to be renewed.
- scope - The permissions granted by the Access Token (for example, urn:iam:t.authenticate urn:iam:m.meclient).

3. **User Authentication - Provide Username**

This step initiates the user authentication process. The client sends the user's login name to the authentication endpoint, along with the x-flow-state received in the initial authorization request. This informs the system about the user attempting to authenticate and the current state of their session.

```
POST https://{{sspHost}}/{{apiPathTenant}}/auth/v1/authenticate
```

User Authentication (Provide Username) - Request and Response

Request:

```
{
```

```
"subject": "{{userLoginName}}",
"action": "authenticate",
"ipAddress": "1.1.1.2",
"channel": "web",
"acrValues": []
}
```

Where,

- subject: The user's login name who is attempting to authenticate.
- action: Specifies the action being performed, which is authentication in this case.
- ipAddress: The IP address of the client making the authentication request.
- channel: The channel or medium through which the authentication request is being made.
- acrValues: Authentication Context Class Reference values.

Response:

```
{
"flowState":
 "UHh4OTdkQ3BWUmNySkxub2FKbHc0dHl6WklyUytBRFZmRGlBWmxNNThJRitvNzRUOWUwYkRZVDh0WTRmaHA0OGJPM1hac0dLYm12U3JxVzYxWGkwVm
"userName": "malbail",
"nextaction": "PASSWORD_AUTH",
"currentFactors": [
"PASSWORD"
],
"additional": {
"userName": "malbail",
"idpName": "internal",
"idpGuid": "internal",
"idpType": "internal",
"passwordResetURL": "https://<sspHost>/default/ui/v1/signin/initiatePasswordReset?x-flow-
state=UHh4OTdkQ3BWUmNySkxub2FKbHc0dHl6WklyUytBRFZmRGlBWmxNNThJRitvNzRUOWUwYkRZVDh0WTRmaHA0OGJPM1hac0dLYm12U3JxVzYxWG
"currentFactorLevel": 1,
"predicatesForCurrentFactors": [
{
"factor": "PASSWORD",
"predicate": "internal",
"providerAmr": "PWD"
}
],
"signinExpMins": 60,
"identityProviders": []
}
}
```

Where,

- flowState: The current x-flow-state to maintain the authentication session.
- userName: The user's login name (malbail in this example).
- nextaction: Indicates the next expected action in the authentication flow, such as PASSWORD_AUTH.
- currentFactors: An array listing the authentication factors currently being used (for example, PASSWORD).
- additional: Contains supplementary authentication information:

- userName: "malbail" - The user's login name.
- idpName: "internal" - The identity provider name.
- idpGuid: "internal" - The identity provider GUID.
- idpType: "internal" - The type of identity provider.
- passwordResetURL: URL for password reset functionality.
- currentFactorLevel: 1 - The current authentication factor level.
- predicatesForCurrentFactors: Array containing factor details including factor type, predicate, and provider AMR.
- signinExpMins: 60 - Session expiration time in minutes.
- identityProviders: Array of available identity providers.

4. **User Authentication - Provide Password**

Following the username submission, this step authenticates the user by verifying their password. The client sends the user's credentials (or an indicator that the password has been provided) along with the flowState to the designated password authenticator endpoint.

```
POST https://{{sspHost}}/{{apiPathTenant}}/factor/v1/PasswordAuthenticator
```

User Authentication (Provide Password) - Request and Response

Request:

```
{
// user password in plain text or encrypted using tenant's public signing certificate
"password": "{{defaultPassword}}"
}
```

Where,

- Enter the password for the user.

Response

```

"authCompleteUrl": "https://<sspHost>/default/oauth2/v1/authcomplete?x-flow-
state=UHh4OTdkQ3BWUmNySkxub2FKbHc0dHl6WklyUytBRFZmRGlBWmxNNThJRitvNzRUOWUwYkRZVDh0WTRmaHA0OGJPM1hac0dLYm12U3JxVzYxWG
"additional": {
"idpName": "internal",
"idpGuid": "internal",
"idpType": "internal",
"passwordResetURL": "",
"authLevelsData": {
"c95ae9c1-eca0-42e3-afa7-bba019aa82c0+malbail+1": "PASSWORD"
},
"currentFactorLevel": 1,
"amrForCompletedFactors": [
"PWD"
],
"lastObligation": "PASSWORD"
}
}
```

Where,

- flowState: The current x-flow-state to maintain the authentication session.
- userName: The user's login name.
- nextaction: Indicates that authentication is now allowed
  - If the next action is (AUTH_ALLOWED), **skip step 5 and go to step 6**.
  - If the next action is (CONSENT_AUTH), **go to step 5**.
- data: Contains additional information about the authentication result:
  - message: "Success" - Indicates the authentication status.
  - passwordResetURL: URL for password reset functionality if needed.
- authCompleteUrl: The URL to redirect to once the authentication flow is fully completed.
- additional: Contains supplementary authentication details:
  - idpName: "internal" - The identity provider name used for authentication.
  - idpGuid: "internal" - The identity provider GUID.
  - idpType: "internal" - The type of identity provider.
  - passwordResetURL: URL for password reset.
  - authLevelsData: Authentication level data mapping.
  - currentFactorLevel: 1 - The current authentication factor level achieved.
  - amrForCompletedFactors: ["PWD"] - Authentication Method Reference for completed factors.
  - lastObligation: "PASSWORD" - The last authentication obligation that was fulfilled.

5. **Consent Updater**: (Optional step) This step is performed if there are consents added in the resource server application privileges.

```
POST https://{{sspHost}}/{{apiPathTenant}}/factor/v1/ConsentUpdater
```

Consent Updater - Request and Response

Request:

```
{
    // consentGiven of true indicates that the user has given consent to the requested scopes
    "consentGiven": true
}
```

Where,

- Provide the consent as true or false for the given privileges.

Response

```
{
    "flowState": "VG5sWUlFMUFtWWlTOUNFZkhlQlZuS0tKakVsZ00vc...",
    "userName": "internaluser",
    "nextaction": "AUTH_ALLOWED",
    "deviceID": "798f053b8bc4453b8a832c2685926ae2",
    "data": {
        "consentUpdated": true
    },
    "authCompleteUrl": "https://example.com/default/oauth2/v1/authcomplete?x-flow-
state=VG5sWUlFMUFtWWl...",
    "additional": {
        "idpName": "internal",
        "idpGuid": "internal",
        "idpType": "internal",
        "passwordResetURL": "",
        "authLevelsData": {
            "da2a6ee2-c549-4265-97a8-6ff0ab47ef86+internaluser+1": "PASSWORD"
```

```
            },
            "currentFactorLevel": 1,
            "amrForCompletedFactors": [
                "PWD"
            ]
        }
    }
```

Where,

- flowState: The current x-flow-state to maintain the authentication session after consent processing.
- userName: The user's login name who provided the consent.
- nextaction: "AUTH_ALLOWED" - Indicates that authentication is now allowed after consent has been processed.
- deviceID: Unique identifier for the device used in the authentication flow.
- data: Contains information about the consent operation:
  - consentUpdated: true - Indicates whether the user's consent for the requested scopes has been successfully updated.
- authCompleteUrl: The URL to redirect to once the authentication flow is fully completed after consent processing.
- additional: Contains supplementary authentication details:
  - idpName: "internal" - The identity provider name used for authentication.
  - idpGuid: "internal" - The identity provider GUID.
  - idpType: "internal" - The type of identity provider.
  - passwordResetURL: URL for password reset.
  - authLevelsData: Authentication level data mapping.
  - currentFactorLevel: 1 - The current authentication factor level achieved.
  - amrForCompletedFactors: ["PWD"] - Authentication Method Reference for completed factors.

6. **Authentication Flow Completion and Redirect**:
   Once the user successfully authenticates, the authorization server redirects the user's browser to the pre-configured redirect URL (client application's callback URL). This redirect includes crucial information for the client to proceed with obtaining tokens.

   ```
   GET {{authCompleteUrl}}
   ```

   Authentication Flow Completion and Redirect - Request and Response
   Where,

   - authCompleteUrl - this is the configured redirect URL where the user is redirected to after the authentication completion.

   Response:The response retrieves the authorization code and the redirect URL.

   ```
   https://www.example.com?X-TRANSACTION-ID=28b8eb92-a9e3-4e93-831c-
   ed79abb69816&code=86QjvgQ3XAzcMQMNDZnOKiYB3iQ03o&session_state=4758a76a6f8490858abbb1334173d6ede2f1ecfff3ef57d0e9921
   ```

   Where,

   - X-TRANSACTION-ID: A unique identifier for the entire transaction.
   - code: This is the authorization code, a temporary, single-use code that the client exchanges for an Access Token and optionally an ID Token (example value-86QjvgQ3XAzcMQMNDZnOKiYB3iQ03o)
   - session_state: A value that represents the current session state, used to detect changes in the authentication session and provide additional security for the OAuth 2.0 flow.

7. **Exchange Authorization Code for Access Token**:
   The client application, having received the authorization code in the previous step, now makes a final request to the token endpoint. This request exchanges the authorization code for the actual Access Token (AT) and potentially an ID Token (IT). This Access Token is then used to securely access protected resources on the resource server.

   ```
   POST https://{{sspHost}}/{{apiPathTenant}}/oauth2/v1/token
   ```

Exchange Authorization Code for Access Token - Request and Response
Key Parameters (in Request Body or as Form Data)

Key	Value
code	The authorization code obtained in Step 5 (for example, 86QjvgQ3XAzcMQMNDZnOKiYB3iQ03o).

Response: A JSON object containing the final Access Token, its type, expiration, and granted scopes.

```
{
"access_token":
 "eyJ4NXQjUzI1NiI6IjdvcXZva2tnSkZ0dWd0TEhyem5QSGE0NkNIbGNGVGZmam1wSHRCY2E1T3MiLCJ4NXQiOiJJbUhCcWRMTDRnWWpiUERJOW9qWk
NnoFizuPJYgDIJohStaTQW3eI56nMvbfGsBpeUxuSokmydbD5dyWLfQS0cmbNc8omTNhPj8hauRTrpQ_0yzXJT31wo9V4IN1lqpPAlbgWE1MJTiDyGG0
ertuzm-z-QL2WM2YUDNnL1wNpOph41MtSWeg",
"token_type": "Bearer",
"expires_in": 3600,
"scope": "promote hire"
}
```

Where,

- access_token: The JWT (JSON Web Token) that grants access to protected resources.
- token_type: "Bearer" - Indicates the type of token issued. "Bearer" means the token should be included in the Authorization header as "Bearer <access_token>" when making requests to protected resources.
- expires_in: 3600 - The lifetime of the access token in seconds. In this case, 3600 seconds (1 hour) indicates when the token will expire and need to be renewed.
- scope - The permissions granted by the Access Token (for example, promote and hire).

Decoded AT:

```
{
"sub": "90390e76-4076-4885-bf3c-762f4fe88557",
"idp_name": "internal",
"user_dn": "90390e76-4076-4885-bf3c-762f4fe88557",

"idp_type": "internal",
"client_tname": "default",
"client_tid": "181b8f45-e1dc-45cf-8d5b-7811b6c4f19b",
"ver": "1.0",
"hasgroups": false,
```

```
"azpacr": "1",
"tname": "default",
"tok_type": "AT",
"user_riskscore": 100,
"user_ipaddress": "198.51.100.255",
"user_amr": [
"PWD"
],
"aud": [
"https://hr.com"
],
"nbf": 1762247296,
"user_zfp": false,
"client_transactionid": "ssp:3a9379e5-0cd9-4d6d-be4e-5a7cbf8a5047",
"user_aal": "AAL1",
"tok_source": "AZC",
"user_acr": "urn:iam:acr:aal1"
}
```

This completes the OIDC flow, resulting in the client application possessing an Access Token that can be used to interact with the protected resource server on behalf of the authenticated user.

Securing MCP Servers with Symantec Identity Security Platform

Learn how to secure MCP servers using IDSP

Overview

This document provides comprehensive technical instructions on securing Model Context Protocol (MCP) servers using Identity Security Platform (IDSP). The process involves onboarding MCP servers as resource server applications and configuring MCP clients to access them securely through OAuth 2.0 and OpenID Connect protocols.

Model Context Protocol (MCP)

Model Context Protocol (MCP) is an emerging standard that enables Artificial Intelligence (AI) applications to interact with external systems through standardized tool interfaces. MCP servers expose executable tools, accessible resources, and prompts that AI applications can consume to perform operations, access data, and integrate with various backend systems.

Key Components of MCP:

- **MCP Server**: A service that exposes executable tools, accessible resources, and prompts through standardized HTTP/HTTPS endpoints.
  - **Tools**: Discrete functions that perform specific operations (for example, data retrieval, file operations, API calls)
  - **Resources**: Data or content accessible to authenticated clients (for example, documents, databases, external APIs)
  - **Prompts**: Reusable prompt templates that can be invoked by clients to generate consistent outputs
- **MCP Client**: AI applications or other clients that consume server capabilities by invoking tools, accessing resources, and using prompts.

MCP servers typically implement OAuth 2.0 resource server patterns, making them compatible with standard identity and access management solutions. The protocol includes a discovery mechanism through the "`https://{{IDSPHost}}/{{apiPathTenant}}/.well-known/oauth-protected-resource/mcp`" endpoint, which provides security metadata, exposed scopes, and application information.

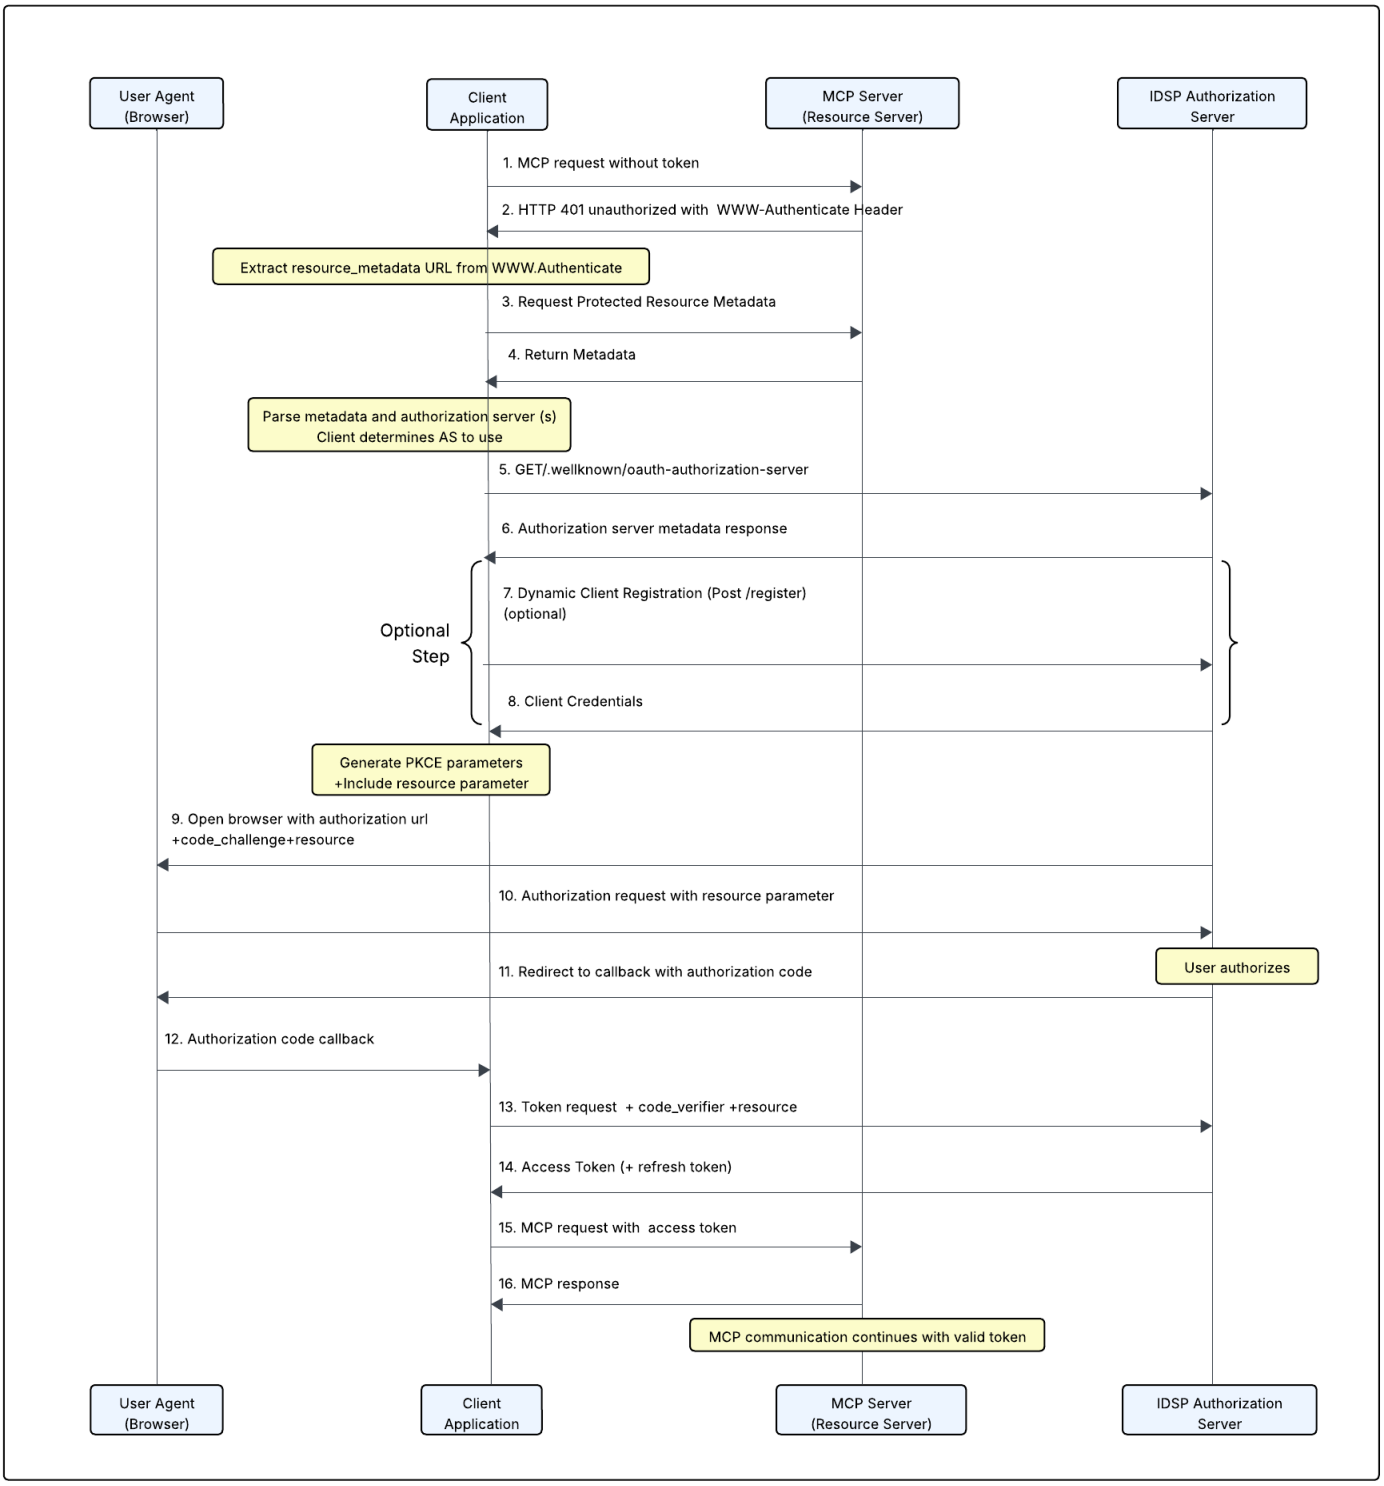
Integration Architecture

The integration of MCP servers with IDSP follows the standard OAuth 2.0 resource server pattern:

1. **MCP servers** register with IDSP as resource server applications, defining their scopes and access requirements
2. **MCP clients** authenticate with IDSP and obtain access tokens with appropriate scopes
3. **Token validation** occurs at the MCP server, which validates bearer tokens against IDSP
4. **Authorization enforcement** ensures that only authorized principals (users, groups, or client applications) can access specific tools and resources

This architecture provides enterprise-grade security while maintaining the flexibility and extensibility required for AI-driven tool execution contexts. The standardized approach ensures compatibility with existing OAuth 2.0 and OpenID Connect ecosystems.

Figure 19: Integration Architecture of MCP servers with IDSP



Gathering MCP Server Properties

Before onboarding an MCP server as a resource server application in IDSP, you need to collect the following information:

- **Resource** URL: The base URL of the MCP server (for example, https://hr.com/mcp)
- **Scopes**: List of scopes exposed by the resource (for example, hire, promote, transfer)
- **Resource Name**: Display name for the application (for example, HR)

Onboarding MCP Server as a Resource Server Application

Learn about the steps to onboard MCP server as a Resource Server application in IDSP.

Step 1. Create Resource Server Application

The first step is to provision the Model Context Protocol (MCP) server as a resource server application in IDSP using the following API and adhearing to the guidelines mentioned in the subsequent sections:

```
POST https://{{IDSPHost}}/{{apiPathTenant}}/admin/v1/Apps
```

Key Requirements:

When creating the resource server, adhere to the following requirements:

1. The resource URL from metadata should be mapped to "primaryAudience" and it must be unique across all apps.
2. The scopes in the metadata should be provisioned as "resourceServerScopes" and mark them as default. If the scopes have standard OAuth claims (like openid, profile, email, etc.), they should be ignored and should not be added as resource server scopes.
3. Mark the application as resource server app (that is, "isResourceServerApp: true")
4. Set the name of the application collected in the gathering phase.

Resource Server Application Payload:

```
{
    "status": "active",
    "name": "HR",
    "resScope": "urn:rs:hr",
    "description": "HR Resource Server Application",
    "skewTimeSecs": 0,
    "passwordAuthoritativeSource": "remote",
    "clientType": "CONFIDENTIAL",
    "allowedOpenIDScopes": [
        "openid",
        "profile",
        "groups",
        "address",
        "offline_access",
        "email"
    ],
    "redirectURIs": [
        "https://www.example.com"
    ],
    "allowedGrantTypes": [
```

```
        "implicit",
        "client_credentials",
        "urn:ietf:params:oauth:grant-type:device_code",
        "authorization_code",
        "urn:ietf:params:oauth:grant-type:jwt-bearer"     ],
    "allowedOperations": [
        "offlineit",
        "introspect",
        "onbehalfof"
    ],
    "supportedJoseHeaderParams": "x5t,x5t#s256",
    "userInfoEndpointResponseFormat": "PLAIN_JSON",
    "itEncryptionTarget": "NONE",
    "isResourceServerApp": true,
    "consentUsagePolicyUrl": "https://policy.hr.com",
    "primaryAudience": "https://hr.com/mcp",
    "resourceServerScopes": [
        {
            "scope": "promote",
            "description": "scope to promote",
            "consentDescription": "Review, approve, and manage employee promo tions within your department",
            "label": "View and manage promotions in your department",
            "consentRequired": true,
            "isDefaultScope": true
        },
        {
            "scope": "hire",
            "description": "scope to hire",
            "consentDescription": "Review, approve, and manage hiring of new employees within your
 department",
            "label": "View and manage hiring in your department",
            "consentRequired": true,
            "isDefaultScope": true
        },
        {
            "scope": "transfer",
            "description": "scope to transfer",
            "consentDescription": "Review, approve, and manage transfer of ne w employees across
 departments",
            "label": "View and manage transfers in and out of your department
",
            "consentRequired": true,
            "isDefaultScope": true
        }
    ],
    "isOidcApp": true
}
```

Step 2: Create Authorization roles

The second step is to create the roles (authorization policies) for the provisioned resource server application using the `POST "https://{{IDSPHost}}/{{apiPathTenant}}/admin/v1/AuthZPolicies"` API. Each role defines who can access which privileges.

Create a separate authorization policy for each scope or group of scopes.

Authorization Policy Payload:

```
{
   "policyName": "HRPromote",
   "description": "HR promote role",
   "displayName": "HR promote role",
   "status": "active",
   "apps": [
       {
           "id": "{{rsAppId}}"
       }
   ],
   "rules": [
       {
           "conditions": {
               "principal": {
                   "clientApp": {
                       "operator": "in",
                       "value": [
                           "<CHANGE-ME>"
                       ]
                   },
                   "user": {
                       "operator": "in",
                       "value": [
                           "<CHANGE-ME>"
                       ]
                   },
                   "group": {
                       "operator": "in",
                       "value": [
                           "<CHANGE-ME>"
                       ]
                   }
               }
           },
           "result": {
               "effect": "grant",
               "msg": "HR promote role",
               "privileges": [
                   "promote"
               ]
           }
       }
   ]
}
```

Where,

- Replace the {{rsAppId}} with the actual resource server application ID returned from Step 1.
- Configure the principal conditions (clientApp, user, or group) based on your access control requirements.

Step 3: Grant Roles to Principals

Grant the roles to principals (users or client applications) using the `POST "https://{{IDSPHost}}/{{apiPathTenant}}/admin/v1/AppRolesDelegator"` API. Prompt the user to provide the username or client application ID for which the roles needs to be granted.

Sample Grant Payload for User

```
{
    "id": "{{promotePolicyId}}",
    "principal": {
        "user": {
            "operator": "in",
            "value": [
                "{{userLoginName}}"
            ]
        }
    }
}
```

Sample Grant Payload for Client Application

```
{
    "id": "{{promotePolicyId}}",
    "principal": {
        "clientApp": {
            "operator": "in",
            "value": [
                "{{clientAppId}}"
            ]
        }
    }
}
```

Where,

- Replace {{promotePolicyId}} with the actual authorization policy ID returned from Step 2, and {{userLoginName}} or {{clientAppId}} with the appropriate principal identifier.

Step 4: Access Instructions

After onboarding, ensure that the newly secured MCP server can be accessed from an MCP client. The URL should match with the resource in the OAuth protected resource endpoint `"https://{{mcpserver-host}}/{{apiPathTenant}}/.well-known/oauthprotected-resource/mcp"` . After onboarding, ensure that the newly secured MCP server can be accessed from an MCP client. The URL should match with the resource in the OAuth protected resource endpoint

Example of Client Configuration:

```
{
    "mcpServers": {
        "appname": {
            "url": "https://hr.com/mcp"
        }
    }
}
```

- Securing MCP Servers with Symantec Identity Security Platform

Onboarding MCP Clients

Learn how to onboard the MCP clients in Symantec Identity Security Platform

Model Context Protocol (MCP) clients are applications that connect to MCP servers to fetch the list of tools, resources, and prompts exposed by the server.

Clients can be of two types:

- Trusted client
- On behalf of (OBO) client

Trusted Clients

Trusted clients integrate with the MCP server directly. These are typically created or registered in Symantec Identity Security Platform offline with necessary privileges.

Characterisitcs of Trusted Clients:

- Clients integrate with the MCP server directly
- Typically created or registered in IDSP offline with necessary privileges
- Access to these clients are secured by various conditions like IP address, country, risk, etc.
- Grant access to the client application for the MCP server roles
- Use client_credentials or JWT bearer grant types

API Endpoint:

```
POST https://{{IDSPHost}}/{{apiPathTenant}}/admin/v1/Apps
```

Trusted Client Application Payload:

```
{
   "status": "active",
   "name": "acmehr",
   "description": "Client Application to access HR Resource server",
   "clientType": "CONFIDENTIAL",
   "allowedOpenIDScopes": [
       "openid",
       "email",
       "profile",
       "urn:iam:sso:idprop"
   ],
   "redirectURIs": [
       "https://www.example.com"
   ],
   "allowedGrantTypes": [
       "urn:ietf:params:oauth:grant-type:jwt-bearer",
       "client_credentials"
   ],
   "allowedOperations": [
       "introspect",
       "offlineit"
```

```
    ],
    "skewTimeSecs": 0,
    "userInfoEndpointResponseFormat": "PLAIN_JSON",
    "supportedJoseHeaderParams": "x5t,x5t#s256"
}
```

Grant Role to Client Applications:

After creating the trusted client, grant access to the client application for the MCP server roles using the `POST "https://{{IDSPHost}}/{{apiPathTenant}}/admin/v1/AppRolesDelegator"` API with the client application grant payload shown in Step 3.

Public or On-Behalf-Of (OBO) Clients

These clients are used on behalf of users to connect to MCP servers. Ensure that the users are granted access to the MCP server or resource server application roles. OBO clients are typically registered by Dynamic Client Registration (DCR).

DCR can handle the following scenarios:

- Single Client Registration
- Template Client for Multiple Registration

Single Client Registration : If only one client needs to be created to access the MCP server, create the client application with the following metadata: `urn:iam:app:useAppAsRegisteredClientInDcr=true`

API Endpoint

```
POST https://{{IDSPHost}}/{{apiPathTenant}}/admin/v1/Apps
```

OBO Client Payload for Single Registration Payload

```
{
    "status": "active",
    "name": "Cursor",
    "description": " ",
    "skewTimeSecs": 0,
    "passwordAuthoritativeSource": "remote",
    "clientType": "PUBLIC",
    "allowedOpenIDScopes": [
        "openid"
    ],
    "redirectURIs": [
        "https://www.example.com",
        "cursor://anysphere.cursor-mcp/oauth/user-isp/callback",
        "cursor://anysphere.cursor-mcp/oauth/user-acme/callback",
        "cursor://anysphere.cursor-mcp/oauth/user-idsp/callback",
        "https://www.cursor.com",
        "cursor://anysphere.cursor-retrieval/oauth/user-sisp/callback"
    ],
    "allowedGrantTypes": [
        "refresh_token",
        "authorization_code"
    ],
    "allowedOperations": [
        "onbehalfof"
    ],
    "userInfoEndpointResponseFormat": "JWT",
```

```
    "itEncryptionTarget": "NONE",
    "samlEntityIdStripe": "1f7731a0-c9ed-45e3-91f6-8f1cf97ee04b",
    "metadata": [
        {
            "name": "agent",
            "value": "cursor"
        },
        {
            "name": "urn:iam:app:useAppAsRegisteredClientInDcr",
            "value": "true"
        }
    ],
    "isOidcApp": true
}
```

Template Client for Multiple Registrations : If the client always invokes the DCR with the same name and IDSP needs to create the client with a unique name, create a client application before enabling the MCP clients with the following metadata: `urn:iam:app:useAppAsTemplateClientinDcr=true`

API Endpoint:

```
POST https://{{IDSPHost}}/{{apiPathTenant}}/admin/v1/Apps
```

OBO Client Payload for Template Client :

```
{
    "status": "active",
    "name": "MCP Inspector",
    "description": " ",
    "skewTimeSecs": 0,
    "passwordAuthoritativeSource": "remote",
    "clientType": "PUBLIC",
    "allowedOpenIDScopes": [
        "address",
        "phone",
        "openid",
        "offline_access",
        "profile",
        "groups",
        "email"
    ],
    "redirectURIs": [
        "http://localhost:6274/oauth/callback",
        "http://localhost:6274/oauth/callback/debug"
    ],
    "allowedGrantTypes": [
        "refresh_token",
        "authorization_code"
    ],
    "allowedOperations": [
        "introspect",
        "onbehalfof"
    ],
    "userInfoEndpointResponseFormat": "JWT",
    "itEncryptionTarget": "NONE",
```

```
    "samlEntityIdStripe": "3c45d411-b26b-4ed9-90c9-a0c0dc35d2d0",
    "metadata": [
        {
            "name": "urn:iam:app:useAppAsTemplateClientinDcr",
            "value": "true"
        },
        {
            "name": "agent",
            "value": "inspector"
        }
    ],
    "label": "MCP Inspector",     "isOidcApp": true
}
```

NOTE
Creating the authentication policy with the app metadata that is configured in the template applications ensures that the policy is applied to all newly created clients with the same template application.

Create Authentication Policy

Create the authentication policy for the client application based on the application metadata. If fine-grained authentication control is necessary, include other conditions supported by authentication policies.

API Endpoint:

```
POST https://{{IDSPHost}}/{{apiPathTenant}}/admin/v1/AuthPolicies
```

Authentication Policy Payload:

```
 {
    "policyName": "Cursor AuthN Policy",
    "description": " ",     "status": "active",
    "matchAnyApp": true,
    "rules": [
        {
            "conditions": {
                "principal": {
                    "user": {
                        "operator": "in",
                        "value": [
                            "*"
                        ]
                    }
                },
                "action": {
                    "operator": "in",
                    "value": [
                        "authenticate"
                    ]
                },
                "context": {
                    "operator": "expression",
                    "value": "(${appmetadata.agent} eq cursor)"
                }
            },
            "result": {
```

```
                "effect": "allow",
                "reAuthenticate": "false",
                "obligations": [
                    "PASSWORD:1"
                ],
                "msg": "Cursor AuthN Rule",
                "mfaFrequency": "OnceForTrustedDevice"
            }
        }
    ]
}
```

Grant Roles to OBO Client Users

For OBO clients, ensure users are granted access to the MCP server roles using the `POST "https://{{IDSPHost}}/{{apiPathTenant}}/admin/v1/AppRolesDelegator"` API . Use the user grant payload from Step 3 to grant roles to users who uses the OBO client.

Reference Links

- Onboarding MCP Server as Resource Server Application
- Securing MCP Servers with IDSP

Symantec Identity Security Platform as CAEP Transmitter/Receiver

Configure the ID LCM WebHook to deliver Continuous Access Evaluation Protocol (CAEP) events to a SCIM endpoint ensuring the endpoint can receive events and is protected by either Basic Auth or OAuth2 security models.

IDSP as CAEP Transmitter

Symantec Identity Security Platform delivers Continuous Access Evaluation Protocol (CAEP) events to the ID LCM WebHook, which is modeled in IDSP as a SCIM endpoint represented by "SCIM Identity Store" resource.

The ID LCM Web Hook is one of the properties under Service Configuration, called "idEventHookConfig".

To configure the ID LCM WebHook, use the following API:

```
PATCH https://{{sspHost}}/{{apiPathTenant}}/admin/v1/Configs
```

Update the Global/Tenant parameter, "idEventHookConfig":

```
{
"name": "idEventHookConfig",
"value": "<SCIMconfigs-id-or-name>, event1, event2,..."
}
```

Where,

- A value that starts with "#" implies a commented out / disabled configuration.
- A SCIMconfigs resource matching given id or name is validated against this event:
  - session.revoke.success - sends a Continuous Access Evaluation Protocol (CAEP) message indicating that the user session is revoked, and includes a list of applications to be notified.

The ID LCM Web Hook is expected to expose "**/Caep"** endpoint to receive CAEP events containing the prescribed payload.

This endpoint is assumed to be protected by one of the following security models:

- Basic Auth security (ID/Secret)
- OAuth2 security with Bearer Token obtained via Client Credentials OAuth grant using Client ID/Secret or Client Assertion

IDSP as CAEP Receiver

The IDSP functions as a CAEP (Continuous Access Evaluation Protocol) listener by exposing the CAEP listener at the following URL:

```
https://{{sspHost}}/{{apiPathTenant}}/identity/v1/Caep
```

This endpoint allows IDSP to receive and process CAEP events.

Auditing in Symantec Identity Security Platform

Learn about the different types of authentication and administration auditing events logged in Symantec Identity Security Platform.

This topic contains the following sections:

- Authentication Events
- Administration Events

Authentication Events

The following table lists different types of authentication auditing events along with their corresponding event IDs that are logged in IDSP.

Table 85: Authentication Events and Event Ids in IDSP

Authentication Event	eventId (Log messages with type=audit)
Initiate Authentication	auth-mgr.auth.initiate
Authentication Successful	auth-mgr.auth.success
Authentication Denied	auth-mgr.auth.failure
Authentication Abandoned	auth-mgr.auth.abandoned
Factor Authentication Successful	factor.me.auth.complete.success
Factor Authentication Failed	factor.me.auth.complete.failure
Factor Auth Initialization Successful	factor.me.auth.initiate.success
Factor Auth Initialization Failed	factor.me.auth.initiate.failure
Factor Registration Successful	factor.me.register.complete.success
Factor Registration Failed	factor.me.register.complete.failure
Factor Register Initialization Successful	factor.me.register.initiate.success
Factor Register Initialization Failed	factor.me.register.initiate.failure
Token issue successful	azserver.token.success
Token issue failed	azserver.token.failure
Token revocation successful	azserver.token.revoke.success
Initiate Authorization flow	azserver.authorize.initiate

Authentication Event	eventId (Log messages with type=audit)
Successful Authorization flow	azserver.authorize.complete.success
Failure Authorization flow	azserver.authorize.complete.failure
Risk evaluation success	risk.eval.succes
Risk evaluation failed	risk.eval.failure
Post Risk evaluation success	risk.posteval.success
Post Risk evaluation failed	risk.posteval.failure
User lock success	factor.me.auth.lock.success
User lock failure	factor.me.auth.lock.failure
User unlock success	factor.me.auth.unlock.success

Administration Events

The following table lists different types of administration audit events along with their corresponding event IDs that are logged in IDSP.

For each successful update operation (admin.<resource>.update.success), the operation also logs two additional entries:

- The object before the update (`-ext-before` extension)
- The object after the update (`-ext-after` extension)

Table 86: Administration Events

Administration Event	eventId (Log messages with type=audit)
Application Events	admin.app.create.success
	admin.app.create.failure
	admin.app.activate.success
	admin.app.activate.failure
	admin.app.deactivate.success
	admin.app.deactivate.failure
	admin.app.delete.success
	admin.app.delete.failure
	admin.app.update.success
	admin.app.update.failure
Authentication Policy Events	admin.authpolicy.create.success
	admin.authpolicy.create.failure
	admin.authpolicy.delete.failure
	admin.authpolicy.delete.success
	admin.authpolicy.update.failure
	admin.authpolicy.update.success
Authorization Policy Events	admin.authzpolicy.create.success
	admin.authzpolicy.update.success
	admin.authzpolicy.delete.success

Administration Event	eventId (Log messages with type=audit)
	admin.authzpolicy.create.failure
	admin.authzpolicy.update.failure
	admin.authzpolicy.delete.failure
Certificate Mgmt Events	admin.cert.create.failure
	admin.cert.create.success
	admin.cert.delete.failure
	admin.cert.delete.success
	admin.cert.update.failure
	admin.cert.update.success
Identity Provider Configuration Events	admin.identityprovider.create.failure
	admin.identityprovider.create.success
	admin.identityprovider.delete.failure
	admin.identityprovider.delete.success
	admin.identityprovider.update.failure
	admin.identityprovider.update.success
	admin.identityprovidermetadata.import.failure
	admin.identityprovidermetadata.import.success
	admin.identityprovidermetadata.update.failure
	admin.identityprovidermetadata.update.success
LDAP Configuration Events	admin.ldapconfig.create.failure
	admin.ldapconfig.create.success
	admin.ldapconfig.delete.failure
	admin.ldapconfig.delete.success
	admin.ldapconfig.update.failure
	admin.ldapconfig.update.success
Credential Mgmt Events triggered by User Self-Service Operations	admin.me.cred.delete.failure
	admin.me.cred.delete.success
	admin.me.cred.update.failure
	admin.me.cred.update.success
	admin.me.cred.regsiter.successs
	admin.me.cred.register.failure
Credential Mgmt Events triggered by Administrator	admin.user.cred.delete.failure
	admin.user.cred.delete.success
	admin.user.cred.update.failure
	admin.user.cred.update.success
Message Events	admin.message.create.failure
	admin.message.create.success
	admin.message.delete.failure

Administration Event	eventId (Log messages with type=audit)
	admin.message.delete.success
	admin.message.update.failure
	admin.message.update.success
Message Provider Events	admin.messageprovider.create.failure
	admin.messageprovider.create.success
	admin.messageprovider.delete.failure
	admin.messageprovider.delete.success
	admin.messageprovider.update.failure
	admin.messageprovider.update.success
Password Encryption Events	admin.password.encrypt.failure
	admin.password.encrypt.success
Token revocation by admin	admin.revoke.success
Locale Events	admin.locale.create.success
	admin.locale.update.success
	admin.locale.delete.success
	admin.locale.create.failure
	admin.locale.update.failure
	admin.locale.delete.failure
Factor transaction signing Events	factor.me.transactionsigning.initiate.success
	factor.me.transactionsigning.initiate.failure
	factor.me.transactionsigning.complete.success
	factor.me.transactionsigning.complete.failure
Opa Events	opa.policyload.success
Identity scim User Events	identity.scim.user.create.success
	identity.scim.user.create.failure
	identity.scim.user.update.success
	identity.scim.user.update.failure
	identity.scim.user.delete.success
	identity.scim.user.delete.failure
Identity scim group Events	identity.scim.group.members.update.success
	identity.scim.group.create.success
	identity.scim.group.create.failure
	identity.scim.group.update.success
	identity.scim.group.update.failure
	identity.scim.group.delete.success
	identity.scim.group.delete.failure
Identity scim me update Events	identity.scim.me.update.success
	identity.scim.me.update.failure

Administration Event	eventId (Log messages with type=audit)
Identity scim bulk update Events	identity.scim.bulk.success
	identity.scim.bulk.failure
Identity scim user account lock/enable Events	identity.scim.user.account.lock.success
	identity.scim.user.account.unlock.success
	identity.scim.user.account.enable.success
	identity.scim.user.account.disable.success
Identity me user Events	identity.me.unlock.success
	identity.me.lock.success
Identity scim password change mandatory Events	identity.scim.user.account.passwordmustchange.set.success
	identity.scim.user.account.passwordmustchange.clear.success
Identity scim password update Events	identity.scim.user.password.update.success
	identity.scim.user.password.update.failure
Identity scim update Events	identity.scim.group.members.update.success
	identity.scim.user.groups.update.success
Identity password reset Events	identity.me.password.reset.initiate.success
	identity.me.password.reset.initiate.failure
	identity.me.password.reset.complete.success
	identity.me.password.reset.complete.failure
Identity password update Events	identity.me.password.update.success
	identity.me.password.update.failure
Secret Events	admin.secret.update
User Events	admin.user.lock.success
	admin.me.user.unlock.success
	admin.user.unlock.success

Resource Deletion in Symantec Identity Security Platform

This document outlines the "Complete resource deletion process" focusing on the force delete functionality using a scheduler for cleanup.

This feature introduces a "force delete" option for specific Symantec Identity Security Platform resources, allowing administrators to immediately delete in-use objects. Instead of preventing deletion, a record of the forcefully deleted resource is created in the database. The "resourcesCleanupScheduler" job cleans up any dangling references to the deleted resource in other operational resources.

Existing API Changes

The existing DELETE APIs for the supported resources are enhanced to accept an optional "**force=true**" query parameter.

- /admin/v1/Apps/{{id}} (DELETE)
- /admin/v1/IdentityProviders/{{id}} (DELETE)
- /admin/v1/CustomProviders/{{id}} (DELETE)
- /admin/v1/ResourceGroups/{{ApplicationGroupId}} (DELETE)
- /admin/v1/AuthZPolicies/{{azPolicyId}} (DELETE)

Changes in the Referencing Objects Helper API

The ReferencingObjectsHelper API (/admin/v1/ReferencingObjectsHelper) has been enhanced to fetch the complete list of Symantec Identity Security Platform resources referring to a given object, which can be used by the Admin or the UI to render the list of dependent objects on the UI to the admin user choosing to force the delete, or the client can choose to force the delete right away.

The "/ReferencingObjectsHelper" API response includes a new parameter, "**allowResourceToBeForcefullyDeletable**", to indicate whether a resource's deletion might violate any system constraints. If this parameter is false, then forceful deletion of that resource is not permitted. The response from "/ReferencingObjectsHelper" API looks as follows -

```
[
{
"id": "304b6c70-e752-4c73-afaa-24d5ba4126e1",
"name": "Sample app group policy",
"type": "urn:iam:res:authnpolicy",
"allowResourceToBeForcefullyDeletable": true
}
]
```

See Referencing Objects Helper API.

Handling Constraints During Force Delete

Force deletion of Apps, AppGroups, or principals may result in policy constraint violations. During force delete operations, multiple existing constraints can be affected. The table below details each constraint type and its corresponding handling mechanism during force deletion.

Table 87: Handling Constraints during force delete in IDSP

Scenario	Handling during force delete	Policy Types applicable	Impact after forceful delete
Single App or AppGroup in a Policy with Force Delete, when "matchAnyApp=false" When a poli cy has only one App or AppGroup assigned to it and the "matchAnyApp" attribute is set to false, the policy requires at least one application to be configured for proper evaluation. Normally, deleting this single app would violate this constraint since it would leave the policy with zero apps while "matchAnyApp=false" demands at least one.	**Force delete is permitted despite the constraint violation.** The system allows the force deletion to proceed despite this constraint violation. However, as a consequence, any policies that are left with zero apps and have "matchAnyApp=false" attribute become non-functional, hence do not get evaluated.	• AuthN Policy • IDP Policy • Risk Policy	Policies with "matchAnyApp=false" and zero apps after force delete do not get evaluated.
Single IDP in Policy with Force Delete When an IDP policy has only one Identity Provider (IDP) configured and that IDP is forcefully deleted, it creates a constraint violation. IDP policies require at least one identity provider to function properly, and removing the sole IDP leaves the policy without any valid identity providers for user authentication routing.	**Force delete is permitted despite the constraint violation.** The system allows the IDP deletion to proceed but renders the affected IDP policies non-functional, as they cannot evaluate authentication requests without any configured identity providers.	• IDP Policy	IDP policies with zero identity providers after force delete do not get evaluated.

Scenario	Handling during force delete	Policy Types applicable	Impact after forceful delete
Single Principal in AuthN Policy with Required Principal Setting When the tenant setting "principalConditionRequiredInPolicy" is enabled (set to 'true'), AuthN or Access policies must maintain at least one principal for proper evaluation. Attempting to force delete the sole principal configured in an AuthN policy violates this mandatory constraint, as it would leave the policy without any principals while the tenant requires principal conditions to be present.	Force delete is **not allowed** and the operation is blocked. The system prevents the deletion and returns a descriptive error message to inform administrators of the constraint violation and affected policy. **Error Message**: Resource can't be deleted as it is the only Principal in AuthN policy 'policy-name' (error-code - 8000145)	• AuthN Policy	

Immediate Deletion of Resources and Scheduler Record Creation

When a DELETE API is invoked with "force=true":

- **Immediate Resource Deletion**: The target resource (e.g., Application, IDP) are immediately deleted.
- **Record Creation in Database**: A new record is created in the database.

Upon immediate deletion, the core operations, such as policy fetches, no longer return the deleted resource object. This ensures that the deleted resource is effectively hidden from operational flows immediately, even while dangling references may temporarily persist until the scheduler performs its cleanup.

The scheduler performs the following cleanup operations for each resource type:

- **Application**: Remove outdated application references in AuthN Policies, AuthZ Policies (clientApps as Principals, Apps), and IDP Policies.
- **IDP**: Remove outdated IDP references in AuthN Policies (IDPs in policy obligations, IDPs in policy principals), AuthZ Policies (User/Group in policy principals), and IDP Policies (IDPs in policy results).
- **Custom Provider**: Remove outdated provider config references in AuthN Policies (custom authenticator, custom password, SM password as obligations) and AuthZ Policies (SM provider as roles).
- **Application Group**: Remove unresolved app group references in AuthN Policies (app groups as subjects), IDP Policies (app groups as subjects), Risk Policies (app groups as subjects), and AuthZ Policies (app groups as Principals).
- **AppRole**: Remove unresolved appRole references in AuthN Policies (Access) (appRole as Principal).

Symantec Identity Security Platform SDKs

Symantec Identity Security Platformprovides a variety of Software Development Kits (SDKs) to promote the development of custom solutions. These SDKs help in creating and deploying applications that integrate with IDSP. Each SDK offers the resources you must create an app, including code samples.

SDK Location

The iOS SDK package can be downloaded from the Support Portal > My Downloads (Search for IDSP in the portal and select the appropriate version number).

This module includes the following topics:

- IDSP Client Release Notes
- IDSP iOS SDK Framework
- IDSP Android SDK
- IDSP Web SDKs
- VIP SDKs

Client Release Notes

View information about the Symantec Identity Security Platform client releases and release packages.

Release information about IDSP iOS and Android clients are covered in this section.

This page includes Release Notes for IDSP iOS and Android SDKs:

- iOS Client Release Notes
- Android Client Release Notes

IDSP iOS Client Release Notes

Table 88: IDSP iOS Client Release Notes

Client	Version	Release Notes	Reference Document
iOS SDK	3.1.5	3.1.5 iOS SDK Release Notes	This release includes bug fixes, and enhancements.
iOS SDK	3.1.4	3.1.4 iOS SDK Release Notes	This release includes bug fixes, and enhancements. **Note: SDK Version Compatibility Requirement**: **Note:** Client applications must upgrade to SDK version 3.1.3 or higher before upgrading the IDSP server to version 4.0 to ensure FIDO registration functionality remains intact and prevent compatibility issues with older SDK versions.
iOS SDK	3.1.3	3.1.3 iOS SDK Release Notes	This release includes bug fixes, and enhancements.
iOS SDK	3.1.2	3.1.2 iOS SDK Release Notes	This release includes bug fixes, and enhancements.
iOS SDK	3.1.1	3.1.1 iOS SDK Release Notes	This release has incremental updates to streamline the SDK functionality. No new functional changes were introduced in this release.
iOS SDK	3.1	3.1 iOS SDK Release Notes	This release has incremental updates to streamline the SDK functionality. No new functional changes were introduced in this release.
iOS SDK	3.0	3.0 iOS SDK Release Notes	This release introduces PASSKEY as an authentication factor, similar to the "SECURITYKEY" and "FIDO" (Biometric) factors.
iOS SDK	2.3.6	2.3.6 iOS SDK Release Notes	This release includes bug fixes, enhancements, and new error codes (809-822) for FIDO WebAuthN functionality. See iOS SDK Error Codes.
iOS SDK	2.3.5	2.3.5 iOS SDK Release Notes	This release includes new error codes for FIDO WebAuthN functionality and SDK initialization. See iOS SDK Error Codes.
iOS SDK	2.3.4	2.3.4 iOS SDK Release Notes	This release includes the necessary privacy manifest file as mandated by Apple.com. See IDSP Manifest File .

Client	Version	Release Notes	Reference Document
iOS SDK	2.3.3	2.3.3 iOS SDK Release Notes	In IDSP version 3.1 and later, when data is encrypted in transit, the server expects the following encryption formats: • PKI encrypted field with the {x5c} prefix (For example, - in-transit encrypted password data) • Symmetric encrypted field with the {enc} prefix (For example, - encrypted device signature data) These changes mean that IDSP iOS SDK v2.3.3 will not function with a IDSP server version lower than 3.1. Therefore, it is necessary to upgrade to IDSP version 3.1 before using IDSP iOS SDK v2.3.3.
iOS SDK	2.3.2	2.3.2 iOS SDK Release Notes	IDSP iOS Core SDK • Setting Up the Network Request Object • Initiate Authentication • Getting the list of fields to be encrypted in the authentication flow – Support for proxy URL configuration to get the list of fields that are required for encryption

For package download details, see Client SDK Packaged Links: Download Locations

IDSP Android Client Release Notes

Table 89: IDSP Android Client Release Notes

Client	Version	Release Notes	Reference Document
Android SDK	3.0.3	Android SDK 3.0.3	In this release, bug fixes and enhancements have been made.
Android SDK	3.0.2	Android SDK 3.0.2	In this release, bug fixes and enhancements have been made.
Android SDK	3.0.1	Android SDK 3.0.1	In this release, bug fixes and enhancements have been made.
Android SDK	3.0	Android SDK 3.0	This release introduces PASSKEY as an authentication factor, similar to the "SECURITYKEY" and "FIDO" (Biometric) factors.
Android SDK	2.3.3	Android SDK 2.3.3	IDSP Android SDK v2.3.3 addresses some potential vulnerabilities.

Client	Version	Release Notes	Reference Document
Android SDK	2.3.2	2.3.2 Android SDK	In IDSP version 3.1 and later, when data is encrypted in transit, the server expects the following encryption formats: • PKI encrypted field with {x5c} prefix - (For example- in transit encrypted password data) • Symmetric encrypted field with {enc} prefix - (For example- encrypted device signature data) These changes mean that IDSP Android SDK v2.3.2 will not work with function with an IDSP server version lower than 3.1. Therefore, it is necessary to upgrade to IDSP version 3.1 before using IDSP Android SDK v2.3.2.
Android SDK	2.3.1	2.3.1 Android SDK	IDSP Android Core SDK • Initiate Authentication • Getting the list of fields to be encrypted in the authentication flow – Support for Proxy URL Configuration

For package download details, see Client SDK Packaged Links: Download Locations

iOS SDK 3.1.5

View information about the iOS Symantec Identity Security Platform 3.1.5 release.

This topic includes the following sections:

- Release Information
- New Features and Improvements
- IDSP iOS SDK Kit Details

Release Information

- Release Title: IDSP iOS SDK
- Release Version: 3.1.5
- Preceding Version: 3.1.4
- Minimum OS Requirement: iOS v15.0 and above
- Release Date: February, 2026

> **NOTE**
> **SDK Version Compatibility Requirement**: Client applications must upgrade to SDK version 3.1.3 or higher before upgrading the IDSP server to version 4.0 to ensure FIDO registration functionality remains intact and prevent compatibility issues with older SDK versions.

New Features and Improvements

- Addressed bug fixes and enhancements.

IDSP iOS SDK Package Details

The latest iOS SDK package can be downloaded from the Support Portal > My Downloads (Search for Symantec Identity Security Platform in the portal and select the appropriate version number).

iOS SDK 3.1.4

View information about the iOS Symantec Identity Security Platform 3.1.4 release.

This topic includes the following sections:

- Release Information
- New Features and Improvements
- IDSP iOS SDK Kit Details

Release Information

- Release Title: IDSP iOS SDK
- Release Version: 3.1.4
- Preceding Version: 3.1.3
- Minimum OS Requirement: iOS v15.0 and above
- Release Date: December, 2025

> **NOTE**
> **SDK Version Compatibility Requirement**: Client applications must upgrade to SDK version 3.1.3 or higher before upgrading the IDSP server to version 4.0 to ensure FIDO registration functionality remains intact and prevent compatibility issues with older SDK versions.

New Features and Improvements

- Introduced FIDO SDK configurations to skip the passcode fallback option when biometric authentication fails. When these configurations are not specified or used with default settings, the SDK maintains existing behavior with no impact on the current FIDO registration and authentication user experience.
- Enhanced error handling for passkey registration and passkey authentication.
- Addressed few other bug fixes and enhancements.

IDSP iOS SDK Package Details

The latest iOS SDK package can be downloaded from the Support Portal > My Downloads (Search for VIP Authentication Hub in the portal and select the appropriate version number).

iOS SDK 3.1.3

View information about the iOS Symantec Identity Security Platform 3.1.3 release.

This topic includes the following sections:

- Release Information
- New Features and Improvements
- IDSP iOS SDK Kit Details

Release Information

- Release Title: IDSP iOS SDK
- Release Version: 3.1.3
- Preceding Version: 3.1.2
- Minimum OS Requirement: iOS v15.0 and above
- Release Date: November, 2025

NOTE
SDK Version Compatibility Requirement: Client applications must upgrade to SDK version 3.1.3 or higher before upgrading the IDSP server to version 4.0 to ensure FIDO registration functionality remains intact and prevent compatibility issues with older SDK versions.

New Features and Improvements

- When a user attempts to register a passkey that is already present on the same device and platform, both the enrollment and authentication flows return an identical error code. This behavior has been addressed by enhancing the error handling for passkey registration and authentication. (DE648771)
- Addressed few other bug fixes and enhancements.

IDSP iOS SDK Package Details

The latest iOS SDK package can be downloaded from the Support Portal > My Downloads (Search for VIP Authentication Hub in the portal and select the appropriate version number).

iOS SDK 3.1.2

View information about the iOS Symantec Identity Security Platform 3.1.2 release.

This topic includes the following sections:

- Release Information

Release Information

- Release Title: IDSP iOS SDK
- Release Version: 3.1.2
- Preceding Version: 3.1.1
- Minimum OS Requirement: iOS v15.0 and above
- Release Date: September, 2025

New Features and Improvements

- Duplicate passkey registrations occured for an application on a given device when a passkey for the same user and domain is already registered, particularly when iCloud Keychain is used for passkey synchronization. This leads to an undesirable state where multiple identical passkeys are registered, impacting user experience. To resolve this duplication issue, "**exclude credential Id list**" has been added.
  This resolution works on devices that run on iOS 17.0 and above.(DE644244)
- Addressed few other bug fixes and enhancements.

IDSP iOS SDK Package Details

The latest iOS SDK package can be downloaded from the Support Portal > My Downloads (Search for VIP Authentication Hub in the portal and select the appropriate version number).

iOS SDK 3.0

View information about the iOS Symantec Identity Security Platform 3.0 release.

This topic includes the following sections:

- Release Information
- New Features and Improvements
- IDSP iOS SDK Kit Details

Release Information

- Release Title: IDSP iOS SDK
- Release Version: 3.0
- Preceding Version: 2.3.6
- Minimum OS Requirement: iOS v15.0 and above
- Release Date: November, 2024

New Features and Improvements

In this release, we have introduced Passkey as an authentication factor, similar to the "Security Key" and "FIDO" (Biometric) factors. The "fidoCredType" parameter in the FIDO Registration (".../factor/v1/FIDORegChallengeGenerator") API differentiates the type of FIDO factor being used during registration. The "fidoCredType" property now supports the following values: `PASSKEY` , `FIDO (Biometric Authentication)` , and `SECURITYKEY` .

NOTE

- In this release, to register a new passkey, you must update or create an Authentication policy which contains the passkey as a factor.
- The "`useFQDN`" setting which was introduced in IDSP v2.2, is now used solely for backward compatibility. Therefore, it is only applicable during authentication (using the ".../factor/v1/FIDOAuthChallengeGenerator" and ".../factor/v1/FIDOAuthChallengeVerifier" APIs) for devices that have already registered passkey.

See Enabling Passkey.

iOS SDK 2.3.3

View information about the iOS Symantec Identity Security Platform 2.3.3 release.

This topic includes the following sections:

- Release Information
- Changes
- IDSP iOS SDK Kit Details

Release Information

- Release Title: IDSP iOS SDK
- Release Version: 2.3.3
- Preceding Version: 2.3.2
- Minimum OS Requirement: iOS v15.0 and above
- Release Date: April 2, 2024

Changes

In IDSP version 3.1 and later, when data is encrypted in transit, the server expects the following encryption formats:

- PKI encrypted field with the {x5c} prefix (For example, - in-transit encrypted password data)
- Symmetric encrypted field with the {enc} prefix (For example, - encrypted device signature data)

These changes mean that IDSP iOS SDK v2.3.3 will not function with a IDSP server version lower than 3.1. Therefore, it is necessary to upgrade to IDSP version 3.1 before using IDSP iOS SDK v2.3.3.

IDSP Android SDK Package Details

The latest Android SDK package can be downloaded from the Support Portal > My Downloads .

iOS SDK 2.3.2

View information about the iOS Symantec Identity Security Platform 2.3.2 release.

This topic includes the following sections:

- Release Information
- New Features and Improvements
- Deprecations
- IDSP Android SDK Kit Details

Release Information

- Release Title: IDSP iOS SDK
- Release Version: 2.3.2
- Preceding Version: 2.3.1
- Minimum OS Requirement: iOS v15.0 and above
- Release Date: 17 February, 2024

New Features and Improvements

IDSP includes the following new features and improvements in iOS SDK 2.3.2 release:

- Introduced a new SDK API, "getFieldsToBeEncryptedInAuthFlow()", which returns the list of the fields that require encryption by the SDK during communication with the IDSP server. For more information, see Getting the list of fields to be encrypted in the authentication flow, and Support for proxy URL configuration to get the list of fields that are required for encryption .
- The Branding Settings related SDK API calls and Network request object initialization SDK API call has been refactored. See Initiate Authentication .
- Following this release, the network request object can be set to the AHCore instance object using the `setAuthHubRequestObject()` SDK API. See Setting Up the Network Request Object .

  NOTE
  If you previously used the `initAuth` SDK API to set the request object for logging network request data, you now must set the IDSP request object by invoking the setAuthHubRequestObject() SDK API on the AHCore instance.

Deprecations

- The following existing initAuth() SDK API which by default calls BrandingSettings SDK API has been deprecated.

```
public func initAuth(serverHost: String,
                     tenant: String,
                     requestHeaders:[String:Any],
                     authRequestParams: [String:Any],
                     authhubRequest: AuthHubBasicRequest?,
                     completionBlock: @escaping (( _ response: AHCoreResult) -> Void)) throws
```

  It has been replaced by the following SDK API:

```
public func initAuth(serverHost: String,
                     tenant: String,
                     requestHeaders:[String:Any],
                     authRequestParams: [String:Any],
                     fieldsTobeEncryptedList:[String]?,
                     completionBlock: @escaping (( _ response: AHCoreResult) -> Void)) throws
```

  NOTE
  It is recommended to use the new initAuth() SDK API that accepts the list of fields using the `fieldsTobeEncryptedList` function argument.

- Release Version: 3.0
- Preceding Version: 2.3.3
- Minimum Android SDK version: Android v24.0 and above
- Release Date: November, 2024

New Features and Improvements

In this release, we have introduced Passkey as an authentication factor, similar to the "Security Key" and "FIDO" (Biometric) factors. The "fidoCredType" parameter in the FIDO Registration (".../factor/v1/FIDORegChallengeGenerator") API differentiates the type of FIDO factor being used during registration. The "fidoCredType" property now supports the following values: `PASSKEY` , `FIDO(Biometric Authentication)` , and `SECURITYKEY` .

NOTE

- In this release, to register a new passkey, you must update or create an Authentication policy which contains the passkey as a factor.
- The "`useFQDN`" setting which was introduced in IDSP v2.2, is now used solely for backward compatibility. Therefore, it is only applicable during authentication (using the ".../factor/v1/FIDOAuthChallengeGenerator" and ".../factor/v1/FIDOAuthChallengeVerifier" APIs) for devices that have already registered passkey.

See Using FIDO Passkey.

Release Information

- Release Title: IDSP Android SDK
- Release Version: 2.3.3
- Preceding Version: 2.3.2
- Minimum OS Requirement: Android v15.0 and above
- Release Date: 6th September, 2024

Changes

IDSP Android SDK v2.3.3 addresses some potential vulnerabilities.

IDSP Android SDK Package Details

The latest Android SDK package can be downloaded from the Support Portal > My Downloads .

Android SDK 2.3.2

View information about the Symantec Identity Security Platform Android 2.3.2 release.

This topic includes the following sections:

- Release Information
- Changes
- IDSP iOS SDK Kit Details

Release Information

- Release Title: IDSP Android SDK
- Release Version: 2.3.2
- Preceding Version: 2.3.1
- Minimum OS Requirement: Android v15.0 and above
- Release Date: 2nd April, 2024

Changes

In IDSP version 3.1 and later, when data is encrypted in transit, the server expects the following encryption formats:

- PKI encrypted field with {x5c} prefix - (For example- in transit encrypted password data)
- Symmetric encrypted field with {enc} prefix - (For example- encrypted device signature data)

These changes mean that IDSP Android SDK v2.3.2 will not function with an IDSP server version lower than 3.1. Therefore, it is necessary to upgrade to IDSP version 3.1 before using IDSP Android SDK v2.3.2.

IDSP Android SDK Package Details

The latest Android SDK package can be downloaded from the Support Portal > My Downloads .

Android SDK 2.3.1

View information about the Symantec Identity Security Platform Android 2.3.1 release.

This topic includes the following sections:

- Release Information
- New Features and Improvements
- Deprecations
- IDSP iOS SDK Kit Details

Release Information

- Release Title: IDSP Android SDK
- Release Version: 2.3.1
- Preceding Version: 2.3.0
- Android SDK Version: Android SDK Version 24 and above
- Minimum OS Requirement: Android 7 and above
- Release Date: 2nd April, 2024

New Features and Improvements

IDSP includes the following new features and improvements in the Android SDK 2.3.1 release:

- Introduced a new SDK API, "getFieldsToBeEncryptedInAuthFlow()", which returns the list of the fields that require encryption by the SDK during communication with the IDSP server. For more information, see Getting the list of fields to be encrypted in the authentication flow, and Support for proxy URL configuration to get the list of fields that are required for encryption .
- The Branding Settings related SDK API calls have been refactored. See Initiate Authentication.

Deprecations

- The following existing initAuth() SDK API which by default calls BrandingSettings SDK API has been deprecated.

```
public void initAuth(String hostName,
                     String tenant,
                     JSONObject body,
                     Map<String, String> headers,
                     VolleyCallback callback) throws AuthError
```

It has been replaced by the following SDK API:

```
public void initAuth(String hostName,
                     String tenant,
                     JSONObject body,
                     Map<String, String> headers,
                     String[] fieldsToBeEncrypted,
                     VolleyCallback callback) throws AuthError
```

- Support for **proxy URL** configuration: The following existing initAuth() SDK API by default calls BrandingSettings SDK API has been deprecated.

```
public void initAuth(String serverUrl,
                     JSONObject body,
                     Map<String, String> headers,
                     VolleyCallback callback) throws AuthError
```

It has been replaced by the following SDK API:

```
public void initAuth(String serverUrl,
                     JSONObject body,
                     Map<String, String> headers,
                     String[] fieldsToBeEncrypted,
                     VolleyCallback callback) throws AuthError
```

NOTE
It is recommended to use the new initAuth() SDK API that accepts the list of fields using the `fieldsTobeEncryptedList` function argument.

IDSP Android SDK Package Details

The latest Android SDK package can be downloaded from the Support Portal > My Downloads .

Client-Server Compatibility Matrix

Explore the compatibility between Symantec Identity Security Platform Client SDKs (Android and iOS) and the IDSP Server component.

This topic includes the following sections:

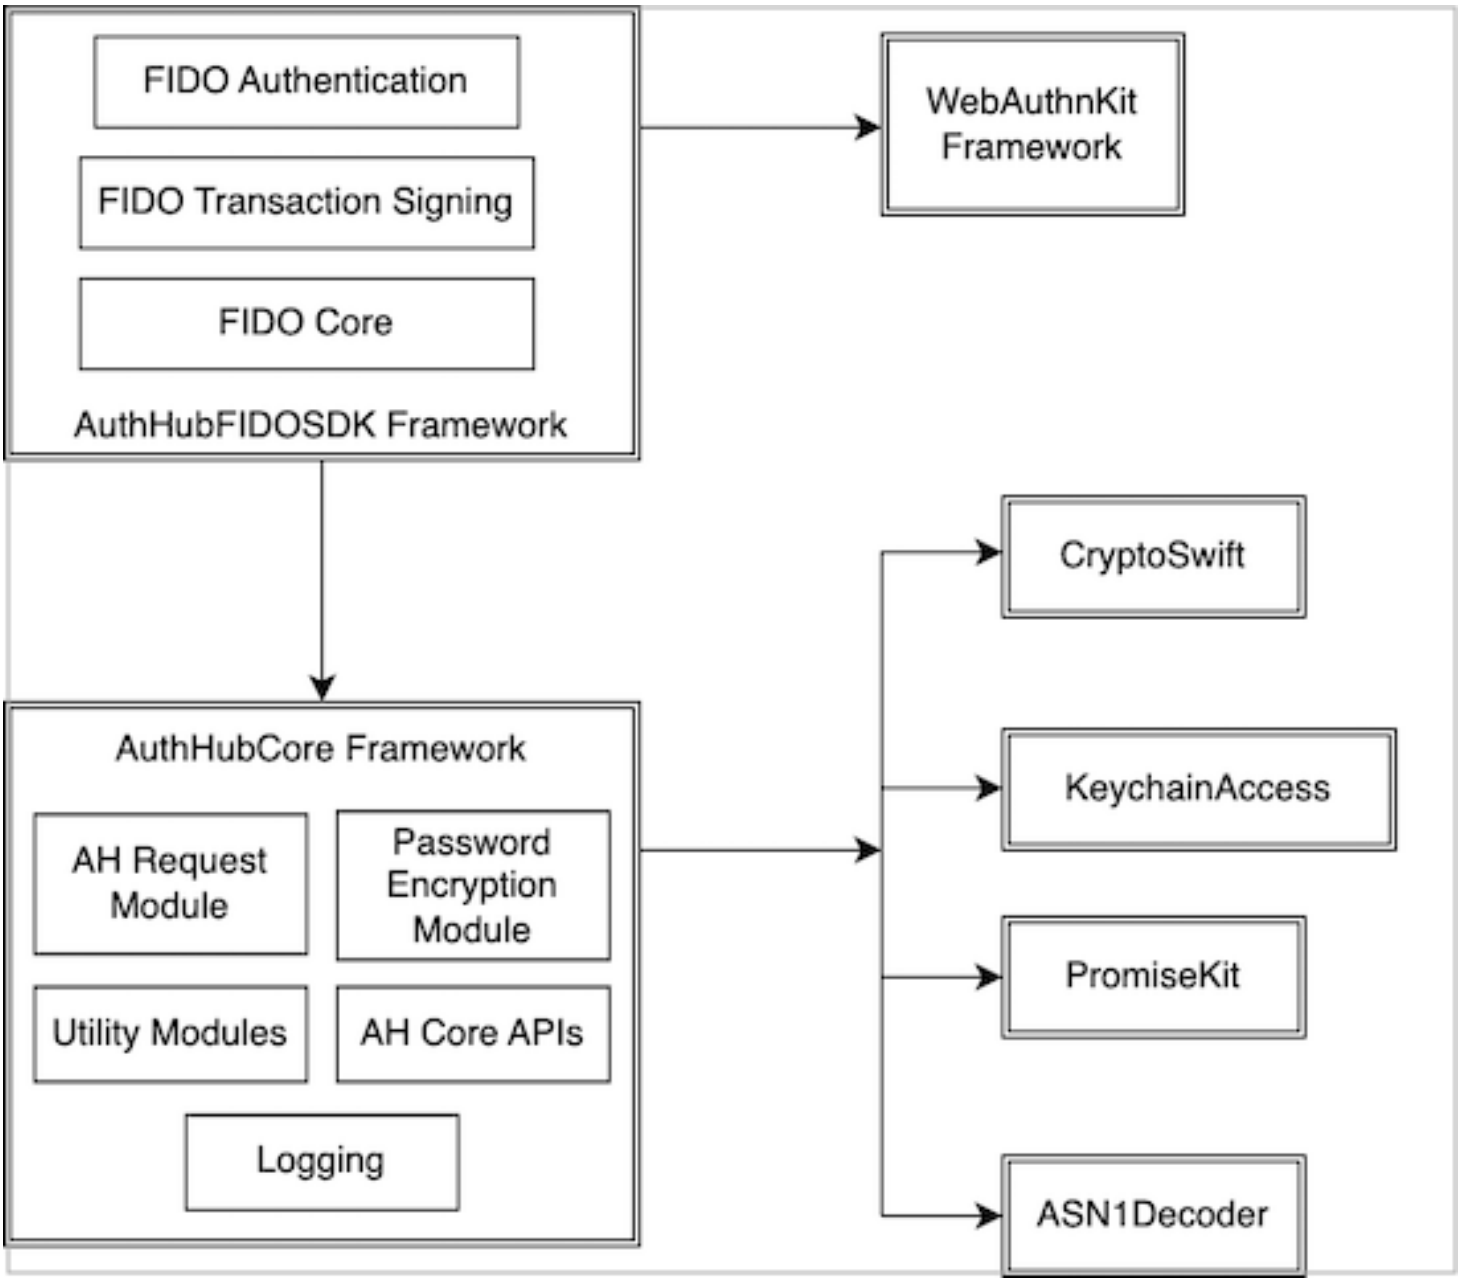
Symantec Identity Security Platform iOS SDK Framework

Integrating the Symantec Identity Security Platform iOS SDK with other customer iOS applications to use the IDSP Core, Password Encryption, and other functionalities.

The IDSP iOS client SDK framework has been explained with the help of the following diagram:

Figure 20: IDSP Client SDK Framework



The IDSP iOS client comprises two frameworks:

- AuthHubCore and AuthHubFIDOSDK

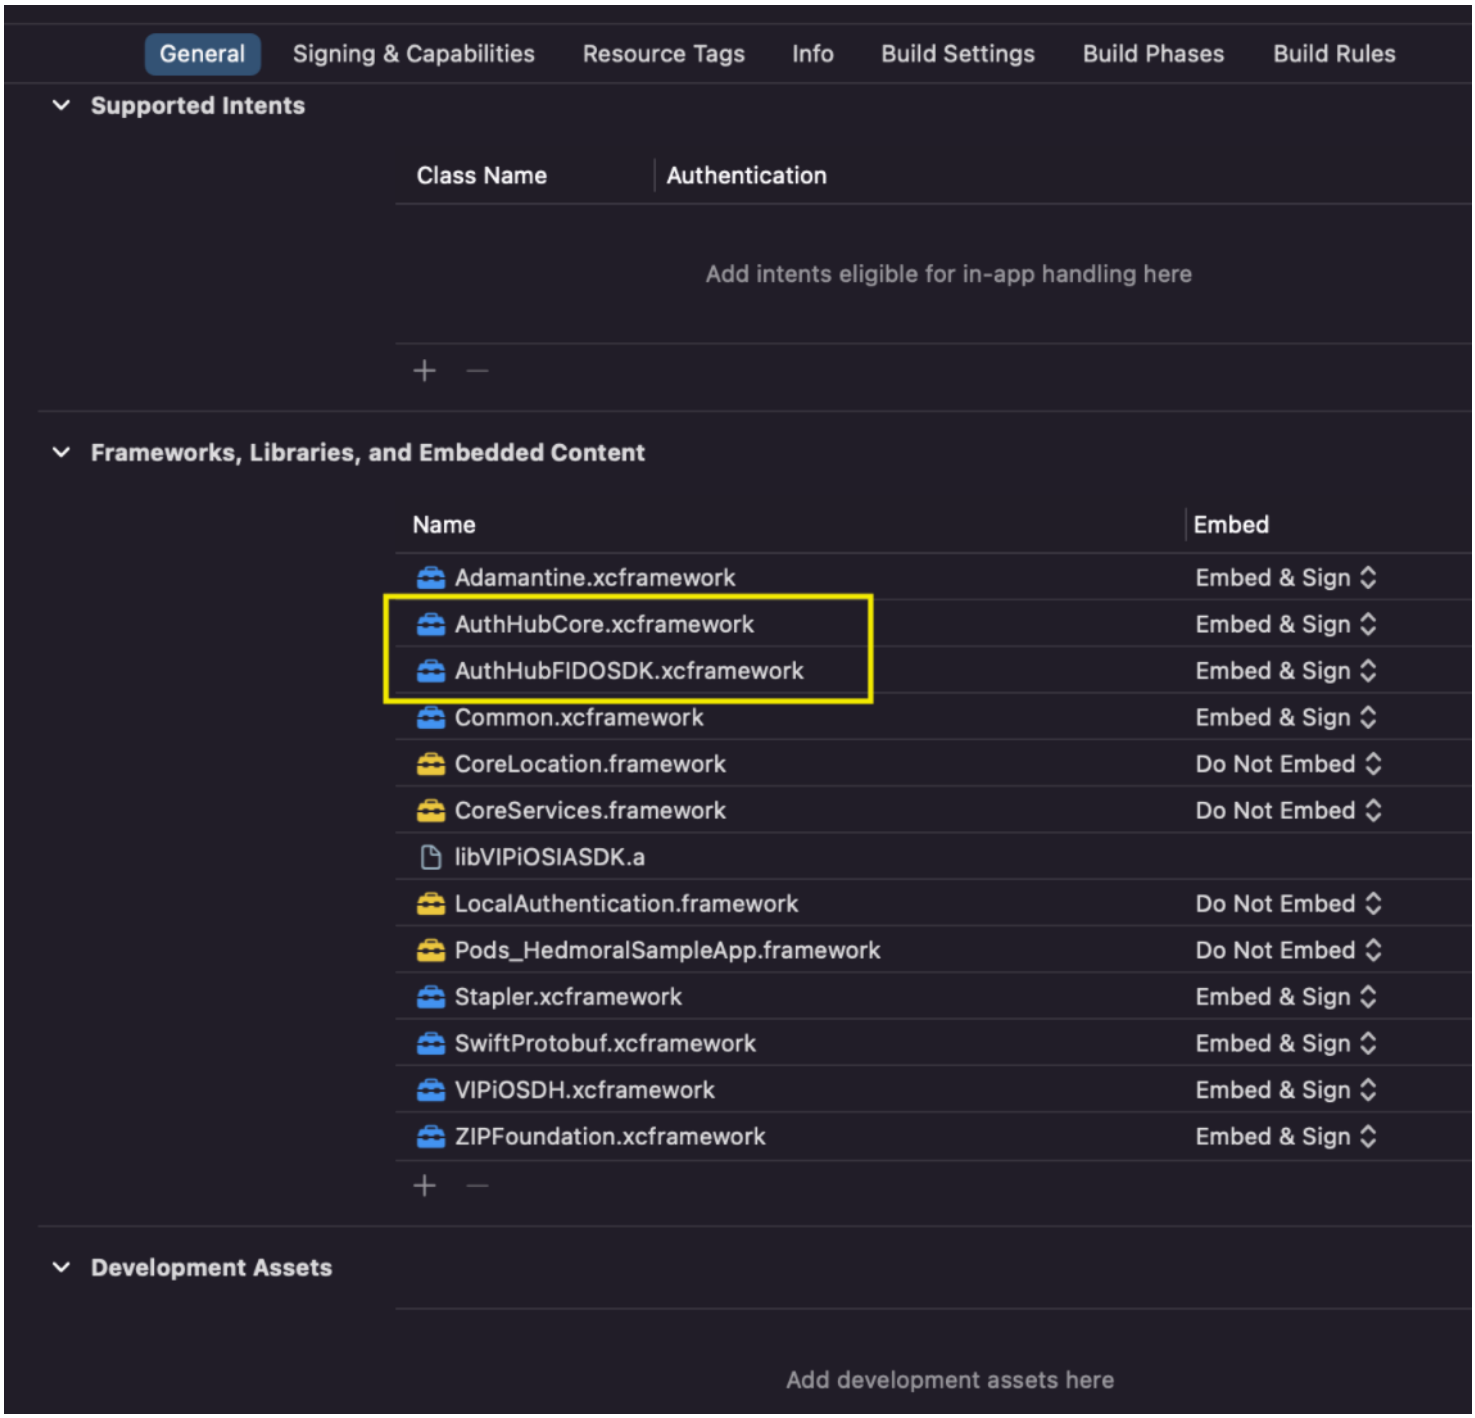
- AuthHubCore SDK includes AH Request Modules, Password Encryption Modules, Network Modules, Logging, and Utility APIs.
- AuthHubFIDOSDK supports APIs related to the FIDO authentication flow, and FIDO Transaction Signing.

Integration with iOS App

Learn about the Symantec Identity Security Platform iOS SDK, facilitating app developers in seamlessly integrating Password Encryption, FIDO (biometric support), and Transaction Signing functionalities into their iOS applications. Additionally, explore the IDSP Privacy Manifest file within this topic.

1. To integrate IDSP iOS SDKs with an iOS application, import and add the **AuthHubCore.xcframework** and **AuthHubFIDOSDK.xcframework** to the (XCode) application project.
   The following image shows the SDK frameworks that are imported into the XCode project:

   Figure 21: SDK Frameworks that are imported to the app project



2. The IDSP iOS SDK has third party pod dependencies, therefore uses the following Cocoa Pods which must be imported using the podfile:
   a. PromiseKit (https://cocoapods.org/pods/PromiseKit)
   b. KeychainAccess (https://cocoapods.org/pods/KeychainAccess)
   c. CryptoSwift (https://cocoapods.org/pods/CryptoSwift)
   d. ASN1Decoder (https://cocoapods.org/pods/ASN1Decoder)
3. Navigate to the XCode project root directory where the `.xcodeproj` file resides.

4. Type the following command to create a pod file in the root directory:
   ```
   $ pod init
   ```
5. Add the following dependencies to the pod file for the previously mentioned pods:
   ```
   # Uncomment the next line to define a global platform for your project
   platform :ios, '13.0'

   target 'iOS_APP_TARGET' do
        use_frameworks!
        inherit! :search_paths
        pod "PromiseKit", "~> 8.2.0"
        pod "KeychainAccess", "~> 4.2.2"
        pod "CryptoSwift", "~> 1.8.4"
        pod "ASN1Decoder", "~> 1.10.0"
   end
   ```
6. Run the following command to install these pods:
   ```
   $ pod install
   ```
   The following pods get installed.

Pod Name	Version
PromiseKit	8.2.0
KeychainAccess	4.2.2
CryptoSwift	1.8.4
ASN1Decoder	1.10.0

After the successful installation of the pods, open `.xcworkspace` and build it.

IDSP Manifest File

The following privacy manifest file has been added in the IDSP iOS SDK 2.3.4 as mandated by Apple.com. Refer to describing data use in privacy manifests link for more information on manifest file mandated by Apple.com.

```
<!-- Privacy manifest file for AuthHub iOS SDK -->

Integration with iOS App with dependent .xcframeworks (without running pod commands)

With Symantec Identity Security Platform iOS SDK v3.0, we are providing `.xcframework` files for the Pod dependencies of AuthHubCore.xcframework and AuthHubFIDOSDK.xcframework. If you are unable to run Pod commands in your development environment due to organizational restrictions, you can directly include these `.xcframework` dependencies in your application project. This way, there is no need to use the pod command to download, install, or build the dependencies.

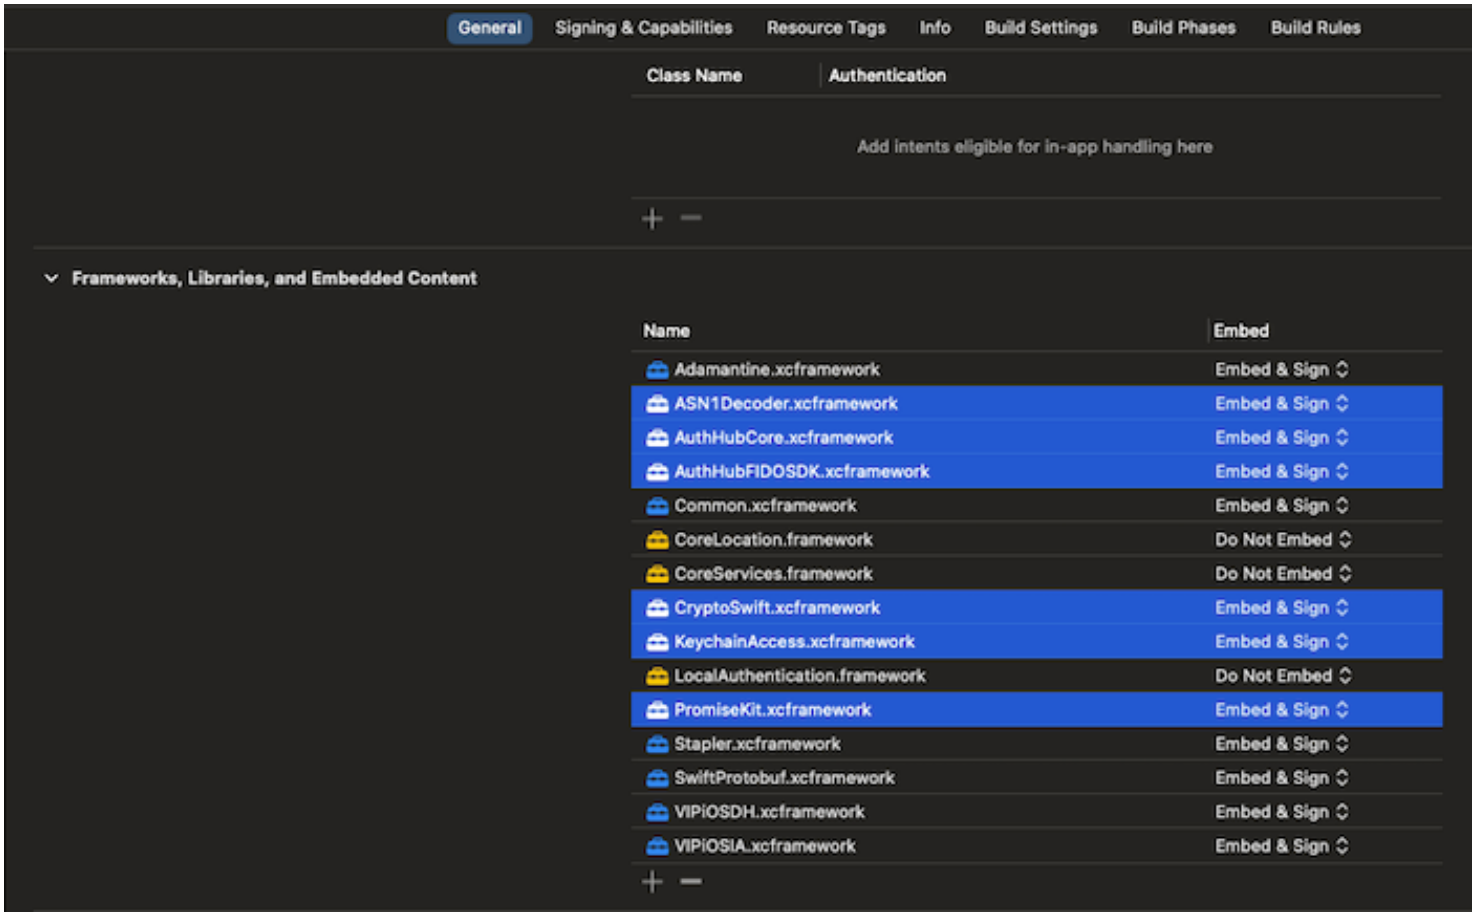
To integrate IDSP iOS SDKs with an iOS application, you must import **AuthHubCore.xcframework** and **AuthHubFIDOSDK.xcframework** to the application project along with dependent `.xcframework` libraries as the following:

- ASN1Decoder.xcframework
- CryptoSwift.xcframework
- KeychainAccess.xcframework
- PromiseKit.xcframework

These `.xcframework` libraries are available to download from the IDSPvalidation site as "**AH-Pods-Dependencies.zip**" file.

The following image shows the `.xcframeworks` that are imported to the app project:

Figure 22: SDK Frameworks that are imported to the app project



Symantec Identity Security Platform iOS Core SDK

Symantec Identity Security Platform Core SDK includes IDSP Request Module, Password Encryption Module, Network Module, and Utility APIs.

AuthHubCore.xcframework APIs and Integration Flow

This section includes the following sub-sections:

- Network Request Module
- IDSP Core APIs
  - Create an instance of the AuthHubCore.framework AHCore class
  - Setting Up the Network Request Object
  - Initiate Authentication
  - Data Encryption ("Password" and "Device Signature")
    - Get the list of fields to be encrypted in the authentication flow
      - Support for proxy URL configuration to get the list of fields that are required for encryption
    - Encryption Check
      - Support for proxy URL configuration for encryption check
    - Encrypt "Password" and "Device Signature"

IDSP Network Request Module

IDSP Network Request Module is a part of the AuthHubCore framework. The IDSP Client SDK APIs are designed to handle the network request and response for all the IDSP APIs, such as, "/authentication", "/BrandingSettings" and have complete control over them. Apart from handling essential API request payload/headers/query params, if you intend to customize the network layer to use it for tasks like adding custom headers or supporting SSL pinning, you need to implement three interfaces in your application to handle the network request customization. These interfaces are provided by IDSP and are explained in the following sections:

- ***AuthHubEndPoint***: This interface provides the set of APIs that mobile applications can implement to customize the network request. Using these API implementation, the mobile application can override the headers, add custom headers, or add new parameters to the request payload as required.
  This interface defines the following APIs -

```
func setRequestPayloadParameters(_ params: [String: Any]!)
func setRequestHeaders(_ headers: [String: Any]!)
func build() throws -> URLRequest
```

  The following table explains the APIs of this interface:

API Name	Description
setRequestPayloadParameters()	Accepts the map of key-value pairs which is sent in the JSON request body of the network request.
setRequestHeaders()	Accepts the map of key-value pairs which is sent as a request header of the network request.
build()	Builds an actual network request object which is sent to the IDSP server.

- ***AuthHubRequestLogger***: This interface provides the APIs required for logging the network level data and logs the time that is required for the network calls. The AuthHubRequestLogger provides the ability to log network request level information, such as request headers, request body, request response body, and response time.

  NOTE
  The AuthHubRequestLogger interface must be implemented if you want to add custom logging to the network request object.

  This interface defines the following APIs -

```
func enableLog(enable: Bool)
func setLoggingType(type: RequestLoggingType)
func logRequestData(responseTime: Int64, endPoint: AuthHubEndpoint, respDict: [String : AnyObject]?)
```

  The following table explains the APIs of this interface:

API Name	Description
enableLog()	Enables logging for a network request. By default it is ***disabled***.
setLoggingType()	Sets the logging type of the request logger. The RequestLoggingType is an ***enum*** that can have these values: ***resp_time***, ***data***, and ***none***. • resp_time - This type of logger logs only the response time • data - This type of logger logs the request data, such as, headers, request body, response body and response time • none - This type of logger does not log any data
logRequestData()	This API is used for logging the request data as per the RequestLoggingType.

  – ***AHRequestLogger*** :This class is the default implementation of the AuthHubRequestLogger interface. By default, this class logs all request data to the console.

NOTE
You must create an instance of this class and must initialize it with the name of the log file, if you want the logger to write logs to the file.

- ***AHAPIRequest***: This interface provides the APIs required to handle network level functionality, such as, sending requests, logging network request. This interface defines the following APIs -

```
func sendRequest(endpoint: AuthHubEndpoint) async throws -> AHRequestResult
func setRequestLogger(requestLogger: AuthHubRequestLogger)
```

The following table explains the APIs of this interface:

API Name	Description
sendRequest()	This API accepts the AuthHubEndpoint instance object.
setRequestLogger()	This API sets the AuthHubRequestLogger object for the network request object.

  - ***AuthHubBasicRequest***: This class is the default implementation of the ***AHAPIRequest*** interface.

The following example shows a sample implementation of the network request interface that is defined previously.

```
import Foundation
import AuthHubCore

class SampleAuthHubRequest : AuthHubBasicRequest {
  func addRequestHeaders(endpoint: AuthHubEndpoint) -> [String:Any] {
      let urlPath = endpoint.path
      var newHeaders = endpoint.headers
      switch(urlPath) {
      case .brandingSettings:
            newHeaders["HEDMORAL_BRANDING_SETTINGS"] = "HEDMORAL_BRANDING_VALUE";
            break;
      case .authHubPublicKey:
            newHeaders["HEDMORAL_PUBLIC_KEY"] = "HEDMORAL_PUBLIC_KEY_VALUE";
            break;
      case .serverNonceGenerator:
            newHeaders["HEDMORAL_SERVER_NONCE"] = "HEDMORAL_SERVER_NONCE_VALUE";
            break;
      case .authEndpoint:
            newHeaders["HEDMORAL_INIT_AUTH"] = "HEDMORAL_INIT_AUTH_VALUE";
            break;
      case .registerChallengeGenerator:
            newHeaders["HEDMORAL_REG_CHAL_GEN"] = "HEDMORAL_REG_CHAL_GEN_VALUE";
            break;
      case .registerChallengeVerifier:
            newHeaders["HEDMORAL_REG_CHAL_VERIFY"] = "HEDMORAL_REG_CHAL_VERIFY_VALUE";
            break;
      case .authChallengeGenerator:
            newHeaders["HEDMORAL_AUTH_CHAL_GEN"] = "HEDMORAL_AUTH_CHAL_GEN_VALUE";
            break;
      case .authChallengeVerifier:
            newHeaders["HEDMORAL_AUTH_CHAL_VERIFY"] = "HEDMORAL_AUTH_CHAL_VERIFY_VALUE";
            break;
      case .txnSignChallengeGenerator:
            newHeaders["HEDMORAL_TXN_CHAL_GEN"] = "HEDMORAL_TXN_CHAL_GEN_VALUE";
```

```
            break;
      case .txnSignChallengeVerifier:
            newHeaders["HEDMORAL_TXN_CHAL_VERIFY"] = "HEDMORAL_AUTH_CHAL_VERIFY_VALUE";
            break;
      @unknown default:
            newHeaders["HEDMORAL_DEFAULT_HEADER"] = "HEDMORAL_DEFAULT_HEADER_VALUE";
            break;
      }
      return newHeaders;
 }
  override func sendRequest(endpoint: AuthHubEndpoint) async throws -> AHRequestResult {
      let newHeaders = addRequestHeaders(endpoint: endpoint)
      endpoint.setRequestHeaders(newHeaders)
      return try await super.sendRequest(endpoint: endpoint)
 }
}
```

The following example shows how to use the sample request that was created in the previous example to initialize the IDSP FIDO SDK instance:

```
let ahfidosdk = AHFIDOSDK.getInstance()

/*Create instance of SampleAuthHubRequest*/
let hedmoralRequestObject = SampleAuthHubRequest()

/*Create instance of AHRequestLogger and enable it*/
let ahReqLogger = AuthHubCore.AHRequestLogger(fileName: nil)
ahReqLogger.enableLog(enable: true)

/*Set request logger for created request object*/
hedmoralRequestObject.setRequestLogger(requestLogger: ahReqLogger)

/*Create instance of AHRequestLogger and enable it*/
ahfidosdk.initFIDO(serverHost: "example.broadcom.com", tenant: "default", authhubRequest:
 hedmoralRequestObject)
```

IDSP Core Framework APIs

This section includes the IDSP Core Framework APIs:

Create an instance of the AuthHubCore.framework AHCore class

- To create an instance of the **AuthHubCore.framework AHCore** class, invoke the **getInstance()** API. The API returns a singleton instance of the AHCore class.

  ```
  public static func getInstance() -> AHCore
  ```

- To get the version of the **AuthHubCore.framework,** invoke the **getVersion() API.** The currently supported version of the **AuthHubCore.framework** is 2.3.2.

  ```
  public static func getVersion() -> String
  ```

Setting Up the Network Request Object

To set the network request object, call the AuthHubCore API, ***setAuthHubRequestObject()***

```
public func setAuthHubRequestObject(authhubRequest: AuthHubBasicRequest)
```

The API parameters have been described in the following table:

Name	Type	Description
authhubRequest	AuthHubBasicRequest	This is an optional parameter and can be set to nil value. As a developer, if you intend to customise the network request wh request body param), then implement AHAPIRequest interface. T of the AHAPIRequest interface. When the initAuth() is invoked wit implementation of AHAPIRequest interface that is; AuthHubBasicl

Initiate Authentication

- Use the **initAuth** function to initiate the authentication flow by invoking the POST `https://${SSP_FQDN}/<tenantName>/auth/v1/authenticate` API. Use this function at all existing places where you are invoking the */* **authenticate** API.

  NOTE

  - To know the value of ${SSP_FQDN} environment variable, see Configuring IDSP Environment Variables.
  - The default value for `<tenantName>` is "default".
  - Replace the text {{text}} including {{}} characters with appropriate values, in all the endpoints shown in the above table.

    For example:

    `https://{{host}}/{{tenantName}}/auth/v1/authenticate`

    should look similar to:

    `https://example.com/default/auth/v1/authenticate`
  - To know more about the scopes that are required to secure these APIs, refer to the Rest APIs and Associated Privileges section.

API Signature

```
public func initAuth(serverHost: String,
                     tenant: String,
                     requestHeaders:[String:Any],
                     authRequestParams: [String:Any],
                     fieldsTobeEncryptedList:[String]?,
                     completionBlock: @escaping (( _ response: AHCoreResult) -> Void)) throws
```

The API parameters are described in the following table:

Name	Type	Description
serverHost	string	This is the IDSP server host.
tenant	string	This is the tenant name.
requestHeaders	dictionary	The requestHeaders is the collection of IDSP FIDO Server specific headers that are required for REST API calls. The following parameters should be passed with proper values: • Authorization

authRequestParams	dictionary	This is a collection of parameters that are required for '/authenticate' REST API calls. The following sample parameters can be passed as a dictionary object:
		`{`
		`"subject": "{{userLoginid}}",`
		`"channel": "mobile",`
		`"ipAddress": "10.10.123.124",`
		`"action":"authenticate",`
		`"rememberMe" : true,`
		`"device": {`
		`"signature": {`
		`"iaAuthData":`
		`"_v02MyUgNGgYOi88OTk0emB7ZXV9GDQ2PDshOiY9bnUcOyEwOXUYNDZ1GgZ1DXVkZQpk`
		`NzclNDA6PzozOj06MDMyPDA9PzQ8KTw7ITAnOzQ5eDs0Njl4JTkgMjw7czMlJTxoczMlIS`
		`}`
		`}`
		`}`

fieldsTobeEncryptedList	string array	• This is optional parameter and can be set to nil value. • The list of string array contains the list of the fields which needs encryption. This list of fields can be obtained from getFieldsToBeEncryptedInAuthFlow() API. The list of fields that are sent to initAuth() decides whether server nonce is required to encrypt field in the transit.
completionBlock	closure block	Represents the closure block that the SDK passes to the calling API. The closure block returns the AHCoreResult object as a response. AHCoreResult is a struct object containing data (dictionary object), code (API response), and message (string) as members.

The completionBlock closure returns a AHCoreResult struct object as defined here:

```
public struct AHCoreResult {
 public init(code: Int, message: String, data: [String:Any]) {
     self.code = code
     self.message = message
     self.data = data
 }
 public var code : Int

 public var message : String

 public var data : [String:Any]

}
```

- ***Example: API call with Server Host and Tenant***

```
do
{
 //set network request object in AuthCore
 ahCore.setAuthHubRequestObject(authhubRequest:hedmoralRequestObject)

 //get access token from server
```

```
 var jsonResponse = getAccessTokenFromAHServer()
 var accessToken = "Bearer \(jsonResponse["access_token"] as! String)"
 var reqHeaders = [String:Any]()
 reqHeaders["Authorization"] = accessToken

 /*get list of the fields from BrandingSettings API*/
 let brandingSettingsHeaders:[String:String] = [AHConstants.HttpHeader.KeyAz:accessToken]
 try ahCore.getFieldsToBeEncryptedInAuthFlow(serverHost: serverHost,
                                             tenant: tenant,
                                             requestHeaders:brandingSettingsHeaders)
{ result in
     if(result.code == AHResult.Code.SUCCESS) {
         //On success, fetch the list of the fields which needs encryption
         let fieldsToBeEncrypted = result.data[AHConstants.GenericKeys.FieldsToBeEncrypted] as? [String] ??
 []
         //pass on the list to initAuth()
         try ahCore.initAuth(serverHost: serverHost,
                             tenant: tenant,
                             requestHeaders: reqHeaders,
                             authRequestParams: paramBodyRequest,
                             fieldsTobeEncryptedList:fieldsToBeEncrypted) { response in
             if response.data["errorCode"] != nil {
                 let errorCode = response.data["errorCode"] as! String
                 let code = Int(errorCode)!
                 var errorMsg = response.data["errorMessage"] as? String ?? ""
                 if(!errorMsg.isEmpty) {
                     print("Error: message - \(errorMsg) and code: \(errorCode)")
                 }
             }
             else {
                 if let flowState = response.data["flowState"] as? String {
                    print(flowState)
             }
             guard let nextAction = response.data["nextaction"] else {
                   Logger().logMessage(message: "Next Action not set!!")
                   return
             }
             //handle nevigation to next page based on response from AH server
             navigateToNextPageBasedOnNextAction()
         }
      }
 }
}
```

This function is used for initiating the authentication flow by invoking the POST `https://<proxyUrl>/auth/v1/authenticate` API. This API also supports the **proxy URL** configuration for the IDSP instance where the tenant name is not required as part of the URL. This function should be used at all the existing places where you are invoking the **/authenticate** API.

API Signature

```
public func initAuth(serverUrl: String,
                 requestHeaders:[String:Any],
                 authRequestParams: [String:Any],
                 fieldsTobeEncryptedList:[String]?,
```

```
completionBlock: @escaping (( _ response: AHCoreResult) -> Void)) throws
```

The API parameters have been described here:

Name	Type	Description
serverURL	string	The endpoint url that can be a proxy url for an IDSP instance.
requestHeaders	dictionary	The requestHeaders is the collection of IDSP FIDO Server specific headers that are required for REST API calls. The following parameters should be passed with proper values: • Authorization
authRequestParams	dictionary	This is a collection of parameters that are required for '/authenticate' REST API calls. The following sample parameters can be passed as a dictionary object: `{ "subject": "{{userLoginid}}", "channel": "mobile", "ipAddress": "10.10.123.124", "action":"authenticate", "rememberMe" : true, "device": { "signature": { "iaAuthData": "_v02MyUgNGgYOi88OTk0emB7ZXV9GDQ2PDshOiY9bnUcOyEwOXUYNDZ1GgZ1DXVkZQpk NzclNDA6PzozOj06MDMyPDA9PzQ8KTw7ITAnOzQ5eDs0Nj14JTkgMjw7czMlJTxoczMlIS } } }`
fieldsTobeEncryptedList	string array	• This is an optional parameter and can be set to nil. • The list of string array contains the list of the fields which needs encryption. This list of fields can be obtained from getFieldsToBeEncryptedInAuthFlow() API. The list of fields sent to initAuth() decides whether server nonce is required to encrypt the fields in the transit.
completionBlock	closure block	Represents the closure block that the SDK passes to the calling API. The closure block returns the AHCoreResult object as a response. AHCoreResult is a struct object containing data (dictionary object), code (API response), and message (string) as members.

The completionBlock closure returns a AHCoreResult struct object as defined here:

```
public struct AHCoreResult {
 public init(code: Int, message: String, data: [String:Any]) {
     self.code = code
     self.message = message
     self.data = data
 }
 public

var code : Int
 public
var message : String
 public
var data : [String:Any]
```

```
}
```

- ***Example: API call with Proxy URL***

```
do
{
 //set network request object in AuthCore
 ahCore.setAuthHubRequestObject(authhubRequest:hedmoralRequestObject)

 //get access token from server
 var jsonResponse = getAccessTokenFromAHServer()
 var accessToken = "Bearer \(jsonResponse["access_token"] as! String)"
 var reqHeaders = [String:Any]()
 reqHeaders["Authorization"] = accessToken

 /*get list of the fields from BrandingSettings API*/
 let brandingSettingsHeaders:[String:String] = [AHConstants.HttpHeader.KeyAz:accessToken]
 try ahCore.getFieldsToBeEncryptedInAuthFlow(serverUrl: proxyUrl,
                                             requestHeaders:brandingSettingsHeaders)
{ result in
     if(result.code == AHResult.Code.SUCCESS) {
         //On success, fetch the list of the fields which needs encryption
         let fieldsToBeEncrypted = result.data[AHConstants.GenericKeys.FieldsToBeEncrypted] as? [String] ??
 []
         //pass on the list to initAuth()
         try ahCore.initAuth(serverUrl: proxyUrl,
                             requestHeaders: reqHeaders,
                             authRequestParams: paramBodyRequest,
                             fieldsTobeEncryptedList:fieldsToBeEncrypted) { response in
             if response.data["errorCode"] != nil {
                 let errorCode = response.data["errorCode"] as! String
                 let code = Int(errorCode)!
                 var errorMsg = response.data["errorMessage"] as? String ?? ""
                 if(!errorMsg.isEmpty) {
                     print("Error: message - \(errorMsg) and code: \(errorCode)")
                 }
             }
             else {
                 if let flowState = response.data["flowState"] as? String {
                    print(flowState)
             }
             guard let nextAction = response.data["nextaction"] else {
                   Logger().logMessage(message: "Next Action not set!!")
                   return
             }
             //handle nevigation to next page based on response from AH server
             navigateToNextPageBasedOnNextAction()
         }
      }
 }
}
```

Data Encryption

IDSP supports "Password" (In-Transit and At-Rest) encryption and "Device Signature" (In-Transit) encryption.

Prerequisite

To use the iOS client SDK for ***"Password"*** and ***"Device Signature"*** encryption, the following prerequisites must be met.

1. Change the value of the tenant setting, **fieldsToBeEncryptedInAuthFlow** to **"Password", and/or "Device Signature".** The default value is **none,** which indicates that "Password" and "Device Signature" encryption is disabled by default.

```
[
 {
     "name": "fieldsToBeEncryptedInAuthFlow",
     "value": "password, devicesignature"
 }
]
```

2. Integrate the **AuthHubCore.framework** SDK with the iOS application. The SDK includes the APIs that can be called from the iOS application context to achieve "Password" and "Device Signature" encryption.

   NOTE
   The **AuthHubCore.framework** SDK file can be download from the Support Portal > My Downloads along with other SDKs.

Get the list of fields to be encrypted in the authentication flow

1. To get a list of the fields that are enabled for encryption, invoke **getFieldsToBeEncryptedInAuthFlow()** function before calling initAuth().

```
public func getFieldsToBeEncryptedInAuthFlow(serverHost: String,
                                             tenant: String,
                                             requestHeaders:[String:Any],
                                             completionBlock: @escaping ( _ response: AHCoreResult) -> Void)
 throws
```

   The API parameters have been described here:

Name	Type	Description
serverHost	string	This is the IDSP server host.
tenant	string	This is the tenant name.
requestHeaders	dictionary	• The requestHeaders is the collection of IDSP FIDO Server specific headers that are required for for "/auth/v1/BrandingSettings" IDSP REST API calls. • In this case, you must pass authorization request header value as reqHeaders["Authorization"] = accessToken as mandatory request header parameter. • Other optional custom headers can be passed as per customer requirement.
completionBlock	closure block	• Represents the closure block that the SDK passes to the calling API. The closure block returns the AHCoreResult object as a response. AHCoreResult is a struct object containing data (dictionary object), code (API response), and message (string) as members. • The data is a dictionary object, message is a string, and the code is the API response code. • The result.data[AHConstants.GenericKeys.FieldsToBeEncrypted] contains list of fields(string array) [String] which can be passed on to the initAuth() API

The completionBlock closure returns an AHCoreResult object, containing a dictionary collection named "data." The result.data dictionary, comprises a key identified as AHConstants.GenericKeys.FieldsToBeEncrypted (specified in the

fieldName argument of the API) and a list of fields in string array format. [String], denoting the fields requiring encryption. Currently, it may include "password," "devicesignature," or both.

```
do
{
 //set network request object in AuthCore
 ahCore.setAuthHubRequestObject(authhubRequest:hedmoralRequestObject)

 //get access token from server
 var jsonResponse = getAccessTokenFromAHServer()
 var accessToken = "Bearer \(jsonResponse["access_token"] as! String)"
 var reqHeaders = [String:Any]()
 reqHeaders["Authorization"] = accessToken

 /*get list of the fields from BrandingSettings API*/
 let brandingSettingsHeaders:[String:String] = [AHConstants.HttpHeader.KeyAz:accessToken]
 try ahCore.getFieldsToBeEncryptedInAuthFlow(serverHost: serverHost,
                                             tenant: tenant,
                                             requestHeaders:brandingSettingsHeaders)
{ result in
     if(result.code == AHResult.Code.SUCCESS) {
         //On success, fetch the list of the fields which needs encryption
         let fieldsToBeEncrypted = result.data[AHConstants.GenericKeys.FieldsToBeEncrypted] as? [String] ?? []
         //pass on the list to initAuth()
         try ahCore.initAuth(serverHost: serverHost,
                             tenant: tenant,
                             requestHeaders: reqHeaders,
                             authRequestParams: paramBodyRequest,
                             fieldsTobeEncryptedList:fieldsToBeEncrypted) { response in
             if response.data["errorCode"] != nil {
                 let errorCode = response.data["errorCode"] as! String
                 let code = Int(errorCode)!
                 var errorMsg = response.data["errorMessage"] as? String ?? ""
                 if(!errorMsg.isEmpty) {
                     print("Error: message - \(errorMsg) and code: \(errorCode)")
                 }
             }
             else {
                 if let flowState = response.data["flowState"] as? String {
                    print(flowState)
             }
             guard let nextAction = response.data["nextaction"] else {
                   Logger().logMessage(message: "Next Action not set!!")
                   return
             }
             //handle nevigation to next page based on response from AH server
             navigateToNextPageBasedOnNextAction()
         }
       }
 }
}
```

Support for proxy URL configuration to get the list of fields that are required for encryption

The following API supports the proxy Url configuration for IDSP instance where tenant name is not required as part of the URL.

```
public func getFieldsToBeEncryptedInAuthFlow(serverUrl: String,
                                             requestHeaders:[String:Any],
                                             completionBlock: @escaping ( _ response: AHCoreResult) -> Void)
 throws
```

The API parameters have been described here:

Name	Type	Description
serverURL	string	The endpoint url that can be a proxy url for an IDSP instance.
requestHeaders	dictionary	• requestHeaders is the collection of AuthHub FIDO Server specific parameters required for "/auth/v1/BrandingSettings" AH REST call. • In this case, developer must pass authorization request header value as reqHeaders["Authorization"] = accessToken as mandatory request header parameter. • Other optional custom headers can be passed as per customer requirement.
completionBlock	closure block	• Represents the closure block that the SDK passes to the calling API. The closure block returns the AHCoreResult object as a response. • AHCoreResult is a struct object containing data (dictionary object), code (API response), and message (string) as members. • The data is a dictionary object, message is a string, and the code is the API response code.

The completionBlock closure returns an AHCoreResult object, containing a dictionary collection named "data." The result.data dictionary, comprises a key identified as AHConstants.GenericKeys.FieldsToBeEncrypted (specified in the fieldName argument of the API) and a list of fields in string array format. [String], denoting the fields requiring encryption. Currently, it may include "password," "devicesignature," or both, as shown in the following example.

```
do
{
 //set network request object in AuthCore
 ahCore.setAuthHubRequestObject(authhubRequest:hedmoralRequestObject)

 //get access token from server
 var jsonResponse = getAccessTokenFromAHServer()
 var accessToken = "Bearer \(jsonResponse["access_token"] as! String)"
 var reqHeaders = [String:Any]()
 reqHeaders["Authorization"] = accessToken

 /*get list of the fields from BrandingSettings API*/
 let brandingSettingsHeaders:[String:String] = [AHConstants.HttpHeader.KeyAz:accessToken]
 try ahCore.getFieldsToBeEncryptedInAuthFlow(serverUrl: proxyUrl,
                                             requestHeaders:brandingSettingsHeaders)
{ result in
     if(result.code == AHResult.Code.SUCCESS) {
         //On success, fetch the list of the fields which needs encryption
         let fieldsToBeEncrypted = result.data[AHConstants.GenericKeys.FieldsToBeEncrypted] as? [String] ?? []
         //pass on the list to initAuth()
```

```
        try ahCore.initAuth(serverUrl: proxyUrl,
                            requestHeaders: reqHeaders,
                            authRequestParams: paramBodyRequest,
                            fieldsTobeEncryptedList:fieldsToBeEncrypted) { response in
            if response.data["errorCode"] != nil {
                let errorCode = response.data["errorCode"] as! String
                let code = Int(errorCode)!
                var errorMsg = response.data["errorMessage"] as? String ?? ""
                if(!errorMsg.isEmpty) {
                    print("Error: message - \(errorMsg) and code: \(errorCode)")
                }
            }
            else {
                if let flowState = response.data["flowState"] as? String {
                   print(flowState)
            }
            guard let nextAction = response.data["nextaction"] else {
                  Logger().logMessage(message: "Next Action not set!!")
                  return
            }
            //handle nevigation to next page based on response from AH server
            navigateToNextPageBasedOnNextAction()
        }
    }
  }
 }
```

Encryption Confirmation

Encryption confirmation for "Password" and "Device Signature" is described in this section.

- ***"Password" Encryption Confirmation***
  Call the **isEncryptionRequiredForField** function to check if the password field is configured for "Password" encryption.

  API Signature

```
 public func isEncryptionRequiredForField(serverHost: String,
                                          tenant: String,
                                          requestHeaders:[String:Any],
