FortiOS 7.2.5 Administration Guide
01-725-791905-20240223

TABLE OF CONTENTS

Change Log **23**
Getting started **25**
Differences between models 25
Low encryption models 25
Using the GUI 25
Connecting using a web browser 26
Menus 26
Tables 27
Entering values 29
GUI-based global search 31
Loading artifacts from a CDN 32
Using the CLI 32
Connecting to the CLI 32
CLI basics 35
Command syntax 41
Subcommands 44
Permissions 46
FortiExplorer management 46
Getting started with FortiExplorer 47
Connecting FortiExplorer to a FortiGate with WiFi 50
Configure FortiGate with FortiExplorer using BLE 51
Running a security rating 54
Upgrading to FortiExplorer Pro 55
Basic administration 55
Basic configuration 56
Registration 58
FortiCare and FortiGate Cloud login 63
Transfer a device to another FortiCloud account 65
Configuration backups 68
Deregistering a FortiGate 76
Fortinet Developer Network access 78
LEDs 81
Alarm levels 85
Troubleshooting your installation 85
Dashboards and Monitors **88**
Using dashboards 88
Using widgets 89
Widgets 91
Viewing device dashboards in the Security Fabric 93
Creating a fabric system and license dashboard 94
Example 94
Dashboards 95
Resetting the default dashboard template 96
Status dashboard 96

Security dashboard ... 99
Network dashboard ... 101
Users & Devices ... 109
WiFi dashboard ... 113
Monitors ... 119
Non-FortiView monitors ... 119
FortiView monitors ... 119
FortiView monitors and widgets ... 120
Adding FortiView monitors ... 121
Using the FortiView interface ... 124
Enabling FortiView from devices ... 127
FortiView sources ... 129
FortiView Sessions ... 130
FortiView Top Source and Top Destination Firewall Objects monitors ... 132
Viewing top websites and sources by category ... 134
Cloud application view ... 137
Network ... 148
Interfaces ... 148
Interface settings ... 150
Physical interface ... 175
VLAN ... 176
Aggregation and redundancy ... 192
Loopback interface ... 196
Software switch ... 196
Hardware switch ... 198
Zone ... 202
Virtual wire pair ... 204
Enhanced MAC VLAN ... 211
VXLAN ... 214
DNS ... 238
Important DNS CLI commands ... 239
DNS domain list ... 242
FortiGate DNS server ... 243
DDNS ... 246
DNS latency information ... 249
DNS over TLS and HTTPS ... 251
DNS troubleshooting ... 256
Explicit and transparent proxies ... 257
Explicit web proxy ... 258
FTP proxy ... 262
Transparent proxy ... 264
Proxy policy addresses ... 267
Proxy policy security profiles ... 274
Explicit proxy authentication ... 278
Transparent web proxy forwarding ... 284
Upstream proxy authentication in transparent proxy mode ... 288
Multiple dynamic header count ... 289
Restricted SaaS access ... 292

Explicit proxy and FortiGate Cloud Sandbox ... 300
Proxy chaining ... 302
WAN optimization SSL proxy chaining ... 307
Agentless NTLM authentication for web proxy ... 315
Multiple LDAP servers in Kerberos keytabs and agentless NTLM domain controllers ... 318
Learn client IP addresses ... 319
Explicit proxy authentication over HTTPS ... 320
mTLS client certificate authentication ... 322
CORS protocol in explicit web proxy when using session-based, cookie-enabled, and captive portal-enabled SAML authentication ... 327
HTTP connection coalescing and concurrent multiplexing for explicit proxy ... 331
DHCP servers and relays ... 333
Default DHCP server for low-end FortiGates ... 333
Basic configuration ... 334
DHCP options ... 337
DHCP addressing mode on an interface ... 344
VCI pattern matching for DHCP assignment ... 347
FortiGate DHCP works with DDNS to allow FQDN connectivity to leased IP addresses ... 349
Static routing ... 349
Routing concepts ... 349
Policy routes ... 363
Equal cost multi-path ... 365
Dual internet connections ... 369
Dynamic routing ... 374
RIP ... 376
OSPF ... 395
BGP ... 412
BFD ... 450
Routing objects ... 459
Multicast ... 468
Multicast routing and PIM support ... 468
Configuring multicast forwarding ... 469
FortiExtender ... 473
WAN extension mode ... 473
LAN extension mode ... 473
Adding a FortiExtender ... 474
Direct IP support for LTE/4G ... 476
Sample LTE interface ... 477
Limitations ... 478
LLDP reception ... 479
Virtual routing and forwarding ... 481
Implementing VRF ... 482
VRF routing support ... 483
Route leaking between VRFs with BGP ... 488
Route leaking between multiple VRFs ... 491
VRF with IPv6 ... 501
IBGP and EBGP support in VRF ... 505

Support cross-VRF local-in and local-out traffic for local services 507
NetFlow 510
Verification and troubleshooting 511
NetFlow templates 511
NetFlow on FortiExtender and tunnel interfaces 524
sFlow 528
Configuring sFlow 528
Link monitor 531
Link monitor with route updates 531
Enable or disable updating policy routes when link health monitor fails 533
Add weight setting on each link health monitor server 535
SLA link monitoring for dynamic IPsec and SSL VPN tunnels 538
IPv6 541
IPv6 overview 541
IPv6 quick start 542
Neighbor discovery proxy 546
IPv6 address assignment 547
NAT66, NAT46, NAT64, and DNS 64 559
DHCPv6 relay 569
IPv6 tunneling 570
IPv6 configuration examples 581
FortiGate LAN extension 613
Diagnostics 619
Using the packet capture tool 619
Using the debug flow tool 623
SD-WAN 628
SD-WAN overview 628
SD-WAN components and design principles 628
SD-WAN designs and architectures 631
SD-WAN quick start 632
Configuring the SD-WAN interface 633
Adding a static route 634
Selecting the implicit SD-WAN algorithm 634
Configuring firewall policies for SD-WAN 635
Link monitoring and failover 635
Results 637
Configuring SD-WAN in the CLI 640
SD-WAN members and zones 642
Topology 643
Configuring SD-WAN member interfaces 643
Configuring SD-WAN zones 645
Using SD-WAN zones 646
Specify an SD-WAN zone in static routes and SD-WAN rules 648
Performance SLA 653
Performance SLA overview 653
Link health monitor 658
Monitoring performance SLA 660
Passive WAN health measurement 665

Passive health-check measurement by internet service and application 670
Mean opinion score calculation and logging in performance SLA health checks 674
Embedded SD-WAN SLA information in ICMP probes 677
SD-WAN application monitor using FortiMonitor 685
SD-WAN rules 688
SD-WAN rules overview 688
Implicit rule 696
Automatic strategy 700
Manual strategy 701
Best quality strategy 702
Lowest cost (SLA) strategy 706
Maximize bandwidth (SLA) strategy 709
Manual interface speedtest 712
Scheduled interface speedtest 713
SD-WAN traffic shaping and QoS 715
SDN dynamic connector addresses in SD-WAN rules 720
Application steering using SD-WAN rules 723
DSCP tag-based traffic steering in SD-WAN 736
ECMP support for the longest match in SD-WAN rule matching 743
Override quality comparisons in SD-WAN longest match rule matching 745
Use an application category as an SD-WAN rule destination 748
Advanced routing 752
Local out traffic 752
Using BGP tags with SD-WAN rules 758
BGP multiple path support 762
Controlling traffic with BGP route mapping and service rules 764
Applying BGP route-map to multiple BGP neighbors 771
Using multiple members per SD-WAN neighbor configuration 776
VPN overlay 782
ADVPN and shortcut paths 783
SD-WAN monitor on ADVPN shortcuts 796
Hold down time to support SD-WAN service strategies 797
SD-WAN integration with OCVPN 799
Adaptive Forward Error Correction 806
Dual VPN tunnel wizard 810
Duplicate packets on other zone members 811
Duplicate packets based on SD-WAN rules 814
Speed tests run from the hub to the spokes in dial-up IPsec tunnels 815
Interface based QoS on individual child tunnels based on speed test results 822
SD-WAN in large scale deployments 825
Advanced configuration 836
SD-WAN with FGCP HA 836
Configuring SD-WAN in an HA cluster using internal hardware switches 843
SD-WAN configuration portability 847
SD-WAN segmentation over a single overlay 853
Matching BGP extended community route targets in route maps 868
Copying the DSCP value from the session original direction to its reply direction 873
SD-WAN cloud on-ramp 876
Configuring the VPN overlay between the HQ FortiGate and cloud FortiGate-VM 877

Configuring the VPN overlay between the HQ FortiGate and AWS native VPN gateway 882
Configuring the VIP to access the remote servers 885
Configuring the SD-WAN to steer traffic between the overlays 888
Verifying the traffic 892
Troubleshooting SD-WAN 898
Tracking SD-WAN sessions 899
Understanding SD-WAN related logs 899
SD-WAN related diagnose commands 902
SD-WAN bandwidth monitoring service 906
Using SNMP to monitor health check 909
Zero Trust Network Access 913
Zero Trust Network Access introduction 913
ZTNA application gateway and IP/MAC based access control 913
ZTNA telemetry, tags, and policy enforcement 914
Application gateway 914
Basic ZTNA configuration components 915
Basic ZTNA configuration 915
Establish device identity and trust context with FortiClient EMS 927
ZTNA scalability support for concurrent endpoints 932
SSL certificate based authentication 934
Full versus simple ZTNA policies NEW 936
ZTNA advanced configurations 943
Access control of unmanageable and unknown devices 943
HTTP2 connection coalescing and concurrent multiplexing for ZTNA 950
ZTNA configuration examples 952
ZTNA HTTPS access proxy example 953
ZTNA HTTPS access proxy with basic authentication example 963
ZTNA TCP forwarding access proxy example 970
ZTNA SSH access proxy example 976
ZTNA application gateway with SAML authentication example 983
ZTNA application gateway with SAML and MFA using FortiAuthenticator example 987
ZTNA IP MAC based access control example 1003
ZTNA IPv6 examples 1010
ZTNA Zero Trust application gateway example 1016
ZTNA access proxy with KDC to access shared drives 1017
ZTNA troubleshooting and debugging commands 1022
Troubleshooting usage and output 1023
ZTNA troubleshooting scenarios 1027
ZTNA access control 1027
IP/MAC based access control 1029
Other useful CLI commands 1031
Policy and Objects 1032
Policies 1032
Firewall policy 1033
NGFW policy 1046
Local-in policy 1062
DoS policy 1066

Access control lists 1073
Interface policies 1074
Source NAT 1075
Destination NAT 1095
Examples and policy actions 1119
Address objects 1152
Address Types 1152
Address Group 1154
Subnet 1154
Dynamic policy — fabric devices 1155
IP range 1157
FQDN addresses 1158
Using wildcard FQDN addresses in firewall policies 1158
Geography based addresses 1161
IPv6 geography-based addresses 1164
Wildcard addressing 1166
Interface subnet 1167
Address group 1168
Address folders 1169
Allow empty address groups 1170
Address group exclusions 1171
FSSO dynamic address subtype 1172
ClearPass integration for dynamic address objects 1176
FortiNAC tag dynamic address 1179
MAC addressed-based policies 1182
ISDB well-known MAC address list 1183
IPv6 MAC addresses and usage in firewall policies 1185
Protocol options 1187
Log oversized files 1187
RPC over HTTP 1187
Protocol port mapping 1187
Common options 1187
Web options 1188
Email options 1189
Traffic shaping 1189
Configuration methods 1190
Traffic shaping policy 1191
Traffic shaping policies 1192
Traffic shaping profiles 1195
Traffic shapers 1205
Global traffic prioritization 1217
DSCP matching and DSCP marking 1220
Examples 1224
Internet Services 1240
Using Internet Service in a policy 1241
Using custom Internet Service in policy 1245
Using extension Internet Service in policy 1247
Global IP address information database 1249
IP reputation filtering 1251

Internet service groups in policies 1253
Allow creation of ISDB objects with regional information 1256
Internet service customization 1258
Look up IP address information from the Internet Service Database page 1259
Internet Service Database on-demand mode 1260
Enabling the ISDB cache in the FortiOS kernel 1263
Security Profiles 1265
Inspection modes 1265
Flow mode inspection (default mode) 1266
Proxy mode inspection 1266
Inspection mode feature comparison 1268
Antivirus 1272
Protocol comparison between antivirus inspection modes 1273
Other antivirus differences between inspection modes 1273
AI-based malware detection 1274
Configuring an antivirus profile 1274
Proxy mode stream-based scanning 1277
Databases 1281
Content disarm and reconstruction 1282
FortiGuard outbreak prevention 1284
External malware block list 1286
Malware threat feed from EMS 1289
Checking flow antivirus statistics 1291
CIFS support 1293
Using FortiSandbox post-transfer scanning with antivirus 1299
Using FortiSandbox inline scanning with antivirus 1301
Using FortiNDR inline scanning with antivirus 1311
Exempt list for files based on individual hash 1314
Web filter 1315
URL filter 1316
FortiGuard filter 1322
Credential phishing prevention 1328
Additional antiphishing settings 1331
Usage quota 1334
Web content filter 1336
Advanced filters 1 1340
Advanced filters 2 1342
Web filter statistics 1347
URL certificate blocklist 1348
Websense Integrated Services Protocol 1348
Inspecting HTTP3 traffic 1349
Configuring web filter profiles with Hebrew domain names 1351
Video filter 1356
Configuring a video filter profile 1356
Filtering based on FortiGuard categories 1356
Filtering based on YouTube channel 1361
Replacement messages displayed in blocked videos NEW 1366
DNS filter 1368

DNS filter behavior in proxy mode 1369
FortiGuard DNS rating service 1369
Configuring a DNS filter profile 1370
FortiGuard category-based DNS domain filtering 1374
Botnet C&C domain blocking 1377
DNS safe search 1380
Local domain filter 1382
DNS translation 1387
Applying DNS filter to FortiGate DNS server 1390
DNS inspection with DoT and DoH 1391
Troubleshooting for DNS filter 1394
Application control 1397
Configuring an application sensor 1398
Basic category filters and overrides 1399
Excluding signatures in application control profiles 1402
Port enforcement check 1404
Protocol enforcement 1404
SSL-based application detection over decrypted traffic in a sandwich topology 1406
Matching multiple parameters on application control signatures 1407
Application signature dissector for DNP3 1410
Blocking QUIC manually 1410
Intrusion prevention 1412
Signature-based defense 1414
Configuring an IPS sensor 1417
IPS configuration options 1420
IPS signature filter options 1425
IPS with botnet C&C IP blocking 1428
IPS signatures for the industrial security service 1433
IPS sensor for IEC 61850 MMS protocol 1434
SCTP filtering capabilities 1436
File filter 1439
Configuring a file filter profile 1441
Supported file types 1445
Email filter 1447
Protocol comparison between email filter inspection modes 1448
Configuring an email filter profile 1448
Local-based filters 1449
FortiGuard-based filters 1456
Third-party-based filters 1458
Filtering order 1458
Protocols and actions 1460
Configuring webmail filtering 1461
Data leak prevention 1462
Protocol comparison between DLP inspection modes 1463
Archiving 1463
Logging and blocking files by file name 1463
Basic DLP settings 1464
Advanced DLP configurations 1467
DLP examples 1469

DLP fingerprinting 1483
VoIP solutions 1487
General use cases 1488
NAT46 and NAT64 for SIP ALG 1492
SIP message inspection and filtering NEW 1500
SIP ALG and SIP session helper 1505
SIP pinholes 1510
SIP over TLS 1512
Voice VLAN auto-assignment 1514
Scanning MSRP traffic 1515
ICAP 1519
ICAP configuration example 1520
ICAP response filtering 1522
Secure ICAP clients 1524
ICAP scanning with SCP and FTP 1525
Web application firewall 1528
Protecting a server running web applications 1529
SSL & SSH Inspection 1530
Configuring an SSL/SSH inspection profile 1531
Certificate inspection 1534
Deep inspection 1535
Protecting an SSL server 1538
Handling SSL offloaded traffic from an external decryption device 1539
SSH traffic file scanning 1541
Redirect to WAD after handshake completion 1542
HTTP/2 support in proxy mode SSL inspection 1543
Define multiple certificates in an SSL profile in replace mode 1544
Disabling the FortiGuard IP address rating 1546
Custom signatures 1547
Configuring custom signatures 1548
Blocking applications with custom signatures 1549
Filters for application control groups 1551
Application groups in traffic shaping policies 1554
Overrides 1558
Web rating override 1558
Using local and remote categories 1566
Web profile override 1568
Profile groups 1572
VPN 1575
IPsec VPNs 1575
General IPsec VPN configuration 1575
Site-to-site VPN 1605
Remote access 1658
Aggregate and redundant VPN 1702
Overlay Controller VPN (OCVPN) 1746
ADVPN 1777
Fabric Overlay Orchestrator 1811
Other VPN topics 1831

VPN IPsec troubleshooting 1870
SSL VPN 1878
SSL VPN best practices 1878
SSL VPN quick start 1881
SSL VPN tunnel mode 1888
SSL VPN web mode 1898
SSL VPN authentication 1916
SSL VPN to IPsec VPN 2006
SSL VPN protocols 2013
Configuring OS and host check 2016
FortiGate as SSL VPN Client 2022
Dual stack IPv4 and IPv6 support for SSL VPN 2031
Disable the clipboard in SSL VPN web mode RDP connections 2042
SSL VPN IP address assignments 2047
Using SSL VPN interfaces in zones 2049
SSL VPN troubleshooting 2052
User & Authentication 2056
Endpoint control and compliance 2057
Per-policy disclaimer messages 2057
Compliance 2059
FortiGuard distribution of updated Apple certificates 2061
Integrate user information from EMS and Exchange connectors in the user store 2062
User definition and groups 2065
Users 2065
User groups 2067
Retail environment guest access 2074
User and user group timeouts 2077
LDAP servers 2078
Configuring an LDAP server 2078
Enabling Active Directory recursive search 2081
Configuring LDAP dial-in using a member attribute 2082
Configuring wildcard admin accounts 2083
Configuring least privileges for LDAP admin account authentication in Active Directory 2085
Tracking users in each Active Directory LDAP group 2086
Tracking rolling historical records of LDAP user logins 2089
Configuring client certificate authentication on the LDAP server 2092
RADIUS servers 2094
Configuring a RADIUS server 2095
Using multiple RADIUS servers 2096
RADIUS AVPs and VSAs 2099
Restricting RADIUS user groups to match selective users on the RADIUS server 2101
Configuring RADIUS SSO authentication 2103
RSA ACE (SecurID) servers 2109
Support for Okta RADIUS attributes filter-Id and class 2113
Sending multiple RADIUS attribute values in a single RADIUS Access-Request 2115
Traffic shaping based on dynamic RADIUS VSAs 2115
RADIUS Termination-Action AVP in wired and wireless scenarios 2122

TACACS+ servers 2126
SAML 2128
Outbound firewall authentication for a SAML user 2128
SSL VPN with FortiAuthenticator as a SAML IdP 2130
Using a browser as an external user-agent for SAML authentication in an SSL VPN connection 2130
SAML authentication in a proxy policy 2134
Configuring SAML SSO in the GUI 2138
Outbound firewall authentication with Azure AD as a SAML IdP 2144
Authentication settings 2155
FortiTokens 2157
FortiToken Mobile quick start 2158
FortiToken Cloud 2166
Registering hard tokens 2166
Managing FortiTokens 2168
FortiToken Mobile Push 2170
Synchronizing LDAP Active Directory users to FortiToken Cloud using the two-factor filter 2172
Troubleshooting and diagnosis 2175
Configuring the maximum log in attempts and lockout period 2179
PKI 2179
Configuring a PKI user 2179
Using the SAN field for LDAP-integrated certificate authentication 2183
Configuring firewall authentication 2187
Creating a locally authenticated user account 2187
Creating a RADIUS-authenticated user account 2188
Creating an FSSO user group 2189
Creating a firewall user group 2191
Defining policy addresses 2191
Creating security policies 2192
FSSO 2193
FSSO polling connector agent installation 2196
FSSO using Syslog as source 2199
Configuring the FSSO timeout when the collector agent connection fails 2201
Authentication policy extensions 2203
Configuring the FortiGate to act as an 802.1X supplicant 2204
Example 2205
Include usernames in logs 2206
Install and configure FSSO Agent 2207
Configure the FortiGate 2209
Log, monitor, and report examples 2211
Wireless configuration 2215
Switch Controller 2216
System 2217
Basic system settings 2217
Advanced system settings 2217
Operating modes 2218

Administrators 2220
Local authentication 2220
Remote authentication for administrators 2221
Administrator account options 2224
REST API administrator 2226
SSO administrators 2228
FortiCloud SSO 2228
Allowing the FortiGate to override FortiCloud SSO administrator user permissions 2229
Password policy 2234
Public key SSH access 2236
Restricting SSH and Telnet jump host capabilities 2237
Remote administrators with TACACS VSA attributes 2238
Administrator profiles 2243
super_admin profile 2243
Creating customized profiles 2243
Displaying execute commands for custom system permissions 2244
Editing profiles 2245
Deleting profiles 2245
Fabric Management 2245
About firmware installations 2247
Firmware maturity levels 2247
Upgrading individual device firmware 2250
Upgrading individual device firmware by following the upgrade path (federated update) 2251
Upgrading all device firmware 2253
Upgrading all device firmware by following the upgrade path (federated update) 2255
Enabling automatic firmware updates 2258
Authorizing devices 2260
Firmware upgrade notifications 2263
Downloading a firmware image 2264
Testing a firmware version 2264
Installing firmware from system reboot 2266
Restoring from a USB drive 2268
Using controlled upgrades 2269
Downgrading individual device firmware 2269
Downloading the EOS support package for supported Fabric devices NEW 2271
Settings 2275
Default administrator password 2275
Changing the host name 2277
Setting the system time 2277
Configuring ports 2281
Setting the idle timeout time 2282
Setting the password policy 2282
Changing the view settings 2282
Setting the administrator password retries and lockout time 2283
TLS configuration 2283
Controlling return path with auxiliary session 2284
Email alerts 2288
Using configuration save mode 2293

Trusted platform module support 2294
Configuring the persistency for a banned IP list 2296
Using the default certificate for HTTPS administrative access 2297
Virtual Domains 2301
VDOM overview 2301
General configurations 2306
Backing up and restoring configurations in multi VDOM mode 2314
Inter-VDOM routing configuration example: Internet access 2317
Inter-VDOM routing configuration example: Partial-mesh VDOMs 2326
High Availability 2340
FortiGate Clustering Protocol (FGCP) 2340
FortiGate Session Life Support Protocol (FGSP) 2340
VRRP 2341
FGCP 2341
FGSP 2409
Standalone configuration synchronization 2460
VRRP 2465
SNMP 2477
Interface access 2477
MIB files 2478
SNMP agent 2478
SNMP v1/v2c communities 2479
SNMP v3 users 2480
Access control for SNMP 2482
Important SNMP traps 2484
SNMP traps and query for monitoring DHCP pool 2485
Replacement messages 2486
Modifying replacement messages 2487
Replacement message images 2488
Replacement message groups 2490
FortiGuard 2493
Anycast 2494
Connection and OCSP stapling 2494
Configuring FortiGuard updates 2496
Configuring a proxy server for FortiGuard updates 2496
Manual updates 2497
Automatic updates 2498
Scheduled updates 2499
Sending malware statistics to FortiGuard 2500
Update server location 2501
Filtering 2502
Online security tools 2503
Anycast and unicast services 2503
Using FortiManager as a local FortiGuard server 2504
Cloud service communication statistics 2505
IoT detection service 2507
FortiAP query to FortiGuard IoT service to determine device details 2510
FortiGate Cloud / FDN communication through an explicit proxy 2510

FDS-only ISDB package in firmware images 2512
Licensing in air-gap environments 2513
License expiration 2515
Feature visibility 2517
Certificates 2517
Automatically provision a certificate 2518
Generate a new certificate 2522
Regenerate default certificates 2523
Import a certificate 2524

Change Log

Date	Change Description
2023-06-08	Initial release.
2023-06-15	Added ZTNA Zero Trust application gateway example on page 1016. Updated User & Authentication on page 2056, Configuring an LDAP server on page 2078, Configuring wildcard admin accounts on page 2083, SSL VPN with LDAP-integrated certificate authentication on page 1932, Explicit proxy authentication on page 278, Using the SAN field for LDAP-integrated certificate authentication on page 2183, Synchronizing LDAP Active Directory users to FortiToken Cloud using the two-factor filter on page 2172, Use Active Directory objects directly in policies on page 1137, and FGSP basic peer setup on page 2411.
2023-06-19	Updated Interface subnet on page 1167, Address objects on page 1152, Interface settings on page 150,and Software switch on page 196.
2023-06-29	Added Neighbor discovery proxy on page 546, IPv6 address assignment on page 547, and DHCPv6 relay on page 569. Updated DNS domain list on page 242.
2023-07-07	Added Configuring an SSL/SSH inspection profile on page 1531. Updated Certificate inspection on page 1534 and One-arm sniffer on page 164.
2023-07-11	Updated IPS configuration options on page 1420.
2023-07-12	Updated FortiCloud SSO on page 2228 and Allowing the FortiGate to override FortiCloud SSO administrator user permissions on page 2229.
2023-07-19	Added IPv6 IPsec VPN on page 572, IPv6 GRE tunnels on page 573, Site-to-site IPv6 over IPv6 VPN example on page 588, Site-to-site IPv4 over IPv6 VPN example on page 596, and Site-to-site IPv6 over IPv4 VPN example on page 605. Updated IPv6 tunneling on page 570, IPv6 configuration examples on page 581, Embedded SD-WAN SLA information in ICMP probes on page 677, Dynamic SNAT on page 1076, Static virtual IPs on page 1095, Virtual server load balance on page 1102, and Force HA failover for testing and demonstrations on page 2392.
2023-07-21	Updated Site-to-site IPv6 over IPv6 VPN example on page 588, Site-to-site IPv4 over IPv6 VPN example on page 596, Site-to-site IPv6 over IPv4 VPN example on page 605, BGP on page 412, and Troubleshooting BGP on page 445.
2023-07-25	Added BIOS-level signature and file integrity checking NEW on page 2551 and Real-time file system integrity checking NEW on page 2555.
2023-08-04	Updated ZTNA HTTPS access proxy example on page 953.
2023-08-10	Added NAT66, NAT46, NAT64, and DNS 64 on page 559 and NAT66 policy on page 559. Updated IPv6 on page 541, NAT46 policy on page 561, and NAT64 policy and DNS64 (DNS proxy) on page 564.

Date	Change Description
2023-08-18	Updated FortiGate LAN extension on page 613.
2023-08-22	Added BGP multi-exit discriminator on page 441. Updated BGP on page 412.
2023-09-01	Updated Configuring the root FortiGate and downstream FortiGates on page 2585.
2023-09-07	Added IPS and AV engine version on page 3156.
2023-09-11	Updated Web content filter on page 1336, Virtual wire pair on page 204, Deep inspection on page 1535, and Hyperscale firewall on page 3106.
2023-09-18	Added ZTNA access proxy with KDC to access shared drives on page 1017. Updated Adaptive Forward Error Correction on page 806.
2023-09-20	Added CLI troubleshooting cheat sheet on page 3157.
2023-09-28	Updated ZTNA access proxy with KDC to access shared drives on page 1017.
2023-10-18	Updated Dynamic SNAT on page 1076.
2023-12-07	Updated Using VLAN sub-interfaces in virtual wire pairs on page 208.
2024-01-11	Updated Filtering based on FortiGuard categories on page 1356 and Blocking QUIC manually on page 1410.
2024-01-25	Updated ZTNA access proxy with KDC to access shared drives on page 1017.
2024-02-20	Updated Virtual patching on the local-in management interface on page 1150.
2024-02-23	Added Enabling the ISDB cache in the FortiOS kernel on page 1263.

Getting started

This section explains how to get started with a FortiGate.

Differences between models

Not all FortiGates have the same features, particularly entry-level models (models 30 to 90). A number of features on these models are only available in the CLI.

Consult your model's QuickStart Guide, hardware manual, or the Feature / Platform Matrix for further information about features that vary by model.

FortiGate models differ principally by the names used and the features available:

- Naming conventions may vary between FortiGate models. For example, on some models the hardware switch interface used for the local area network is called *lan*, while on other units it is called *internal*.
- Certain features are not available on all models. Additionally, a particular feature may be available only through the CLI on some models, while that same feature may be viewed in the GUI on other models.
  If you believe your FortiGate model supports a feature that does not appear in the GUI, go to *System* > *Feature Visibility* and confirm that the feature is enabled. For more information, see Feature visibility on page 2517.

Low encryption models

Some FortiGate models support a low encryption (LENC) license. With an LENC license, FortiGate devices are considered low encryption models and are identified by *LENC*, for example FG-100E-LENC.

LENC models cannot use or inspect high encryption protocols, such as 3DES and AES. LENC models only use 56-bit DES encryption to work with SSL VPN and IPsec VPN, and they are unable to perform SSL inspection.

For a list of FortiGate models that support an LENC license, see FortiGate LENC Models.

Using the GUI

This section presents an introduction to the graphical user interface (GUI) on your FortiGate.

The following topics are included in this section:

- Connecting using a web browser
- Menus
- Tables

- Entering values
- GUI-based global search
- Loading artifacts from a CDN on page 32

For information about using the dashboards, see Dashboards and Monitors on page 88.

Connecting using a web browser

In order to connect to the GUI using a web browser, an interface must be configured to allow administrative access over HTTPS or over both HTTPS and HTTP. By default, an interface has already been set up that allows HTTPS access with the IP address 192.168.1.99.

Browse to https://192.168.1.99 and enter your username and password. If you have not changed the admin account's password, use the default user name, `admin`, and leave the password field blank.

The GUI will now display in your browser, and you will be required to provide a password for the administrator account.

To use a different interface to access the GUI:

1. Go to *Network* > *Interfaces* and edit the interface you wish to use for access. Take note of its assigned IP address.
2. In *Administrative Access*, select *HTTPS*, and any other protocol you require. You can also select *HTTP*, although this is not recommended as the connection will be less secure.
3. Click *OK*.
4. Browse to the IP address using your chosen protocol.
   The GUI will now be displayed in your browser.

Menus

If you believe your FortiGate model supports a menu that does not appear in the GUI, go to *System* > *Feature Visibility* and ensure the feature is enabled. For more information, see Feature visibility on page 2517.

The GUI contains the following main menus, which provide access to configuration options for most FortiOS features:

Dashboard	The dashboard displays various widgets that display important system information and allow you to configure some system options. For more information, see Dashboards and Monitors on page 88.
Network	Options for networking, including configuring system interfaces and routing options. For more information, see Network on page 148.
Policy & Objects	Configure firewall policies, protocol options, and supporting content for policies, including schedules, firewall addresses, and traffic shapers. For more information, see Policy and Objects on page 1032.
Security Profiles	Configure your FortiGate's security features, including Antivirus, Web Filter, and Application Control.

	For more information, see Security Profiles on page 1265.
VPN	Configure options for IPsec and SSL virtual private networks (VPNs). For more information, see IPsec VPNs on page 1575 and SSL VPN on page 1878.
User & Authentication	Configure user accounts, groups, and authentication methods, including external authentication and single sign-on (SSO).
WiFi & Switch Controller	Configure the unit to act as a wireless network controller, managing the wireless Access Point (AP) functionality of FortiWiFi and FortiAP units. On certain FortiGate models, this menu has additional features allowing for FortiSwitch units to be managed by the FortiGate. For more information, see Wireless configuration on page 2215 and Switch Controller on page 2216.
System	Configure system settings, such as administrators, HA, FortiGuard, and certificates. For more information, see System on page 2217.
Security Fabric	Access the physical topology, logical topology, automation, and settings of the Fortinet Security Fabric. For more information, see Fortinet Security Fabric on page 2580.
Log & Report	Configure logging and alert email as well as reports. For more information, see Log and Report on page 2971.

Tables

Many GUI pages contain tables of information that can be filtered and customized to display specific information in a specific way. Some tables allow content to be edited directly on that table, or rows to be copied and pasted.

Navigation

Some tables contain information and lists that span multiple pages. Navigation controls will be available at the bottom of the page.

Filters

Filters are used to locate a specific set of information or content in a table. They can be particularly useful for locating specific log entries. The filtering options vary, depending on the type of information in the log.

Depending on the table content, filters can be applied using the filter bar, using a column filter, or based on a cell's content. Some tables allow filtering based on regular expressions.

Administrators with read and write access can define filters. Multiple filters can be applied at one time.

To manually create a filter:

1. Click *Add Filter* at the top of the table. A list of the fields available for filtering is shown.
2. Select the field to filter by.
3. Enter the value to filter by, adding modifiers as needed.
4. Press *Enter* to apply the filter.

To create a column filter:

1. Click the filter icon on the right side of the column header
2. Choose a filter type from the available options.
3. Enter the filter text, or select from the available values.
4. Click *Apply*.

To create a filter based on a cell's content:

1. Right click on a cell in the table.
2. Select a filtering option from the menu.

Column settings

Columns can be rearranged, resized, and added or removed from tables.

To add or remove columns:

1. Right a column header, or click the gear icon on the left side of the header row that appears when hovering the cursor over the headers.
2. Select columns to add or remove.
3. Click *Apply*.

To rearrange the columns in a table:

1. Click and drag the column header.

To resize a column:

1. Click and drag the right border of the column header.

To resize a column to fit its contents:

1. Click the dots or filter icon on the right side of the column header and select *Resize to Contents*.

To resize all of the columns in a table to fit their content:

1. Right a column header, or click the gear icon on the left side of the header row that appears when hovering the cursor over the headers.
2. Click *Best Fit All Columns*.

To reset a table to its default view:

1. Right a column header, or click the gear icon on the left side of the header row that appears when hovering the cursor over the headers.
2. Click *Reset Table*.
   Resetting a table does not remove filters.

Editing objects

In some tables, parts of a configuration can be edited directly in the table. For example, security profiles can be added to an existing firewall policy by clicking the edit icon in a cell in the *Security Profiles* column.

Copying rows

In some tables, rows can be copied and pasted using the right-click menu. For example, a policy can be duplicated by copying and pasting it.

Entering values

Numerous fields in the GUI and CLI require text strings or numbers to be entered when configuring the FortiGate. When entering values in the GUI, you will be prevented from entering invalid characters, and a warning message will be shown explaining what values are not allowed. If invalid values are entered in a CLI command, the setting will be rejected when you apply it.

- Text strings on page 29
- Numbers on page 30

Text strings

Text strings are used to name entities in the FortiGate configuration. For example, the name of a firewall address, administrator, or interface are all text strings.

The following characters cannot be used in text strings, as they present cross-site scripting (XSS) vulnerabilities:

- " - double quotes
- ' - single quote
- > - greater than
- < - less than

Most GUI text fields prevent XSS vulnerable characters from being added.

VDOM names and hostnames can only use numbers (0-9), letters (a-z and A-Z), dashes, and underscores.

The `tree` CLI command can be used to view the number of characters allowed in a name field. For example, entering the following commands show that a firewall address name can contain up to 80 characters, while its FQDN can contain 256 characters:

```
tree firewall address
-- [address] --*name    (80)
             |- uuid
             |- subnet
             |- type
             |- sub-type
             |- clearpass-spt
             |- [macaddr] --*macaddr    (128)
             |- start-ip
             |- end-ip
             |- fqdn    (256)
             |- country         (3)
             |- wildcard-fqdn   (256)
             |- cache-ttl       (0,86400)
             |- wildcard
             |- sdn     (36)
             |- [fsso-group] --*name    (512)
             |- interface       (36)
             |- tenant  (36)
             |- organization    (36)
             |- epg-name        (256)
             |- subnet-name     (256)
             |- sdn-tag         (16)
             |- policy-group    (16)
             |- obj-tag         (256)
             |- obj-type
             |- tag-detection-level     (16)
             |- tag-type        (64)
             |- dirty
             |- comment
             |- associated-interface    (36)
             |- color   (0,32)
             |- filter
             |- sdn-addr-type
             |- node-ip-only
             |- obj-id
             |- [list] --*ip    (36)
                       |- obj-id        (128)
                       +- net-id        (128)
             |- [tagging] --*name       (64)
                          |- category   (64)
                          +- [tags] --*name     (80)
             |- allow-routing
             +- fabric-object
```

Numbers

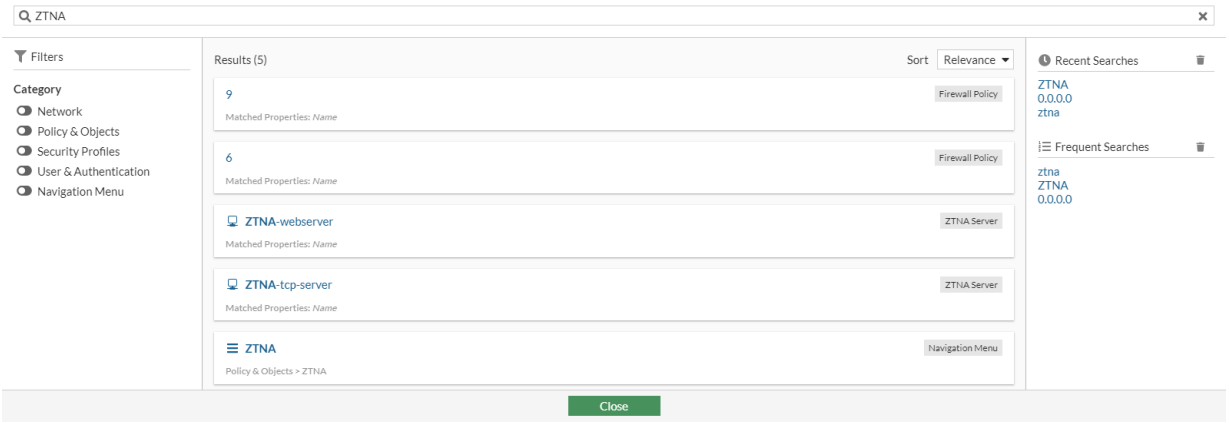
Numbers are used to set sizes, rated, addresses, port numbers, priorities, and other such numeric values. They can be entered as a series of digits (without commas or spaces), in a dotted decimal format (such as IP addresses), or separated by colons (such as MAC addresses). Most numeric values use base 10 numbers, while some use hexadecimal values.

Most GUI and CLI fields prevent invalid numbers from being entered. The CLI help text includes information about the range of values allowed for applicable settings.

GUI-based global search

The global search option in the GUI allows users to search for keywords appearing in objects and navigation menus to quickly access the object and configuration page. Click the magnifying glass icon in the top-left corner of the banner to access the global search.

The global search includes the following features:

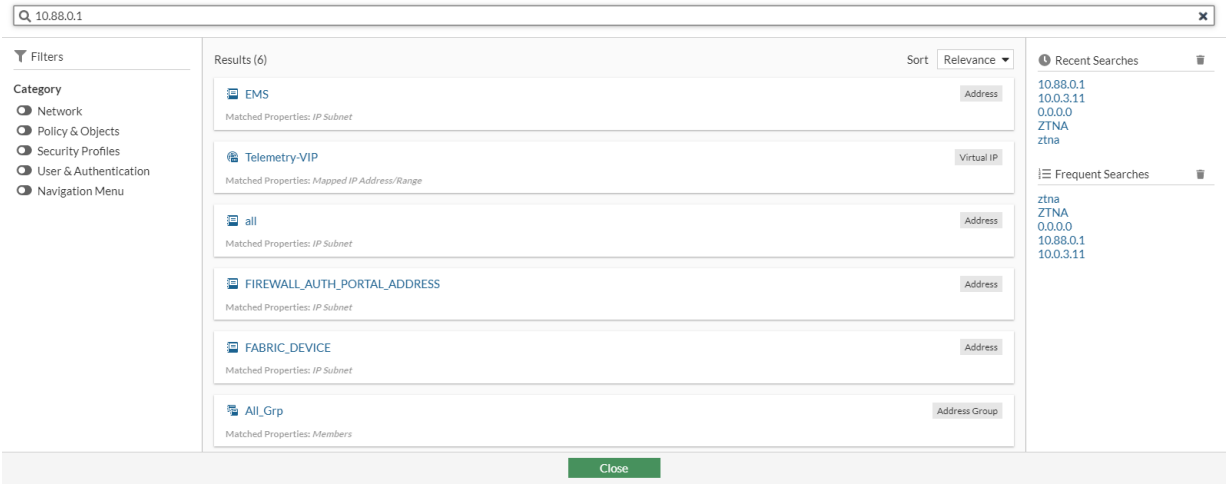


- Keep a history of frequent and recent searches
- Sort results alphabetically by increasing or decreasing order, and relevance by search weight
- Search by category
- Search in Security Fabric members (accessed by the Security Fabric members dropdown menu in the banner)

Examples

In this example, searching for the word *ZTNA* yields the following results:

- Firewall policy object *9*, which contains ZTNA in the property value, *Name*. The name of the policy is ZTNA-TCP.
- ZTNA server object *ZTNA-webserver*, which contains ZTNA in the property value, *Name*.
- ZTNA navigation menu item under *Policy & Objects* > *ZTNA*.



Since CMDB objects have a higher search weight (50) than navigation objects (20), the navigation menu result appears at the bottom.

In this example, searching for the address *10.88.0.1* yields the following results:

- Address object *EMS* that has a subnet of 10.88.0.1/32, which matches the search term.
- Virtual IP object *Telemetry-VIP* that has a mapped IP range of 10.88.0.1, which matches the search term.
- Address objects *all*, *FIREWALL_AUTH_PORTAL_ADDRESS*, and *FABRIC_DEVICE* that have IP subnets of 0.0.0.0/0, which the searched term falls into.
- Address group object *All_Grp* that contains members addresses that have IP subnets of 0.0.0.0/0, which the searched term falls into.

Sorting by *Relevance* will display address objects that are more closely matched at the top (10.88.0.1), and more loosely matched at the bottom (0.0.0.0).

Loading artifacts from a CDN

To improve GUI performance, loading static GUI artifacts cached in CDN (content delivery network) servers closer to the user instead of the FortiGate can be enabled. This allows the GUI to load more quickly with less latency for administrators who are accessing the FortiGate remotely. Upon failure, the files fall back to loading from the FortiGate. The CDN is only used after successful administrator logins.

To configure loading static GUI files from a CDN:

```
config system global
    set gui-cdn-usage {enable | disable}
end
```

Using the CLI

The Command Line Interface (CLI) can be used in lieu of the GUI to configure the FortiGate. Some settings are not available in the GUI, and can only be accessed using the CLI.

This section briefly explains basic CLI usage. For more information about the CLI, see the FortiOS CLI Reference.

- Connecting to the CLI on page 32
- CLI basics on page 35
- Command syntax on page 41
- Subcommands on page 44
- Permissions on page 46

Connecting to the CLI

You can connect to the CLI using a direct console connection, SSH, the FortiExplorer app on your iOS device, or the CLI console in the GUI.

You can access the CLI outside of the GUI in three ways:

- Console connection: Connect your computer directly to the console port of your FortiGate.
- SSH access: Connect your computer through any network interface attached to one of the network ports on your FortiGate.
- FortiExplorer: Connect your device to the FortiExplorer app on your iOS device to configure, manage, and monitor your FortiGate. See FortiExplorer management on page 46 for details.

To open a CLI console, click the _> icon in the top right corner of the GUI. The console opens on top of the GUI. It can be minimized and multiple consoles can be opened.

To edit policies and objects directly in the CLI, right-click on the element and select *Edit in CLI*.

Console connection

A direct console connection to the CLI is created by directly connecting your management computer or console to the FortiGate using its DB-9 or RJ-45 console port.

Direct console access to the FortiGate may be required if:

- You are installing the FortiGate for the first time and it is not configured to connect to your network.
- You are restoring the firmware using a boot interrupt. Network access to the CLI will not be available until after the boot process has completed, making direct console access the only option.

To connect to the FortiGate console, you need:

- A console cable to connect the console port on the FortiGate to a communications port on the computer. Depending on your device, this is one of:
  - null modem cable (DB-9 to DB-9)
  - DB-9 to RJ-45 cable (a DB-9-to-USB adapter can be used)
  - USB to RJ-45 cable
- A computer with an available communications port
- Terminal emulation software

To connect to the CLI using a direct console connection:

1. Using the console cable, connect the FortiGate unit's console port to the serial communications (COM) port on your management computer.
2. Start a terminal emulation program on the management computer, select the COM port, and use the following settings:

Bits per second	9600
Data bits	8
Parity	None
Stop bits	1
Flow control	None

3. Press *Enter* on the keyboard to connect to the CLI.
4. Log in to the CLI using your username and password (default: *admin* and no password).
   You can now enter CLI commands, including configuring access to the CLI through SSH.

SSH access

SSH access to the CLI is accomplished by connecting your computer to the FortiGate using one of its network ports. You can either connect directly, using a peer connection between the two, or through any intermediary network.

If you do not want to use an SSH client and you have access to the GUI, you can access the CLI through the network using the CLI console in the GUI.

SSH must be enabled on the network interface that is associated with the physical network port that is used.

If your computer is not connected either directly or through a switch to the FortiGate, you must also configure the FortiGate with a static route to a router that can forward packets from the FortiGate to the computer. This can be done using a local console connection, or in the GUI.

To connect to the FortiGate CLI using SSH, you need:

- A computer with an available serial communications (COM) port and RJ-45 port
- An appropriate console cable
- Terminal emulation software
- A network cable
- Prior configuration of the operating mode, network interface, and static route.

To enable SSH access to the CLI using a local console connection:

1. Using the network cable, connect the FortiGate unit's port either directly to your computer's network port, or to a network through which your computer can reach the FortiGate.
2. Note the number of the physical network port.
3. Using direct console connection, connect and log into the CLI.
4. Enter the following command:

```
config system interface
    edit <interface_str>
        append allowaccess ssh
    next
end
```

   Where `<interface_str>` is the name of the network interface associated with the physical network port, such as `port1`.
5. Confirm the configuration using the following command to show the interface's settings:

```
show system interface <interface_str>
```

   For example:

```
show system interface port1
    config system interface
        edit "port1"
            set vdom "root"
            set ip 192.168.1.99 255.255.255.0
            set allowaccess ping https ssh
            set type hard-switch
            set stp enable
            set role lan
```

```
            set snmp-index 6
        next
    end
```

Connecting using SSH

Once the FortiGate is configured to accept SSH connections, use an SSH client on your management computer to connect to the CLI.

The following instructions use PuTTy. The steps may vary in other terminal emulators.

To connect to the CLI using SSH:

1. On your management computer, start PuTTy.
2. In the *Host Name (or IP address)* field, enter the IP address of the network interface that you are connected to and that has SSH access enabled.
3. Set the port number to 22, if it is not set automatically.
4. Select *SSH* for the *Connection type*.
5. Click *Open*. The SSH client connect to the FortiGate.
   The SSH client may display a warning if this is the first time that you are connecting to the FortiGate and its SSH key is not yet recognized by the SSH client, or if you previously connected to the FortiGate using a different IP address or SSH key. This is normal if the management computer is connected directly to the FortiGate with no network hosts in between.
6. Click *Yes* to accept the FortiGate's SSH key.
   The CLI displays the log in prompt.
7. Enter a valid administrator account name, such as `admin`, then press *Enter*.
8. Enter the administrator account password, then press *Enter*.
   The CLI console shows the command prompt (FortiGate hostname followed by a `#`). You can now enter CLI commands.

If three incorrect log in or password attempts occur in a row, you will be disconnected. If this occurs, wait for one minute, then reconnect and attempt to log in again.

CLI basics

Basic features and characteristics of the CLI environment provide support and ease of use for many CLI tasks.

Help

Press the question mark (?) key to display command help and complete commands.

- Press the question mark (?) key at the command prompt to display a list of the commands available and a description of each command.
- Enter a command followed by a space and press the question mark (?) key to display a list of the options available for that command and a description of each option.
- Enter a command followed by an option and press the question mark (?) key to display a list of additional options available for that command option combination and a description of each option.

- Enter a question mark after entering a portion of a command to see a list of valid complete commands and their descriptions. If there is only one valid command, it will be automatically filled in.

Shortcuts and key commands

Shortcut key	Action
?	List valid complete or subsequent commands. If multiple commands can complete the command, they are listed with their descriptions.
Tab	Complete the word with the next available match. Press multiple times to cycle through available matches.
Up arrow or Ctrl + P	Recall the previous command. Command memory is limited to the current session.
Down arrow, or Ctrl + N	Recall the next command.
Left or Right arrow	Move the cursor left or right within the command line.
Ctrl + A	Move the cursor to the beginning of the command line.
Ctrl + E	Move the cursor to the end of the command line.
Ctrl + B	Move the cursor backwards one word.
Ctrl + F	Move the cursor forwards one word.
Ctrl + D	Delete the current character.
Ctrl + C	Abort current interactive commands, such as when entering multiple lines. If you are not currently within an interactive command such as `config` or `edit`, this closes the CLI connection.
\ then Enter	Continue typing a command on the next line for a multiline command. For each line that you want to continue, terminate it with a backslash (\ ). To complete the command, enter a space instead of a backslash, and then press *Enter*.

Command tree

Enter `tree` to display the CLI command tree. To capture the full output, connect to your device using a terminal emulation program and capture the output to a log file. For some commands, use the `tree` command to view all available variables and subcommands.

Command abbreviation

You can abbreviate words in the command line to their smallest number of non-ambiguous characters.

For example, the command `get system status` could be abbreviated to `g sy stat`.

Adding and removing options from lists

When configuring a list, the `set` command will remove the previous configuration.

For example, if a user group currently includes members A, B, and C, the command `set member D` will remove members A, B, and C. To avoid removing the existing members from the group, the command `set members A B C D` must be used.

To avoid this issue, the following commands are available:

append	Add an option to an existing list. For example, `append member D` adds user D to the user group without removing any of the existing members.
select	Clear all of the options except for those specified. For example, `select member B` removes all member from the group except for member B.
unselect	Remove an option from an existing list. For example, `unselect member C` removes only member C from the group, without affecting the other members.

Environment variables

The following environment variables are support by the CLI. Variable names are case-sensitive.

$USERFROM	The management access type (`ssh`, `jsconsole`, and so on) and the IPv4 address of the administrator that configured the item.
$USERNAME	The account name of the administrator that configured the item.
$SerialNum	The serial number of the FortiGate.

For example, to set a FortiGate device's host name to its serial number, use the following CLI command:

```
config system global
    set hostname $SerialNum
end
```

Special characters

The following characters cannot be used in most CLI commands: `<`, `>`, `(`, `)`, `#`, `'`, and `"`

If one of those characters, or a space, needs to be entered as part of a string, it can be entered by using a special command, enclosing the entire string in quotes, or preceding it with an escape character (backslash, \).

To enter a question mark (`?`) or a tab, *Ctrl* + *V* or *Ctrl* + *Shift* + - must be entered first.

Question marks and tabs cannot be copied into the CLI Console or some SSH clients. They must be typed in.

Character	Keys
?	Ctrl + V or Ctrl + Shift + - then ?
Tab	Ctrl + V then Tab
Space (as part of a string value, not to end the string)	Enclose the string in single or double quotation marks: "`Security Administrator`" or '`Security Administrator`'. Precede the space with a backslash: `Security\ Administrator`.
' (as part of a string value, not to begin or end the string)	\'
" (as part of a string value, not to begin or end the string)	\"
\	\\

Using grep to filter command output

The `get`, `show`, and `diagnose` commands can produce large amounts of output. The `grep` command can be used to filter the output so that it only shows the required information.

The grep command is based on the standard UNIX grep, used for searching text output based on regular expressions.

For example, the following command displays the MAC address of the internal interface:

```
get hardware nic internal | grep Current_HWaddr
    Current_HWaddr        00:09:0f:cb:c2:75
```

The following command will display all TCP sessions that are in the session list, including the session list line number in the output:

```
get system session list | grep -n tcp
```

The following command will display all of the lines in the HTTP replacement message that contain `URL` or `url`:

```
show system replacemsg http | grep -i url
```

The following options can also be used:

```
-A <num> After
-B <num> Before
-C <num> Context
```

The `-f` option is available to support contextual output, in order to show the complete configuration. The following example shows the difference in the output when `-f` is used versus when it is not used:

Without `-f`:

```
show | grep ldap-group1
    edit "ldap-group1"
        set groups "ldap-group1"
```

With `-f`:

```
show | grep -f ldap-group1
    config user group
        edit "ldap-group1"
```

```
            set member "pc40-LDAP"
        next
    end
    config firewall policy
        edit 2
            set srcintf "port31"
            set dstintf "port32"
            set srcaddr "all"
            set action accept
            set identity-based enable
            set nat enable
            config identity-based-policy
                edit 1
                    set schedule "always"
                    set groups "ldap-group1"
                    set dstaddr "all"
                    set service "ALL"
                next
            end
        next
    end
```

Language support and regular expressions

Characters such as ñ and é, symbols, and ideographs are sometimes acceptable input. Support varies depending on the type of item that is being configured. CLI commands, objects, field names, and options must use their exact ASCII characters, but some items with arbitrary names or values can be input using your language of choice. To use other languages in those cases, the correct encoding must be used.

Input is stored using Unicode UTF-8 encoding, but is not normalized from other encodings into UTF-8 before it is stored. If your input method encodes some characters differently than in UTF-8, configured items may not display or operate as expected.

Regular expressions are especially impacted. Matching uses the UTF-8 character values. If you enter a regular expression using a different encoding, or if an HTTP client sends a request in a different encoding, matches may not be what is expected.

For example, with Shift-JIS, backslashes could be inadvertently interpreted as the symbol for the Japanese yen (¥), and vice versa. A regular expression intended to match HTTP requests containing monetary values with a yen symbol may not work it if the symbol is entered using the wrong encoding.

For best results:

- use UTF-8 encoding, or
- use only characters whose numerically encoded values are the same in UTF-8, such as the US-ASCII characters that are encoded using the same values in ISO 8859-1, Windows code page 1252, Shift-JIS, and other encoding methods, or
- for regular expressions that must match HTTP requests, use the same encoding as your HTTP clients.

HTTP clients may send requests in encodings other than UTF-8. Encodings usually vary based on the client's operating system or input language. If the client's encoding method cannot be predicted, you might only be able to match the parts of the request that are in English, as the values for English characters tend to be encoded identically, regardless of the encoding method.

If the FortiGate is configured to use an encoding method other than UTF-8, the management computer's language may need to be changed, including the web browse and terminal emulator. If the FortiGate is configured using non-ASCII characters, all the systems that interact with the FortiGate must also support the same encoding method. If possible, the same encoding method should be used throughout the configuration to avoid needing to change the language settings on the management computer.

The GUI and CLI client normally interpret output as encoded using UTF-8. If they do not, configured items may not display correctly. Exceptions include items such as regular expression that may be configured using other encodings to match the encoding of HTTP requests that the FortiGate receives.

To enter non-ASCII characters in a terminal emulator:

1. On the management computer, start the terminal client.
2. Configure the client to send and receive characters using UTF-8 encoding.
   Support for sending and receiving international characters varies by terminal client.
3. Log in to the FortiGate.
4. At the command prompt, type your command and press *Enter*.
   Words that use encoded characters may need to be enclosed in single quotes (').
   Depending on your terminal client's language support, you may need to interpret the characters into character codes before pressing *Enter*. For example, you might need to enter: `edit '\743\601\613\743\601\652'`
5. The CLI displays the command and its output.

Screen paging

By default, the CLI will pause after displaying each page worth of text when a command has multiple pages of output. this can be useful when viewing lengthy outputs that might exceed the buffer of terminal emulator.

When the display pauses and shows `--More--`, you can:

- Press *Enter* to show the next line,
- Press *Q* to stop showing results and return to the command prompt,
- Press an arrow key, *Insert*, *Home*, *Delete*, *End*, *Page Up*, or *Page Down* to show the next few pages,
- Press any other key to show the next page, or
- Wait for about 30 seconds for the console to truncate the output and return to the command prompt.

When pausing the screen is disabled, press *Ctrl* + *C* to stop the output and log out of the FortiGate.

To disable pausing the CLI output:

```
config system console
    set output standard
end
```

To enable pausing the CLI output:

```
config system console
    set output more
end
```

Changing the baud rate

The baud rate of the local console connection can be changed from its default value of 9600.

To change the baud rate:

```
config system console
    set baudrate {9600 | 19200 | 38400 | 57600 | 115200}
end
```

Editing the configuration file

The FortiGate configuration file can be edited on an external host by backing up the configuration, editing the configuration file, and then restoring the configuration to the FortiGate.

Editing the configuration file can save time is many changes need to be made, particularly if the plain text editor that you are using provides features such as batch changes.

To edit the configuration file:

1. Backup the configuration. See Configuration backups on page 68 for details.
2. Open the configuration file in a plain text editor that supports UNIX-style line endings.
3. Edit the file as needed.

Do not edit the first line of the configuration file.

This line contains information about the firmware version and FortiGate model. If you change the model number, the FortiGate will reject the configuration when you attempt to restore it.

4. Restore the modified configuration to the FortiGate. See Configuration backups on page 68 for details.
The FortiGate downloads the configuration file and checks that the model information is correct. If it is correct, the configuration file is loaded and each line is checked for errors. If a command is invalid, that command is ignored. If the configuration file is valid, the FortiGate restarts and loads the downloaded configuration.

Command syntax

When entering a command, the CLI console requires that you use valid syntax and conform to expected input constraints. It rejects invalid commands. Indentation is used to indicate the levels of nested commands.

Each command line consists of a command word, usually followed by configuration data or a specific item that the command uses or affects.

Notation

Brackets, vertical bars, and spaces are used to denote valid syntax. Constraint notations, such as `<address_ipv4>`, indicate which data types or string patterns are acceptable value input.

All syntax uses the following conventions:

Angle brackets < >	Indicate a variable of the specified data type.
Curly brackets { }	Indicate that a variable or variables are mandatory.
Square brackets [ ]	Indicate that the variable or variables are optional. For example: `show system interface [<name_str>]` To show the settings for all interfaces, you can enter `show system interface` To show the settings for the Port1 interface, you can enter `show system interface port1`.
Vertical bar |	A vertical bar separates alternative, mutually exclusive options. For example: `set protocol {ftp | sftp}` You can enter either `set protocol ftp` or `set protocol sftp`.

Space	A space separates non-mutually exclusive options.
	For example:
	`set allowaccess {ping https ssh snmp http fgfm radius-acct probe-response capwap ftm}`
	You can enter any of the following:
	`set allowaccess ping`
	`set allowaccess https ping ssh`
	`set allowaccess http https snmp ssh ping`
	In most cases, to make changes to lists that contain options separated by spaces, you need to retype the entire list, including all the options that you want to apply and excluding all the options that you want to remove.

Optional values and ranges

Any field that is optional will use square-brackets. The overall config command will still be valid whether or not the option is configured.

Square-brackets can be used is to show that multiple options can be set, even intermixed with ranges. The following example shows a field that can be set to either a specific value or range, or multiple instances:

```
config firewall service custom
    set iprange <range1> [<range2> <range3> ...]
end
```

next

The `next` command is used to maintain a hierarchy and flow to CLI commands. It is at the same indentation level as the preceding `edit` command, to mark where a table entry finishes.

The following example shows the next command used in the subcommand `entries`:

```
config dlp filepattern
    edit <1>
        set name <name>
        set comment [comment]
        config entries
            edit <2>
                set filter-type {pattern | type}
            next
```

After configuring table entry `<2>` then entering `next`, the `<2>` table entry is saved and the console returns to the `entries` prompt:

```
FGT60E1Q23456789 (entries) #
```

You can now create more table entries as needed, or enter `end` to save the table and return to the `filepattern` table element prompt.

end

The `end` command is used to maintain a hierarchy and flow to CLI commands.

The following example shows the same command and subcommand as the `next` command example, except `end` has been entered instead of `next` after the subcommand:

```
config dlp filepattern
    edit <1>
        set name <name>
        set comment [comment]
        config entries
            edit <2>
                set filter-type {pattern | type}
    end
```

Entering `end` will save the `<2>` table entry and the table, and exit the `entries` subcommand entirely. The console returns to the filepattern table element prompt:

```
FGT60E1Q23456789 (1) #
```

Subcommands

Subcommands are available from within the scope of some commands. When you enter a subcommand level, the command prompt changes to indicate the name of the current command scope. For example, after entering:

```
config system admin
```

the command prompt becomes:

```
(admin)#
```

Applicable subcommands are available until you exit the command, or descend an additional level into another subcommand. Subcommand scope is indicated by indentation.

For example, the `edit` subcommand is only available in commands that affects tables, and the `next` subcommand is available only in the `edit` subcommand:

```
config system interface
   edit port1
      set status up
   next
end
```

The available subcommands vary by command. From a command prompt under the `config` command, subcommands that affect tables and fields could be available.

Table subcommands

edit <table_row>	Create or edit a table value.
	In objects such as security policies, `<table_row>` is a sequence number. To create a new table entry without accidentally editing an existing entry, enter `edit 0`. The CLI will confirm that creation of entry 0, but will assign the next unused number when the entry is saved after entering `end` or `next`.
	For example, to create a new firewall policy, enter the following commands:
	`config firewall policy`
	`edit 0`
	`....`
	`next`
	`end`
	To edit an existing policy, enter the following commands:
	`config firewall policy`
	`edit 27`
	`....`
	`next`
	`end`
	The `edit` subcommand changes the command prompt to the name of the table value that is being edited.

delete <table_row>	Delete a table value.
	For example, to delete firewall policy 30, enter the following commands:
	`config firewall policy`
	`delete 30`
	`end`

purge	Clear all table values. The `purge` command cannot be undone. To restore purged table values, the configuration must be restored from a backup.

move	Move an ordered table value.
	In the firewall policy table, this equivalent to dragging a policy into a new position. It does not change the policy's ID number.
	For example, to move policy 27 to policy 30, enter the following commands:
	`config firewall policy`
	`move 27 to 30`
	`end`
	The `move` subcommand is only available in tables where the order of the table entries matters.

clone <table_row> to <table_row>	Make a clone of a table entry.
	For example, to create firewall policy 30 as a clone of policy 27, enter the following commands:
	`config firewall policy`
	`clone 27 to 30`
	`end`
	The `clone` subcommand may not be available for all tables.

rename <table_row> to <table_row>	Rename a table entry.
	For example to rename an administrator from Flank to Frank, enter the following commands:
	`config system admin`
	`rename Flank to Frank`
	`end`
	The `rename` subcommand is only available in tables where the entries can be renamed.

get	List the current table entries.
	For example, to view the existing firewall policy table entries, enter the following commands:
	`config firewall policy`
	`get`

show	Show the configuration. Only table entries that are not set to default values are shown.
end	Save the configuration and exit the current `config` command.

Purging the `system interface` or `system admin` tables does not reset default table values. This can result in being unable to connect to or log in to the FortiGate, requiring the FortiGate to be formatted and restored.

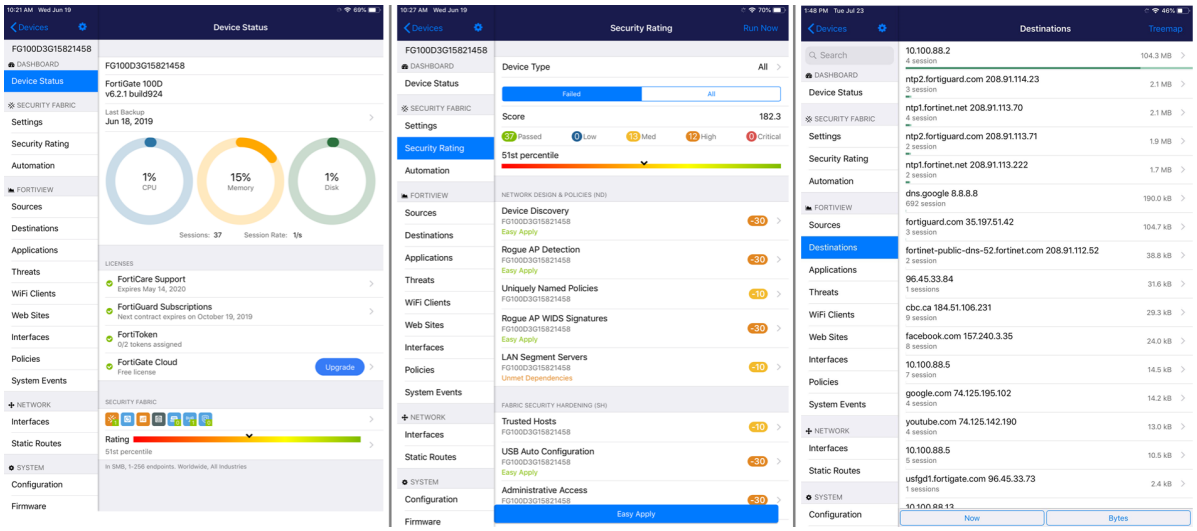
Field subcommands

set <field> <value>	Modify the value of a field.

	For example, the command `set fsso enable` sets the `fsso` field to the value `enable`.
unset	Set the field to its default value.
select	Clear all of the options except for those specified. For example, if a group contains members A, B, C, and D, to remove all members except for B, use the command `select member B`.
unselect	Remove an option from an existing list. For example, if a group contains members A, B, C, and D, to remove only member B, use the command `unselect member B`.
append	Add an option to an existing multi-option table value.
clear	Clear all the options from a multi-option table value.
get	List the configuration of the current table entry, including default and customized values.
show	Show the configuration. Only values that are not set to default values are shown.
next	Save changes to the table entry and exit the `edit` command so that you can configure the next table entry.
abort	Exit the command without saving.
end	Save the configuration and exit the current `config` command.

Permissions

Administrator (or access) profiles control what CLI commands an administrator can access by assigning read, write, or no access to each area of FortiOS. For information, see Administrator profiles on page 2243.



Read access is required to view configurations. Write access is required to make configuration changes. Depending on your account's profile, you may not have access to all CLI commands. To have access to all CLI commands, an administrator account with the *super_admin* profile must be used, such as the *admin* account.

Accounts assigned the *super_admin* profile are similar to the root administrator account. They have full permission to view and change all FortiGate configuration options, including viewing and changing other administrator accounts.

To increase account security, set strong passwords for all administrator accounts, and change the passwords regularly.

FortiExplorer management

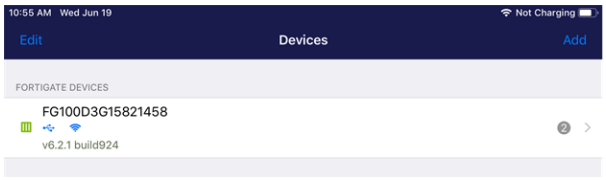
FortiExplorer for iOS is a user-friendly application that helps you to rapidly provision, deploy, and monitor Security Fabric components from your iOS device.

FortiExplorer for iOS requires iOS 10.0 or later and is compatible with iPhone, iPad, and Apple TV. It is supported by FortiOS 5.6 and later, and is available on the App Store for iOS devices.

FortiExplorer is also available for support on Android on the Google Play Store. Steps for configuring FortiExplorer for Android may differ from what is included in the guide.

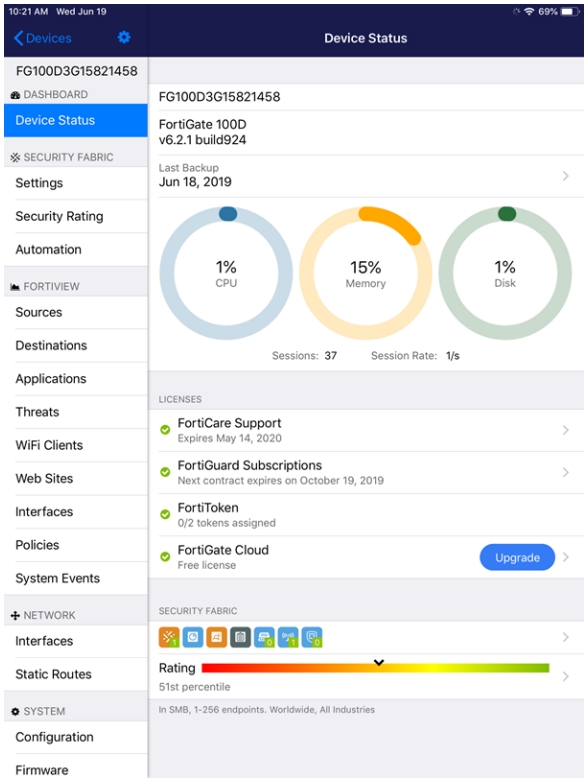
Advanced features are available with the purchase of FortiExplorer Pro. Paid features include the ability to add more than two devices, and firmware upgrades for devices with active licenses.

Up to six members can use this app with 'Family Sharing' enabled in the App Store.



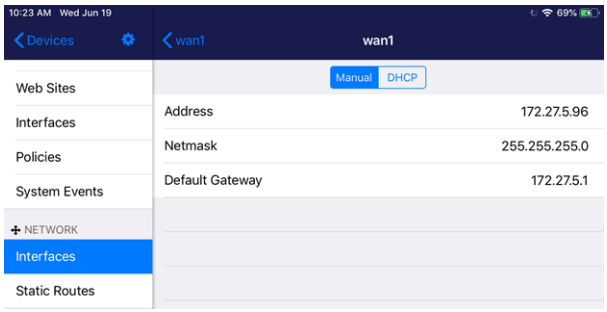
Firmware upload requires a valid firmware license. Users can download firmware for models with a valid support contract.

Getting started with FortiExplorer

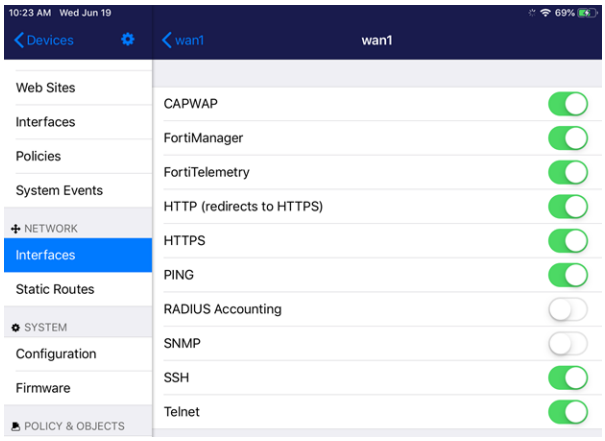


If your FortiGate is accessible on a wireless network, you can connect to it using FortiExplorer provided that your iOS device is on the same network. See Connecting FortiExplorer to a FortiGate with WiFi. If your 200F series or 80F series FortiGate is in close proximity, you can connect to it using FortiExplorer using Bluetooth Low Energy (BLE). See Configure FortiGate with FortiExplorer using BLE on page 51. Otherwise, you will need to physically connect your iOS device to the FortiGate using a USB cable.

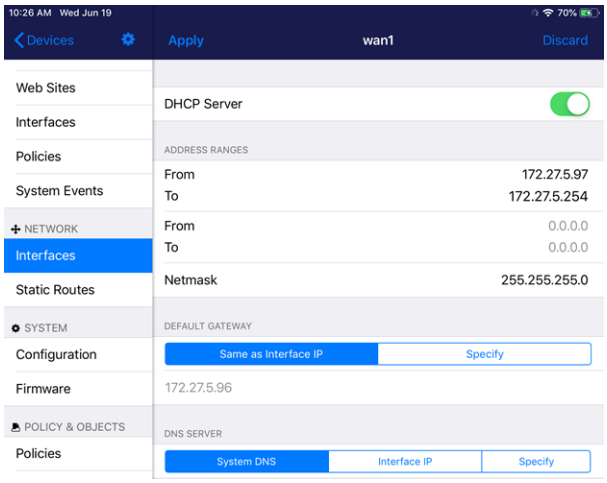
To connect and configure a FortiGate with FortiExplorer using a USB connection:



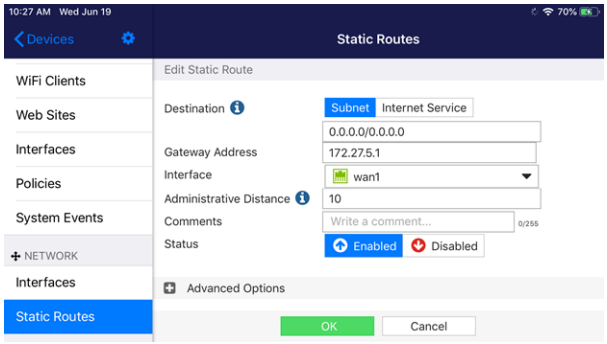
1. Connect your iOS device to your FortiGate USB A port. If prompted on your iOS device, *Trust* this computer.
2. Open FortiExplorer and select your FortiGate from the *FortiGate Devices* list . A blue USB icon will indicate that you are connected over a USB connection.



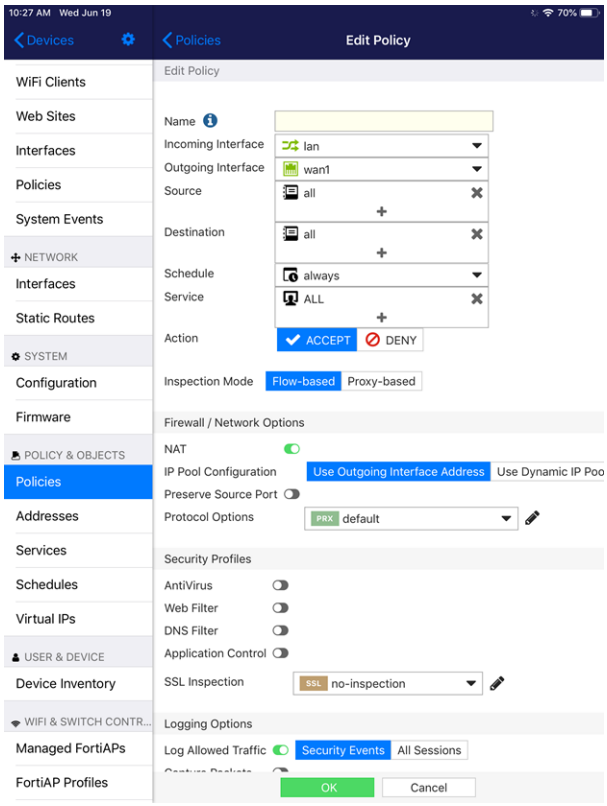
3. On the *Login* screen, select *USB*.
4. Enter the default *Username* (`admin`) and leave the *Password* field blank.
5. Optionally, select *Remember Password*.
6. Tap *Done* when you are ready.
   FortiExplorer opens the FortiGate management interface to the *Device Status* page:



7. Go to *Network* > *Interfaces* and configure the WAN interface or interfaces.
8. The *wan1* interface *Address* mode is set to *DHCP* by default. Set it to *Manual* and enter its *Address*, *Netmask*, and *Default Gateway*, and then *Apply* your changes.



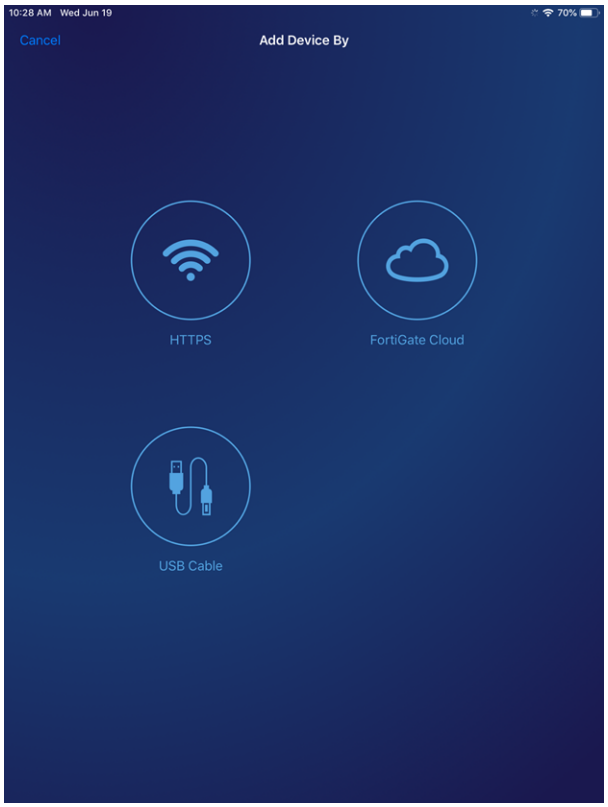
9. Optionally, configure *Administrative Access* to allow *HTTPS* access. This will allow administrators to access the FortiGate GUI using a web browser.



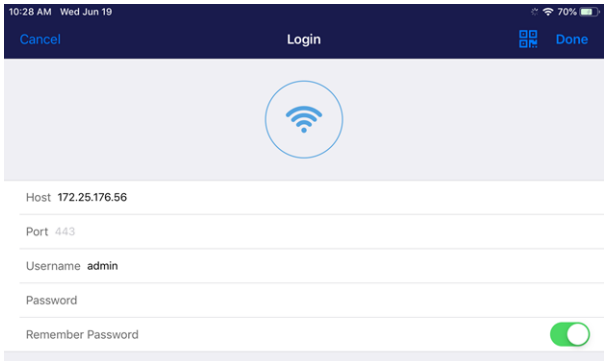
10. Go to *Network* > *Interfaces* and configure the local network (internal) interface.
11. Set the *Address* mode as before and configure *Administrative Access* if required.
12. Configure a *DHCP Server* for the internal network subnet.

13. Return to the internal interface using the < button at the top of the screen.
14. Go to *Network* > *Static Routes* and configure the static route to the gateway.

15. Go to *Policy & Objects* > *Firewall Policy* and edit the Internet access policy. Enter a *Name* for the policy, enable the required *Security Profiles*, configure *Logging Options*, then tap *OK*.



Connecting FortiExplorer to a FortiGate with WiFi



You can wirelessly connect to the FortiGate if your iOS device and the FortiGate are both connected to the same wireless network.

To connect and configure a FortiGate with FortiExplorer wirelessly:

1. Open the FortiExplorer app and tap *Add* on the *Devices* page.
2. On the *Add Device By* page, tap *HTTPS*.

3. Enter the *Host* information, *Username*, and *Password*.
4. If required, change the default *Port* number, and optionally enable *Remember Password*.

5. Tap *Done*.
6. If the FortiGate device identity cannot be verified, tap *Connect* at the prompt.
   FortiExplorer opens the FortiGate management interface to the *Device Status* page.

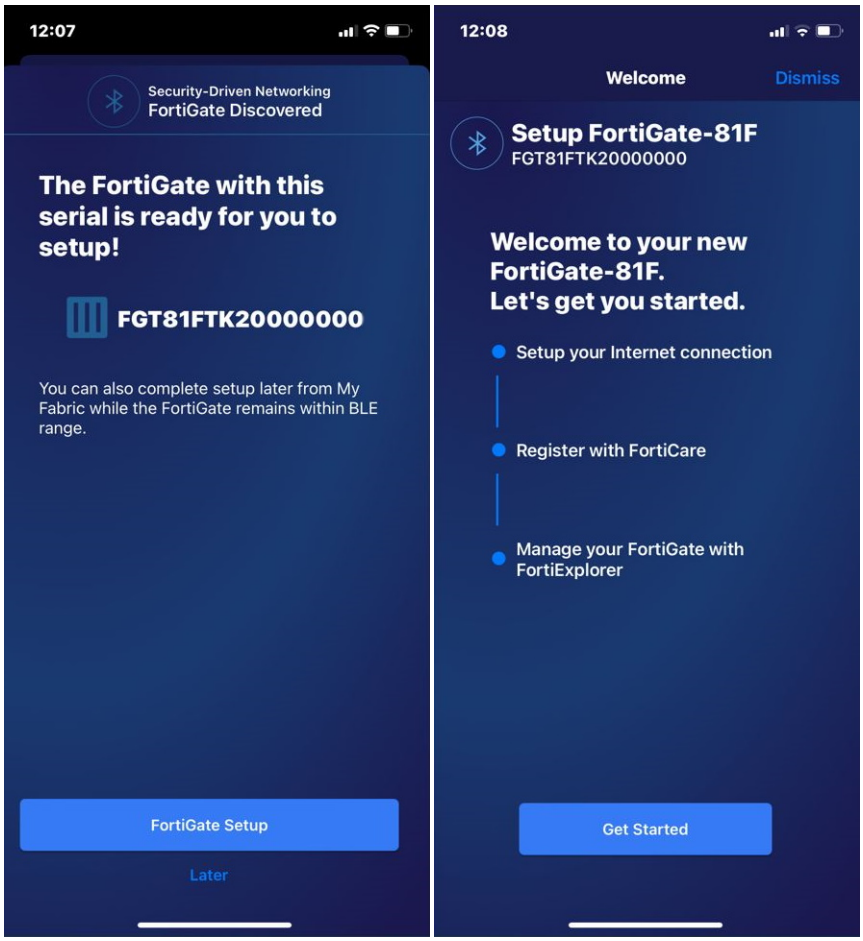
Configure FortiGate with FortiExplorer using BLE

FortiGate 200F series and 80F series devices can be initially configured in FortiExplorer using Bluetooth Low Energy (BLE).

The state of the status LED on the device shows if BLE is enabled. See the device QuickStart guides for more information about LED states: FortiGate 200F Series QuickStart Guide and FortiGate 80F Series QuickStart Guide.

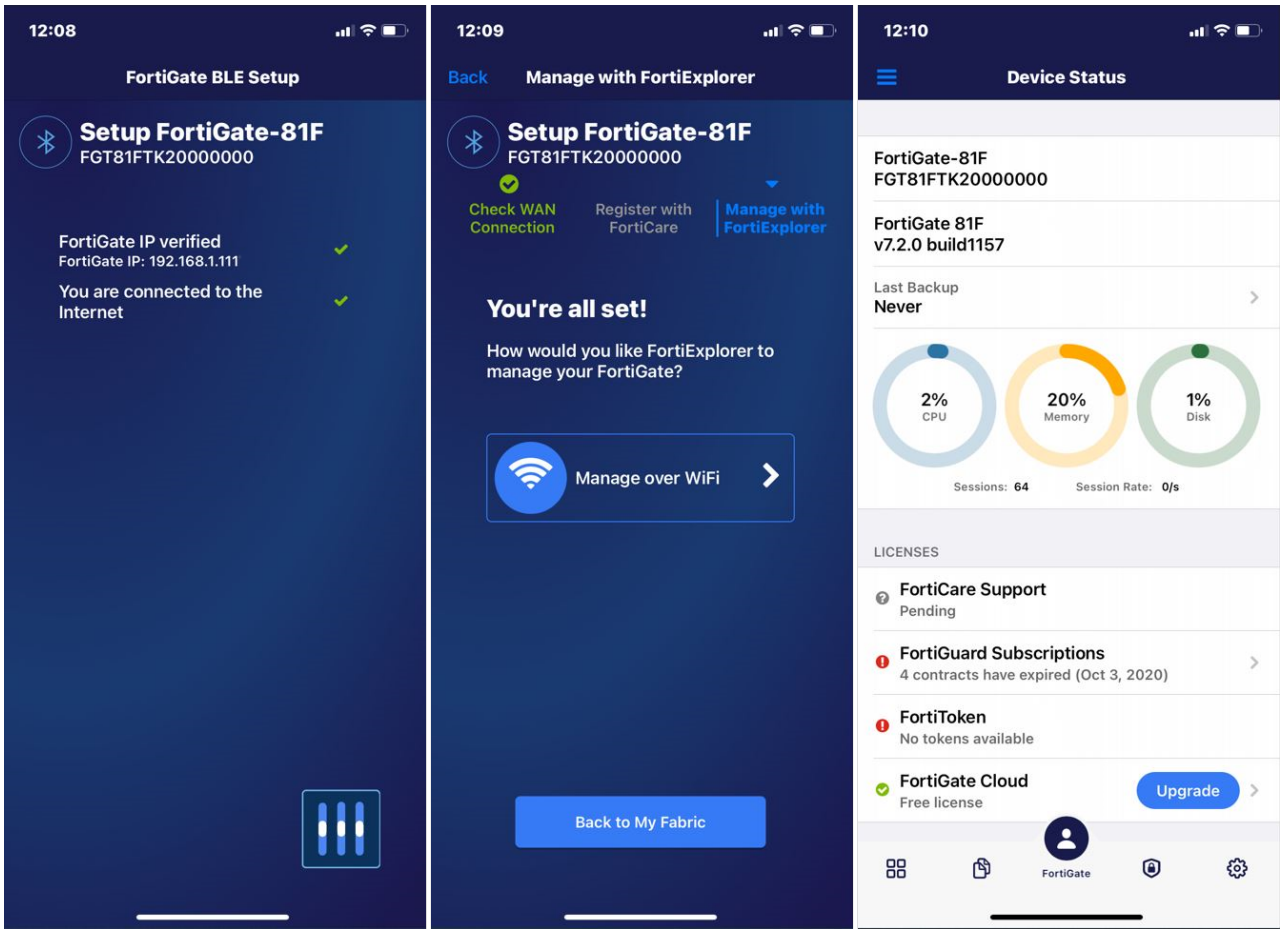
When the status LED is flashing green, pressing and holding the reset button for five seconds or longer will reset the device to factory default settings.

BLE is enabled or disabled in the following scenarios after the FortiGate boots up:



- In factory default settings:
  - After the FortiGate has finished booting up (when the console login prompt is shown), the status LED will be flashing amber or red to indicate that BLE is enabled.
  - If the FortiGate is configured without using BLE, BLE will immediately be disabled and the status LED will turn solid green.
  - If the FortiGate is configured using BLE, the LED will continue flashing until the configuring device disconnects from BLE, after which BLE is disabled and the status LED turns sold green.
- Not in factory default configuration:
  - One minute after the FortiGate has finished booting up (when the console login prompt is shown), the status LED will turn solid green. Press and hold the reset button for one second. The status LED will start flashing to indicate that BLE is enabled.
  - If no BLE connection is made with the FortiGate, BLE will be disabled after one minute and the status LED will turn solid green.
  - If the FortiGate is configured without using BLE, BLE will immediately be disabled and the status LED will turn solid green.
  - If the FortiGate is configured using BLE, the LED will continue flashing until the configuring device disconnects from BLE, after which BLE is disabled and the status LED turns sold green.

To enable BLE for one minute when the FortiGate is running and not in factory default configuration:



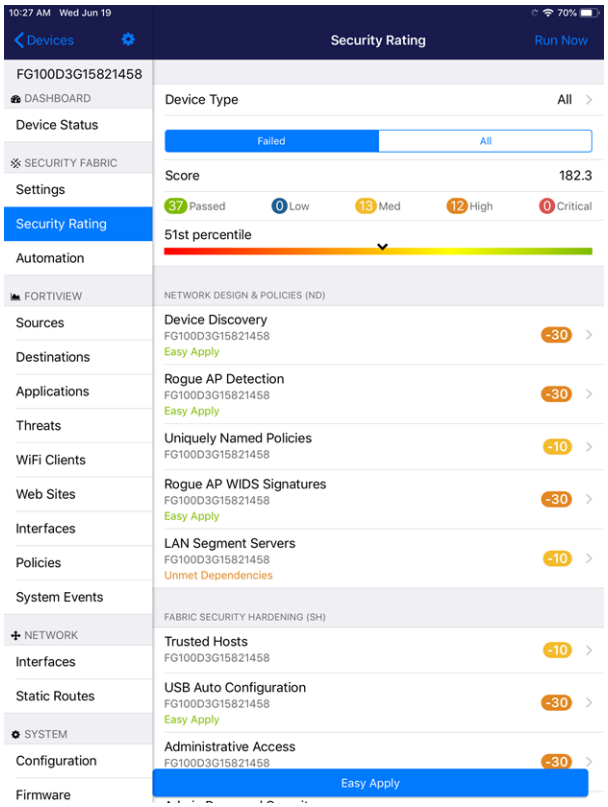
```
# diagnose bluetooth enable 1
```

To connect to and configure a FortiGate with FortiExplorer using BLE:

1. Ensure that BLE is enabled on the FortiGate device.
2. Enable Bluetooth on your iOS device and open the FortiExplorer app.
   If the app has detected the FortiGate device, the device's serial number will be shown.

3. Log into the FortiGate in the app using the default credentials: *admin* and no password.
4. If this is the first time logging into the device, set a password.
5. Optionally, register with FortiCare.
6. Configure the FortiGate, including the WAN and internal interfaces, static routes, and other required settings.

After configuring the FortiGate and disconnecting, BLE is disabled.



To check the status of BLE on the FortiGate:

```
diagnose hardware test ble
diagnose bluetooth status
diagnose bluetooth get_bt_version
diagnose bluetooth clean_bt_mode
```

Running a security rating

After configuring your network, run a security rating check to identify vulnerabilities and highlight best practices that could improve your network's security and performance.

Go to *Security Fabric* > *Security Rating* and follow the steps to determine the score. See Security rating on page 2725 for more information.

Upgrading to FortiExplorer Pro

FortiExplorer Pro allows you to add unlimited devices, and download firmware images for devices with active licenses.

To upgrade to FortiExplorer Pro:

1. In FortiExplorer, go to *Settings*.
2. Tap *Manage Subscription*.
3. Follow the on-screen prompts.

Basic administration

This section contains information about basic FortiGate administration that you can do after you installing the unit in your network.

- Basic configuration on page 56
- Registration on page 58
- FortiCare and FortiGate Cloud login on page 63
- Transfer a device to another FortiCloud account on page 65
- Configuration backups on page 68
- Deregistering a FortiGate on page 76
- Fortinet Developer Network access on page 78

Basic configuration

This topic will help you configure a few basic settings on the FortiGate as described in the Using the GUI on page 25 and Using the CLI on page 32 sections, including:

- Configuring an interface on page 56
- Configuring the hostname on page 56
- Configuring the default route on page 57
- Ensuring internet and FortiGuard connectivity on page 57
- Using the default certificate for HTTPS administrative access on page 57

Configuring an interface

It is unlikely the default interface configuration will be appropriate for your environment and typically requires some effort of the administrator to use these settings, such as being physically near the FortiGate to establish a serial connection. Therefore, the first step is to configure an interface that can be used to complete the FortiGate configuration.

To configure an interface in the GUI:

1. Go to *Network* > *Interfaces*. Select an interface and click *Edit*.
2. Enter an *Alias*.
3. In the *Address* section, enter the *IP/Netmask*.
4. In *Administrative Access* section, select the access options as needed (such as *PING*, *HTTPS*, and *SSH*).
5. Optionally, enable *DHCP Server* and configure as needed.
6. Click *OK*.

To configure an interface in the CLI:

```
config system interface
    edit "port2"
        set ip 203.0.113.99 255.255.255.0
        set allowaccess ping https ssh
        set alias "Management"
    next
end
```

Configuring the hostname

Setting the FortiGate's hostname assists with identifying the device, and it is especially useful when managing multiple FortiGates. Choose a meaningful hostname as it is used in the CLI console, SNMP system name, device name for FortiGate Cloud, and to identify a member of an HA cluster.

To configure the hostname in the GUI:

1. Go to *System* > *Settings*.
2. Enter a name in the *Host name* field.
3. Click *Apply*.

To configure the hostname in the CLI:

```
config system global
    set hostname 200F_YVR
end
```

Configuring the default route

Setting the default route enables basic routing to allow the FortiGate to return traffic to sources that are not directly connected. The gateway address should be your existing router or L3 switch that the FortiGate is connected to. If you are directly connecting to the FortiGate, you may choose your endpoint's IP address as the gateway address. Set the interface to be the interface the gateway is connected to.

To configure the default route in the GUI:

1. Go to *Network* > *Static Routes* and click *Create New*.
2. Leave the destination subnet as *0.0.0.0/0.0.0.0*. This is known as a default route, since it would match any IPv4 address.
3. Enter the *Gateway Address*.
4. Select an *Interface*.
5. Click *OK*.

To configure the default route in the CLI:

```
config router static
    edit 0
        set gateway 192.168.1.254
        set device port1
    next
end
```

Ensuring internet and FortiGuard connectivity

This step is not necessary for the configuration; however, it is necessary in order to keep your FortiGate up to date against the latest threats. Updates are provided to FortiGates that are registered and make a request to the FortiGuard network to verify if there are any more recent definitions.

Use `execute ping <domain.tld>` to ensure the DNS resolution is able to resolve the following FortiGuard servers:

- fds1.fortinet.com
- service.fortiguard.net
- update.fortiguard.net

You also need to ensure the necessary ports are permitted outbound in the event your FortiGate is behind a filtering device. Refer to the Ports and Protocols document for more information.

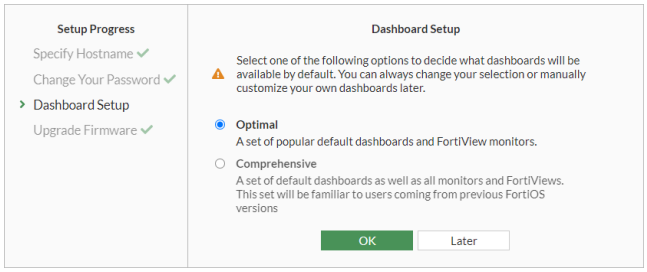
Using the default certificate for HTTPS administrative access

By default, the FortiGate uses the Fortinet_GUI_Server certificate for HTTPS administrative access. Administrators should download the CA certificate and install it on their PC to avoid warnings in their browser. See Using the default

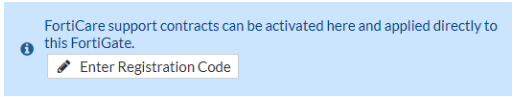
certificate for HTTPS administrative access on page 2297 for more information.

Registration

The FortiGate, and then its service contract, must be registered to have full access to Fortinet Customer Service and Support, and FortiGuard services. The FortiGate can be registered in either the FortiGate GUI or the FortiCloud support portal. The service contract can be registered from the FortiCloud support portal.



The service contract number is needed to complete registrations on the FortiCloud support portal. You can find this 12-digit number in the email that contains your service registration document (sent from do-not-reply-contract@fortinet.com) in the service entitlement summary.

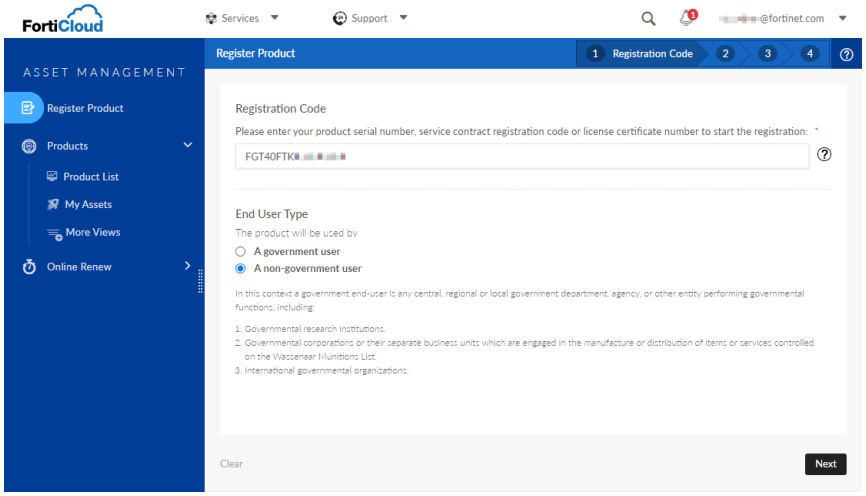


To register your FortiGate in the GUI:

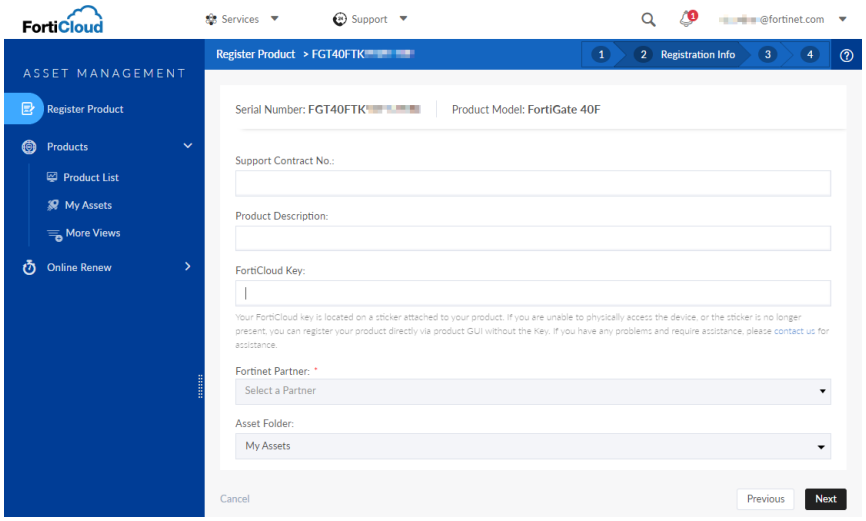
1. Connect to the FortiGate GUI. A dialog box appears, which indicates the steps you should take to complete the setup of your FortiGate. These steps include:
   a. *Specify Hostname*
   b. *Change Your Password*
   c. *Dashboard Setup*
   d. *Upgrade Firmware*

   If you completed the Basic configuration on page 56, the hostname and password steps are already marked as complete (checkmark). If you chose to deploy the latest firmware, the *Upgrade Firmware* step is marked as complete.
2. Click *Begin* to complete the dashboard setup. Two options appear (*Optimal* and *Comprehensive*).

3. Select the desired setting and click *OK*. The *Dashboard* > *Status* page opens. Note that the licenses are grayed out because the device or virtual machine is not registered.
4. Go to *System* > *FortiGuard* and click *Enter Registration Code*.

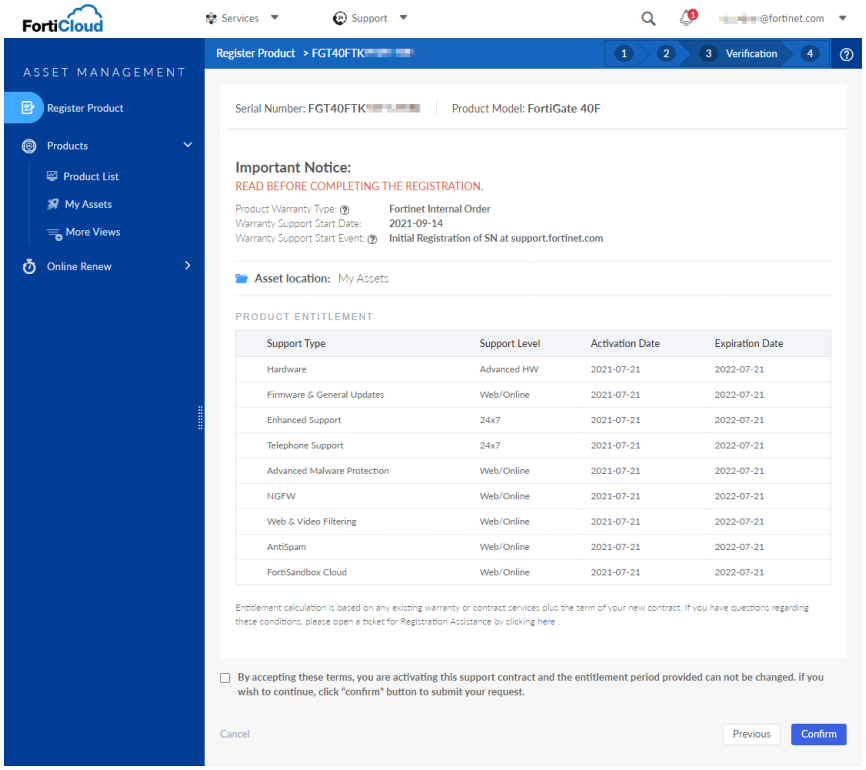


5. Enter the contract registration code from your service registration document.
6. Click *OK*.

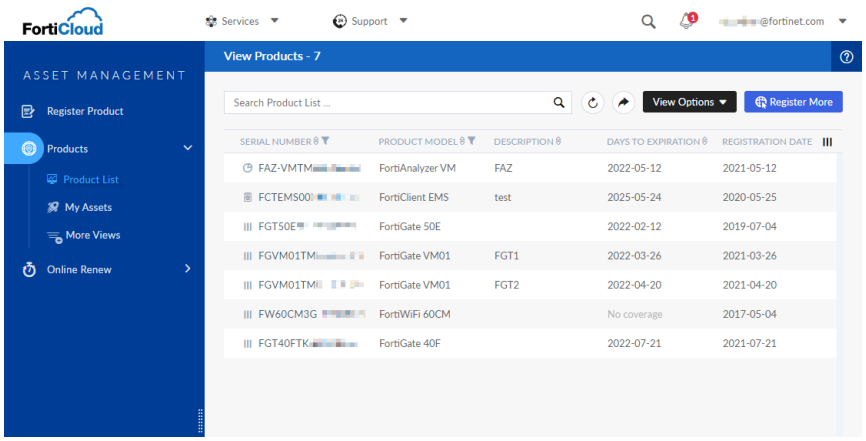


To register the FortiGate on the FortiCloud support portal:

1. Go to support.fortinet.com and log in using your FortiCloud account credentials. If you do not have an account, click *Register* to create one.
2. In the left-side menu, click *Register Product*.



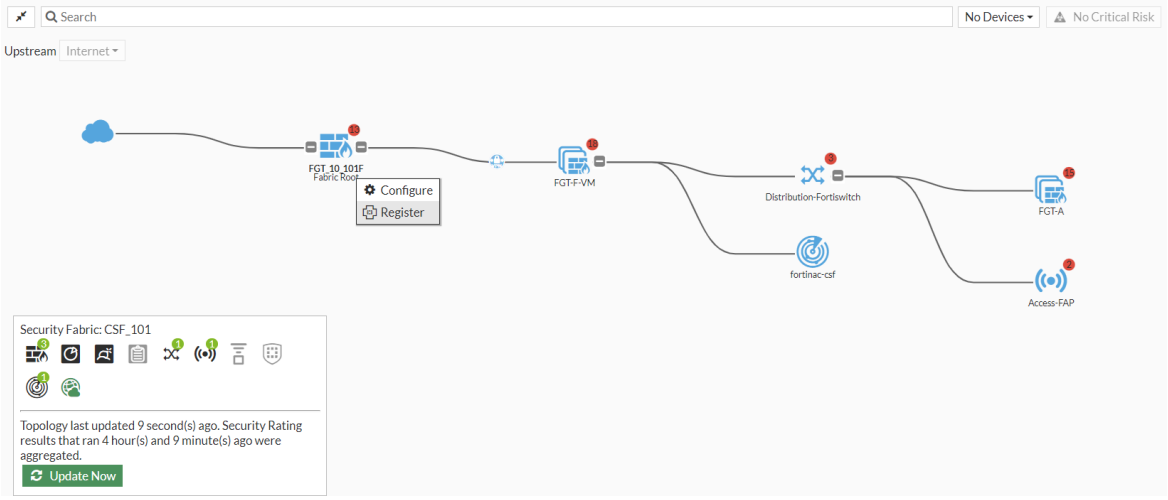
3. Enter the product serial number or license certificate number for a VM, select an end user type, then click *Next*.



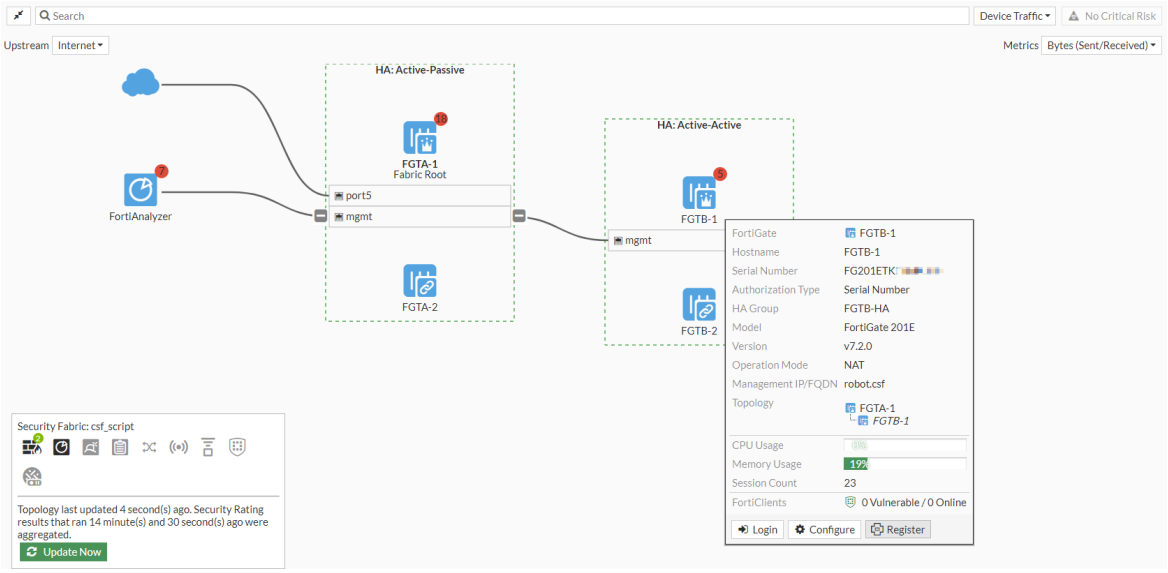
4. Enter the *Support Contract* number and *FortiCloud Key* (optionally, enter a product description), then click *Next*.

5. Review the product entitlement information, select the checkbox to accept the terms, then click *Confirm*.

6. Go to *Products* > *Product List*. The FortiGate is now visible in the product list.

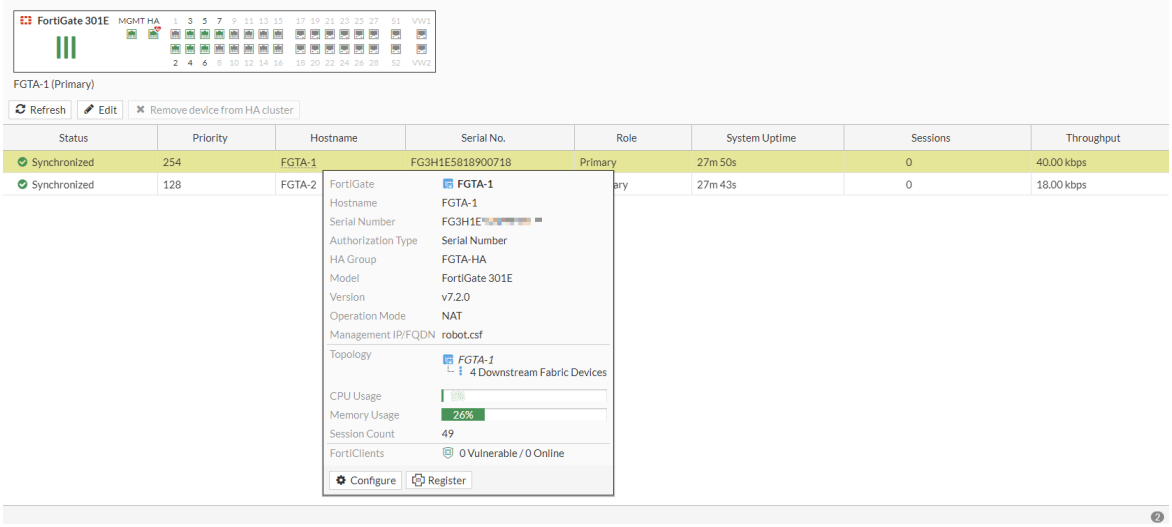


FortiCare Register button



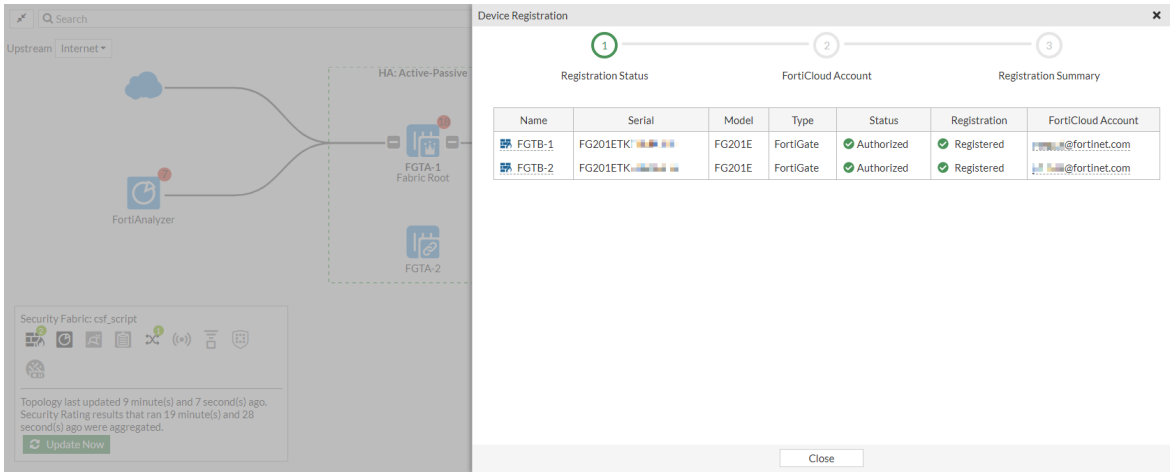
The FortiCare *Register* button is displayed in the GUI on various Fabric and device related pages and widgets available for FortiGates.

There are two methods to access the *Register* button:



- Right-click on a device in a topology.
  Security Fabric > *Physical Topology* page:

- Hover over a device to display the tooltip.
  Security Fabric > *Logical Topology* page:



System > *HA* page:

The *Register* button is also accessible from tooltips for devices on the *Managed FortiAPs* and *Managed FortiSwitches pages*.

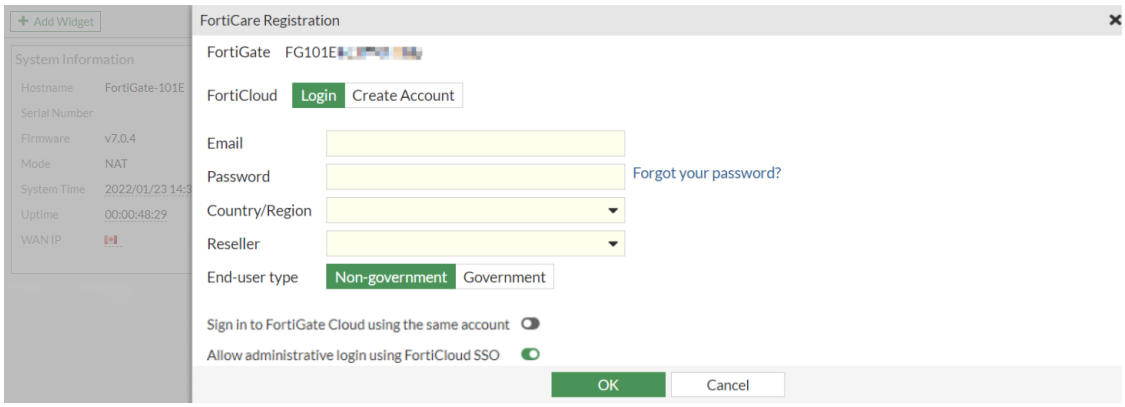
Clicking *Register* opens the *Device Registration* pane. If a device is already registered, the pane still opens and displays the device information.

Primary and secondary HA members can be registered to FortiCare at the same time from the primary unit by using the *Register* button. The secondary unit will register through the HA proxy. In this example, a HA member is registered from the *Physical Topology* page.

To register a HA member to FortiCare:

1. On the primary unit, go to *Security Fabric* > *Physical Topology*.
2. Hover over the HA member and click *Register*. The *Device Registration* pane opens.
3. Select the device and click *Register*.
4. Enter the required FortiCloud account information (password, country or region, reseller) and click *Submit*.
5. Once the registration is complete, click *Close*.

FortiCare and FortiGate Cloud login

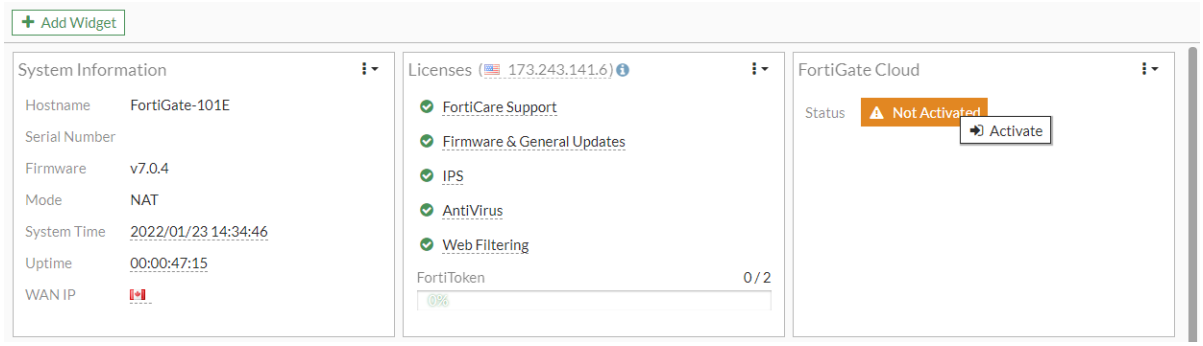


With FortiCloud, FortiOS supports a unified login to FortiCare and FortiGate Cloud. The FortiGate Cloud setup is a subset of the FortiCare setup.

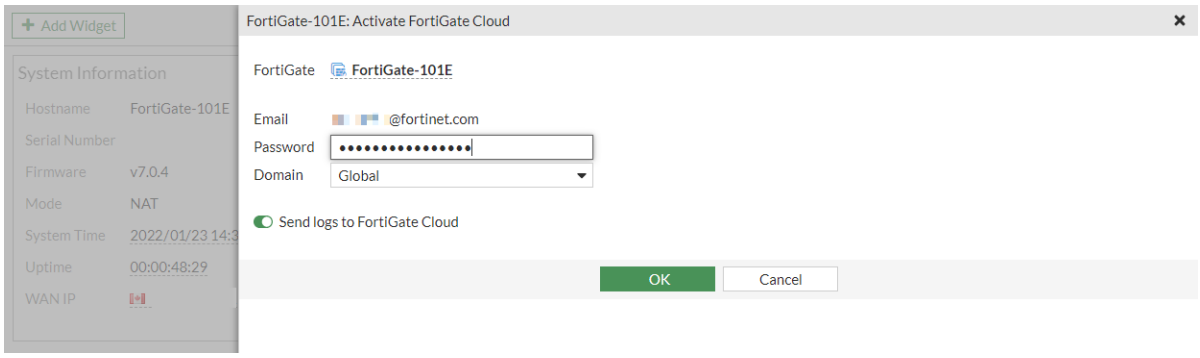
- If the FortiGate is not registered, activating FortiGate Cloud will force you to register with FortiCare.
- If a FortiGate is registered in FortiCare using a FortiCloud account, then only that FortiCloud account can be used to activate FortiGate Cloud.
- If a different FortiCloud account was already used to activate FortiGate Cloud, then a notification asking you to migrate to FortiCloud is shown in the GUI after upgrading FortiOS.

The CLI can be used to activate FortiGate Cloud without registration, or with a different FortiCloud account.

To activate FortiGate Cloud and register with FortiCare at the same time:

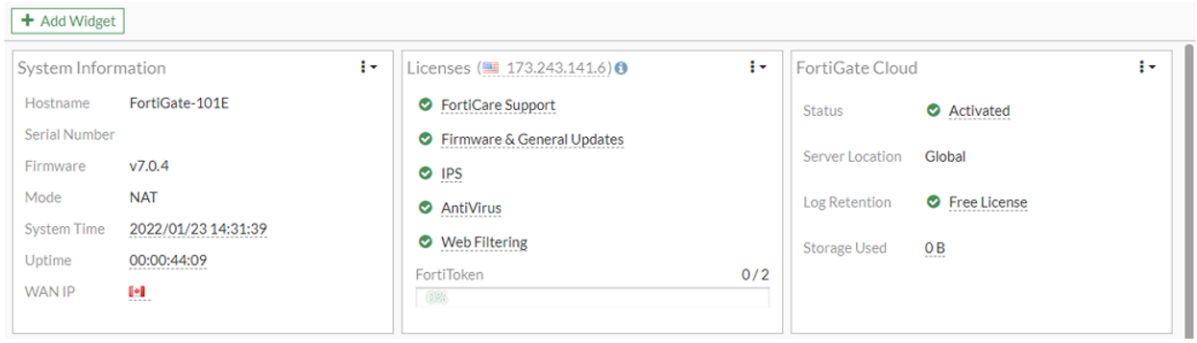


1. Go to *Dashboard* > *Status*.
2. In the FortiGate Cloud widget, click *Not Activated* > *Activate*.
   You must register with FortiCare before activating FortiGate Cloud.



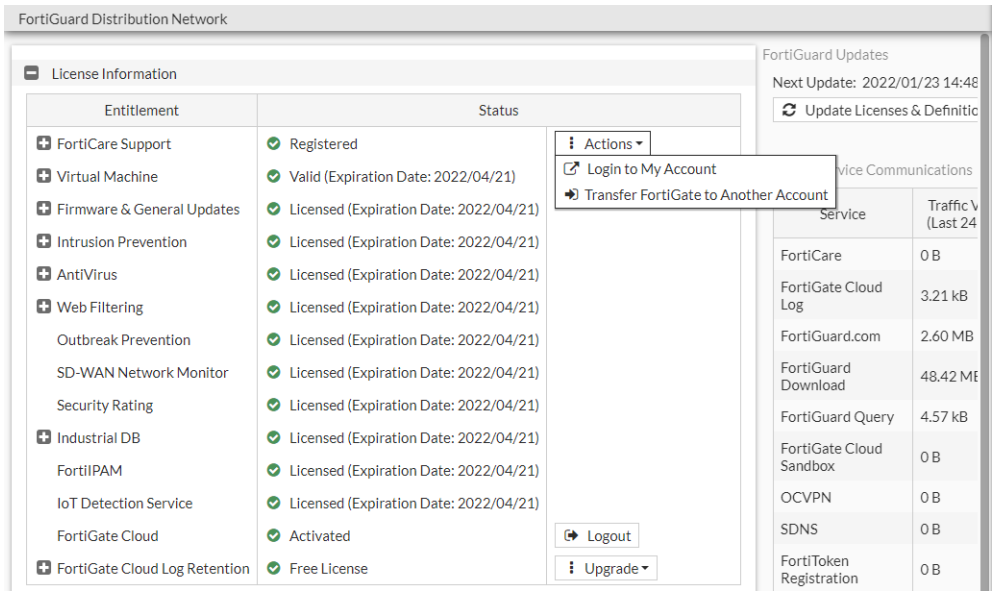
3. Enter your FortiCare *Email* address and *Password*.
4. Select your *Country/Region*, *Reseller*, and *End-user type*.
5. Enable *Sign in to FortiGate Cloud using the same account*.
6. Click *OK*.

To activate FortiGate Cloud on an already registered FortiGate:

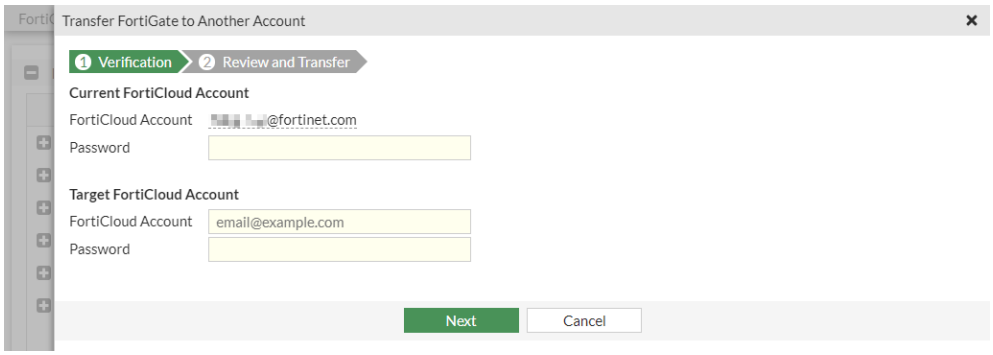


1. Go to *Dashboard* > *Status*.
2. In the *FortiGate Cloud* widget, click *Not Activated* > *Activate*.

3. Enter the password for the account that was used to register the FortiGate.



4. Click *OK*.
   The *FortiGate Cloud* widget now shows the activated FortiCloud account.



To migrate from the activated FortiGate Cloud account to the registered FortiCloud account:

1. Go to *System* > *FortiGuard*.
2. In the *FortiCare Support* row, click *Actions* > *Transfer FortiGate to Another Account*.

3. Enter the *Password* of the current FortiCloud account.

4. Enter the target *FortiCloud Account* name and *Password*, then click *Next*.
5. Review the information in the *From* and *To* fields, then click *Transfer*.

To activate FortiGate Cloud using an account that is not used for registration:

1. Enter the following with the credentials for the account being used to activate FortiGate Cloud:

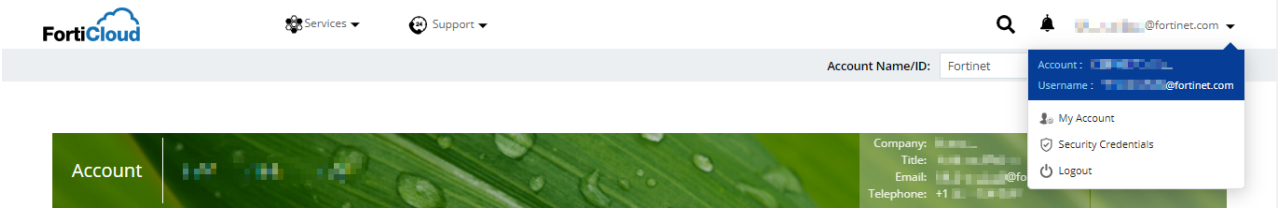
```
# execute fortiguard-log login <account_id> <password>
```

2. Check the account type:

```
# diagnose fdsm contract-controller-update
Protocol=2.0|Response=202|Firmware=FAZ-4K-FW-2.50-
100|SerialNumber=FAMS000000000000|Persistent=false|ResponseItem=HomeServer:172.16.95.151
:443*AlterServer:172.16.95.151:443*Contract:20200408*NextRequest:86400*UploadConfig:Fals
e*ManagementMode:Local*ManagementID:737941253*AccountType:multitenancy

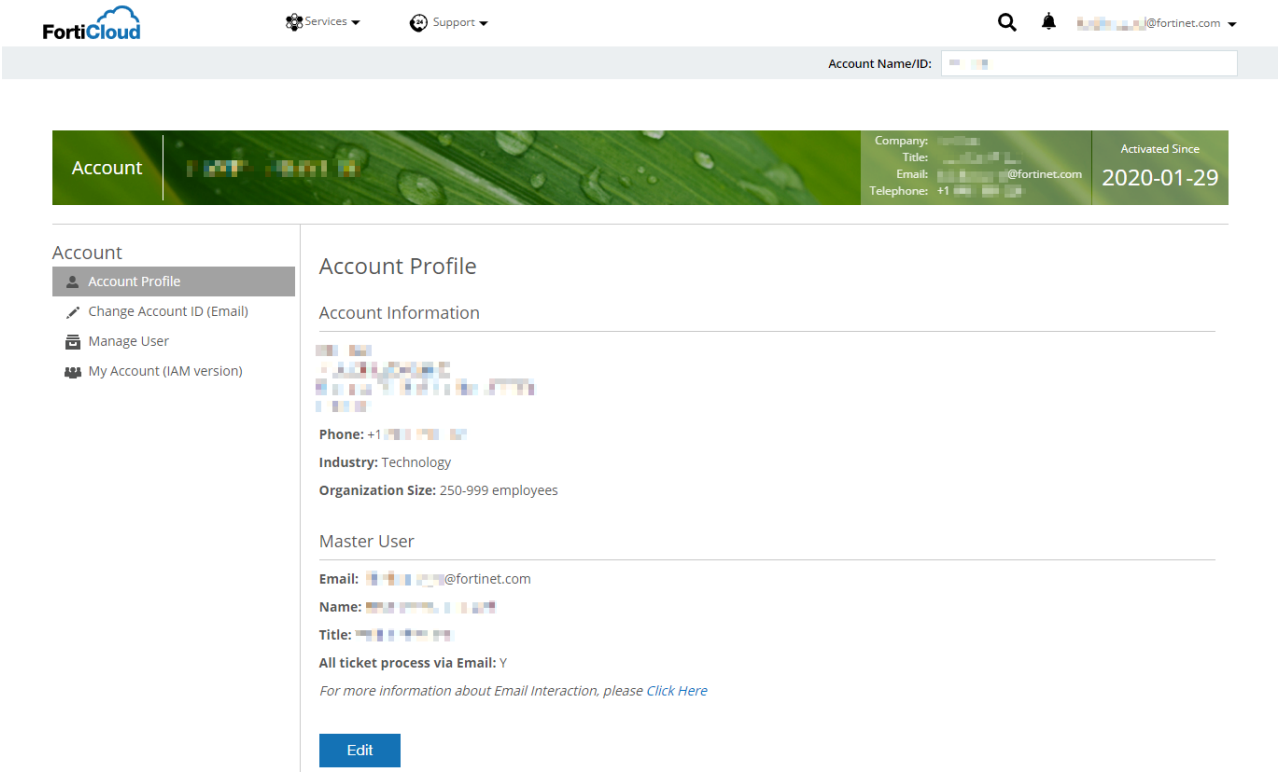
Result=Success
```

A FortiCloud account that is not used for the support portal account cannot be used to register FortiGate. Attempting to activate FortiGate Cloud with this type of account will fail.



Transfer a device to another FortiCloud account

Master account users can transfer a device from one FortiCloud/FortiCare account to another. Users can transfer a device up to three times within a twelve-month time period. If more transfers are required within the twelve-month time period, contact Technical Support to request the transfer.

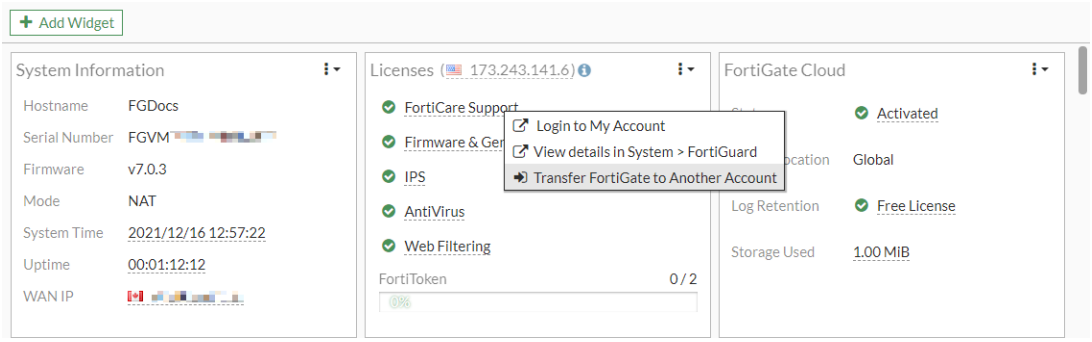


Requirements:

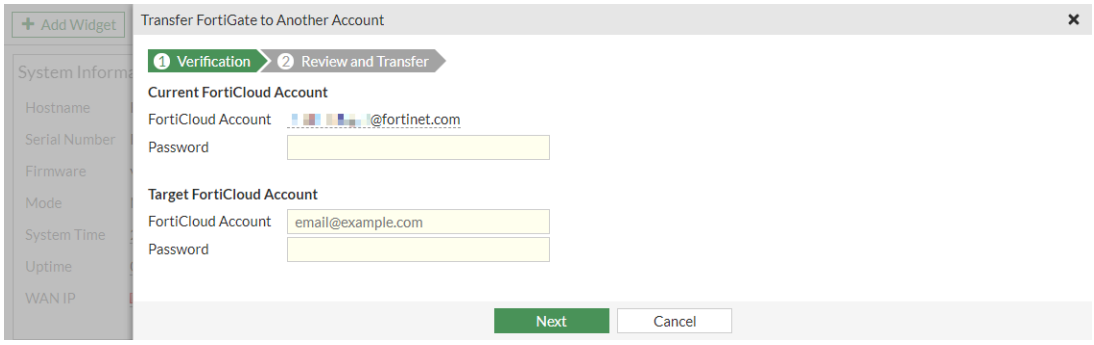
To transfer an account, you must:

- Have access to the FortiGate, as well as both the FortiCloud and FortiCare accounts.
- Be a master account user.
  To verify if you are the master account user, log in to support.fortinet.com. Click the username, then select *My Account*.

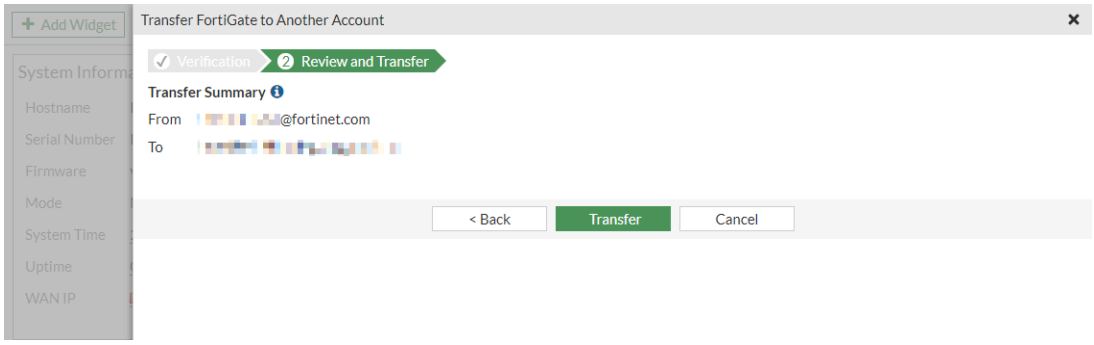
The *Account Profile* page opens.



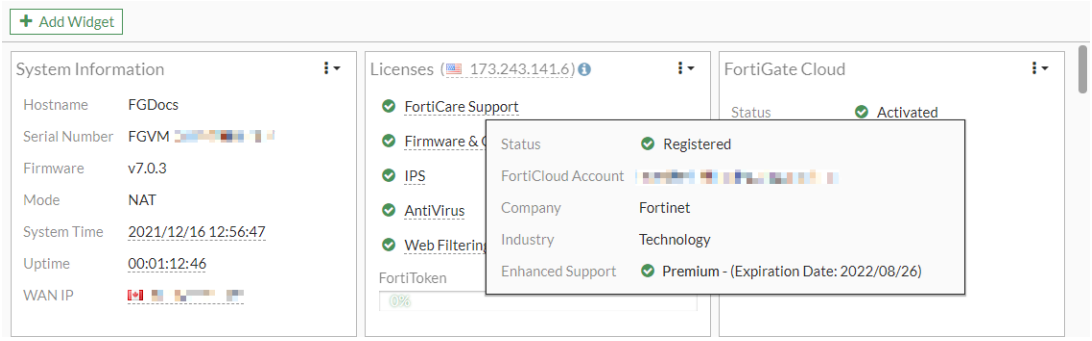
To transfer an account in the GUI:



1. Go to *Dashboard* > *Status*.
2. In the *Licenses* widget, click the *FortiCare Support* link, then click *Transfer FortiGate to Another Account*.



You can also transfer an account from *System* > *FortiGuard*.



3. In the *Current FortiCloud Account* fields, enter the username and password for the current account. In the *Target FortiCloud Account* fields, enter the new username and password.
4. Click *Next*.

5. Review the information, then click *Transfer*.

After the transfer is complete, the new the FortiCloud account is displayed in the *Licenses* widget.

Configuration backups

Once you successfully configure the FortiGate, it is extremely important that you back up the configuration. In some cases, you may need to reset the FortiGate to factory defaults or perform a TFTP upload of the firmware, which will erase the existing configuration. In these instances, the configuration on the device will have to be recreated, unless a backup can be used to restore it.

You can use the GUI or CLI to back up the configuration in FortiOS or YAML format. You have the option to save the configuration file in FortiOS format to various locations including the local PC, USB key, FTP, and TFTP server. FTP and TFTP are only configurable through the CLI. In YAML format, configuration files can be backed up or restored on an FTP or TFTP server through the CLI.

This topic includes the following information:

- Backing up and restoring configurations from the GUI on page 68
- Backing up and restoring configurations from the CLI on page 71
- Configuration revision on page 75
- Restore factory defaults on page 76
- Secure file copy on page 76

Backing up and restoring configurations from the GUI

Configurations can be backed up using the GUI to your PC or a USB disk.

Field	Description
Scope	When the FortiGate is in multi-vdom mode and a user is logged in as a global administrator.
Backup to	You can choose where to save the configuration backup file. • *Local PC*: Save the configuration file to your PC. • *USB Disk*: Save the configuration file to an external USB disk. This option is not available if there is no USB drive inserted in the USB port. You can also back up to FortiManager using the CLI.
File format	The configuration file can be saved in FortiOS or YAML format.
Password mask	Use password masking when sending a configuration file to a third party. When password masking is enabled, passwords and secrets will be replaced in the configuration file with `FortinetPasswordMask`.
Encryption	Enable *Encryption* to encrypt the configuration file. A configuration file cannot be restored on the FortiGate without a set password. Encryption must be enabled on the backup file to back up VPN certificates.

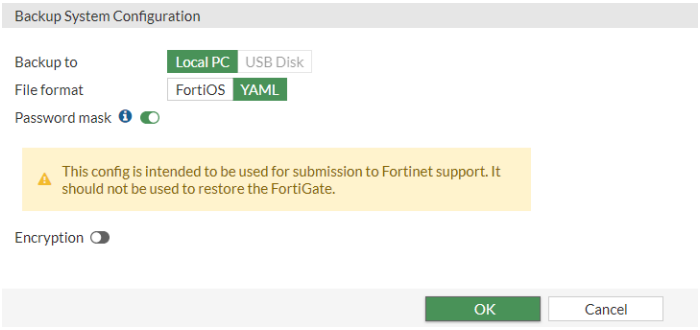
To back up the configuration in FortiOS format using the GUI:

1. Click on the user name in the upper right-hand corner of the screen and select *Configuration* > *Backup*.
2. Direct the backup to your *Local PC* or to a *USB Disk*.

3. Enable *Encryption*.

This is recommended to secure your backup configurations and prevent unauthorized parties from reloading your configuration.

4. Enter a password, and enter it again to confirm it. This password will be required to restore the configuration.
5. Click *OK*.
6. When prompted, select a location on the PC or USB disk to save the configuration file. The configuration file will have a .conf extension.



To back up the configuration in YAML format using the GUI:

1. Click on the user name in the upper right-hand corner of the screen and select *Configuration* > *Backup*.
2. Direct the backup to your *Local PC* or to a *USB Disk*.
3. Select *YAML* for the *File format*.
4. Click *OK*.

When backing up a configuration that will be shared with a third party, such as Fortinet Inc. Support, passwords and secrets should be obfuscated from the configuration to avoid information being unintentionally leaked. Password masking can be completed in the *Backup System Configuration* page and in the CLI. When password masking is enabled, passwords and secrets will be replaced in the configuration file with `FortinetPasswordMask`.

To mask passwords in the GUI:

1. Click on the username in the upper right-hand corner of the screen and select *Configuration* > *Backup*.
2. Select *YAML* as the *File format*.
3. Enable *Password mask*. A warning message is displayed.

4. Click *OK*. The configuration file is saved to your computer with passwords and secrets obfuscated.

The following is an example of output with password masking enabled:

```
config system admin
    edit "1"
        set accprofile "prof_admin"
        set vdom "root"
        set password FortinetPasswordMask
    next
end
config vpn ipsec phase1-interface
    edit "vpn-1"
```

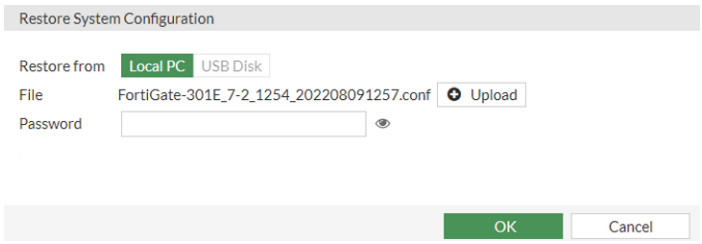
```
        set interface "port1"
        set peertype any
        set net-device disable
        set proposal aes128-sha256 aes256-sha256 aes128-sha1 aes256-sha1
        set comments "VPN: vpn-1 (Created by VPN wizard)"
        set wizard-type static-fortigate
        set remote-gw 172.16.200.55
        set psksecret FortinetPasswordMask
    next
end
config wireless-controller vap
    edit "ssid-1"
        set passphrase FortinetPasswordMask
        set schedule "always"
    next
end
```

Restoring configuration files from the GUI

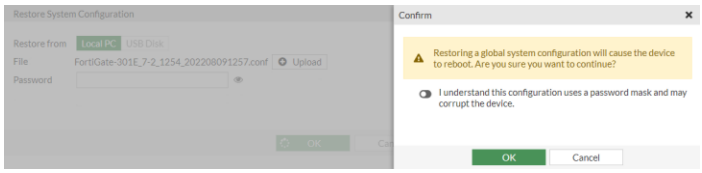
Configuration files can be used to restore the FortiGate to a previous configuration in the *Restore System Configuration* page.

To restore the FortiGate configuration using the GUI:

1. Click on the user name in the upper right-hand corner of the screen and select *Configuration* > *Restore*.
2. Identify the source of the configuration file to be restored: your *Local PC* or a *USB Disk*.
   The *USB Disk* option will not be available if no USB drive is inserted in the USB port. You can restore from the FortiManager using the CLI.
3. Click *Upload*, locate the configuration file, and click *Open*.
4. Enter the password if required.
5. Click *OK*.



When restoring a configuration file that has password masking enabled, obfuscated passwords and secrets will be restored with the password mask.



Restoring the FortiGate with a configuration with passwords obfuscated is not recommended.

To restore an obfuscated YAML configuration using the GUI:

1. Click on the user name in the upper right-hand corner of the screen and select *Configuration* > *Restore*.
2. Click *Upload*. The File Explorer is displayed.
3. Navigate to the configuration file and click *Open*.

4. (Optional) Enter the file password in the *Password* field.
5. Click *OK*. The *Confirm* pane is displayed with a warning.

6. Toggle the acknowledgment.
7. Click *OK*.

Backing up and restoring configurations from the CLI

Configuration backups in the CLI are performed using the `execute backup` commands and can be backed up in FortiOS and YAML format.

Configuration files can be backed up to various locations depending on the command:

- `flash`: Backup the configuration file to the flash drive.
- `ftp`: Backup the configuration file to an FTP server.
- `management-station`: Backup the configuration file to a management station, such as FortiManager or FortiGate Cloud.
- `sftp`: Backup the configuration file to a SFTP server.
- `tftp`: Backup the configuration file to a TFTP server.
- `usb`: Backup the configuration file to an external USB drive.
- `usb-mode`: Backup the configuration file for USB mode.

Command	Description
`# execute backup config`	Back up the configuration in FortiOS format. Backup your configuration file to: • `flash` • `ftp` • `management-station` • `sftp` • `tftp` • `usb` • `usb-mode`
`# execute backup full-config`	Backup the configuration, including backups of default configuration settings. Backup your configuration file to:

Command	Description
	• ftp • sftp • tftp • usb • usb-mode
# execute backup yaml-config	Backup the configuration in YAML format. Backup your configuration file to: • ftp • tftp
# execute backup obfuscated-config	Backup the configuration with passwords and secrets obfuscated. Backup your configuration file to: • ftp • management-station • sftp • tftp • usb
# execute backup obfuscated-full-config	Backup the configuration (including default configuration settings) with passwords and secrets obfuscated. Backup your configuration file to: • ftp • sftp • tftp • usb
# execute backup obfuscated-yaml-config	Backup the configuration in YAML format with passwords and secrets obfuscated. Backup your configuration file to: • ftp • tftp

To back up the configuration in FortiOS format using the CLI:

For FTP, note that port number, username are optional depending on the FTP site:

```
# execute backup config ftp <backup_filename> <ftp_server>[<:ftp_port>] [<user_name>]
[<password>] [<backup_password>]
```

or for TFTP:

```
# execute backup config tftp <backup_filename> <tftp_servers> [<backup_password>]
```

or for SFTP:

```
# execute backup config sftp <backup_filename> <sftp_server>[<:sftp_port>] <user> <password>
[<backup_password>]
```

or:

```
# execute backup config management-station <comment>
```

or:

```
# execute backup config usb <backup_filename> [<backup_password>]
```

Use the same commands to backup a VDOM configuration by first entering the commands:

```
config vdom
    edit <vdom_name>
```

See Backing up and restoring configurations in multi VDOM mode on page 2314 for more information.

When backing up a configuration in YAML format, if it is not already specified in the file name, `.yaml` will be appended to the end. For example, if the file name entered is `301E.conf`, the name will become `301E.conf.yaml` after the configuration is backed up.

To back up the configuration in YAML format using the CLI:

```
# execute backup yaml-config {ftp | tftp} <filename> <server> [username] [password]
```

For example:

```
# execute backup yaml-config  tftp  301E.conf 172.16.200.55
    Please wait...
    The suffix '.yaml' will be appended to the filename if user does not add it
specifically.
    Connect to tftp server 172.16.200.55 ...
    #
    Send config file to tftp server OK.
```

Configuration files can be configured with obfuscated passwords and secrets to not unintentionally leak information when sharing configuration files with third parties.

To mask passwords in a configuration backup in the CLI:

```
# execute backup obfuscated-config {ftp | management-station | sftp | tftp | usb}
```

To mask passwords in the full configuration backup in the CLI:

```
# execute backup obfuscated-full-config {ftp | sftp | tftp | usb}
```

To mask passwords in a configuration backup with YAML formatting in the CLI:

```
# execute backup obfuscated-yaml-config {ftp | tftp}
```

If a configuration is being backed up on a server, server information must be included with the command. Other information that may be required with an `execute backup` command includes file names, passwords, and comments.

Restoring configuration files from the CLI

Configuration files can be used to restore the FortiGate using the CLI.

Command	Description
`# execute restore config`	Restore a configuration that is in FortiOS or YAML format. The file format is automatically detected when it is being restored. Configurations can be loaded from: • `flash`: Load the configuration file from flash to firewall. • `ftp`: Load the configuration file from an FTP server. • `management-station`: Load the configuration from a management station. • `tftp`: Load the configuration from from a TFTP server. • `usb`: Load the configuration file from an external USB disk to firewall. • `usb-mode`: Load the configuration file from an external USB disk and reboot.

To restore the FortiGate configuration using the CLI:

For FTP, note that port number, username are optional depending on the FTP site:

```
# execute restore config ftp <backup_filename> <ftp_server>[<:port>] [<user_name>]
[<password>] [<backup_password>]
```

or for TFTP:

```
# execute restore config tftp <backup_filename> <tftp_server> [<backup_password>]
```

For restoring the configuration from FortiManager or FortiGate Cloud:

```
# execute restore config management-station normal <revision ID>
```

or:

```
# execute restore config usb <backup_filename> [<backup_password>]
```

The FortiGate will load the configuration file and restart. Once the restart has completed, verify that the configuration has been restored.

Troubleshooting

When restoring a configuration, errors may occur, but the solutions are usually straightforward.

Error message	Reason and Solution
Configuration file error	This error occurs when attempting to upload a configuration file that is incompatible with the device. This may be due to the configuration file being for a different model or being saved from a different version of firmware. **Solution**: Upload a configuration file that is for the correct model of FortiGate device and the correct version of the firmware.
Invalid password	When the configuration file is saved, it can be protected by a password. The password entered during the upload process is not matching the one associated with the configuration file. **Solution**: Use the correct password if the file is password protected.

Configuration revision

You can manage multiple versions of configuration files on models that have a 512MB flash memory and higher. Revision control requires either a configured central management server or the local hard drive, if your FortiGate has this feature. Typically, configuration backup to local drive is not available on lower-end models.

Central management server

The central management server can either be a FortiManager unit or FortiGate Cloud.

If central management is not configured on your FortiGate, a message appears instructing you to either enable central management, or obtain a valid license.

To enable central management from the GUI:

1. Go to *Security Fabric* > *Fabric Connectors* and double-click the *Central Management* card.
2. Set the *Status* to *Enabled* and select a *Type*.
3. Click *OK*.

To enable central management from the CLI:

```
config system central-management
    set type {fortimanager | fortiguard}
    set mode backup
    set fmg <IP address>
end
```

To backup to the management server:

```
# execute backup config management-station <comment>
```

To view a backed up revision:

```
# execute restore config management-station normal 0
```

To restore a backed up revision:

```
# execute restore config management-station normal <revision ID>
```

Backing up to a local disk

When revision control is enabled on your FortiGate unit, and configuration backups have been made, a list of saved revisions of those backed-up configurations appears.

Configuration backup occurs by default with firmware upgrades but can also be configured to occur every time you log out.

To configure configuration backup when logging out:

```
config system global
  set revision-backup-on-logout enable
end
```

To manually force backup:

```
# execute backup config flash <comment>
```

Configuration revisions are viewed by clicking on the user name in the upper right-hand corner of the screen and selecting *Configuration* > *Revisions*.

To view a list of revisions backed up to the disk from the CLI:

```
# execute revision list config
```

To restore a configuration from the CLI:

```
# execute restore config flash <revision ID>
```

Restore factory defaults

There may be a need to reset the FortiGate to its original defaults; for example, to begin with a fresh configuration. There are two options when restoring factory defaults. The first resets the entire device to the original out-of-the-box configuration.

You can reset the device with the following CLI command:

```
# execute factoryreset
```

When prompted, type `y` to confirm the reset.

Alternatively, in the CLI you can reset the factory defaults but retain the interface and VDOM configuration with the following command:

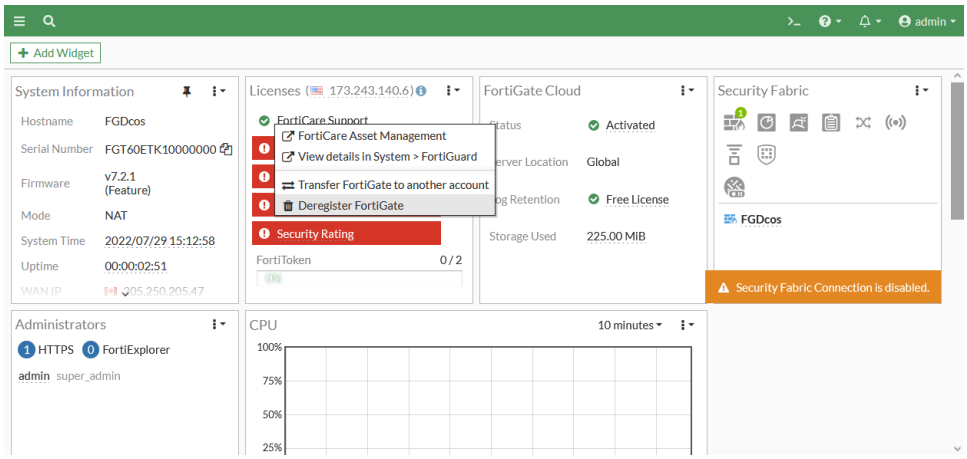
```
# execute factoryreset2
```

Secure file copy

You can also back up and restore your configuration using Secure File Copy (SCP). See How to download a FortiGate configuration file and upload firmware file using secure file copy (SCP).

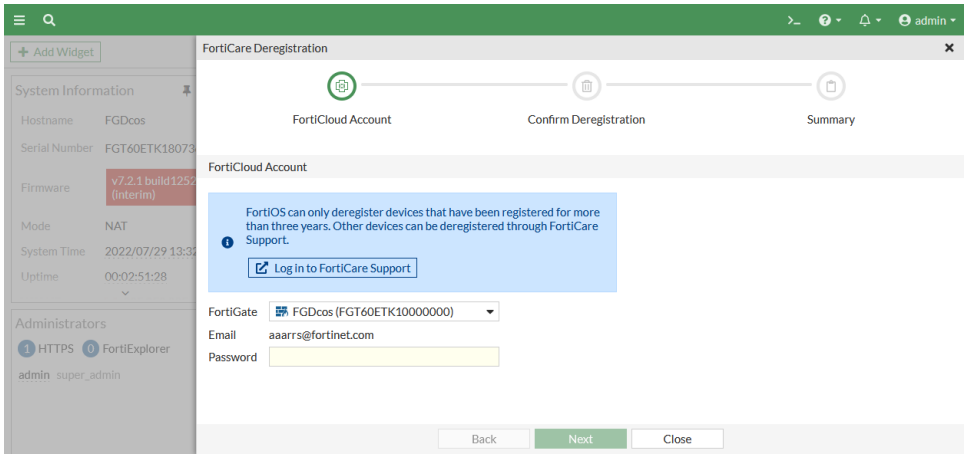
You enable SCP support using the following command:

```
config system global
    set admin-scp enable
end
```



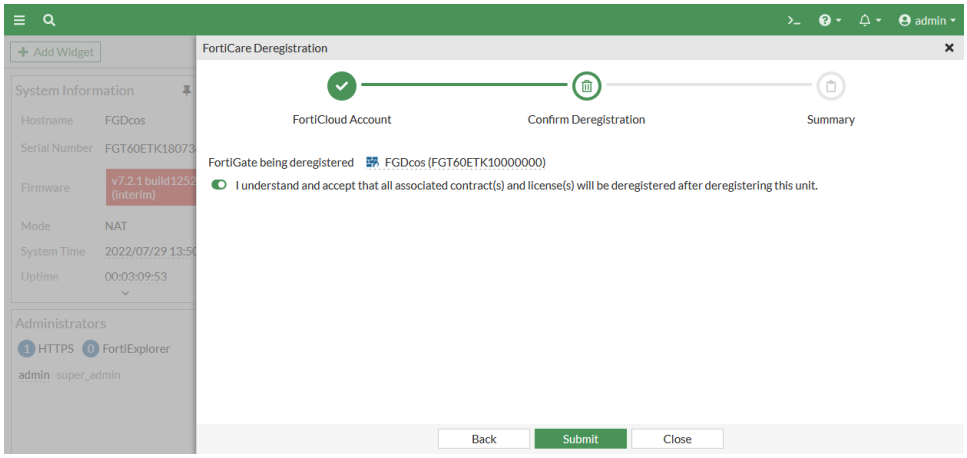
For more information about this command and about SCP support, see config system global.

Deregistering a FortiGate

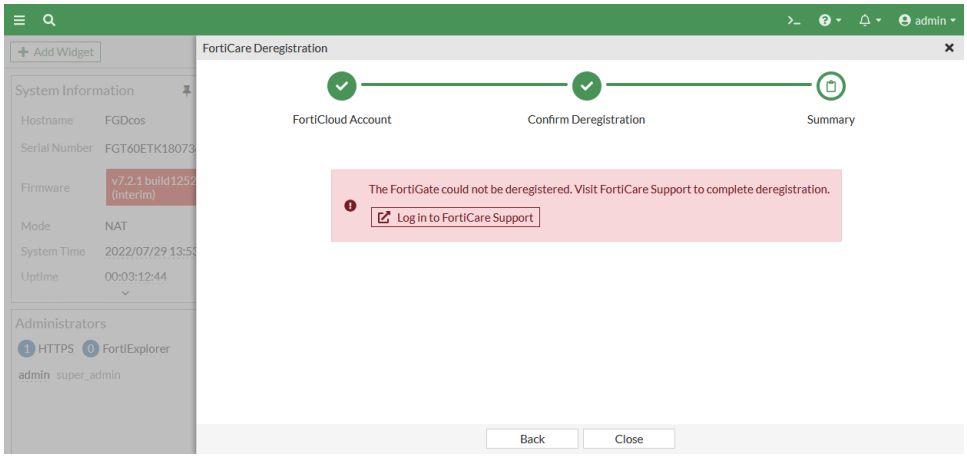


An administrator can deregister a FortiGate, if the device has been registered for three or more years, using the GUI or CLI, without having to contact FortiCare administration. After the device is deregistered, all associated contracts are also deregistered, and all of the administrator's information is wiped.

To deregister the FortiGate in the GUI:



1. Go to *Dashboard* > *Status*.
2. In the License widget, click *FortiGate Support* and select *Deregister FortiGate*.



The FortiCare Deregistration pane opens.

3. Enter your password then click *Next*.
4. Confirm the FortiGate deregistration then click *Submit*.

If the FortiGate has been registered for less then three years, the deregistration will fail.

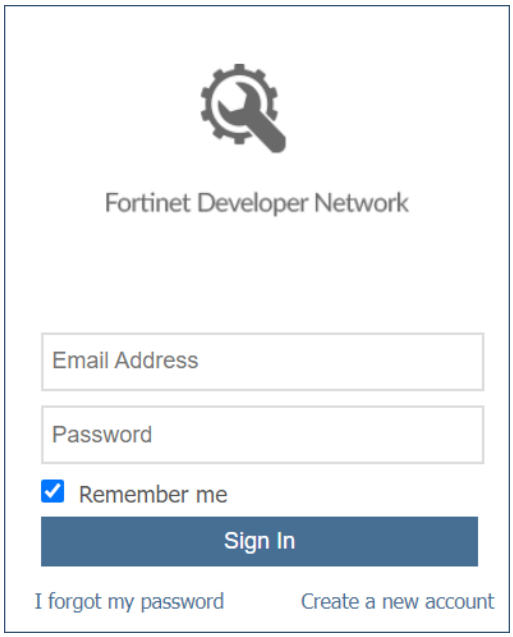
To deregister the FortiGate in the CLI:

```
# diagnose forticare direct-registration product-deregister <accountID> <password>
```

If the FortiGate has been registered for less then three years, the deregistration will fail:

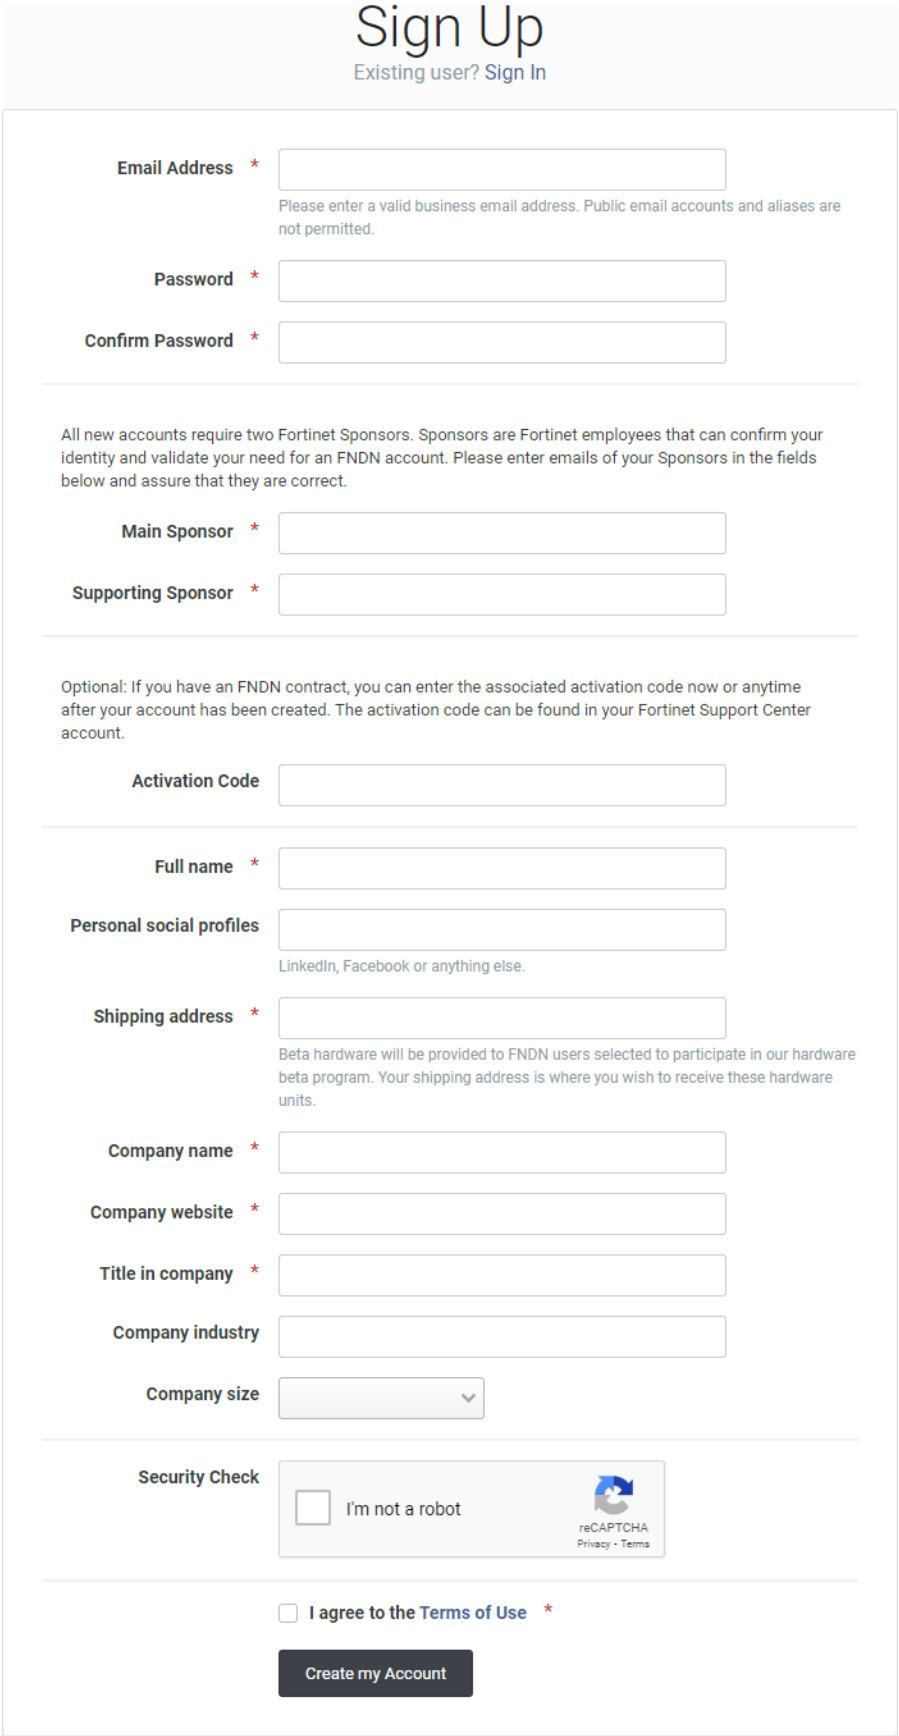
```
forticare_product_deregister:1335: Failed to get response (rc = 0, http_code = 403)
Unit deregistration unsuccessful.
```

Fortinet Developer Network access



The Fortinet Developer Network (FNDN) is a subscription-based community that helps administrators enhance and increase the effectiveness of Fortinet products. Administrators can access the FortiAPI forum in FNDN to help create applications that interact with Fortinet products, such as custom web portals, automated deployment and provisioning systems, and scripted tasks. FNDN makes it easy for administrators and Fortinet professionals to interact, share sample code, and upload their own tools. The FortiOS REST API documentation is available within the FortiAPI forum.

All FNDN users must be sponsored by two Fortinet employees. The sponsors must be able to confirm the user's identity and need for access. Approvals from both sponsors are required before access is granted to new users. The sponsors' email addresses are required to create a new FNDN account.



Basic and licensed access options are available. Refer to the Fortinet Developer Network data sheet for more information.

To create an FNDN account:

1. Obtain sponsorship from two Fortinet employees.
2. Go to the FNDN website, https://fndn.fortinet.net/. The log in page appears.

3. Click *Create a new account*. The *Sign Up* page appears.
4. Enter the information in the form fields and agree to the *Terms of Use*.

Sign Up
Existing user? Sign In
Email Address *
Please enter a valid business email address. Public email accounts and aliases are not permitted.
Password *
Confirm Password *
All new accounts require two Fortinet Sponsors. Sponsors are Fortinet employees that can confirm your identity and validate your need for an FNDN account. Please enter emails of your Sponsors in the fields below and assure that they are correct.
Main Sponsor *
Supporting Sponsor *
Optional: If you have an FNDN contract, you can enter the associated activation code now or anytime after your account has been created. The activation code can be found in your Fortinet Support Center account.
Activation Code
Full name *
Personal social profiles
LinkedIn, Facebook or anything else.
Shipping address *
Beta hardware will be provided to FNDN users selected to participate in our hardware beta program. Your shipping address is where you wish to receive these hardware units.
Company name *
Company website *
Title in company *
Company industry
Company size
Security Check
I'm not a robot
reCAPTCHA

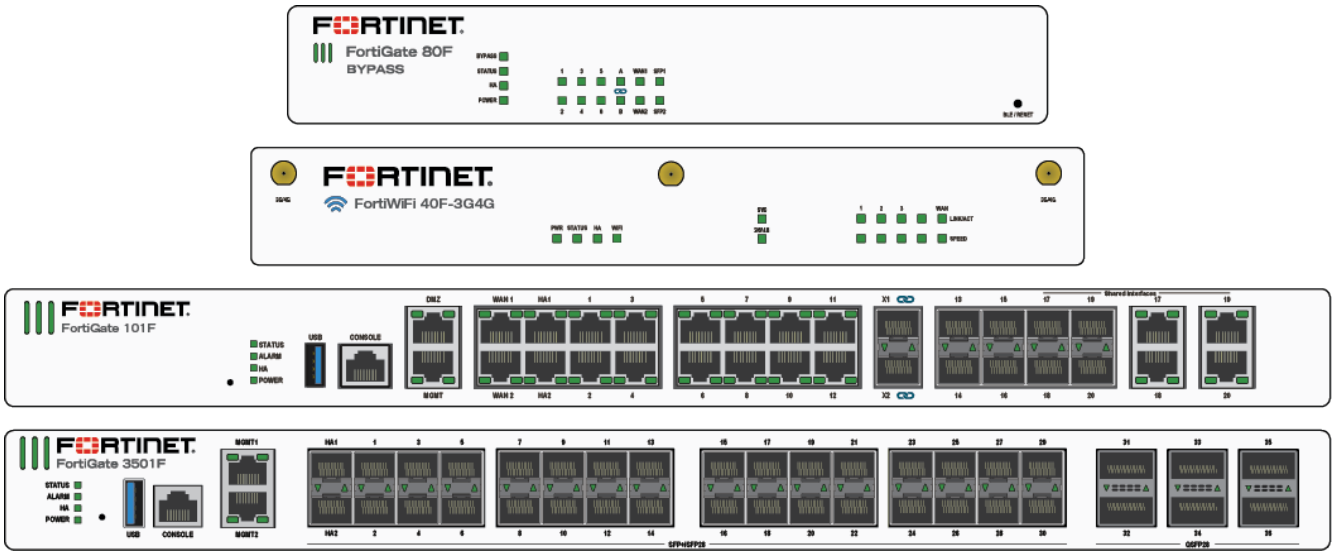
I agree to the Terms of Use *
Create my Account



5. Click *Create my Account*.

   New accounts are reviewed and approved by an FNDN administrator. After both sponsors approve the request, an FNDN administrator reviews the request and approves account access in around one business day if all requirements are met.

LEDs

Check your device's QuickStart guide for specific LED information: FortiGate QuickStart Guides.

The following faceplates show where the LEDs are typically found on FortiGate models:

LED	State	Description
Logo	Green	The unit is on
	Blue	The FortiWiFi unit is on
	Off	The unit is off
Power (PWR)	Green	The unit is on and/or both power supplies are functioning
	Amber	One power supply is functioning
	Flashing Amber	Power supply failure
	Red	The unit is on, but only one power supply is functional
	Flashing Red	Power failure
	Off	The unit is off

LED	State	Description
Status (STA)	Green	Normal
	Flashing Green	Booting up
	Amber	Major or minor alarm
	Flashing Amber	BLE is on
	Red	Major alarm
	Flashing Red	BLE is on
	Off	The unit is off
Bypass (BYP)	Amber	Bypass Port Pair is active
	Off	Bypass Port Pair is off
Alarm	Red	Major alarm
	Amber	Minor alarm
	Off	No alarms
HA	Green	Operating in an HA cluster
	Amber or Red	HA failover
	Off	HA disabled
Max PoE	Green, Amber, or Red	Maximum PoE power allocated
	Off	PoE power available or normal
PoE	Green	Power delivered
	Flashing Green	Error or PoE device requesting power
	Off	No PoE device connected or no power delivered
SVC	Green	SVC is on
	Flashing Green	SVC activity
	Off	SVC is off
3G / 4G	Green	3G / 4G service is on
	Flashing Green	3G / 4G activity
	Off	3G / 4G service is off
WiFi	Green	WiFi connected
	Flashing Green	WiFi activity
	Off	WiFi is off

LED	State	Description
Power Supply	Green	Power supply operating normally
	Flashing Green	Power detected, but power supply not providing power or is in standby mode
	Amber	Power output is off, there is a power supply error, or there is no input power but the redundant supply is on
	Flashing Amber	Power supply error or warning events, or the power supply should be replaced
	Red	Cord unplugged or power lost
	Flashing Red	Power supply warning events
	Off	Power not detected
Power Supply OK	Green	Standby rail and main output on
	Flashing Green	Standby rail and main output off
	Off	Error or no AC power input
Power Supply Fail	Amber	Main output or fan error detected
	Flashing Amber	Power supply warning event detected
	Off	No errors or no power
Power Supply Input	Green	Input voltage within normal range
	Flashing Green	Over or under voltage warning
	Off	No input power
Power Supply Output	Green	Output voltage normal
	Flashing Green	Standby mode
	Amber	Critical error
	Flashing Amber	Warning
	Off	No output
Fan	Green	Fan(s) operating normally
	Flashing Green	Fan switching/initialization in progress
	Amber	Fan failure
	Red	Fan error, RPM too low or too high, or both fan sets have at least one alert
	Flashing Red	One fan set has at least one alert
	Off	Fan error or fan is off

Port LEDs

LED	State	Description
Ethernet	Green	Connected at 1 Gbps
	Flashing Green	Transmitting and receiving data at 1 Gbps
	Amber	Connected at 10/100 Mbps
	Flashing Amber	Transmitting and receiving data at 10/100 Mbps
	Off	No link established
Ethernet Link/Activity	Green	Connected
	Flashing Green	Transmitting data
	Off	No link established
Ethernet Speed	Green	Connected at 1 Gbps
	Amber	Connected at 100 Mbps
	Off	Not connected or connected at 10 Mbps
Ethernet 10G Link/Activity	Green	Connected
	Flashing Green	Transmitting data
	Off	No link established
Ethernet 10G Speed	Green	Connected at 10 Gbps
	Amber	Connected at 5 Gbps, 2.5 Gbps, or 1 Gbps
	Off	Not connected or connected at 100 Mbps
PoE	Green	PoE power on or PoE device receiving power
	Amber	Providing power
	Red	Connected but not powered
	Off	PoE power off or no device receiving power
SFP	Green	Connected at 1 Gbps
	Flashing Green	Data activity
	Off	No link established
SFP+	Green	Connected at 10 Gbps or 1 Gbps
	Flashing Green	Data activity
	Off	No link established

LED	State	Description
SFP28	Green	Connected at 25 Gbps, 10 Gbps, or 1 Gbps
	Flashing Green	Data activity
	Off	No link established
QSFP28	Green	Connected at 100 Gbps or 40 Gbps
	Flashing Green	Data activity
	Off	No link established

Alarm levels

Minor alarm

Also called an IPMI non-critical (NC) alarm, it indicates a temperature or power level outside of the normal operating range that is not considered a problem. For a minor temperature alarm, the system could respond by increasing the fan speed. A non-critical threshold can be an upper non-critical (UNC) threshold (for example, a high temperature or a high power level) or a lower non-critical (LNC) threshold (for example, a low power level).

Major alarm

Also called an IPMI critical or critical recoverable (CR) alarm, it indicates that the system is unable to correct the cause of the alarm, and that intervention is required. For example, the cooling system cannot provide enough cooling to reduce the temperature. It can also mean that the conditions are approaching the outside limit of the allowed operating range. A critical threshold can also be an upper critical (UC) threshold (such as a high temperature or high power level) or a lower critical (LC) threshold (such as a low power level).

Critical alarm

Also called an IPMI non-recoverable (NR) alarm, it indicates that the system has detected a temperature or power level that is outside of the allowed operating range and physical damage is possible.

Troubleshooting your installation

If your FortiGate does not function as desired after installation, try the following troubleshooting tips:

1. **Check for equipment issues**
   Verify that all network equipment is powered on and operating as expected. Refer to the QuickStart Guide for information about connecting your FortiGate to the network.
2. **Check the physical network connections**
   Check the cables used for all physical connections to ensure that they are fully connected and do not appear damaged, and make sure that each cable connects to the correct device and the correct Ethernet port on that device.

3. **Verify that you can connect to the internal IP address of the FortiGate**
   Connect to the GUI from the FortiGate's internal interface by browsing to its IP address. From the PC, try to ping the internal interface IP address; for example, `ping 192.168.1.99`. If you cannot connect to the internal interface, verify the IP configuration of the PC. If you can ping the interface but can't connect to the GUI, check the settings for administrative access on that interface. Alternatively, use SSH to connect to the CLI, and then confirm that HTTPS has been enabled for Administrative Access on the interface.
4. **Check the FortiGate interface configurations**
   Check the configuration of the FortiGate interface connected to the internal network (under *Network* > *Interfaces*) and check that *Addressing mode* is set to the correct mode.
5. **Verify the security policy configuration**
   Go to *Policy & Objects* > *Firewall Policy* and verify that the internal interface to Internet-facing interface security policy has been added and is located near the top of the policy list. Check the *Active Sessions* column to ensure that traffic has been processed (if this column does not appear, right-click on the table header and select *Active Sessions*). If you are using NAT mode, check the configuration of the policy to make sure that *NAT* is enabled and that *Use Outgoing Interface Address* is selected.
6. **Verify the static routing configuration**
   Go to *Network* > *Static Routes* and verify that the default route is correct. Go to *Monitor* > *Routing Monitor* and verify that the default route appears in the list as a static route. Along with the default route, you should see two routes shown as *Connected*, one for each connected FortiGate interface.
7. **Verify that you can connect to the Internet-facing interface's IP address**
   Ping the IP address of the Internet-facing interface of your FortiGate. If you cannot connect to the interface, the FortiGate is not allowing sessions from the internal interface to Internet-facing interface. Verify that PING has been enabled for *Administrative Access* on the interface.
8. **Verify that you can connect to the gateway provided by your ISP**
   Ping the default gateway IP address from a PC on the internal network. If you cannot reach the gateway, contact your ISP to verify that you are using the correct gateway.
9. **Verify that you can communicate from the FortiGate to the Internet**
   Access the FortiGate CLI and use the command `execute ping 8.8.8.8`. You can also use the `execute traceroute 8.8.8.8` command to troubleshoot connectivity to the Internet.
10. **Verify the DNS configurations of the FortiGate and the PCs**
    Check for DNS errors by pinging or using traceroute to connect to a domain name; for example: `ping www.fortinet.com`.

    If the name cannot be resolved, the FortiGate or PC cannot connect to a DNS server and you should confirm that the DNS server IP addresses are present and correct.
11. **Confirm that the FortiGate can connect to the FortiGuard network**
    Once the FortiGate is on your network, you should confirm that it can reach the FortiGuard network. First, check the *License Information* widget to make sure that the status of all FortiGuard services matches the services that you have purchased. Go to *System* > *FortiGuard*, and, in the Filtering section, click *Test Connectivity*. After a minute, the GUI should indicate a successful connection. Verify that your FortiGate can resolve and reach FortiGuard at `service.fortiguard.net` by pinging the domain name. If you can reach this service, you can then verify the connection to FortiGuard servers by running the command `diagnose debug rating`. This displays a list of FortiGuard IP gateways you can connect to, as well as the following information:
    - `Weight`: Based on the difference in time zone between the FortiGate and this server
    - `RTT`: Return trip time
    - `Flags`: D (IP returned from DNS), I (Contract server contacted), T (being timed), F (failed)
    - `TZ`: Server time zone
    - `Curr Lost`: Current number of consecutive lost packets
    - `Total Lost`: Total number of lost packets

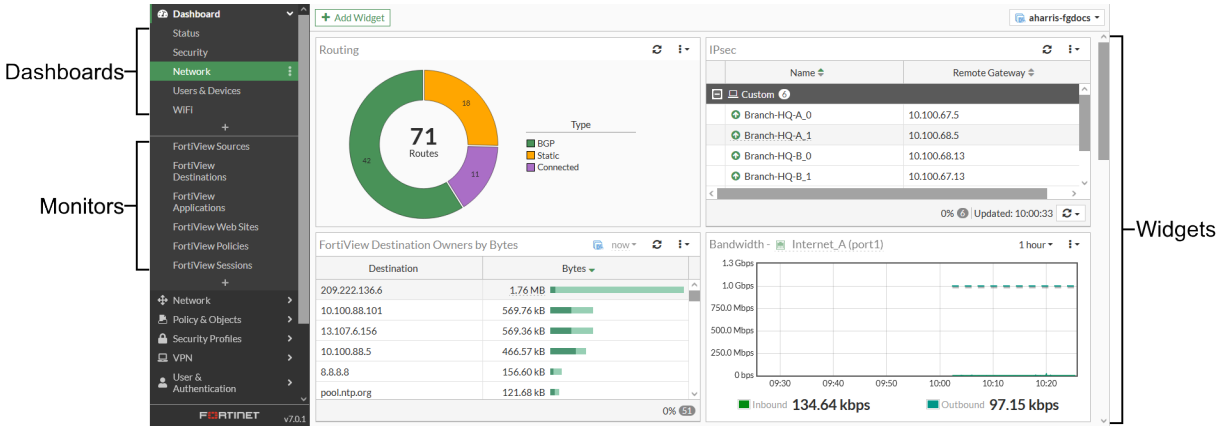
12. **Consider changing the MAC address of your external interface**
    Some ISPs do not want the MAC address of the device connecting to their network cable to change. If you have added a FortiGate to your network, you may have to change the MAC address of the Internet-facing interface using the following CLI command:

```
config system interface
   edit <interface>
      set macaddr <xx:xx:xx:xx:xx:xx>
   end
end
```

13. **Check the FortiGate bridge table (transparent mode)**
    When a FortiGate is in transparent mode, the unit acts like a bridge sending all incoming traffic out on the other interfaces. The bridge is between interfaces on the FortiGate unit. Each bridge listed is a link between interfaces. Where traffic is flowing between interfaces, you expect to find bridges listed. If you are having connectivity issues and there are no bridges listed, that is a likely cause. Check for the MAC address of the interface or device in question. To list the existing bridge instances on the FortiGate, use the following CLI command:

```
diagnose netlink brctl name host root.b
show bridge control interface root.b host.
fdb: size=2048, used=25, num=25, depth=1
Bridge root.b host table
port no device devname mac addr ttl attributes
3 4 wan1 00:09:0f:cb:c2:77 88
3 4 wan1 00:26:2d:24:b7:d3 0
3 4 wan1 00:13:72:38:72:21 98
4 3 internal 00:1a:a0:2f:bc:c6 6
1 6 dmz 00:09:0f:dc:90:69 0 Local Static
3 4 wan1 c4:2c:03:0d:3a:38 81
3 4 wan1 00:09:0f:15:05:46 89
3 4 wan1 c4:2c:03:1d:1b:10 0
2 5 wan2 00:09:0f:dc:90:68 0 Local Static
```

14. **Use FortiExplorer if you cannot connect to the FortiGate over Ethernet**
    If you cannot connect to the FortiGate GUI or CLI, you may be able to connect using FortiExplorer. Refer to the QuickStart Guide or see the section on FortiExplorer for more details.
15. **Either reset the FortiGate to factory defaults or contact Fortinet Support for assistance**
    To reset the FortiGate to factory defaults, use the CLI command `execute factoryreset`. When prompted, type `y` to confirm the reset.



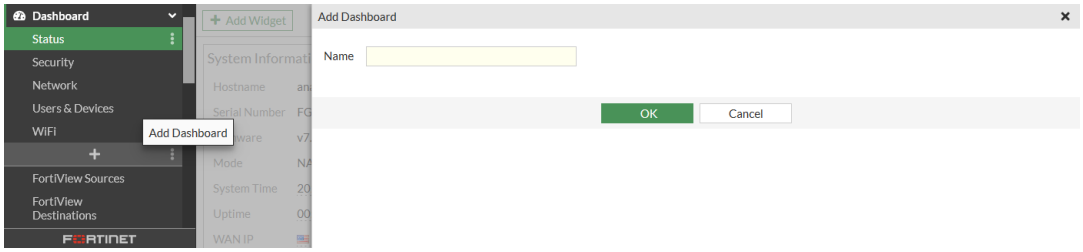
If you require further assistance, visit the Fortinet Support website.

Dashboards and Monitors

FortiOS includes predefined dashboards so administrators can easily monitor device inventory, security threats, traffic, and network health. You can customize the appearance of a default dashboard to display data pertinent to your Security Fabric or combine widgets to create custom dashboards. Many dashboards also allow you to switch views between fabric devices.

Each dashboard contains a set of widgets that allow you to view drilldown data and take actions to prevent threats. Use widgets to perform tasks such as viewing device inventory, creating and deleting DHCP reservations, and disconnecting dial-up users. You can add or remove widgets in a dashboard or save a widget as a standalone monitor.

Monitors display information in both text and visual format. Use monitors to change views, search for items, view drilldown information, or perform actions such as quarantining an IP address. FortiView monitors for the top categories are located below the dashboards. All of the available widgets can be added to the tree menu as a monitor.



Using dashboards

You can combine widgets to create custom dashboards. You can also use the dropdown in the tree menu to switch to another device in the Security Fabric.

To create a new dashboard:

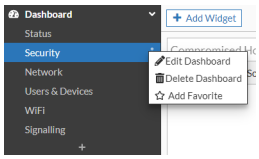
1. Under *Dashboard*, click the *Add Dashboard* button. The *Add Dashboard* window opens.

2. Enter a name in the *Name* field and click *OK*. The new dashboard opens.

To add a widget to a dashboard:

1. In the tree menu, select a dashboard.
2. In the banner, click *Add Widget*. The *Add Dashboard Widget* pane opens.
3. Click the *Add* button next to the widget. You can use the *Search* field to search for a widget. Enable *Show More* to view more widgets in a category.
4. Configure the widget settings, then click *Add Widget*.
5. Click *Close*.
6. (Optional) Click and drag the widget to the desired location in the dashboard.

To edit a dashboard:

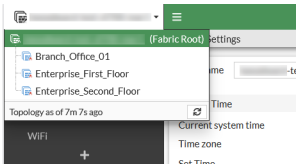


1. Click the *Actions* menu next to the dashboard and select*Edit Dashboard*.

2. Edit the dashboard and click *OK*.

To delete a dashboard:

1. Click the *Actions* menu next to the dashboard and select *Delete Dashboard*.

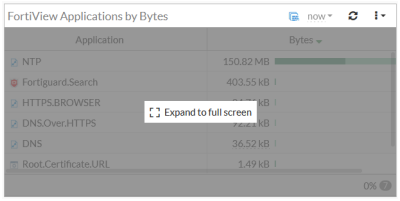


2. Click *Delete Dashboard* . The *Confirm* dialog opens.
3. *Click OK.*

You cannot delete the *Status* dashboard.

To switch to another device in the Security Fabric:

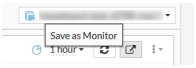
1. In the tree menu, click the device name and select a fabric device from dropdown.



Using widgets

You can convert a widget to a standalone monitor, change the view type, configure tables, and filter data.

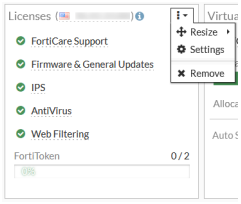
To save a dashboard widget as a monitor:



1. Hover over the widget and click *Expand to full screen*.

Full screen mode is not supported in all widgets.

---



2. In the widget, click *Save as Monitor*. The *Add Monitor* window opens.

3. (Optional) Enter a new name for the monitor in the *Name* field.
4. Click *OK*.

To view the widget settings:

1. Click the menu dropdown at the right side of the widget and select *Settings*.

2. Configure the widget settings and click *OK*.

The settings will vary depending on the widget.

To configure a table in the widget:

1. Hover over the left side of the table header and click *Configure Table*.

2. Configure the table options:

Option	Description
Best Fit All Columns	Resizes all of the columns in a table to fit their content.
Reset Table	Resets the table to the default view.
Select Columns	Adds or removes columns from the view.

3. Click *Apply*.

To filter or configure a column in a table:

1. Hover over a column heading, and click *Filter/Configure Column*.

2. Configure the column options.

Option	Description
Resize to Contents	Resizes the column to fit the content.
Group by this Column	Groups the table rows by the contents in the selected column.

3. Click *Apply*.
4. To filter a column, enter a value in the *Filter* field, and click *Apply*.

Filtering is not supported in all widgets.

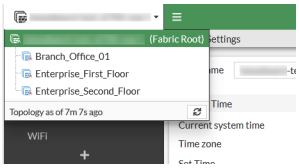
Widgets

Dashboards are created per VDOM when VDOM mode is enabled.For information about VDOM mode, see Virtual Domains on page 2301.

Some dashboards and widgets are not available in Multi-VDOM mode.

The following table lists the available widgets in VDOM mode:

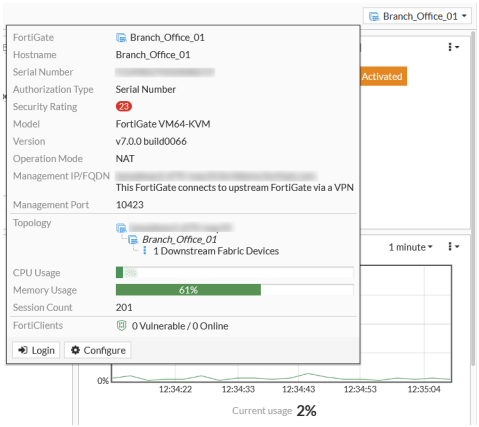
Category	Widgets
FortiView	• FortiView Application Bandwidth FortiView



Category	Widgets
	• Applications FortiView Cloud Applications • FortiView Destination Interfaces FortiView • Destination Owners FortiView Destinations • FortiView Policies FortiView Sessions • FortiView Source Interfaces FortiView • Sources FortiView VPN FortiView Web • Categories FortiView Countries/Regions • FortiView Destination Firewall Objects • FortiView Interface Pairs FortiView Search • Phrases FortiView Servers FortiView Source • Firewall Objects FortiView Sources - WAN • FortiView Traffic Shaping
Security Fabric	• Fabric Device • FortiGate Cloud • Security Fabric Status
Network	• DHCP • Interface Bandwidth • IP Pool Utilization • IPsec • Routing • SD-WAN • SSL-VPN • Top IP Pools by Assigned IPs  The *Interface Bandwidth* widget can monitor a maximum of 25 interfaces.
System	• Administrators • Botnet Activity • HA Status • License Status • System Information • Top System Events • Virtual Machine
Resource Usage	• CPU Usage • Disk Usage • Log Rate Memory Usage • Session Rate • Sessions
Security	• Advanced Threat Protection Statistics • Compromised Hosts

Category	Widgets
	• FortiClient Detected Vulnerabilities • GTP Tunnel Rate • GTP Tunnels • Host Scan Summary • Quarantine • Top Endpoint Vulnerabilities • Top Failed Authentication • Top FortiSandbox Files • Top Threats • Top Threats - WAN
User & Authentication	• Device Inventory • Firewall Users • FortiClient • FortiGuard Quota • FortiSwitch NAC VLANs • Top Admin Logins • Top Vulnerable Endpoint Devices • Top Cloud Users
WiFi	• Channel Utilization • Clients By FortiAP • FortiAP Status • Historical Clients • Interfering SSIDs • Login Failures • Rogue APs • Signal Strength • Top WiFi Clients

Viewing device dashboards in the Security Fabric

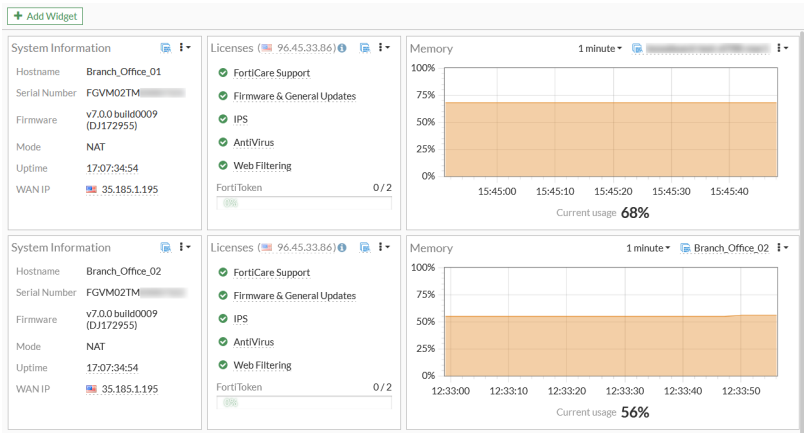


Use the device dropdown to view the dashboards in downstream fabric devices. You can also create dedicated device dashboards or log in and configure fabric devices.

To view the dashboards in fabric devices, click the device dropdown at the left side of the page, and select a device from the list.

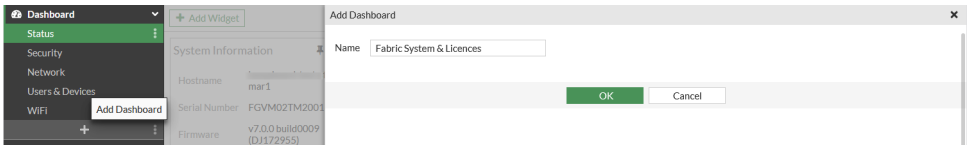
The device dropdown is available in the *Status*, *Security*, *Network*, *Users & Devices*, and *WiFi* dashboards. You can also enable the dropdown when you create a dashboard.

To log in to or configure a fabric device, hover over the device name until the device dialog opens and then select *Login* or *Configure*.



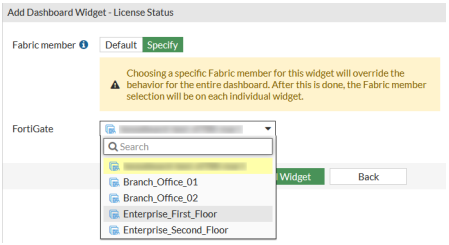
Creating a fabric system and license dashboard

Create a dashboard summary page to monitor all the fabric devices in a single view. You can use this dashboard to monitor aspects of the devices such as system information, VPN and routing.



Example

The following image is an example of a *Fabric System & License* dashboard to monitor the *System Information*, *Licenses*, and *Memory* usage for *Branch_Office_01* and *Branch_Office_02*.



To create a system dashboard:

1. Click the *Add Dashboard* button. The *Add Dashboard* window opens.

2. In the *Name* field, enter a name such as *Fabric System & Licenses*, and click *OK*. The new dashboard appears.
3. In the banner, click *Add Widget*. The *Add Dashboard Widget* window opens. You can use the *Search* field to search for a specific widget (for example, *License Status*, *System Information*, and *Memory Usage*).
4. Click the *Add* button next to widget. The *Add Dashboard Widget* window opens.
5. In the *Fabric member* area, select *Specify* and select a device in the Security Fabric.

6. Click *Add Widget*. The widget is added to the dashboard.
   Repeat this step for all the devices you want to view in the dashboard.
7. (Optional) Arrange the widgets in the dashboard by fabric device.

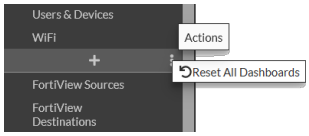
Dashboards

A dashboard is a collection of widgets that show the status of your devices, network, and Security Fabric at a glance. Widgets are condensed monitors that display a summary of the key details about your FortiGate pertaining to routing, VPN, DHCP, devices, users, quarantine, and wireless connections.

The following dashboards are included in the dashboard templates:

Dashboard	Default Template	Use these widgets to:
Status	• Comprehensive • Optimal	• View the device serial number, licenses, and administrators • View the status of devices in the security fabric • Monitor CPU and Memory usage • Monitor IPv4 and IPv6 sessions • View VMs and Cloud devices
Security	• Optimal	• View compromised hosts and host scan summary • View top threats and vulnerabilities
Network	• Optimal	• Monitor DHCP clients • Monitor IPsec VPN connections • Monitor current routing table • Monitor SD-WAN status • Monitor SSL-VPN connections

Dashboard	Default Template	Use these widgets to:
Users & Devices	• Optimal	• View users and devices connected to the network • Identify threats from individual users and devices • View FortiGuard and FortiClient data • Monitor traffic bandwidth over time
WiFi	• Comprehensive • Optimal	• View FortiAP status, channel utilization, and clients • View login failures and signal strength • View the number of WiFi clients

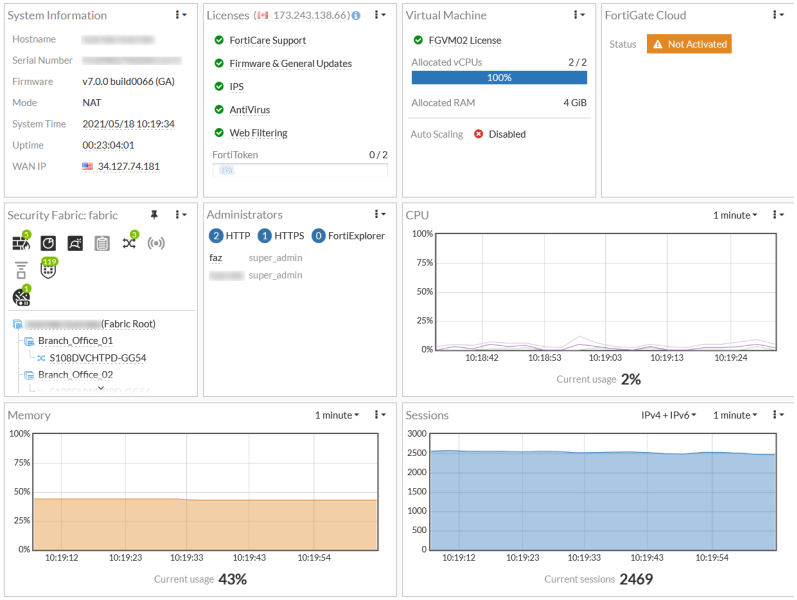


Resetting the default dashboard template

You can use the GUI to change the default dashboard template. The *Optimal* template contains a set of popular default dashboards and FortiView monitors. The *Comprehensive* template contains a set of default dashboards as well as all of the FortiView monitors.

Resetting the default template will delete any custom dashboards and monitors, and reset the widget settings.

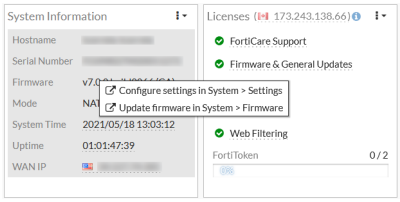
To reset all dashboards:



1. Click the *Actions* menu next to *Add Dashboard* or *Add Monitor* and click *Reset All Dashboards*. The *Dashboard Setup* window opens.

2. Select *Optimal* or *Comprehensive* and click *OK*.

Status dashboard



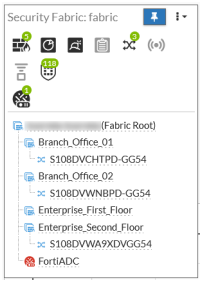
The *Status* dashboard provides an overview of your FortiGate device and the devices in your Security Fabric. If your FortiGate is a virtual machine, information about the virtual machine is also displayed in the dashboard.

Updating system information

The *System Information* widget contains links to the *Settings* module where you can update the *System Time*, *Uptime*, and *WAN IP*.

A notification will appear in the *Firmware* field when a new version of FortiOS is released. Click *Update firmware in System > Firmware* to view the available versions and update FortiOS.

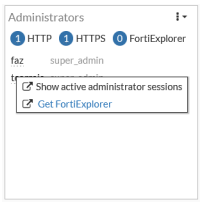
Viewing Fabric devices



The *Security Fabric* widget provides a visual overview of the devices connected to the Fabric and their connection status. Hover of a device icon to view more information about the device.

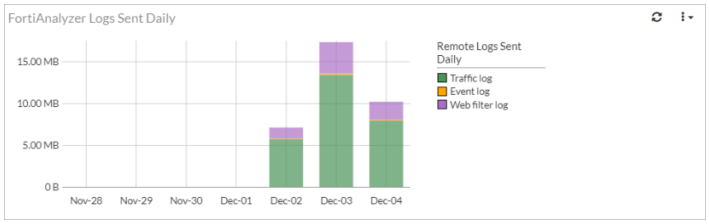
Click a device in the Fabric to:

- View the device in the physical or logical topology
- Register, configure, deauthorize, or log in to the device
- Open *Diagnostics and Tools*
- View the *FortiClient Monitor*



These options will vary depending on the device.

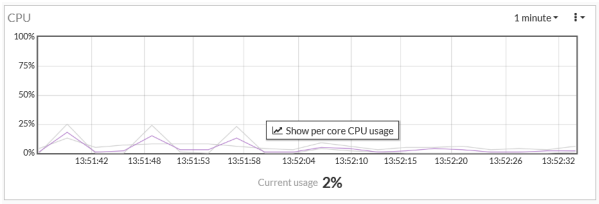
Click *Expand & Pin hidden content* to view all the devices in the Fabric at once.



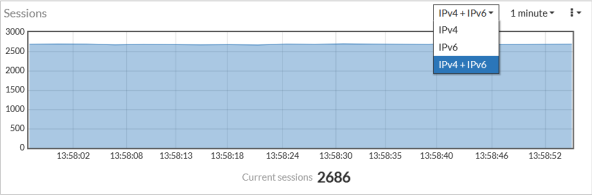
Viewing administrators

The *Administrators* widget displays the active administrators and their access interface. Click the username to view the *Active Administrator Sessions* monitor. You can use the monitor to end an administrator's session.

Viewing logs sent for remote logging source



The *Logs Sent* widget displays chart for remote logging sources (FortiAnalyzer, FortiGate Cloud, and FortiAnalyzer Cloud) sent daily.



Resource widgets

The resource widgets show the current usage statistics for *CPU*, *Memory*, and *Sessions*.

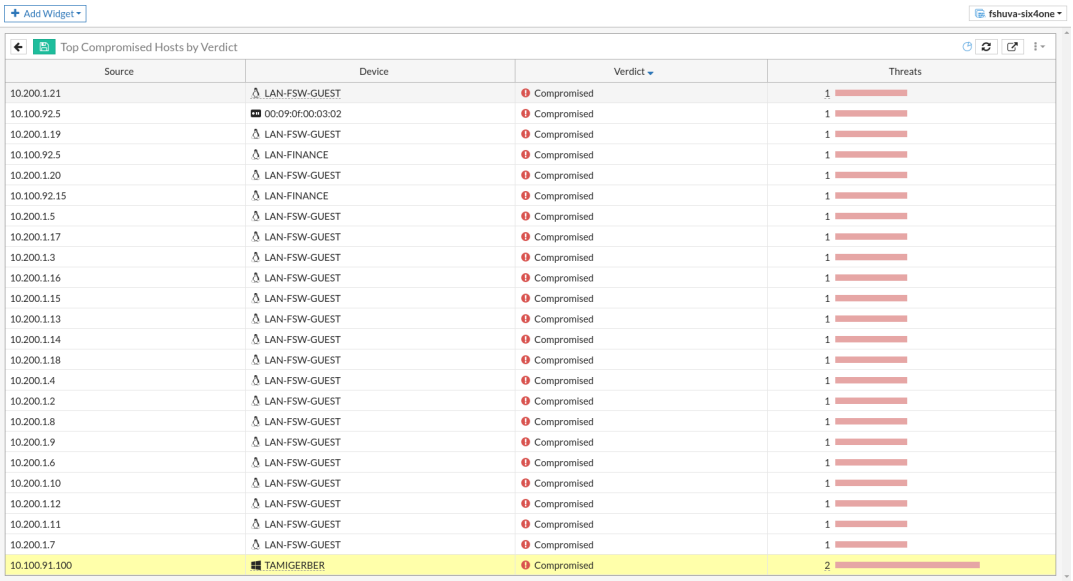
Click the *CPU* monitor to show the per core CPU usage.

You can switch between *IPv4*, *IPv6*, or *IPv4+IPv6* in the *Sessions* monitor.

Security dashboard

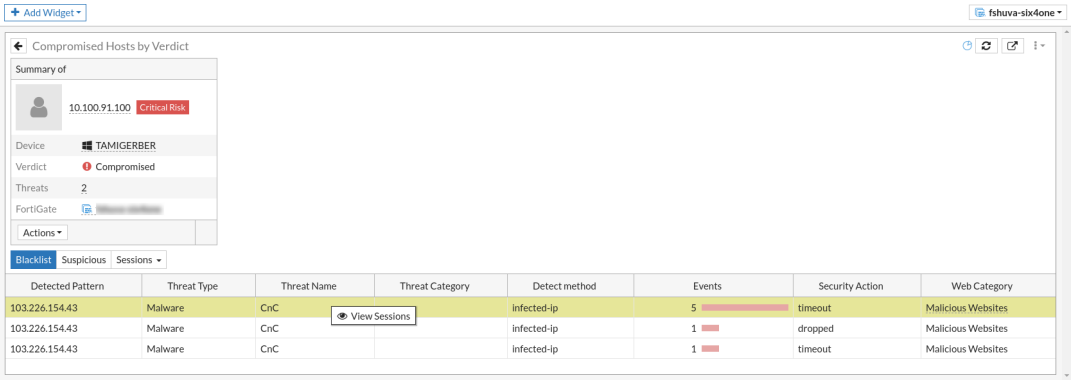
The widgets in the *Security* dashboard provide a snapshot of the current threats and vulnerabilities targeting your Security Fabric.

The *Security* dashboard contains the following widgets:



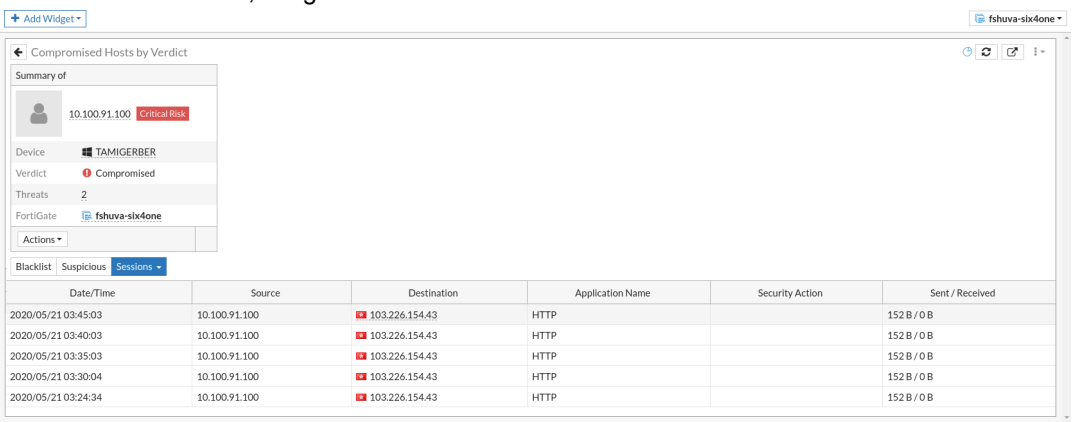
Widget	Description
Compromised Hosts by Verdict	Shows the session information for a compromised host. See Viewing session information for a compromised host on page 99.
Top Threats by Threat Level	Shows the top traffic sessions aggregated by threat. You can expand the widget to view drilldown information about the *Threat*, *Threat Category*, *Threat Level*, *Threat Score* and *Sessions*.
FortiClient Detected Vulnerablities	Shows a summary of vulnerabilities detected by FortiClient. FortiClient must be enabled.
Host Scan Summary	Shows a summary of hosts scanned. Hover over a color in the chart to view the number of hosts by category. Click the chart to view the *FortiClient Monitor* or *Device Inventory* monitor.
Top Vulnerable Endpoint Devices by Detected Vulnerabilities	Shows a summary devices aggregated by vulnerabilities. Expand the widget to view drilldown information about the *Device*, *Source* and *Detected Vulnerablities*.

Viewing session information for a compromised host



You can use the *Compromised Hosts by Verdict* widget to view the session information for a compromised host.

To view session information for a compromised host in the GUI:

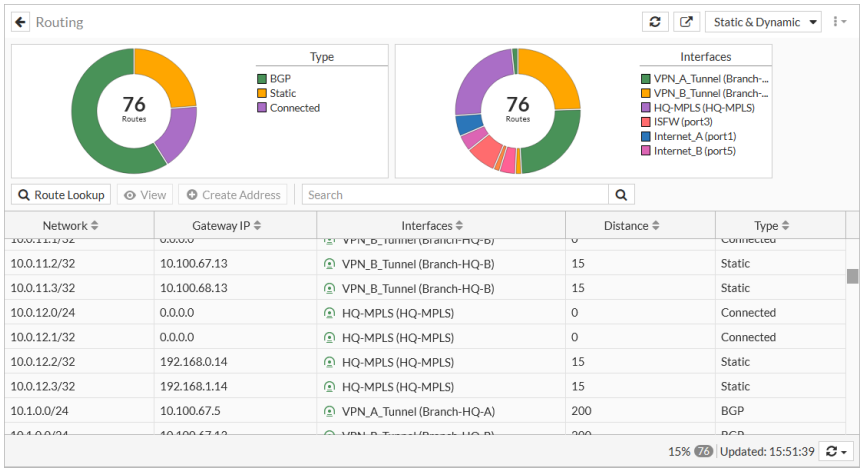


1. Go to *Dashboard* > *Security* and expand the *Compromised Hosts by Verdict* widget.

2. Double-click a compromised host to view the session information. You can also right-click a compromised host, and select *View Sessions*.

3. Double-click a session, or right-click the session and select *View Sessions* to view the information.

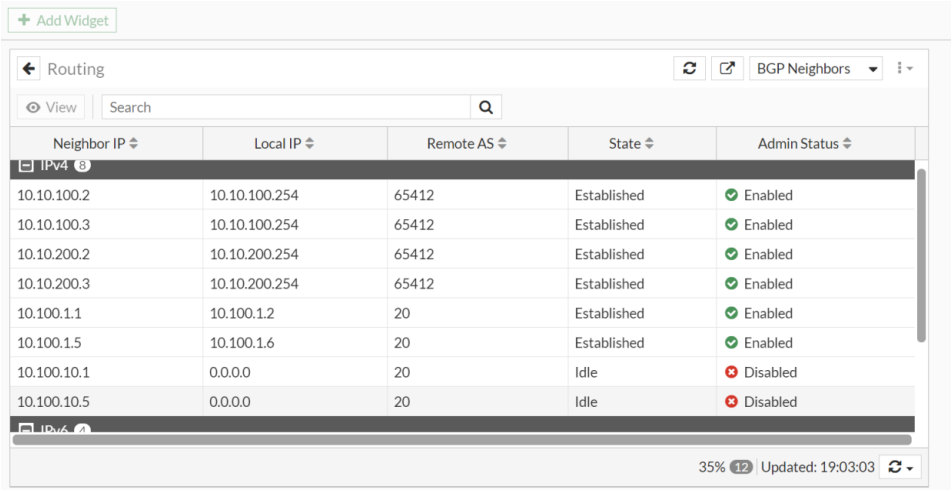
Network dashboard



The widgets in the Network dashboard show information related to networking for this FortiGate and other devices connected to your Security Fabric. Use this dashboard to monitor the status of Routing, DHCP, SD-WAN, IPsec and SSL VPN tunnels. All of the widgets in the *Network* dashboard can be expanded to full screen and saved as a monitor.

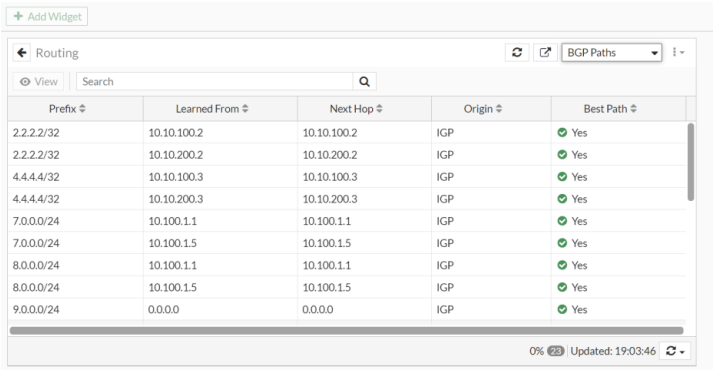
The *Network* dashboard contains the following widgets:

Widget	Description
Static & Dynamic Routing	Shows the static and dynamic routes currently active in your routing table. The widget also includes policy routes, BGP neighbors and paths, and OSPF neighbors. See Static & Dynamic Routing monitor on page 101.
DHCP	Shows the addresses leased out by FortiGate's DHCP servers. See DHCP monitor on page 104.
SD-WAN	Shows a summary of the SD-WAN status, including ADVPN shortcut information.
IPsec	Shows the connection statuses of your IPsec VPN site to site and dial-up tunnels. See IPsec monitor on page 105.
SSL-VPN	Shows a summary of remote active users and the connection mode. See SSL-VPN monitor on page 107.
IP Pool Utilization	Shows IP pool utilization.

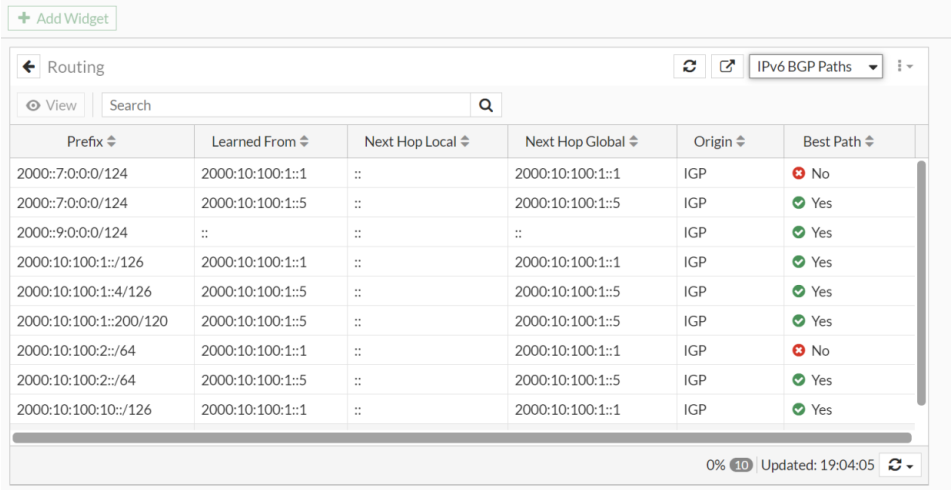


Static & Dynamic Routing monitor

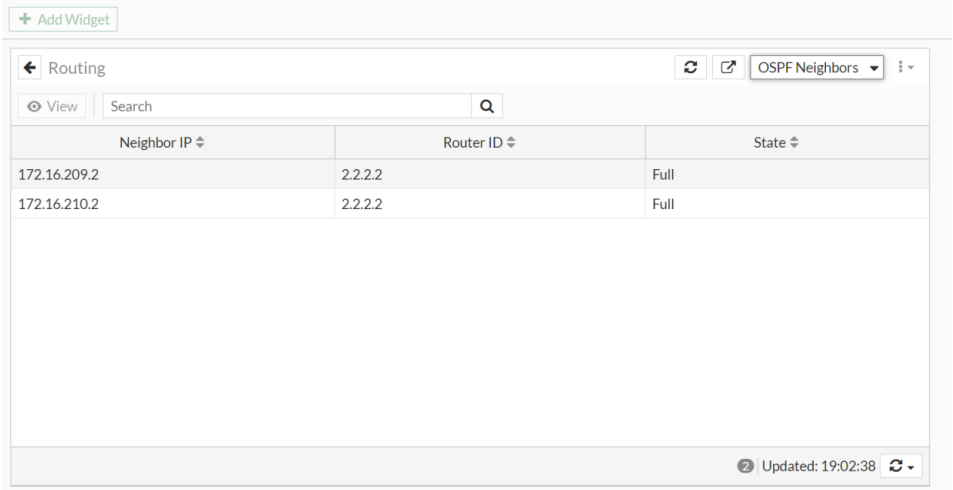
The *Static & Dynamic Routing Monitor* displays the routing table on the FortiGate, including all static and dynamic routing protocols in IPv4 and IPv6. You can also use this monitor to view policy routes, BGP neighbors and paths, and OSPF neighbors.



To view the routing monitor in the GUI:



1. Go to *Dashboard* > *Network*.
2. Hover over the *Routing* widget, and click *Expand to Full Screen*. The *Routing* monitor is displayed.
3. To view neighbors and paths, click the monitors dropdown at the top of the page.
   BGP Neighbors



BGP Paths

IPv6 BGP Paths

OSPF Neighbors

4. To filter the *Interfaces* and *Type* columns:
   a. Click the *Static & Dynamic* tab.
   b. Hover over the column heading, and click the *Filter/Configure Column* icon.

   c. Click *Group By This Column*, then click *Apply*.
5. (Optional) Click *Save as Monitor* to save the widget as monitor.

To look up a route in the GUI:

1. Click *Route Lookup*.
2. Enter an IP address in the *Destination* field, then click *Search*. The matching route is highlighted on the *Routing* monitor.

To view the routing table in the CLI:

```
# get route info routing-table all
```

Sample output:

```
Codes: K - kernel, C - connected, S - static, R - RIP, B - BGP
O - OSPF, IA - OSPF inter area
N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
E1 - OSPF external type 1, E2 - OSPF external type 2
i - IS-IS, L1 - IS-IS level-1, L2 - IS-IS level-2, ia - IS-IS inter area
* - candidate default

Routing table for VRF=0
S* 0.0.0.0/0 [1/0] via 10.0.10.1, To-HQ-A
[1/0] via 10.0.12.1, To-HQ-MPLS
[1/0] via 10.10.11.1, To-HQ-B
[1/0] via 10.100.67.1, port1

To view neighbors and paths
```

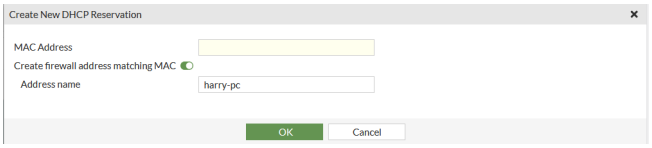
DHCP monitor

The DHCP monitor shows all the addresses leased out by FortiGate's DHCP servers. You can use the monitor to revoke an address for a device, or create, edit, and delete address reservations.

To view the DHCP monitor:

1. Go to *Dashboard* > *Network*.
2. Hover over the *DHCP* widget, and click *Expand to Full Screen*.

To filter or configure a column in the table, hover over the column heading and click *Filter/Configure Column*.



To revoke a lease:

1. Select a device in the table.
2. In the toolbar, click *Revoke*, or right-click the device, and click *Revoke Lease(s)*. The *Confirm* page is displayed.
3. Click *OK*.

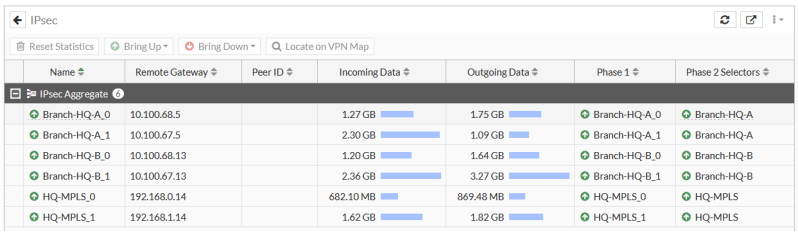
A confirmation window opens only if there is an associated address reservation. If there is no address, the lease will be removed immediately upon clicking *Revoke*.

To create a DHCP reservation:

1. Select a server in the table.
2. In the toolbar, click *Reservation*, or right-click the device and click *Create DHCP Reservation*. The *Create New DHCP Reservation* page is displayed.
3. Configure the DHCP reservation settings.

4. Click *OK*.

To view top sources by bytes:



1. Right-click a device in the table and click *Show in FortiView*. The *FortiView Sources by Bytes* widget is displayed.

To view the DHCP lease list in the CLI:

```
# execute dhcp lease-list
```

IPsec monitor

The IPsec monitor displays all connected Site to Site VPN, Dial-up VPNs, and ADVPN shortcut tunnel information. You can use the monitor to bring a phase 2 tunnel up or down or disconnect dial-up users. A notification appears in the monitor when users have not enabled two-factor authentication.

To view the IPsec monitor in the GUI:

1. Go to *Dashboard* > *Network*.
2. Hover over the *IPsec* widget, and click *Expand to Full Screen*. A warning appears when an unauthenticated user is detected.

   To filter or configure a column in the table, hover over the column heading and click *Filter/Configure Column*.

3. Hover over a record in the table. A tooltip displays the *Phase 1* and *Phase 2* interfaces. A warning appears next to a user who has not enabled two-factor authentication.

To reset statistics:

1. Select a tunnel in the table.
2. In the toolbar, click *Reset Statistics* or right-click the tunnel, and click *Reset Statistics*. The *Confirm* dialog is displayed.
3. Click *OK*.

To bring a tunnel up:

1. Select a tunnel in the table.
2. Click *Bring Up*, or right-click the tunnel, and click *Bring Up*. The *Confirm* dialog is displayed.
3. Click *OK*.

To bring a tunnel down:

1. Select a tunnel in the table.
2. Click *Bring Down*, or right-click the tunnel, and click *Bring Down*. The *Confirm* dialog is displayed.
3. Click *OK*.

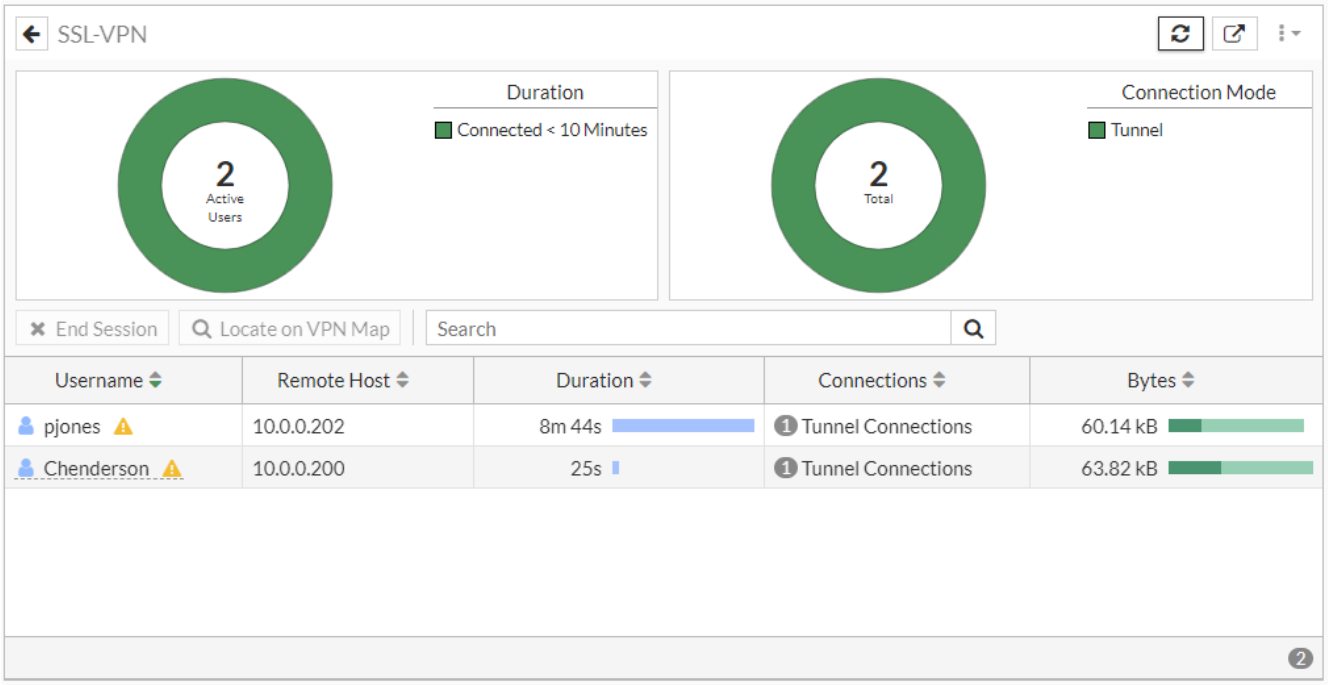
To locate a tunnel on the VPN Map:

1. Select a tunnel in the table.
2. Click *Locate on VPN Map*, or right-click the tunnel, and click *Locate on VPN Map*. The *VPN Location Map* is displayed.

To view the IPsec monitor in the CLI:

```
# diagnose vpn tunnel list
```

Sample output:



```
list all ipsec tunnel in vd 0

```

SSL-VPN monitor

The SSL-VPN monitor displays remote user logins and active connections. You can use the monitor to disconnect a specific connection. The monitor will notify you when VPN users have not enabled two-factor authentication.

To view the SSL-VPN monitor in the GUI:

1. Go *Dashboard* > *Network*.
2. Hover over the *SSL-VPN* widget, and click *Expand to Full Screen*.The *Duration* and *Connection Summary* charts are displayed at the top of the monitor.

To filter or configure a column in the table, hover over the column heading and click *Filter/Configure Column*.

To disconnect a user:

1. Select a user in the table.
2. In the table, right-click the user, and click *End Session*. The Confirm window opens.
3. Click *OK*.

To monitor SSL-VPN users in the CLI:

```
# get vpn ssl monitor
```

Sample output

```
SSL VPN Login Users:
Index User Group Auth Type Timeout From HTTP in/out HTTPS in/out
0 amitchell TAC 1(1) 296 10.100.64.101 3838502/11077721 0/0
1 mmiles Dev 1(1) 292 10.100.64.101 4302506/11167442 0/0

SSL VPN sessions:
Index User Group Source IP Duration I/O Bytes Tunnel/Dest IP
```

Users & Devices

The *Users & Devices* dashboard shows the current status of users and devices connected to your network. All of the widgets can be expanded to view as monitor. In monitor view, you can create firewall addresses, deauthenticate a user, or remove a device from the network.

The *User & Devices* dashboard contains the following widgets:

Widget	Description
Device Inventory	Shows a summary of the hardware and software that is connected to the network. See Device inventory on page 109.
FortiClient	Shows a summary of the FortiClient endpoints.
Firewall Users	Shows a summary of the users logged into the network.
Quarantine	Shows a summary of quarantined devices.
FortiSwitch NAC VLANs	Shows a summary of VLANs assigned to devices by FortiSwitch NAC policies.

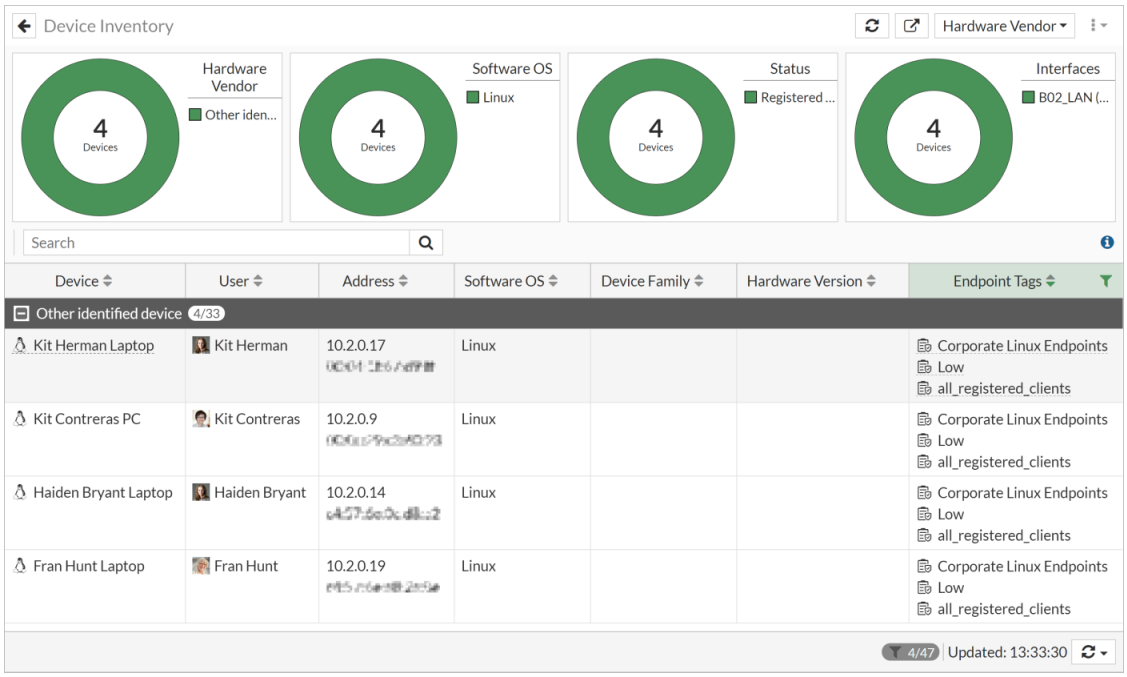
Device inventory

You can enable device detection to allow FortiOS to monitor your networks and gather information about devices operating on those networks, including:

- MAC address
- IP address
- Operating system
- Hostname
- Username
- Endpoint tags
- When FortiOS detected the device and on which interface

You can enable device detection separately on each interface in *Network* > *Interfaces*.

Device detection is intended for devices directly connected to your LAN and DMZ ports. The widget is only available when your *Interface Role* is *LAN*, *DMZ* or *Undefined*. It is not available when the role is WAN.



You can also manually add devices to Device Inventory to ensure that a device with multiple interfaces displays as a single device.

To view the device inventory monitor:

1. Go to *Dashboard* > *Users & Devices*.
   If you are using the Comprehensive dashboard template, go to *Dashboard* > *Device Inventory Monitor*.
2. Hover over the *Device Inventory* widget, and click *Expand to Full Screen*. The *Device Inventory* monitor is displayed.

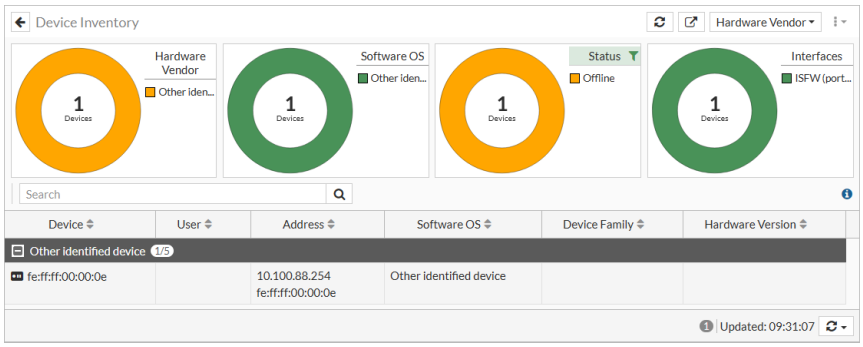
To filter or configure a column in the table, hover over the column heading, and click *Filter/Configure Column*. See Device inventory and filtering on page 110.

Device inventory and filtering

The *Device Inventory* widget contains a series of summary charts that provide an overview of the hardware, operating system, status, and interfaces. You can use these clickable charts to simplify filtering among your devices.

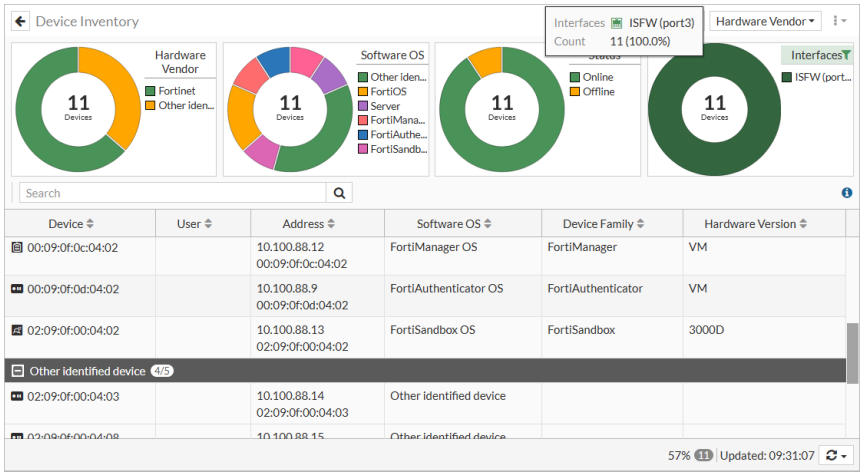
To view the device inventory and apply a filter:

1. Go to *Dashboard* > *Users & Devices*.
   If you are using the Comprehensive dashboard template, go to *Dashboard* > *Device Inventory Monitor*. See .
2. Hover over the *Device Inventory* widget, and click *Expand to Full Screen*. The *Device Inventory* monitor is displayed.
3. To filter the order of the charts by operating system, click the dropdown in the top menu bar and select *Software OS*.
4. To filter a chart, click an item in the legend or chart area. The table displays the filter results.
5. To combine filters, hover over a column heading and click *Filter/Configure Column*.



6. Click the filter icon in the top-right corner of the chart to remove the filter.

Filter examples

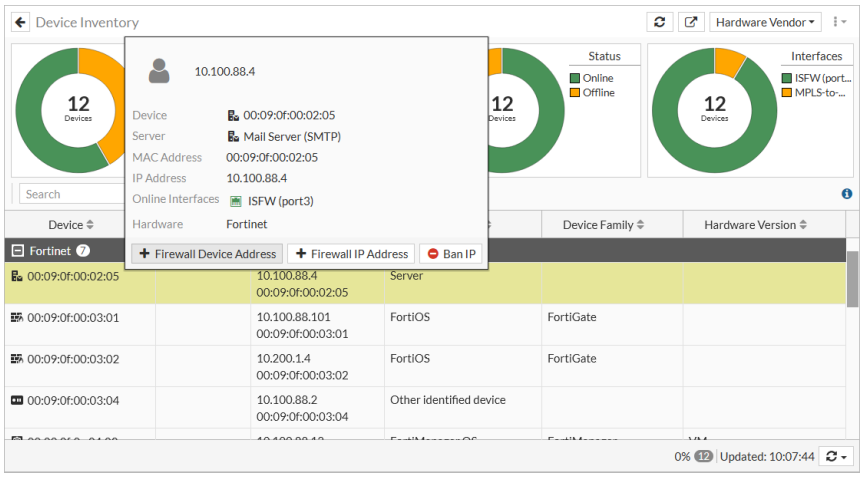


To filter all offline devices:

1. In the *Status* chart, click *Offline* in the legend or on the chart itself.

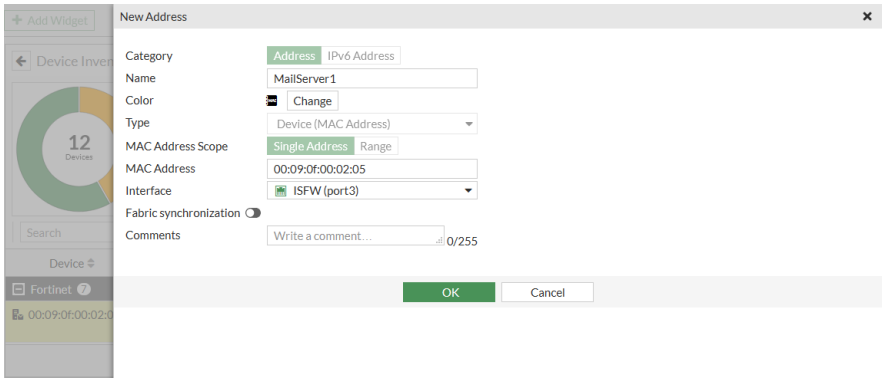
To filter all devices discovered on port3:

1. In the *Interfaces* chart, click *port3*.



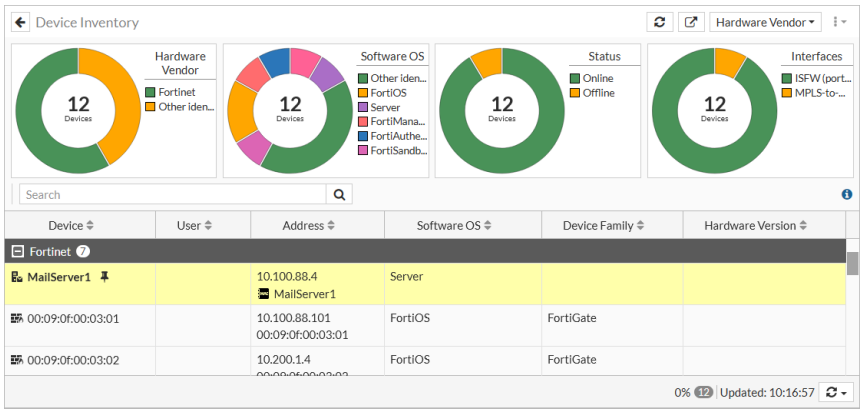
Adding MAC-based addresses to devices

Assets detected by device detection appear in the *Device Inventory* widget. You can manage policies around devices by adding a new device object (MAC-based address) to a device. Once you add the MAC-based address, the device can be used in address groups or directly in policies.



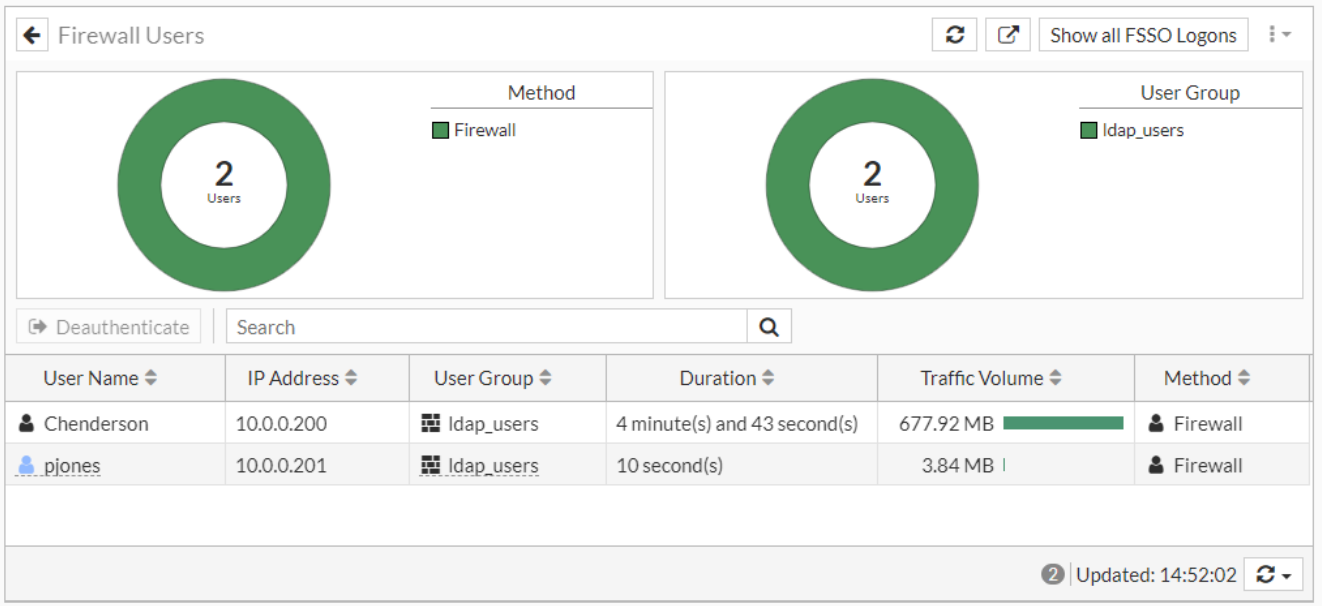
To add a MAC-based address to a device:

1. Go to *Dashboard* > *Users & Devices*.
   If you are using the Comprehensive dashboard template, go to *Dashboard* > *Device Inventory Monitor*. See .
2. Hover over the *Device Inventory* widget, and click *Expand to Full Screen*. The *Device Inventory* monitor is displayed.



3. Click a device, then click *Firewall Device Address*. The *New Address* dialog is displayed.

4. In the *Name* field, give the device a descriptive name so that it is easy to in the *Device* column.
5. Configure the *MAC Address*.



6. Click *OK*, then refresh the page. The MAC address icon appears in the *Address* column next to the device name.

Firewall Users monitor

The Firewall Users monitor displays all firewall users currently logged in. You can use the monitor to diagnose user-related logons or to highlight and deauthenticate a user.

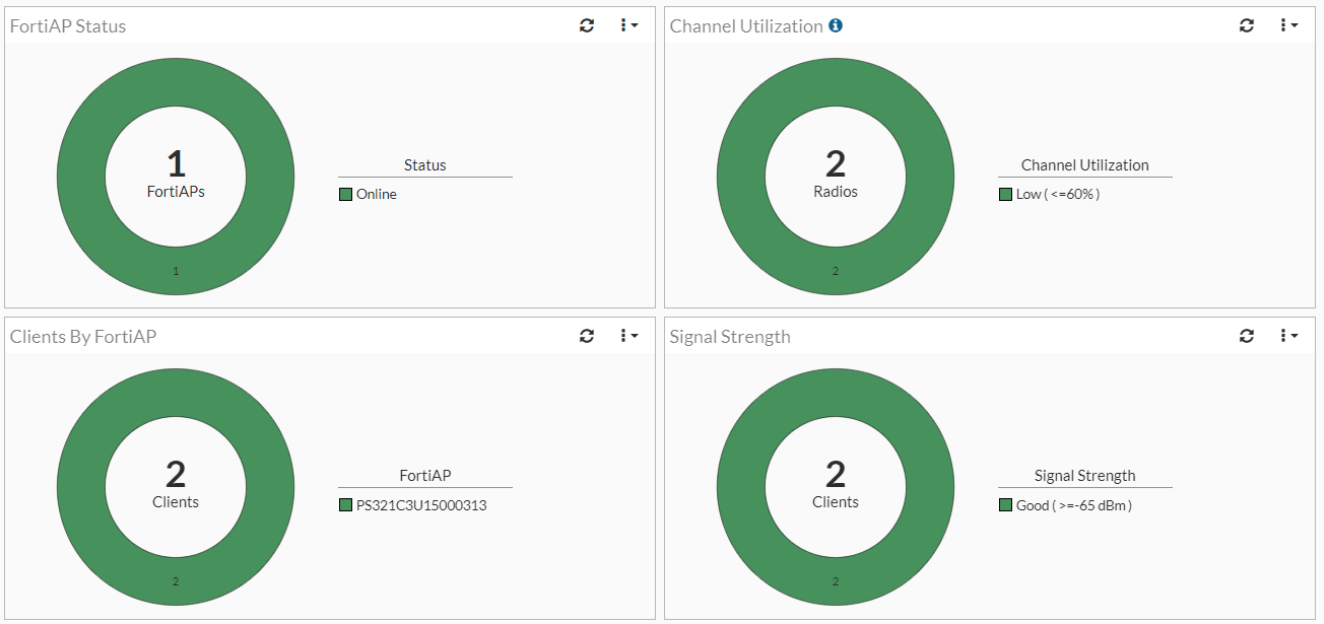
To view the firewall monitor:

1. Go to *Dashboard* > *Users & Devices*.
   If you are using the Comprehensive dashboard template, go to *Dashboard* > *Firewall User Monitor*. See .
2. Hover over the *Firewall Users* widget, and click *Expand to Full Screen*.
3. To show FSSO logons, click *Show all FSSO Logons* at the top right of the page.

To filter or configure a column in the table, hover over the column heading and click *Filter/Configure Column*.

To deauthenticate a user:

1. Go to *Dashboard* > *Users & Devices*.
2. Hover over the *Firewall Users* widget, and click *Expand to Full Screen*.
3. (Optional) Use the *Search* field to search for a specific user.
4. In the toolbar, click *Deauthenticate*, or right-click the user, and click *Deauthenticate*. The *Confirm* dialog is displayed.
5. Click *OK*.



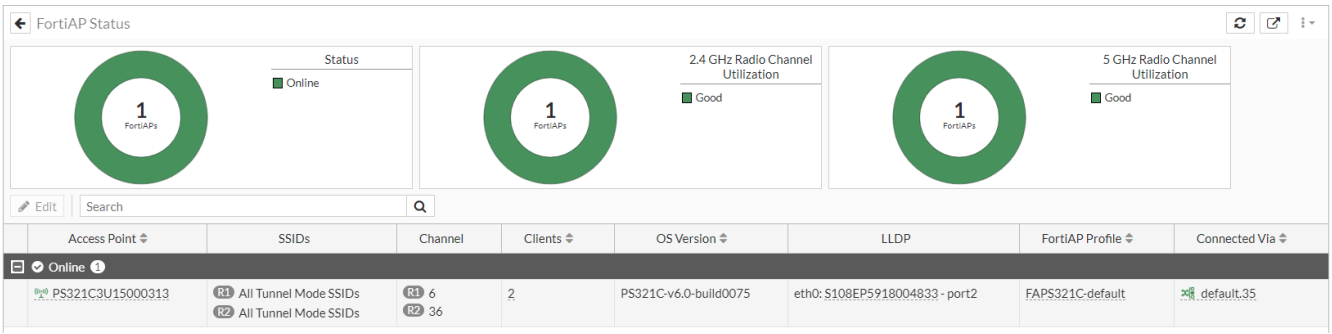
To view firewall users in the CLI:

```
# diagnose firewall auth list
```

WiFi dashboard

The *WiFi* dashboard provides an overview of your WiFi network's performance, including FortiAP status, channel utilization, WiFi clients and associated information, login failures, and signal strength.

To access the WiFi dashboard, go to *Dashboard* > *WiFi*.

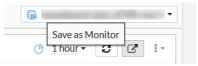


The WiFi dashboard can be customized per your requirements. To learn more about using and modifying dashboards and widgets, see Dashboards and Monitors on page 88.

This section describes the following monitors available for the WiFi Dashboard:

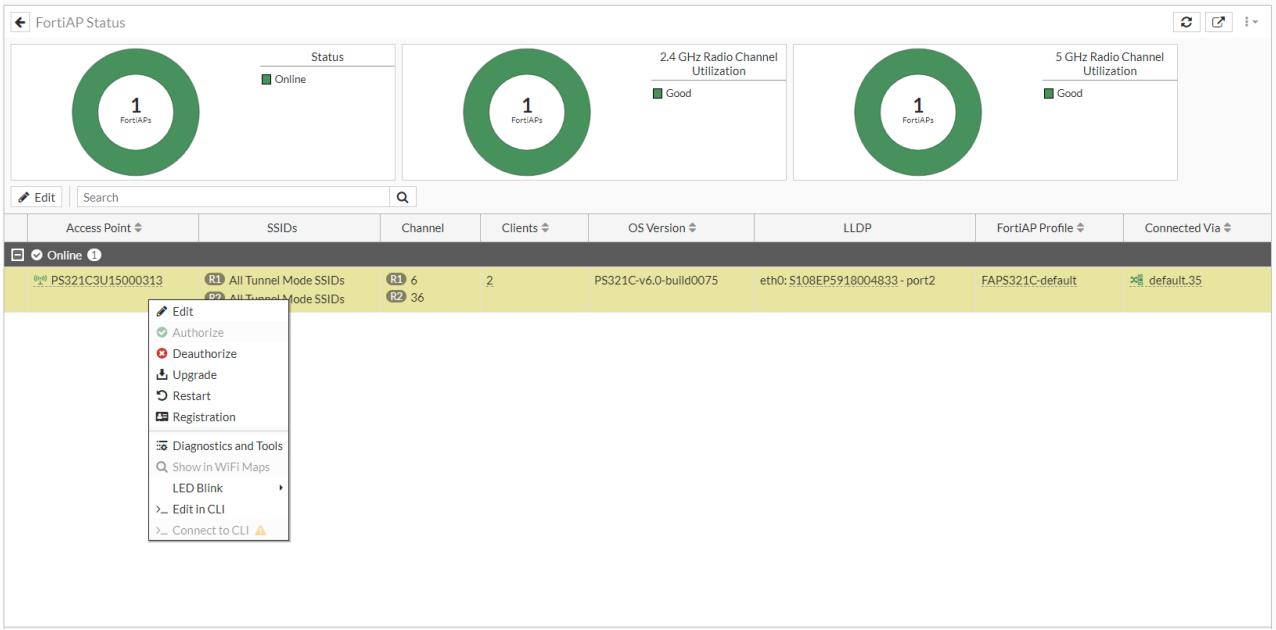
- FortiAP Status monitor on page 114
- Clients by FortiAP monitor on page 116

FortiAP Status monitor



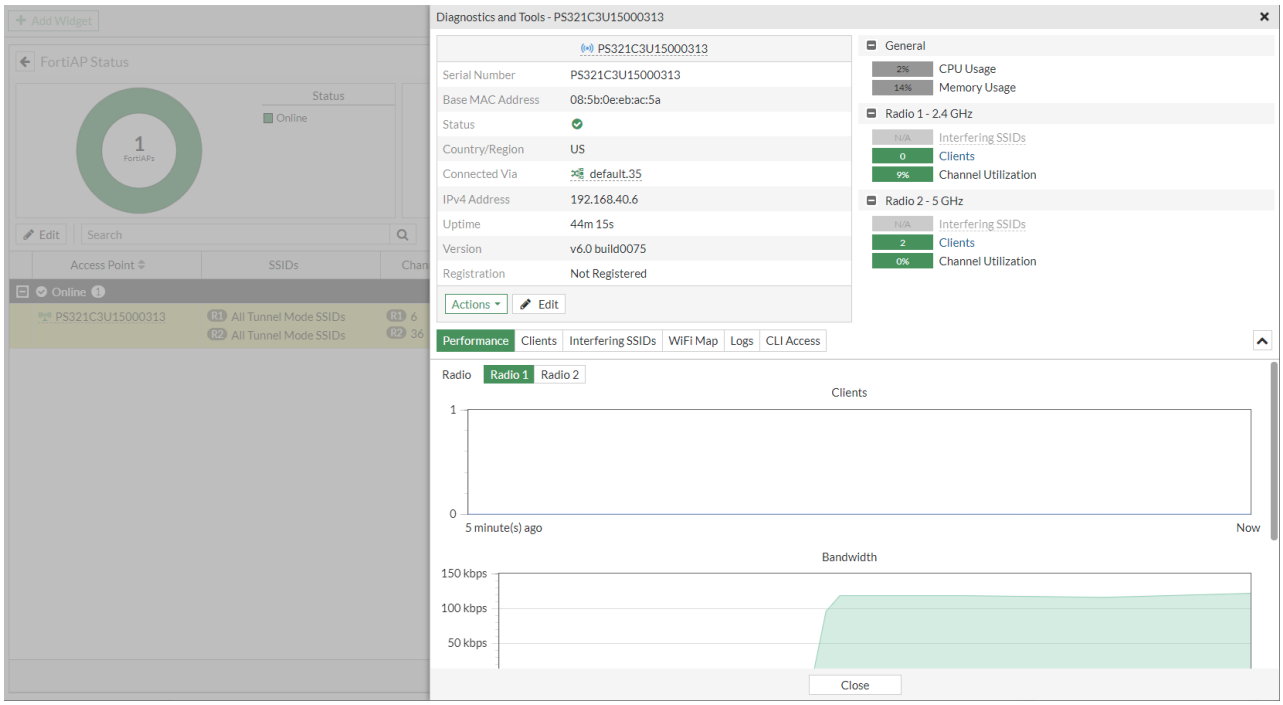
The *FortiAP Status* monitor displays the status and the channel utilization of the radios of FortiAP devices connected to a FortiGate. It also provides access to tools to diagnose and analyze connected APs.

To view the *FortiAP Status* monitor:



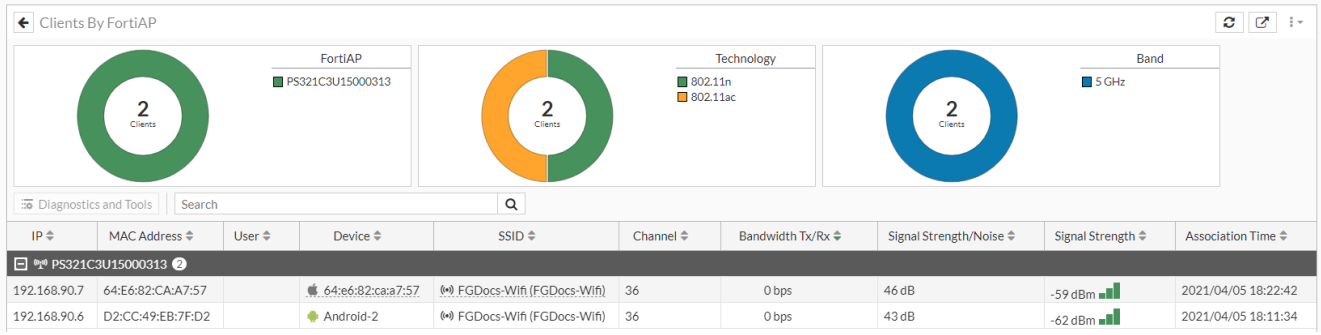
1. Go to *Dashboard* > *WiFi*.
2. Hover over the *FortiAP Status* widget, and click *Expand to Full Screen*. The *FortiAP Status* monitor opens.

3. (Optional) Click *Save as Monitor* to save the widget as monitor.



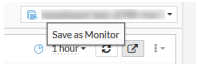
To view the Diagnostics and Tools menu:

1. Right-click an *Access Point* in the table, and click *Diagnostics and Tools*. The *Diagnostics and Tools* dialog opens.



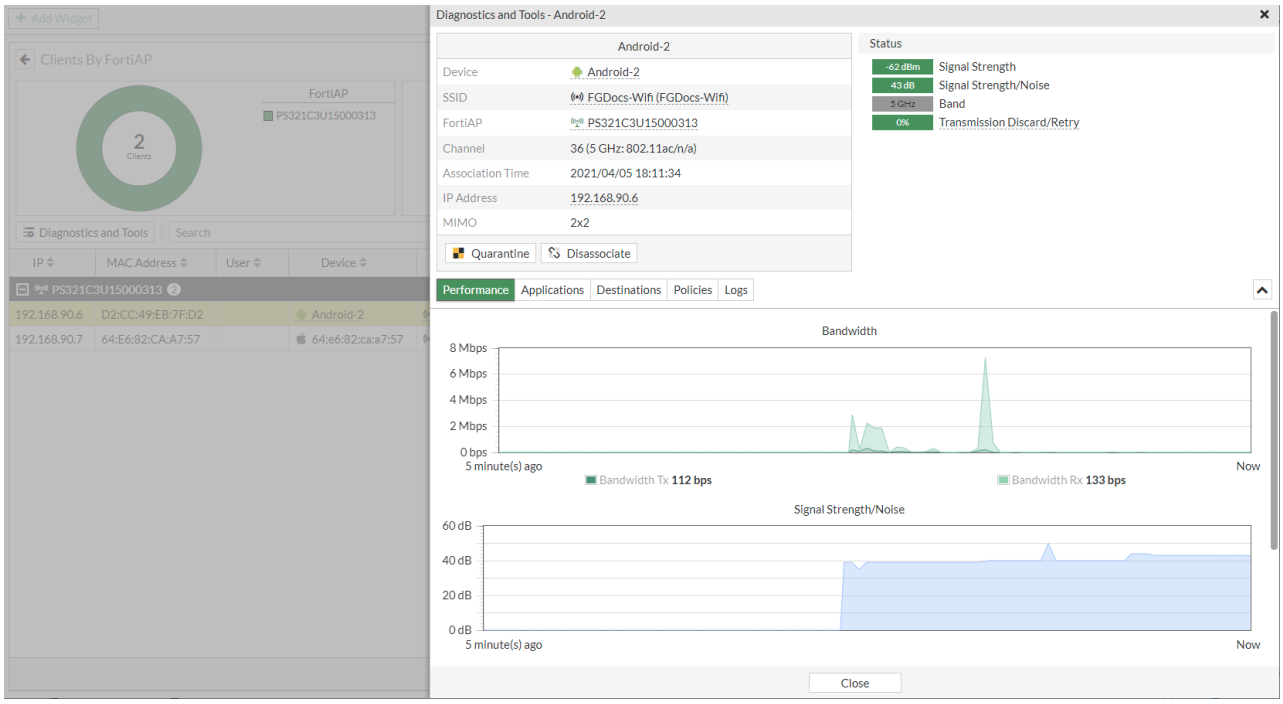
2. To monitor and analyze the FortiAP device, click on the tabs in the *Diagnostics and Tools* dialog, such as *Clients*, *Spectrum Analysis*, *VLAN Probe*, and so on.

The *Diagnostics and Tools* dialog is similar to the device dialog from *WiFi & Switch Controller* > *Managed FortiAPs*. To learn more about the various tabs and their functions, see Spectrum analysis of FortiAP E models, VLAN probe report, and Standardize wireless health metrics.



Clients by FortiAP monitor

The *Clients by FortiAP* monitor allows you to view detailed information about the health of individual WiFi connections in the network. It also provides access to tools to diagnose and analyze connected wireless devices.



To view the *Clients by FortiAP* monitor:

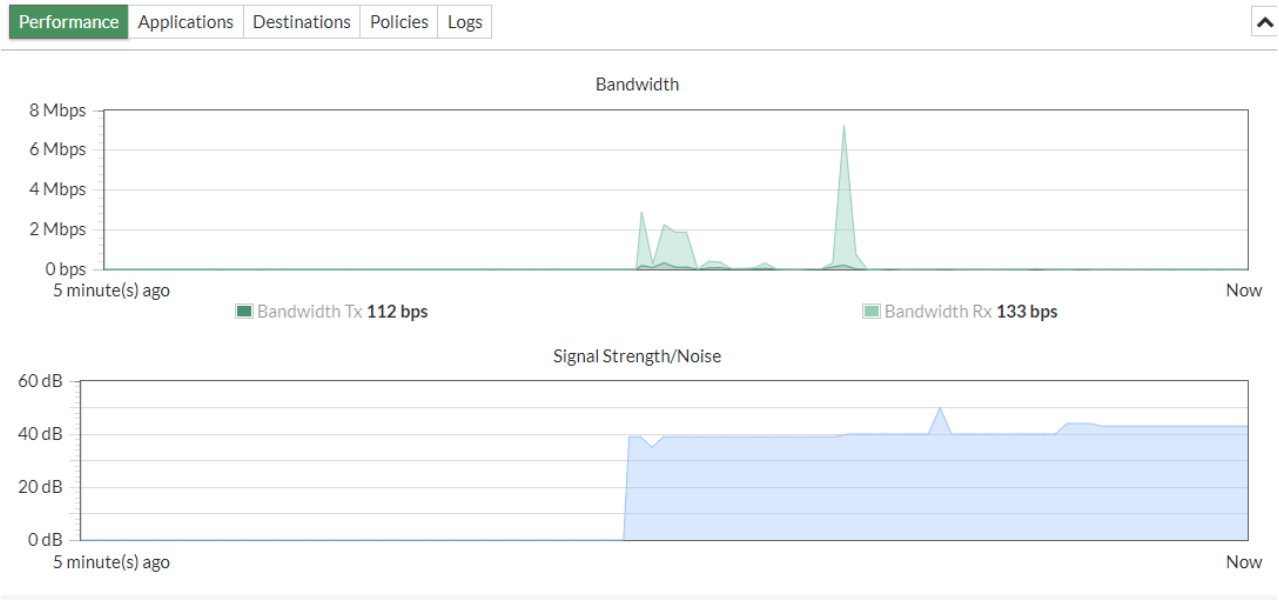
1. Go to *Dashboard* > *WiFi*.
2. Hover over the *Clients by FortiAP* widget, and click *Expand to Full Screen*. The *Clients by FortiAP* monitor opens.
3. (Optional) Click *Save as Monitor* to save the widget as monitor.

To view the summary page for a wireless client:

1. Right-click a client in the table and select *Diagnostics and Tools*. The *Diagnostics and Tools - <device>* page is displayed.

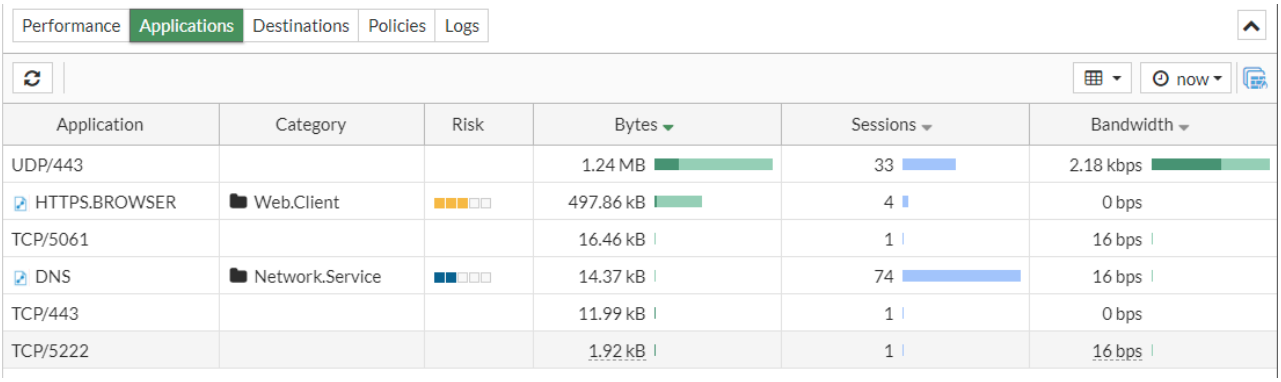
2. (Optional) Click *Quarantine* to quarantine the client,
3. (Optional) Click *Disassociate* to disassociate the client.

Health status



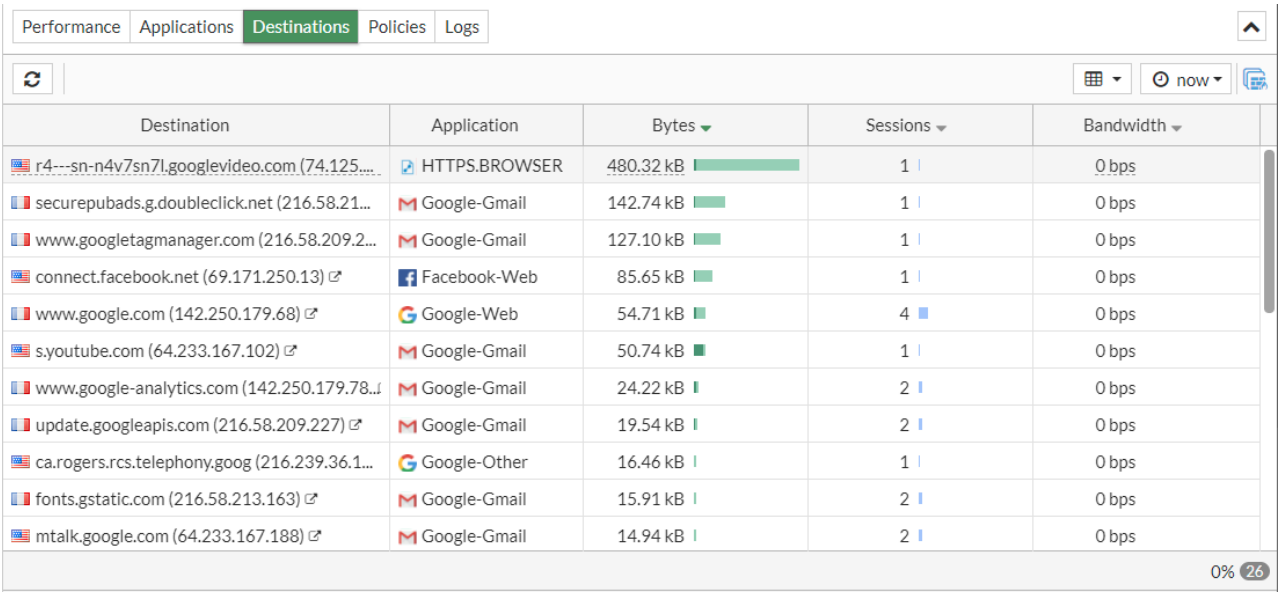
The *Status* section displays the overall health for the wireless connection. The overall health of the connection is:

- Good if the value range for all three conditions are *Good*
- Fair or poor if one of the three conditions is *Fair* or *Poor* respectively.

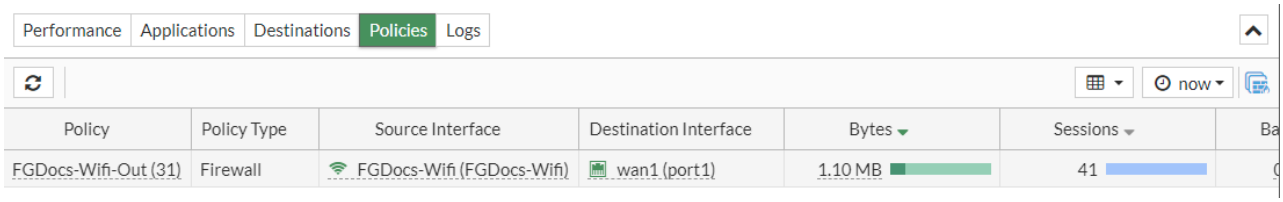


Condition	Value Range
Signal Strength	• *Good > -56dBm* • *-56dBm > Fair > -75dBm* • *Poor < -75dBm*
Signal Strength/Noise	• *Good > 39dBm* • *20dBm < Fair < 39dBm* • *Poor < 20dBm*
Band	• *Good = 5G band* • *Fair = 2.4G band*

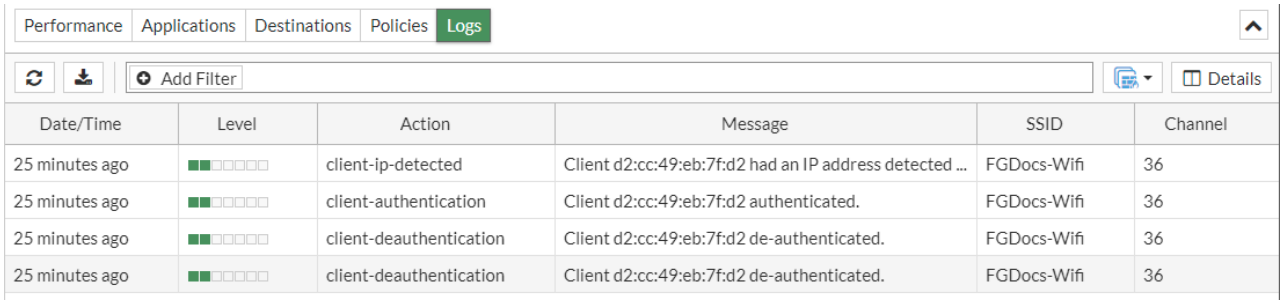
The summary page also has the following FortiView tabs:



- *Performance*



- *Applications*



- *Destinations*

- *Policies*

- *Logs*

Monitors

FortiGate supports both FortiView and Non-FortiView monitors. FortiView monitors are driven by traffic information captured from logs and real-time data. Non-FortiView monitors capture information from various real-time state tables on the FortiGate.

Non-FortiView monitors

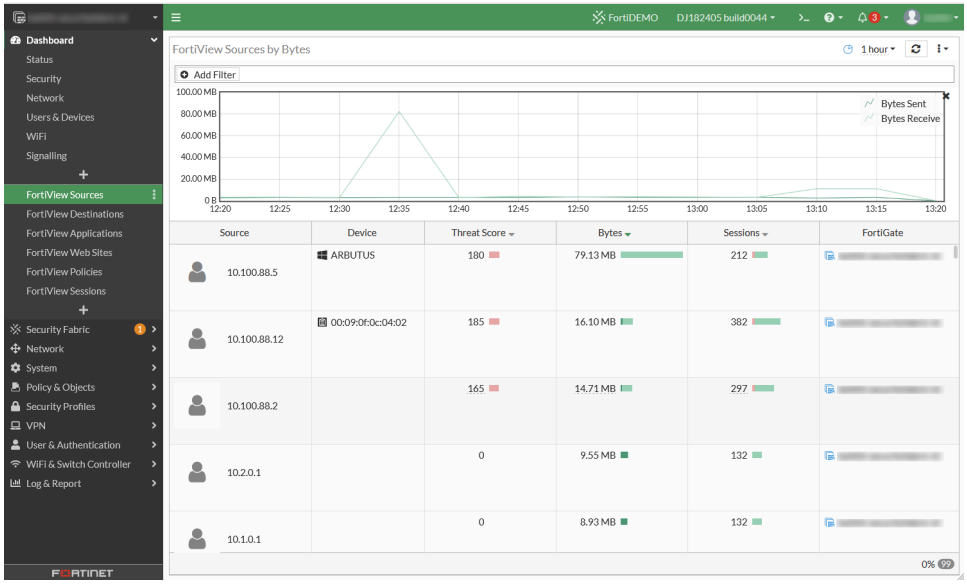
Non-FortiView monitors capture information on various state tables, such as the routes in the routing table, devices in the device inventory, DHCP leases in the DHCP lease table, connected VPNs, clients logged into the wireless network, and much more. These monitors are useful when troubleshooting the current state of the FortiGate, and to identify whether certain objects are in the state table or not. For more information, see Dashboards on page 95.

FortiView monitors

FortiView is the FortiOS log view tool and comprehensive monitoring system for your network. FortiView integrates real-time and historical data into a single view on your FortiGate. It can log and monitor network threats, keep track of administration activities, and more.

Use FortiView monitors to investigate traffic activity such as user uploads and downloads, or videos watched on YouTube. You can view the traffic on the whole network by user group or by individual. FortiView displays the information in both text and visual format, giving you an overall picture of your network traffic activity so that you can quickly decide on actionable items.

FortiView is integrated with many UTM functions. For example, you can quarantine an IP address directly in FortiView or create custom devices and addresses from a FortiView entry.



The logging range and depth will depend on the FortiGate model.

The *Optimal* template contains a set of popular default dashboards and FortiView monitors. The *Comprehensive* template contains a set of default dashboards as well as all of the FortiView monitors. See Dashboards on page 95.

Template	Monitors
Optimal	• FortiView Sources • FortiView Destinations • FortiView Applications • FortiView Web Sites • FortiView Policies • FortiView Sessions
Comprehensive	• FortiView Sources • FortiView Destinations • FortiView Applications • FortiView Web Sites • FortiView Threats • FortiView Compromised Hosts • FortiView Policies • FortiView Sessions • Device Inventory Monitor • Routing Monitor • DHCP Monitor • SD-WAN Monitor • FortiGuard Quota Monitor • IPsec Monitor • SSL-VPN Monitor • Firewall User Monitor • Quarantine Monitor • FortiClient Monitor • FortiAP Clients Monitor • Rogue APs Monitor

FortiView monitors and widgets

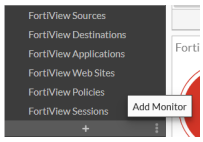
FortiView monitors are available in the tree menu under *Dashboards*. The menu contains several default monitors for the top categories. Additional FortiView monitors are available as widgets that can be added to the dashboards. You can also add FortiView monitors directly to the tree menu with the Add (**+**) button.

Core FortiView monitors

The following default monitors are available in the tree menu:

Dashboard	Usage
FortiView Sources	Displays Top Sources by traffic volume and drilldown by Source.
FortiView Destinations	Displays Top Destinations by traffic volume and drilldown by Destination.
FortiView Applications	Displays Top Applications by traffic volume and drilldown by Application.
FortiView Web Sites	Displays Top Websites by session count and drilldown by Domain.
FortiView Policies	Displays Top Policies by traffic volume and drilldown by Policy number
FortiView Sessions	Displays Top Sessions by traffic source and can be used to end sessions.

Usage is based on default settings. The pages may be customized further and sorted by other fields.



You can quarantine a host and ban an IP from all of the core FortiView monitors.

Adding FortiView monitors

Non-core FortiView monitors are available in the *Add monitor* pane. You can add a FortiView widget to a dashboard or the tree menu as a monitor.

To add a monitor to the tree menu:

1. In the tree menu, under the monitors section, click *Add Monitor* (+). The *Add Monitor* window opens.

2. Click *Add* next to a monitor. You can use the *Search* field to search for a specific monitor.
3. In the *FortiGate* area, select *All FortiGates* or *Specify* to select a FortiGate device in the security fabric.
4. (Optional) In the *Data Source* area, select *Specify* and select a source device.
5. From the *Time Period* dropdown, select the time period. This option is not available in all monitors.
6. In the *Visualization* area, select *Table View* or *Bubble Chart*.
7. From the *Sort By* dropdown, select the sorting method.
8. Click *Add Monitor*. The monitor is added to the tree menu.

Monitors by category

Usage is based on the default settings. The monitors may be customized further and sorted by other fields.

LANDMARK

Widget	Sort by	Usage
Applications	Bytes/Sessions/Bandwidth/Packets	Displays top applications and drilldown by application.
Application Bandwidth	Bytes/Bandwidth	Displays bandwidth for top applications and drilldown by application.
Cloud Applications	Bytes/Sessions/Files(Up/Down)	Displays top cloud applications and drilldown by application.
Cloud Users	Bytes/Sessions/Files(Up/Down)	Displays top cloud users and drilldown by cloud user.
Compromised Hosts	Verdict	Displays compromised hosts and drilldown by source.
Countries/Regions	Bytes/Sessions/Bandwidth/Packets	Displays top countries/regions and drilldown by countries/regions.
Destination Firewall Objects	Bytes/Sessions/Bandwidth/Packets	Displays top destination firewall objects and drilldown by destination objects.
Destination Owners	Bytes/Sessions/Bandwidth/Packets	Displays top destination owners and drilldown by destination.
Destinations	Bytes/Sessions/Bandwidth/Packets	Displays top destinations and drilldown by destination.

Widget	Sort by	Usage
Search Phrases	Count	Displays top search phrases and drilldown by search phrase.
Source Firewall Objects	Bytes/Sessions/Bandwidth/Packets	Displays top search phrases and drilldown by source object.
Sources	Bytes/Sessions/Bandwidth/Packets	Displays top sources and drilldown by source.
Threats	Threat level/Threat Score/Sessions	Displays top threats and drilldown by threat.
Traffic Shaping	Dropped Bytes/Bytes/Sessions/Bandwidth/Packets	Displays top traffic shaping and drilldown by shaper.
Web Categories	Bytes/Sessions/Bandwidth/Packets	Displays top web categories and drilldown by category.
Web Sites	Bytes/Sessions/Bandwidth/Packets	Displays top web sites and drilldown by domain.
WiFi Clients	Bytes/Sessions	Displays top WiFi clients and drilldown by source.

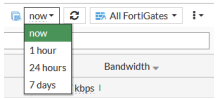
WAN

Widget	Sort by	Usage
Servers	Bytes/Sessions/Bandwidth/Packets	Displays top servers and drilldown by server address.
Sources	Bytes/Sessions/Bandwidth/Packets	Displays top sources and drilldown by device.
Threats	Threat Level/Threat Score/Sessions	Displays top threats and drilldown by threat.

All Segments

Widget	Sort by	Usage
Admin Logins	Configuration Changes/Logins/Failed Logins	Displays top admin logins by username.
Destination Interfaces	Bytes/Sessions/Bandwidth/Packets	Displays top destination interfaces by destination interface.
Endpoint Vulnerabilities	Severity	Displays top endpoint vulnerabilities by vulnerability name.
Failed Authentication	Failed Attempts	Displays top failed authentications by failed authentication source.
FortiSandbox Files	Submitted	Displays top FortiSandbox files by file name.

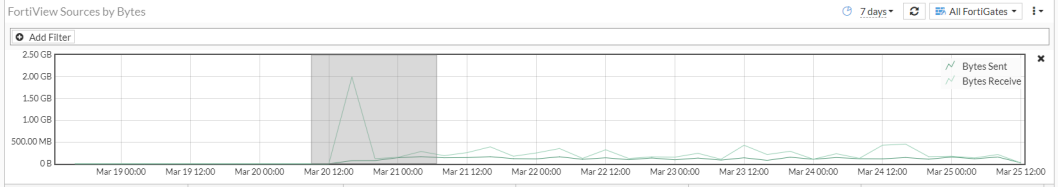
Widget	Sort by	Usage
Interface Pairs	Bytes/Sessions/Bandwidth/Packets	Displays top interface pairs by source interface.
Policies	Bytes/Sessions/Bandwidth/Packets	Displays top policies by policy.
Source Interfaces	Bytes/Sessions/Bandwidth/Packets	Displays top source interfaces by source interface.
System Events	Level/Events	Displays top system events by event name.
VPN	Connections/Bytes	Displays top VPN connections by user.
Vulnerable Endpoint Devices	Detected Vulnerabilities	Displays top vulnerable endpoint devices by device.



A maximum of 25 interfaces can be monitored at one time on a device.

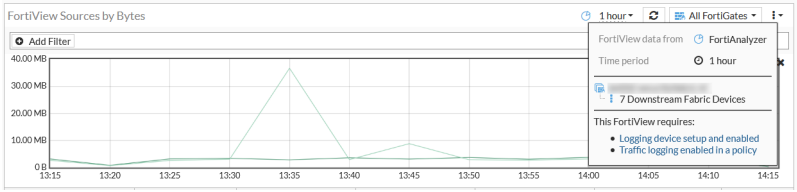
Using the FortiView interface

Use the FortiView interface to customize the view and visualizations within a monitor to find the information you are looking for. The tools in the top menu bar allow you to change the time display, refresh or customize the data source, and filter the results. You can also right-click a table in the monitor to view drilldown information for an item.



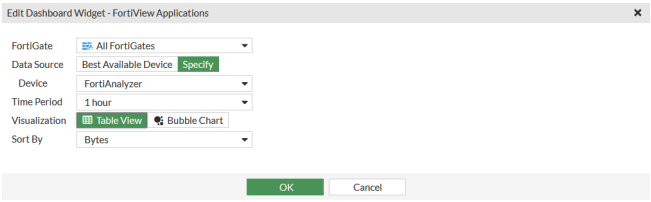
Real-time and historical charts

Use the *Time Display* dropdown to select the time period to display on the current monitor. Time display options vary depending on the monitor and can include real-time information (*now*) and historical information (*1 hour*, *24 hours*, and *7 days*).



Disk logging or remote logging must be enabled to view historical information.

You can create a custom time range by selecting an area in table with your cursor.

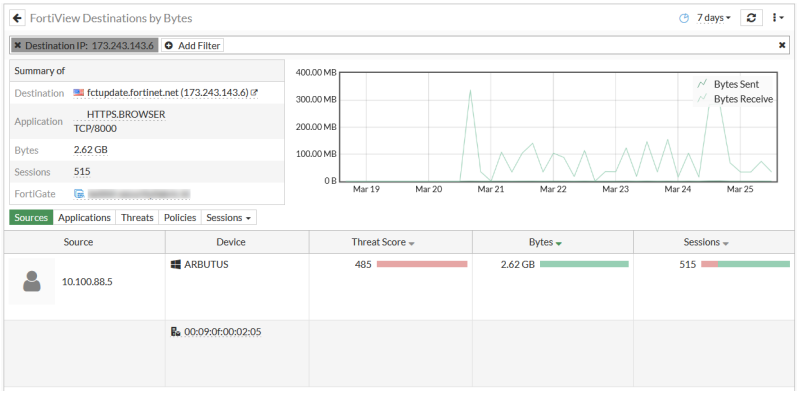


The icon next to the time period identifies the data source (FortiGate Disk, FortiAnalyzer, or FortiGate Cloud). You can hover over the icon to see a description of the device.

Data source

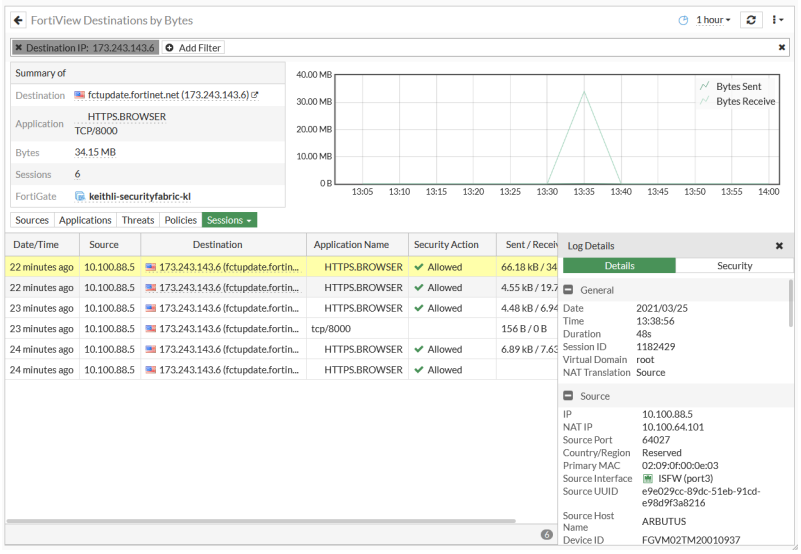
FortiView gathers information from a variety of data sources. If there are no log disk or remote logging configured, the data will be drawn from the FortiGate's session table, and the *Time Period* is set to *Now*.

Other data sources that can be configured are:



- FortiGates (disk)
- FortiAnalyzer
- FortiGate Cloud

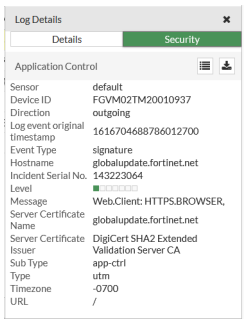
When *Data Source* is set to *Best Available Device*, FortiAnalyzer is selected when available, then FortiGate Cloud, and then FortiGate Disk.



Drilldown information

Double-click or right-click an entry in a FortiView monitor and select *Drill Down to Details* to view additional details about the selected traffic activity. Click the *Back* icon in the toolbar to return to the previous view.

You can group drilldown information into different drilldown views. For example, you can group the drilldown information in the *FortiView Destinations* monitor by *Sources*, *Applications*, *Threats*, *Policies*, and *Sessions*.



Double-click an entry to view the logs in *Sessions* view. Double-click a session to view the logs.

Graph	• The graph shows the bytes sent/received in the time frame. real time does not include a chart. • Users can customize the time frame by selecting a time period within the graph.
Summary of	• Shows information such as the user/avatar, avatar/source IP, bytes, and sessions total for the time period. • Can quarantine host (access layer quarantine) if they are behind a FortiSwitch or FortiAP. • Can ban IP addresses, adds the source IP address into the quarantine list.

Tabs	• Drilling down entries in any of these tabs (except sessions tab) will take you to the underlying traffic log in the sessions tab.
	• *Applications* shows a list of the applications attributed to the source IP. This can include scanned applications (using Application Control in a firewall policy or unscanned applications.
	`config log gui-display`
	`set fortiview-unscanned-apps enable`
	`end`
	• *Destinations* shows destinations grouped by IP address/FQDN.
	• *Threats* lists the threats caught by UTM profiles. This can be from antivirus, IPS, Web Filter, Application Control, etc.
	• *Web Sites* contains the websites which were detected either with webfilter, or through FQDN in traffic logs.
	• *Web Categories* groups entries into their categories as dictated by the Web Filter Database.
	• *Policies* groups the entries into which polices they passed through or were blocked by.
	• *Sessions* shows the underlying logs (historical) or sessions (real time). Drilldowns from other tabs end up showing the underlying log located in this tab.
	• *Search Phrases* shows entries of search phrases on search engines captured by a Web Filter UTM profile, with deep inspection enabled in firewall policy.
	• More information can be shown in a tooltip while hovering over these entries.

To view matching logs or download a log, click the *Security* tab in the *Log Details* .

Enabling FortiView from devices

You can enable FortiView from SSD disk, FortiAnalyzer and FortiGate Cloud.

FortiView from disk

FortiView from disk is available on all FortiGates with an SSD disk.

Restrictions

Model	Supported view
Desktop models (100 series) with SSD	Five minutes and one hour
Medium models with SSD	Up to 24 hours

Large models (1500D and above) with SSD	Up to seven days
	To enable seven days view:
	`config log setting`
	`set fortiview-weekly-data enable`
	`end`

Configuration

A firewall policy needs to be in place with traffic logging enabled. For optimal operation with FortiView, internal interface roles should be clearly defined as LAN. DMZ and internet facing or external interface roles should be defined as WAN.

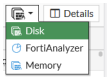
To configure logging to disk:

```
config log disk setting
   set status enable
end
```

To include sniffer traffic and local-deny traffic when FortiView from Disk:

```
config report setting
   set report-source forward-traffic sniffer-traffic local-deny-traffic
end
```

This feature is only supported through the CLI.



Troubleshooting

Use `execute report flush-cache` and `execute report recreate-db` to clear up any irregularities that may be caused by upgrading or cache issues.

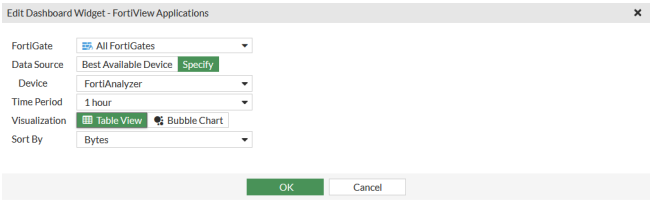
Traffic logs

To view traffic logs from disk:

1. Go to *Log & Report*, and select either the *Forward Traffic*, *Local Traffic*, or *Sniffer Traffic* views.
2. In the top menu bar, click *Log location* and select *Disk*.

FortiView from FortiAnalyzer

Connect FortiGate to a FortiAnalyzer to increase the functionality of FortiView. Adding a FortiAnalyzer is useful when adding monitors such as the *Compromised Hosts*. FortiAnalyzer also allows you to view historical information for up to seven days.



Requirements

- A FortiGate or FortiOS
- A compatible FortiAnalyzer (see Compatibility with FortiOS)

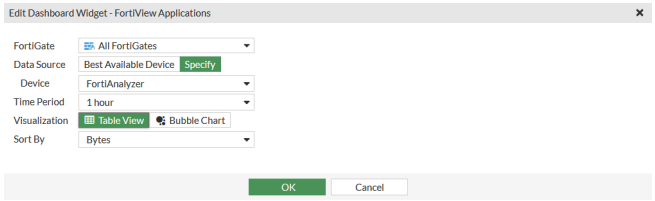
To configure logging to the FortiAnalyzer, see Configuring FortiAnalyzer on page 2595

To enable FortiView from FortiAnalyzer:

1. Go to *Dashboard* > *FortiView Sources*.
2. Select a time range other than *Now* from the dropdown list to view historical data.
3. In top menu, click the dropdown, and select *Settings*. The *Edit Dashboard Widget* dialog is displayed.
   a. In the *Data Source* area, click *Specify*.
   b. From the dropdown, select *FortiAnalyzer*, and click *OK*.

All the historical information now comes from the FortiAnalyzer.

When *Data Source* is set to *Best Available Device*, FortiAnalyzer is selected when available, then FortiGate Cloud, and then FortiGate Disk.



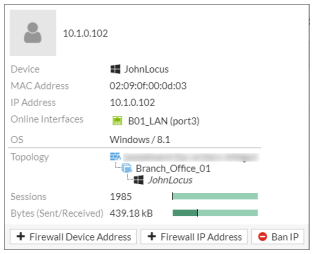
FortiView from FortiGate Cloud

This function requires a FortiGate that is registered and logged into a compatible FortiGate Cloud. When using FortiGate Cloud, the *Time Period* can be set to up to 24 hours.

To configure logging to FortiGate Cloud, see Configuring cloud logging on page 2598.

To enable FortiView with log source as FortiGate Cloud:

1. Go to *Dashboard* > *FortiView Sources*.
2. In the top menu, click the dropdown, and select *Settings*. The *Edit Dashboard Widget* window opens.
   a. In the *Data Source* area, click *Specify*.
   b. From the dropdown, select *FortiGate Cloud*, then click *OK*.



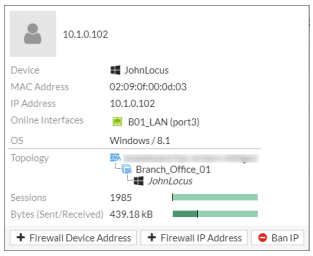
You can select FortiGate Cloud as the data source for all available FortiView pages and widgets.

FortiView sources

The *FortiView Sources* monitor displays top sources sorted by Bytes, Sessions or Threat Score. The information can be displayed in real time or historical views. You can use the monitor to create or edit a firewall device address or IP address definitions, and temporarily or permanently ban IPs.

To add a firewall device address:

1. In the *Device* column, hover over the device MAC address. An information window opens.

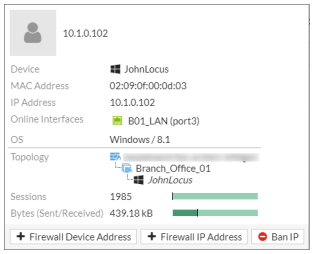


2. Click *Firewall Device Address*. The *New Address* dialog opens.
3. Configure the address settings, and click *Return*.

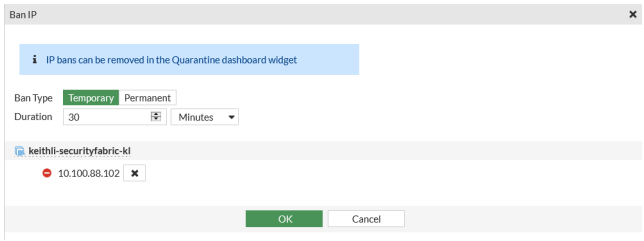
Use the *Name* field to assign a descriptive name to a device so it is easier to find it in the *Device* column. After you finish configuring the device, refresh the page to see the new name in the monitor.

To add a firewall IP address:

1. In the *Device* column, hover over the device MAC address. An information window opens.



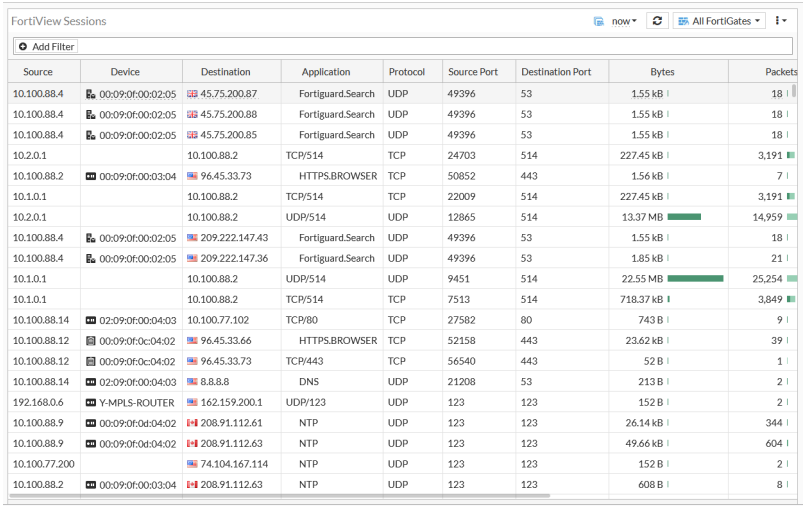
2. Click *Firewall IP Address*. The *New Address* window opens.
3. Configure the address settings, and click *Return*.



Use the *Name* field to assign a descriptive name to a device so it is easier to find it in the *Device* column. After you finish configuring the device, refresh the page to see the new name in the monitor.

To ban an IP address:

1. In the *Device* column, hover over the device MAC address. An information window opens.

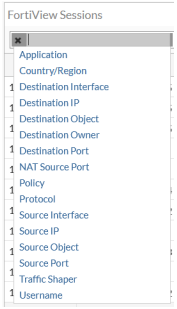


2. Click *Ban IP* . The *Ban IP* dialog is displayed.
3. Configure the ban IP settings, and click *OK*.

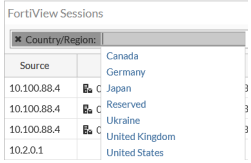
FortiView Sessions

The *FortiView Sessions* monitor displays *Top Sessions* by traffic source and can be used to end sessions.

To view the *FortiView Sessions* dashboard, go to *Dashboard* > *FortiView Sessions*.

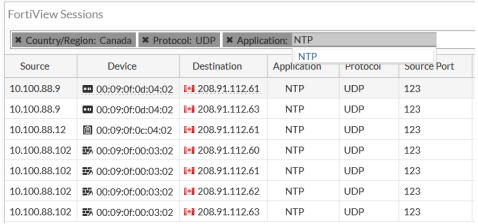


The session table displayed on the *FortiView Sessions* monitor is useful when verifying open connections. For example, if you have a web browser open to browse the Fortinet website, you would expect a session entry from your computer on port 80 to the IP address for the Fortinet website. You can also use a session table to investigate why there are too many sessions for FortiOS to process.



You can filter the sessions displayed in the session table by setting up the available filtering options.

To filter sessions in the session table:



1. Click on the *Add Filter* button at the top of the session table.

2. Select the required filtering option. The session table updates to the filter selection.

3. You may add one or more filters depending upon your requirements. To add more filters, repeat the above steps for a different set of filters.

You can be very specific with how you use filters and target sessions based on different filter combinations. For example, you may want to view all sessions from a device with a particular IP by adding the *Source IP* filter. Similarly, you may need to target all the sessions having a particular *Destination IP* and *Destination Port*, and so on.

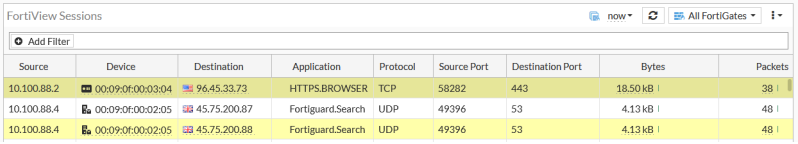
You may also view the session data in the CLI.

To view session data using the CLI:

```
# diagnose sys session list
```

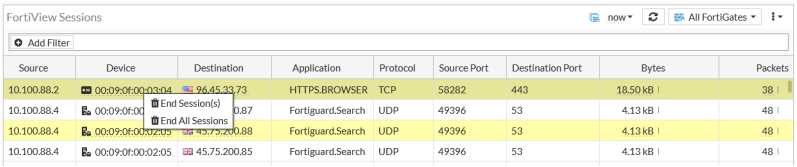
The session table output in the CLI is very large. You can use the supported filters in the CLI to show only the data you need.

To view session data with filters using the CLI:



```
# diagnose sys session filter <option>
```

See to learn more about using the supported filters in the CLI.



You may also decide to end a particular session or all sessions for administrative purposes.

To end sessions from the GUI:

1. Select the session you want to end. To select multiple sessions, hold the *Ctrl* or *Shift* key on your keyboard while clicking the sessions.

2. Right-click on the selected sessions, click on *End Session(s)* or *End All Sessions*.

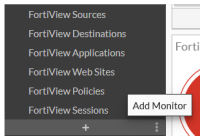
3. Click *OK* in the confirmation dialog.

FortiView Top Source and Top Destination Firewall Objects monitors

The *FortiView Source Firewall Objects* and *FortiView Destination Firewall Objects* monitors leverage UUID to resolve firewall object address names for improved usability.

Requirements

To have a historical *Firewall Objects*-based view, address objects' UUIDs need to be logged.

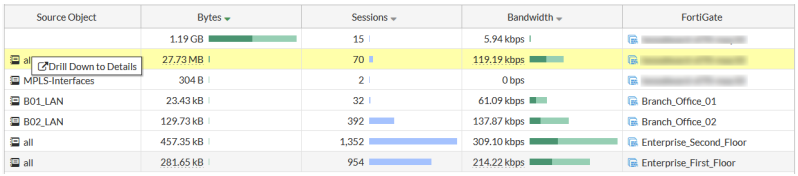


To enable address object UUID logging in the CLI:

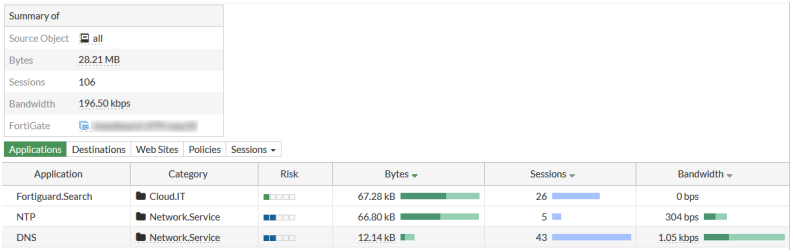
```
config system global
   set log-uuid-address enable
```

```
end
```

To add a firewall object monitor in the GUI:

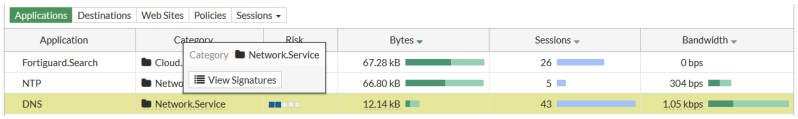


1. Click *Add Monitor*. The *Add Monitor* window opens.



2. In the *Search* field, type *Destination Firewall Objects* and click the *Add* button next to the dashboard name.
3. In the *FortiGate* area, select the FortiGate(s) from the dropdown.
4. In the *Data Source* area, select *Best Available Device* or *Specify*. For information, see Using the FortiView interface on page 124.
5. From the *Time Period* dropdown, select the time period. Select *now* for real-time information, or (*1 hour*, *24 hours*, and *7 days*) for historical information.
6. In the *Visualization* area, select *Table View* or *Bubble Chart*.
7. From the *Sort By* dropdown, select *Bytes*, *Sessions*, *Bandwidth*, or *Packets*.
8. Click *Add Monitor*. The monitor is added to the tree menu.

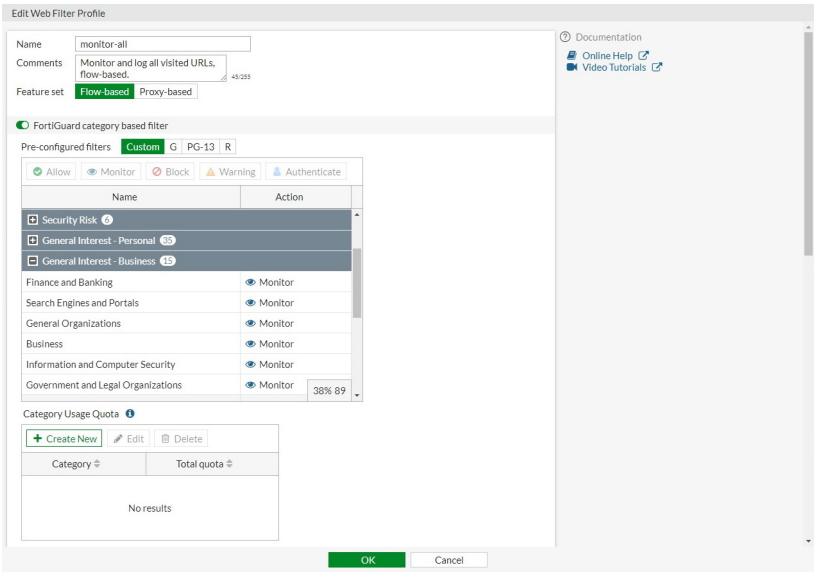
To drill down Firewall Objects:



1. Open the *FortiView Source Firewall Objects* or *FortiView Destination Firewall Objects* monitor.
2. Right-click on any *Source* or *Destination Object* and click *Drill Down to Details*.

3. Click the tabs to sort the sessions by *Application*, *Destinations*, *Web Sites*, or *Policies*.

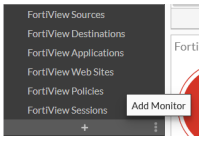
4. To view signatures, click the entry in the *Category* column.



5. To views sessions, right-click an entry and click *View Sessions*, or click the *Sessions* tab.
6. To end a session, right-click an entry in the Sessions tab and select *End Sessions* or *End All Sessions*.

Viewing top websites and sources by category

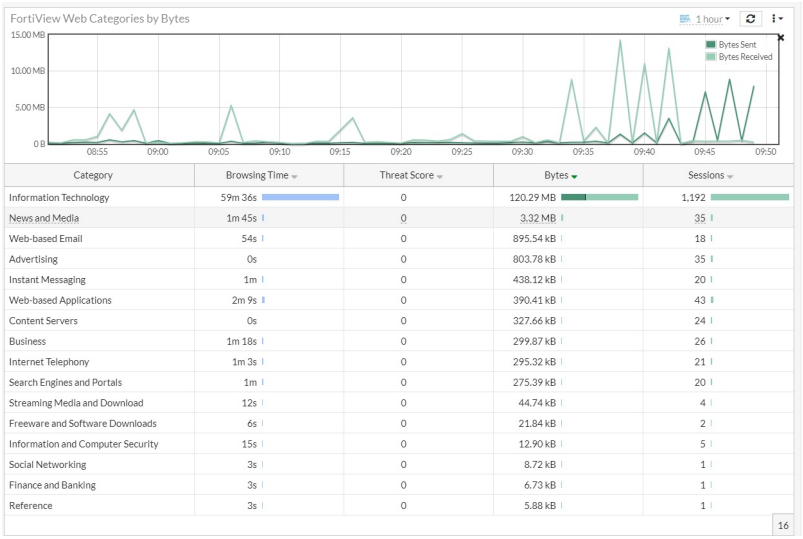
You can use FortiGuard web categories to populate the category fields in various FortiView monitors such as *FortiView Web Categories*, *FortiView Websites* or *FortiView Sources*. To view the categories in a monitor, the web filter profile must be configured to at least monitor for a FortiGuard category based on a web filter and applied to a firewall policy for outbound traffic.



To verify the web filter profile is monitor-only:

1. Go to *Security Profiles* > *Web Filter*.
2. Double-click a web filter that is applied to an outbound traffic firewall policy. The *Edit Web Filter Profile* window opens.
3. Ensure *FortiGuard category based filter* is enabled.
   In the image below, the *General Interest - Business* categories are monitor-only.

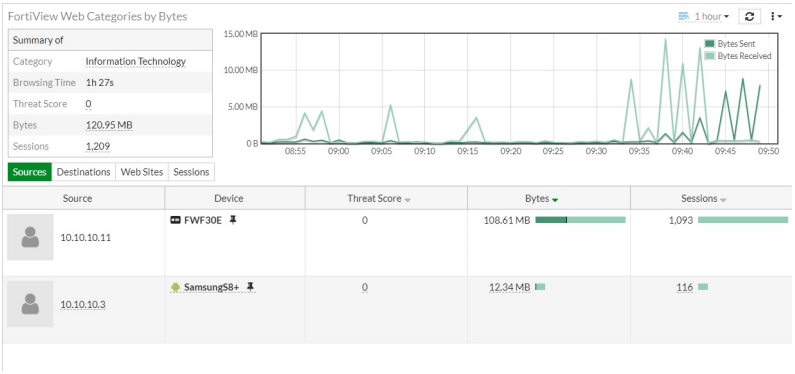
To create a Web categories monitor:



1. Click *Add Monitor*. The *Add Monitor* window opens.

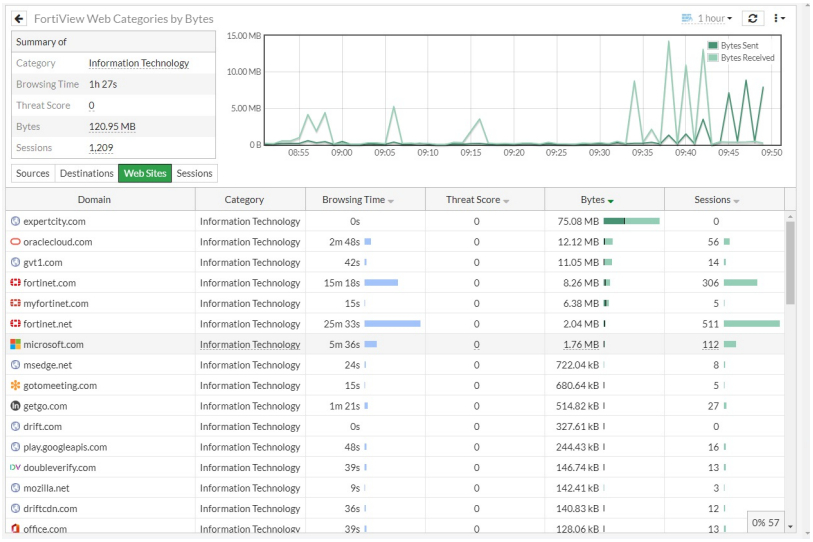
2. In the *Search* field, type *FortiView Web Categories* and click the *Add* button next to the monitor name.
3. In the *FortiGate* area, select the FortiGate(s) from the dropdown.
4. In the *Data Source* area, click *Best Available Device* or *Specify* to select a device in the security fabric.
5. From the *Time Period* dropdown, select a time period greater than *Now*.
6. From the *Sort By* dropdown, select *Bytes*, *Sessions*, *Bandwidth*, or *Packets*.
7. Click *Add Monitor*. The widget is added to the tree menu.

Viewing the web filter category



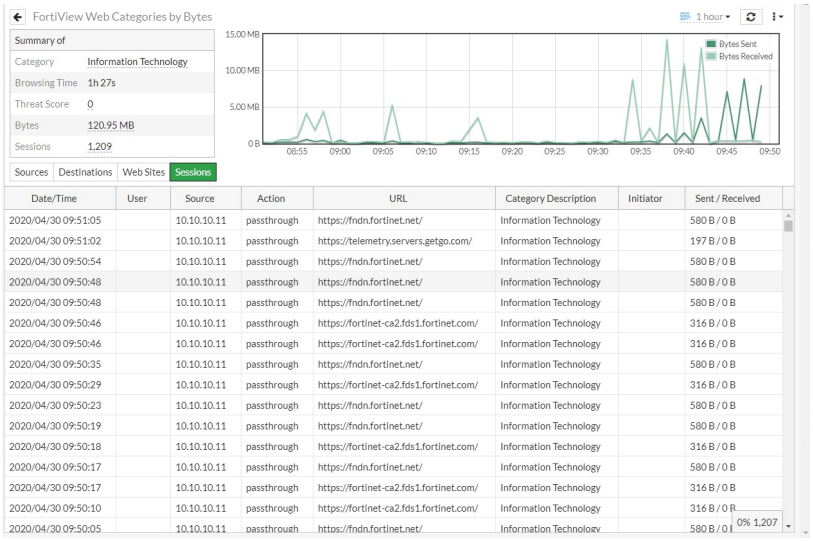
The web filter category name appears in the *Category* column of the dashboard.

Category	Browsing Time	Threat Score	Bytes	Sessions
Information Technology	59m 36s	0	120.29 MB	1,192
News and Media	1m 45s	0	3.32 MB	35
Web-based Email	54s	0	895.54 kB	18
Advertising	0s	0	803.78 kB	35
Instant Messaging	1m	0	438.12 kB	20
Web-based Applications	2m 9s	0	390.41 kB	43
Content Servers	0s	0	327.66 kB	24
Business	1m 18s	0	299.87 kB	26
Internet Telephony	1m 3s	0	295.32 kB	21
Search Engines and Portals	1m	0	275.39 kB	20
Streaming Media and Download	12s	0	44.74 kB	4
Freeware and Software Downloads	6s	0	21.84 kB	2
Information and Computer Security	15s	0	12.90 kB	5
Social Networking	3s	0	8.72 kB	1
Finance and Banking	3s	0	6.73 kB	1
Reference	3s	0	5.88 kB	1

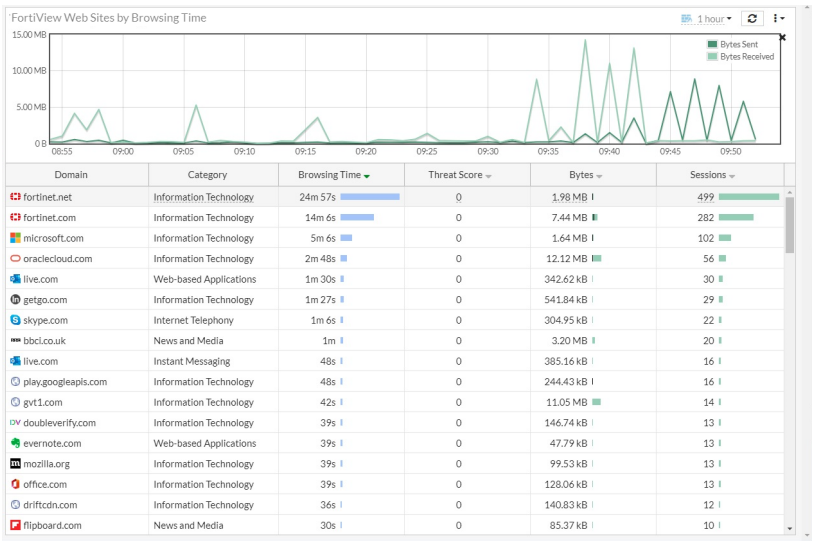


16

Click an entry in the table. The category name appears at the top of the *Summary of* box.



Source	Device	Threat Score	Bytes	Sessions
10.10.10.11	FWF30E	0	108.61 MB	1,093
10.10.10.3	SamsungS8+	0	12.34 MB	116



Click the *Web Sites* tab. The category name appears in the *Category* column.

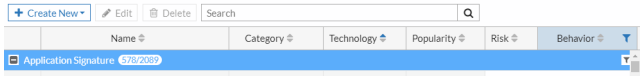
Click the *Sessions* tab. The category name appears in the *Category Description* column.

The category name also appears in the *Category* column in the *FortiView Websites* and *FortiView Sources* monitors.

Cloud application view

To see different cloud application views, set up the following:

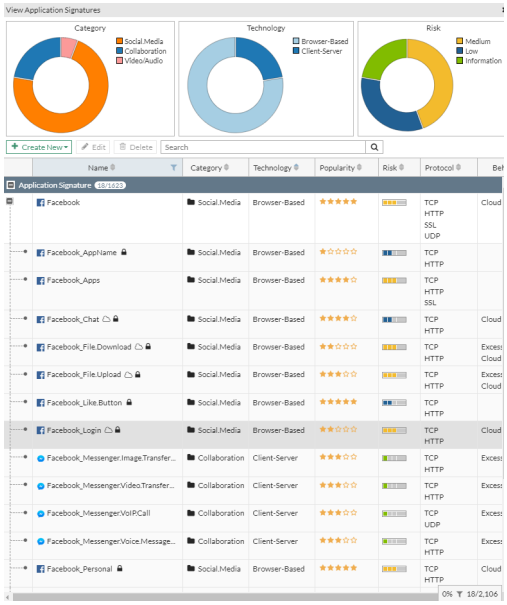
- A FortiGate with a firewall policy that uses the *Application Control* security profile.
- A FortiGate with log data from the local disk or FortiAnalyzer.
- Optional but highly recommended: *SSL Inspection* set to *deep-inspection* in the related firewall policies.



Viewing cloud applications

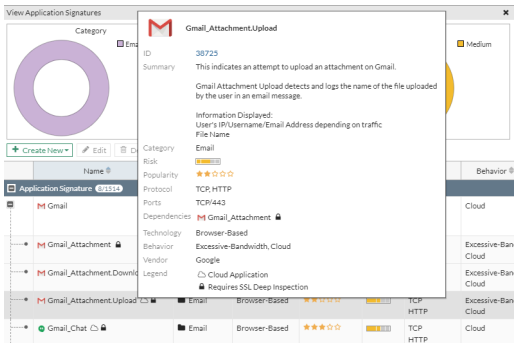
Cloud applications

All cloud applications require *SSL Inspection* set to *deep-inspection* on the firewall policy. For example, `Facebook_File.Download` can monitor Facebook download behavior which requires *SSL deep-inspection* to parse the deep information in the network packets.



To view cloud applications:

1. Go to *Security Profiles* > *Application Control*.
2. Select a relative Application Control profile used by the firewall policy and click *Edit*.
3. On the *Edit Application Sensor* page, click *View Application Signatures*.
4. Hover over a column heading or the *Application Signature* bar. In the right gutter area, click the filter icon to filter the applications.



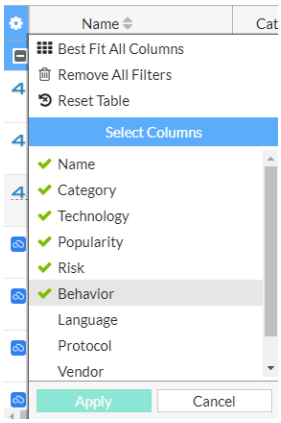
Cloud applications have a cloud icon beside them.

The lock icon indicates that the application requires SSL deep inspection.

5. Hover over an item to see its details.

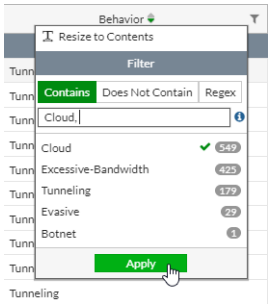
   This example shows *Gmail_Attachment.Download*, a cloud application signature based sensor which requires SSL deep inspection. If any local network user behind the firewall logs into Gmail and downloads a Gmail attachment, that activity is logged.

Applications with cloud behavior



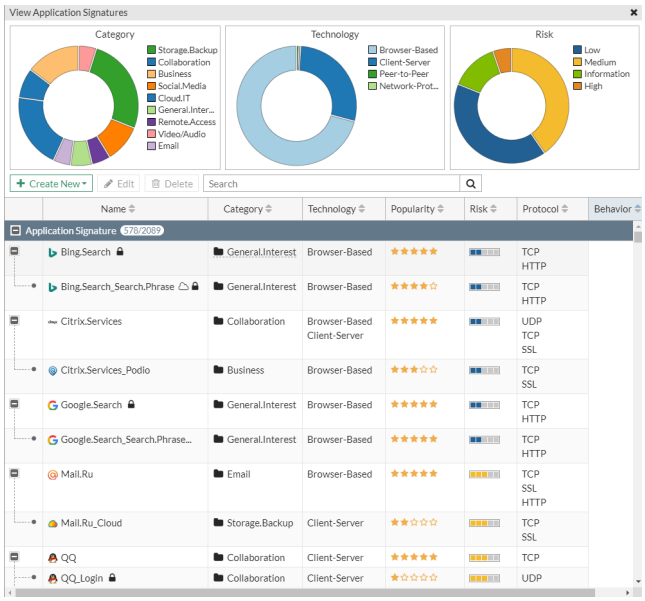
Applications with cloud behavior is a superset of cloud applications.

Some applications do not require SSL deep inspection, such as Facebook, Gmail, and YouTube. This means that if any traffic trigger application sensors for these applications, there is a FortiView cloud application view for that traffic.

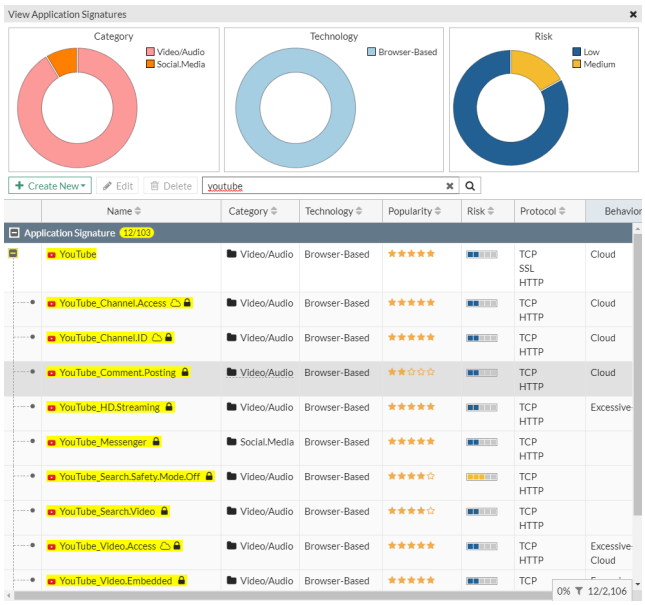


Other applications require SSL deep inspection, such as Gmail attachment, Facebook_Workplace, and so on.

To view applications with cloud behavior:

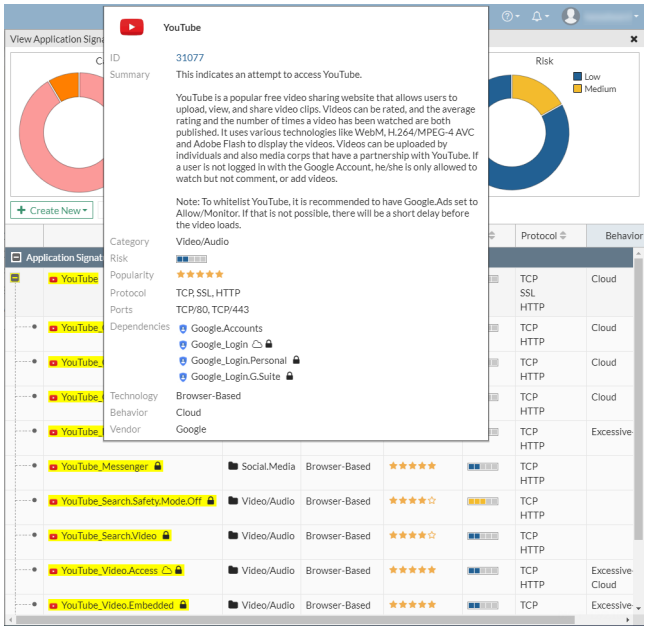


1. In the *Application Signature* page, ensure the *Behavior* column is displayed. If necessary, add the *Behavior* column.
   a. Hover over the left side of the table column headings to display the *Configure Table* icon.
   b. Click *Configure Table* and select *Behavior*.
   c. Click *Apply*.

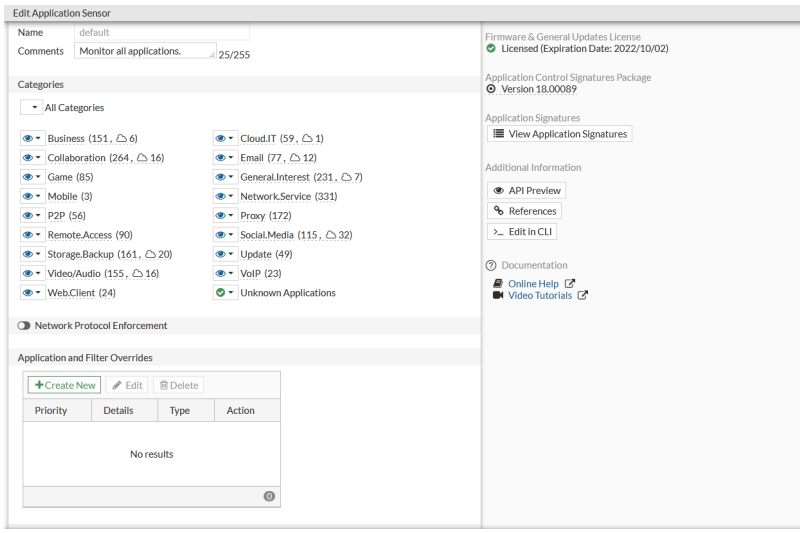


2. Click the filter icon in the *Behavior* column and select *Cloud* to filter by Cloud. Then click *Apply*.

3. The *Application Signature* page displays all applications with cloud behavior.

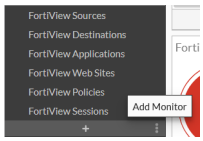


4. Use the *Search* box to search for applications. For example, you can search for *youtube*.



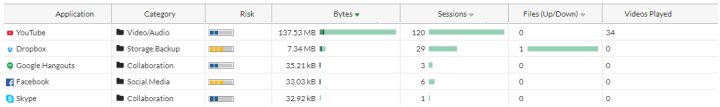
5. Hover over an item to see its details.

   This example shows an application sensor with no lock icon which means that this application sensor does not require SSL deep inspection. If any local network user behind the firewall tries to navigate to the YouTube website, that activity is logged.



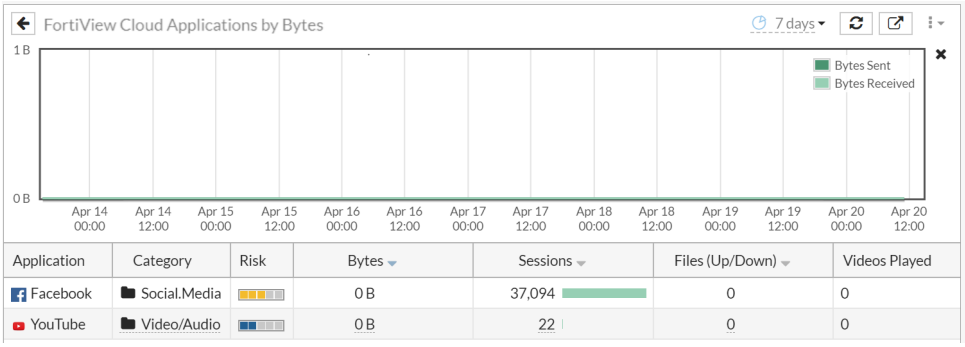
Configuring the Cloud Applications monitor

On the *Edit Application Sensor* page in the *Categories* section, the eye icon next to a category means that category is monitored and logged.



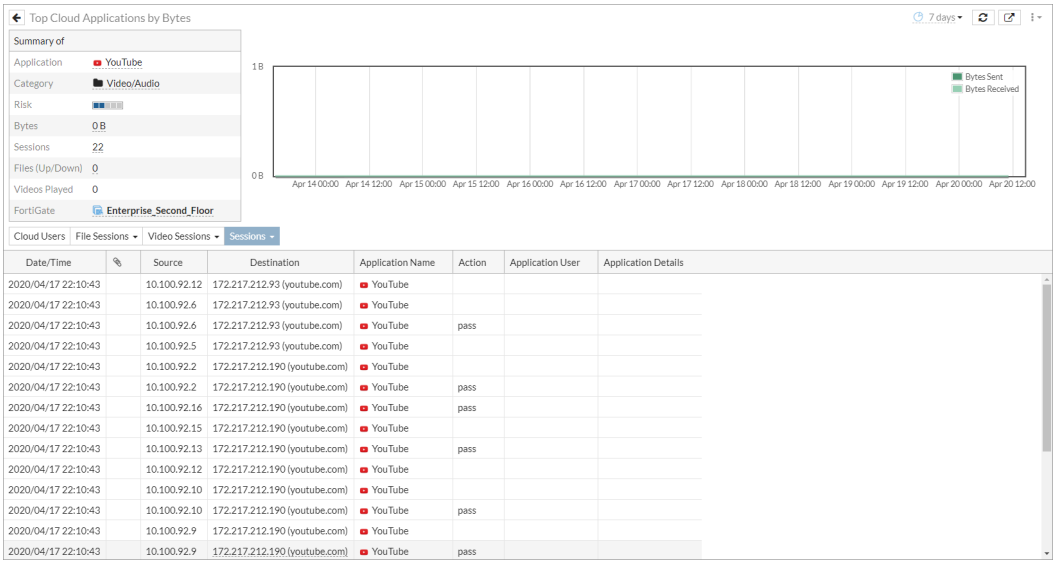
To add the Cloud Applications monitor in the GUI:

1. Click *Add Monitor*. The *Add monitor* window opens.



2. In the *Search* field, enter *FortiView Cloud Applications* and click the *Add* button next to the monitor.
3. In the *FortiGate* area, select the FortiGate(s) from the dropdown.
4. In the *Data Source* area, click *Best Available Device* or *Specify* to select a device in the security fabric.
5. From the *Time Period* dropdown, select a time period greater than *Now*.
6. From the *Sort By* dropdown, select *Bytes*, *Sessions*, or *Files (Up/Down)*.
7. Click *Add Monitor*. The monitor is added to the tree menu.
8. Open the monitor. If SSL deep inspection is enabled in the firewall, then the monitor shows the additional details that are logged, such as *Files (Up/Down)* and *Videos Played*.
   - For YouTube, the *Videos Played* column is triggered by the *YouTube_Video.Play* cloud application sensor. This shows the number of local network users who logged into YouTube and played YouTube videos.
   - For Dropbox, the *Files (Up/Down)* column is triggered by *Dropbox_File.Download* and *Dropbox_File.Upload* cloud application sensors. This shows the number of local network users who logged into Dropbox and uploaded or downloaded files.

Using the Cloud Applications monitor

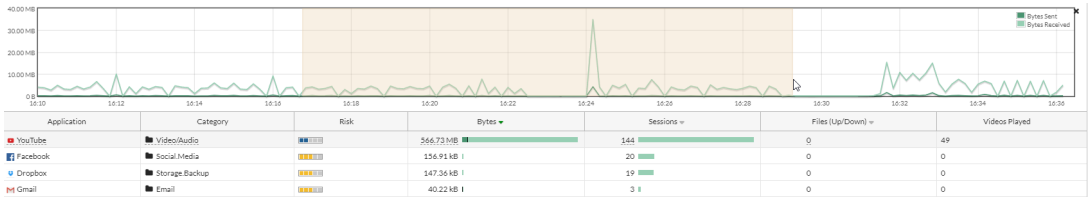


To see additional information in the Cloud Applications monitor:

1. In the tree menu, click the *FortiView Cloud Applications* monitor to open it.

2. For details about a specific entry, double-click the entry or right-click the entry and select *Drill Down to Details*.
3. To see all the sessions for an application, click *Sessions*.

   In this example, the *Application Name* column shows all applications related to YouTube.



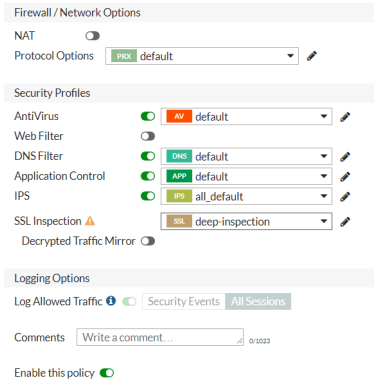
4. To view log details, double-click a session to display the *Log Details* pane.

Sessions monitored by SSL deep inspection (in this example, Youtube_Video.Play) captured deep information such as *Application User*, *Application Details*, and so on. The *Log Details* pane also shows additional deep information such as application *ID*, *Message*, and so on.

Sessions not monitored by SSL deep inspection (YouTube) did not capture the deep information.

5. To display a specific time period, select and drag in the timeline graph to display only the data for that time period.

Top application: YouTube example



Monitoring network traffic with SSL deep inspection

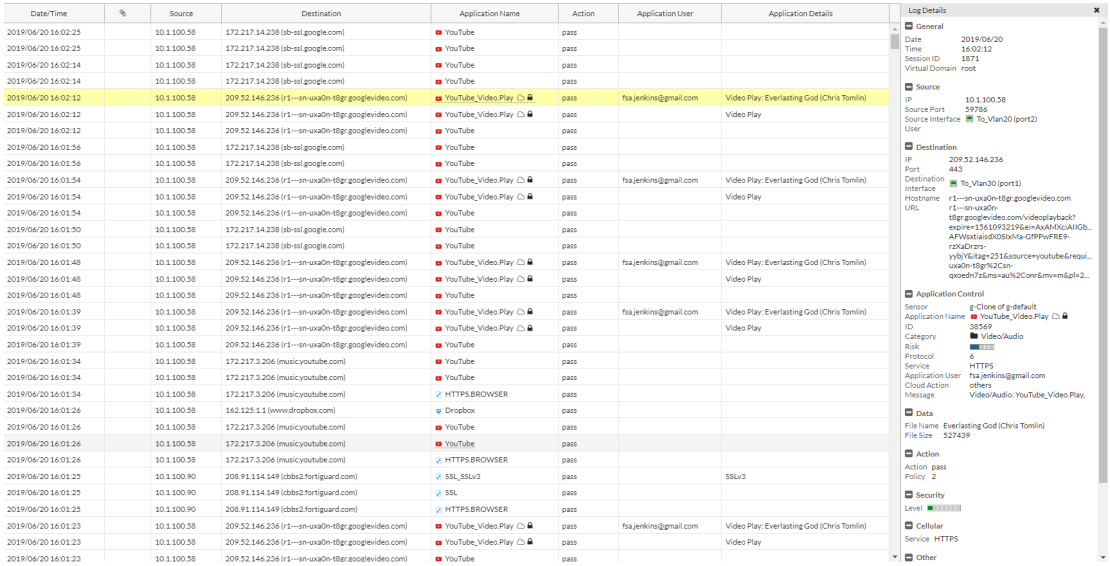
This example describes how to monitor network traffic for YouTube using *FortiView Applications* view with SSL deep inspection.

To monitor network traffic with SSL deep inspection:

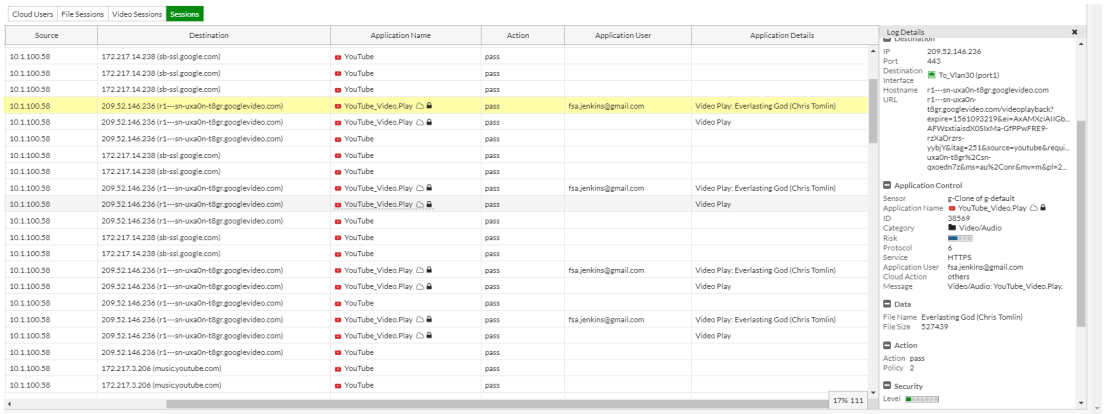
1. Create a firewall policy with the following settings:
   - *Application Control* is enabled.
   - *SSL Inspection* is set to *deep-inspection*.

- *Log Allowed Traffic* is set to *All Sessions*.

2. Go to *Security Profiles* > *Application Control*.
3. Select a relative Application Control profile used by the firewall policy and click *Edit*.
4. Because YouTube cloud applications are categorized into *Video/Audio*, ensure the *Video/Audio* category is monitored. Monitored categories are indicate by an eye icon.
5. Click *View Application Signatures* and hover over YouTube cloud applications to view detailed information about YouTube application sensors.
6. Expand *YouTube* to view the Application Signatures associated with the application.



Application Signature	Description	Application ID
YouTube_Video.Access	An attempt to access a video on YouTube.	16420
YouTube_Channel.ID	An attempt to access a video on a specific channel on YouTube.	44956
YouTube_Comment.Posting	An attempt to post comments on YouTube.	31076
YouTube_HD.Streaming	An attempt to watch HD videos on YouTube.	33104
YouTube_Messenger	An attempt to access messenger on YouTube.	47858
YouTube_Video.Play	An attempt to download and play a video from YouTube.	38569
YouTube_Video.Upload	An attempt to upload a video to YouTube.	22564
YouTube	An attempt to access YouTube. This application sensor does not depend on SSL deep inspection so it does not have a cloud or lock icon.	31077
YouTube_Channel.Access	An attempt to access a video on a specific channel on YouTube.	41598

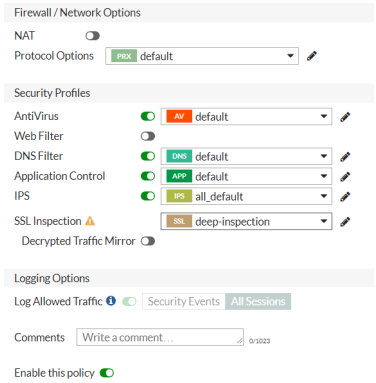


To view the application signature description, click the ID link in the information window.

7. On the test PC, log into YouTube and play some videos.
8. On the FortiGate, go to *Log & Report* > *Security Events* and look for log entries for browsing and playing YouTube videos in the *Application Control* card.

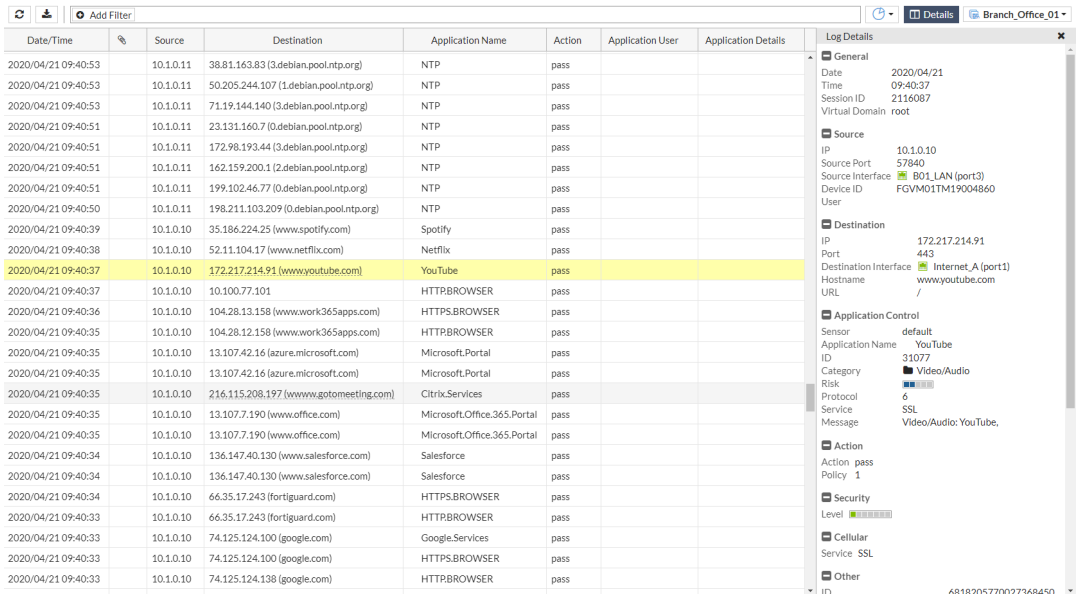
In this example, note the *Application User* and *Application Details*. Also note that the *Application Control ID* is *38569* showing that this entry was triggered by the application sensor *YouTube_Video.Play*.

9. Go to *Dashboard* > *FortiView Applications*.
10. In the *FortiView Applications* monitor, double-click *YouTube* to view the drilldown information.
11. Select the *Sessions* tab to see all the entries for the videos played. Check the sessions for *YouTube_Video.Play* with the ID *38569*.



Monitoring network traffic without SSL deep inspection

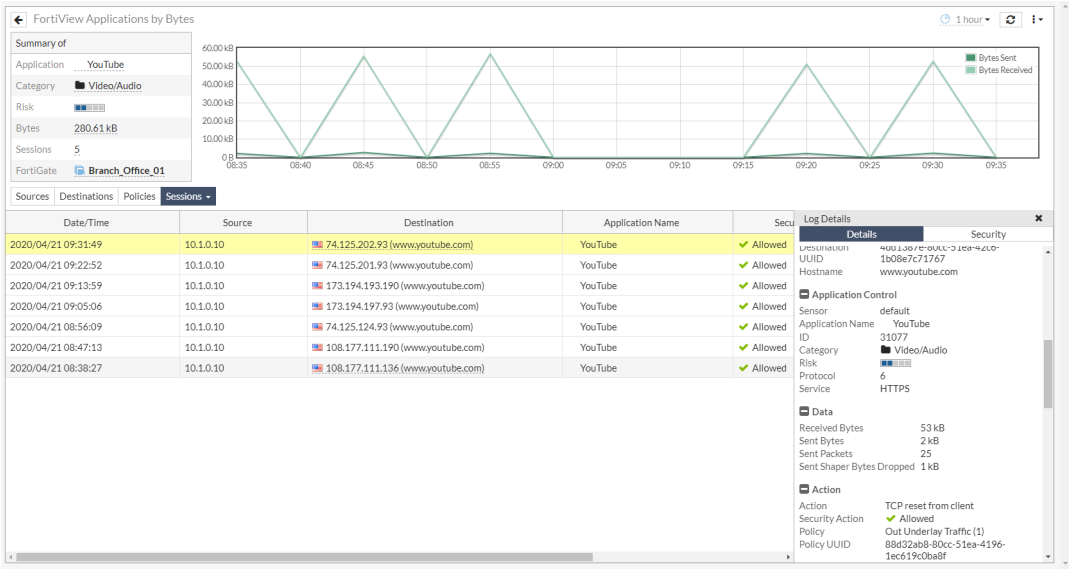
This example describes how to monitor network traffic for YouTube using FortiView cloud application view without SSL deep inspection.



To monitor network traffic without SSL deep inspection:

1. Create a firewall policy with the following settings.
   - *Application Control* is enabled.
   - *SSL Inspection* is set to *certificate-inspection*.

- *Log Allowed Traffic* is set to *All Sessions*.



2. On the test PC, log into YouTube and play some videos.
3. On the FortiGate, go to *Log & Report* > *Security Events* and look for log entries for browsing and playing YouTube videos in the *Application Control* card.
   In this example, the log shows only applications with the name YouTube. The log cannot show YouTube application sensors which rely on SSL deep inspection.

4. Go to *Dashboard* > *FortiView Applications*.
   The *FortiView Application by Bytes* monitor shows the YouTube cloud application without the video played information that requires SSL deep inspection.

5. Double-click *YouTube* and click the *Sessions* tab.
   These sessions were triggered by the application sensor *YouTube* with the ID *31077*. This is the application sensor with cloud behavior which does not rely on SSL deep inspection.

Network

The following topics provide information about network settings:

- NetFlow on page 510
- sFlow on page 528
- Link monitor on page 531
- IPv6 on page 541
- FortiGate LAN extension on page 613
- Diagnostics on page 619

Interfaces

Physical and virtual interfaces allow traffic to flow between internal networks, and between the internet and internal networks. FortiOS has options for configuring interfaces and groups of sub-networks that can scale as your organization grows. The following table lists commonly used interface types.

Interface type	Description
Physical	A physical interface can be connected to with either Ethernet or optical cables. Depending on the FortiGate model, there is a varying number of Ethernet or optical physical interfaces. Some FortiGates have a grouping of interfaces labeled as *lan* that have a built-in switch functionality. See Physical interface on page 175 for more information.
VLAN	A virtual local area network (VLAN) logically divides a local area network (LAN) into distinct broadcast domains using IEEE 802.1Q VLAN tags. A VLAN interface supports VLAN tagging and is associated with a physical interface that can be connected to a device, such as a switch or a router that supports these tags. VLANs can be used on a FortiGate in NAT or transparent mode, and the FortiGate functions differently depending on the operation mode

Interface type	Description
	See VLAN on page 176 for more information.
Aggregate	An aggregate interface uses a link aggregation method to combine multiple physical interfaces to increase throughput and to provide redundancy. FortiOS supports a link aggregation (LAG) interface using the Link Aggregation Control Protocol (LACP) based on IEEE 802.3ad. See Aggregation and redundancy on page 192 for more information.
Redundant	A redundant interface combines multiple physical interfaces where traffic only uses one of the interfaces at a time. Its primary purpose is to provide redundancy. This interface is typically used with a fully-meshed HA configuration. See Aggregation and redundancy on page 192 for more information.
Loopback	A loopback interface is a logical interface that is always up because it has no physical link dependency, and the attached subnet is always present in the routing table. It can be accessed through several physical or VLAN interfaces. See Loopback interface on page 196 for more information.
Software switch	A software switch is a virtual switch interface implemented in firmware that allows member interfaces to be added to it. Devices connected to member interfaces communicate on the same subnet, and packets are processed by the FortiGate's CPU. A software switch supports adding a wireless SSID as a member interface. See Software switch on page 196 for more information.
Hardware switch	A hardware switch is a virtual switch interface implemented at the hardware level that allows member interfaces to be added to it. Devices connected to member interfaces communicate on the same subnet. A hardware switch relies on specific hardware to optimize processing and supports the Spanning Tree Protocol (STP). See Hardware switch on page 198 for more information.
Zone	A zone is a logical group containing one or more physical or virtual interfaces. Grouping interfaces in zones can simplify firewall policy configurations. See Zone on page 202 for more information.
Virtual wire pair	A virtual wire pair (VWP) is an interface that acts like a virtual wire consisting of two interfaces, with an interface at each of the wire. No IP addressing is configured on a VWP, and communication is restricted between the two interfaces using firewall policies. See Virtual wire pair on page 204 for more information.
FortiExtender WAN extension	A FortiExtender WAN extension is a managed interface that allows a connected FortiExtender to provide WAN connectivity to the FortiGate. See FortiExtender on page 473 for more information.
FortiExtender LAN extension	A FortiExtender LAN extension is a managed interface that allows a connected FortiExtender to provide LAN connectivity to the FortiGate. See FortiExtender on page 473 for more information.

Interface type	Description
Enhanced MAC VLAN	An enhanced media access control (MAC) VLAN, or EMAC VLAN, interface allows a physical interface to be virtually subdivided into multiple virtual interfaces with different MAC addresses. In FortiOS, the EMAC VLAN functionality acts like a bridge. See Enhanced MAC VLAN on page 211 for more information.
VXLAN	A Virtual Extensible LAN (VXLAN) interface encapsulates layer 2 Ethernet frames within layer 3 IP packets and is used for cloud and data center networks. See VXLAN on page 214 for more information.
Tunnel	A tunnel virtual interface is used for IPsec interface-based or GRE tunnels and are created when configuring IPsec VPN and GRE tunnels, respectively. The tunnel interface can be configured with IP addresses on both sides of the tunnel since this is a requirement when using a tunnel interface with a dynamic routing protocol. See OSPF with IPsec VPN for network redundancy on page 1706, GRE over IPsec on page 1621, and Cisco GRE-over-IPsec VPN on page 1652 for more information.
WiFi SSID	A WiFi SSID interface is used to control wireless network user access to a wireless local radio on a FortiWiFi or to a wireless access point using a FortiAP. The SSID is created using the *WiFi & Switch Controller* > *SSIDs page*, and it appears in the *Network* > *Interfaces* page once it is created. See Defining a wireless network interface (SSID) in the FortiWiFi and FortiAP Configuration Guide for more information.
VDOM link	A VDOM link allows VDOMs to communicate internally without using additional physical interfaces. See Inter-VDOM routing for more information.

Interface settings

Administrators can configure both physical and virtual FortiGate interfaces in *Network* > *Interfaces*. There are different options for configuring interfaces when FortiGate is in NAT mode or transparent mode.

The available options will vary depending on feature visibility, licensing, device model, and other factors. The following list is not comprehensive.

To configure an interface in the GUI:

1. Go to *Network* > *Interfaces*.
2. Click *Create New* > *Interface*.
3. Configure the interface fields:

Interface Name	Physical interface names cannot be changed.

Alias	Enter an alternate name for a physical interface on the FortiGate unit. This field appears when you edit an existing physical interface. The alias does not appear in logs. The maximum length of the alias is 25 characters.
Type	The configuration type for the interface, such as VLAN, Software Switch. 802.3ad Aggregate, and others.
Interface	This field is available when *Type* is set to *VLAN*. Select the name of the physical interface that you want to add a VLAN interface to. Once created, the VLAN interface is listed below its physical interface in the *Interface* list. You cannot change the physical interface of a VLAN interface.
VLAN ID	This field is available when *Type* is set to *VLAN*. Enter the VLAN ID. The VLAN ID can be any number between 1 and 4094 and must match the VLAN ID added by the IEEE 802.1Q-compliant router or switch that is connected to the VLAN subinterface. The VLAN ID can be edited after the interface is added.
VRF ID	Virtual Routing and Forwarding (VRF) allows multiple routing table instances to coexist on the same router. One or more interface can have a VRF, and packets are only forwarded between interfaces with the dame VRF.
Virtual Domain	Select the virtual domain to add the interface to. Only administrator accounts with the *super_admin* profile can change the *Virtual Domain*.
Interface Members	This section can have different formats depending on the *Type*. Members can be selected for some interface types: • *Software Switch* or *Hardware Switch*: Specify the physical and wireless interfaces joined into the switch. • *802.3ad Aggregate* or *Redundant Interface*: This field includes the available and selected interface lists.
Role	Set the role setting for the interface. Different settings will be shown or hidden when editing an interface depending on the role: • *LAN*: Used to connected to a local network of endpoints. It is default role for new interfaces. • *WAN*: Used to connected to the internet. When WAN is selected, the *Estimated bandwidth* setting is available, and the following settings are not: *DHCP server*, *Create address object matching subnet*, *Device detection*, *Security mode*, *One-arm sniffer*, *Dedicate to extension/fortiap modes*, and *Admission Control*.and will show Estimated Bandwidth settings. • *DMZ*: Used to connected to the DMZ. When selected, *DHCP server* and *Security mode* are not available. • *Undefined*: The interface has no specific role. When selected, *Create address object matching subnet* is not available.
Estimated bandwidth	The estimated WAN bandwidth.

	The values can be entered manually, or saved from a speed test executed on the interface. The values can be used in SD-WAN rules that use the Maximize Bandwidth or Best Quality strategy.
Traffic mode	This option is only available when *Type* is *WiFi SSD*. • *Tunnel*: Tunnel to wireless controller • *Bridge*: Local bridge with FortiAP's interface • *Mesh*: Mesh downlink
Address	
Addressing mode	Select the addressing mode for the interface. • *Manual*: Add an IP address and netmask for the interface. If IPv6 configuration is enabled, you can add both an IPv4 and an IPv6 address. • *DHCP*: Get the interface IP address and other network settings from a DHCP server. • *Auto-managed by IPAM*: Assign subnets to prevent duplicate IP addresses from overlapping within the same Security Fabric. See Configure IPAM locally on the FortiGate on page 156. • *PPPoE*: Get the interface IP address and other network settings from a PPPoE server. This option is only available on the low-end FortiGate models. • *One-Arm Sniffer*: Set the interface as a sniffer port so it can be used to detect attacks. See One-arm sniffer on page 164.
IP/Netmask	If *Addressing Mode* is set to *Manual*, enter an IPv4 address and subnet mask for the interface. FortiGate interfaces cannot have multiple IP addresses on the same subnet.
IPv6 addressing mode	Select the addressing mode for the interface: • *Manual*: Add an IP address and netmask for the interface. • *DHCP*: Get the interface IP address and other network settings from a DHCP server. • *Delegated*: Select an *IPv6 upstream interface* that has DHCPv6 prefix delegation enabled, and enter an *IPv6 subnet* if needed. The interface will get the IPv6 prefix from the upstream DHCPv6 server that is connected to the IPv6 upstream interface, and form the IPv6 address with the subnet configured on the interface.
IPv6 Address/Prefix	If *Addressing Mode* is set to *Manual* and IPv6 support is enabled, enter an IPv6 address and subnet mask for the interface. A single interface can have an IPv4 address, IPv6 address, or both.
Auto configure IPv6 address	Automatically configure an IPv6 address using Stateless Address Auto-configuration (SLAAC). This option is available when *IPv6 addressing mode* is set to *Manual*.
DHCPv6 prefix delegation	Enable/disable DHCPv6 prefix delegation, which can be used to delegate IPv6 prefixes from an upstream DHCPv6 server to another interface or downstream device.

	When enabled, there is an option to enable a *DHCPv6 prefix hint* that helps the DHCPv6 server provide the desired prefix.
Create address object matching subnet	This option is available and automatically enabled when *Role* is set to *LAN* or *DMZ*. This creates an address object that matches the interface subnet and dynamically updates the object when the IP/Netmask changes. See Interface subnet on page 1167 for more information.
Secondary IP Address	Add additional IPv4 addresses to this interface.
Administrative Access	
IPv4 Administrative Access	Select the types of administrative access permitted for IPv4 connections to this interface. See Configure administrative access to interfaces on page 154.
IPv6 Administrative Access	Select the types of administrative access permitted for IPv6 connections to this interface. See Configure administrative access to interfaces on page 154.
DHCP Server	Enable a DHCP server for the interface. See DHCP servers and relays on page 333.
Stateless Address Auto-configuration (SLAAC)	Enable to provide IPv6 addresses to connected devices using SLAAC.
DHCPv6 Server	Select to enable a DHCPv6 server for the interface. When enabled, you can configure *DNS service* settings: *Delegated* (delegate the DNS received from the upstream server), *Same as System DNS*, or *Specify* (up to four servers). You can also enable *Stateful server*to configure the DHCPv6 server to be stateful. Manually enter the IP range, or use Delegated mode to delegate IP prefixes from an upstream DHCPv6 server connected to the upstream interface.
Network	
Device Detection	Enable/disable passively gathering device identity information about the devices on the network that are connected to this interface.
Security Mode	Enable/disable captive portal authentication for this interface. After enabling captive portal authentication, you can configure the authentication portal, user and group access, custom portal messages, exempt sources and destinations/services, and redirect after captive portal.
DSL Settings	
Physical mode	Set to *ADSL* or *VDSL*.
Transfer mode	Set to *PTM* or *ATM*. If the *Transfer mode* is set to *ATM*, the *Virtual channel identification*, *Virtual path identification*, *ATM protocol*, and *MUX type* can be configured.
Traffic Shaping	
Outbound shaping profile	Enable/disable traffic shaping on the interface. This allows you to enforce

	bandwidth limits on individual interfaces. See Interface-based traffic shaping profile on page 1224 for more information.
Miscellaneous	
Comments	Enter a description of the interface of up to 255 characters.
Status	Enable/disable the interface. • *Enabled*: The interface is active and can accept network traffic. • *Disabled*: The interface is not active and cannot accept traffic.

4. Click *OK*.

To configure an interface in the CLI:

```
config system interface
    edit <name>
        set vdom <VDOM_name>
        set mode {static | dhcp | pppoe}
        set ip <IP_address/netmask>
        set security-mode {none | captive-portal | 802.1X}
        set egress-shaping-profile <profile>
        set device-identification {enable | disable}
        set allowaccess {ping https ssh http snmp telnet fgfm radius-acct probe-response
fabric ftm}
        set eap-supplicant {enable | disable}
        set eap-method {peap | tls}
        set eap-identity <identity>
        set eap-password <password>
        set eap-ca-cert <CA_cert>
        set eap-user-cert <user_cert>
        set secondary-IP enable
        config secondaryip
            edit 1
                set ip 9.1.1.2 255.255.255.0
                set allowaccess ping https ssh snmp http
            next
        end
    next
end
```

Configure administrative access to interfaces

You can configure the protocols that administrators can use to access interfaces on the FortiGate. This helps secure access to the FortiGate by restricting access to a limited number of protocols. It helps prevent users from accessing interfaces that you don't want them to access, such as public-facing ports.

As a best practice, you should configure administrative access when you're setting the IP address for a port.

To configure administrative access to interfaces in the GUI:

1. Go to *Network* > *Interfaces*.
2. Create or edit an interface.

3. In the *Administrative Access* section, select which protocols to enable for *IPv4* and *IPv6 Administrative Access*.

Speed Test	Allow this interface to listen to speed test sender requests.
	To allow the FortiGate to be configured as speed test server, configure the following:
	`config system global`
	`  set speedtest-server {enable | disable}`
	`end`
	For more detail, see Speed tests run from the hub to the spokes in dial-up IPsec tunnels on page 815.

HTTPS	Allow secure HTTPS connections to the FortiGate GUI through this interface. If configured, this option is enabled automatically.
HTTP	Allow HTTP connections to the FortiGate GUI through this interface. This option can only be enabled if HTTPS is already enabled.
PING	The interface responds to pings. Use this setting to verify your installation and for testing.
FMG-Access	Allow FortiManager authorization automatically during the communication exchanges between FortiManager and FortiGate devices.
SSH	Allow SSH connections to the CLI through this interface.
SNMP	Allow a remote SNMP manager to request SNMP information by connecting to this interface.
FTM	Allow FortiToken Mobile Push (FTM) access.
RADIUS Accounting	Allow RADIUS accounting information on this interface.
Security Fabric Connection	Allow Security Fabric access. This enables FortiTelemetry and CAPWAP.

FEC implementations on 10G, 25G, 40G, and 100G interfaces

Only supported FEC (forward error correction) implementations are allowed to be configured on 10G, 25G, 40G, and 100G interfaces based on the speed that is selected.

- For 1000M, 10G, or 40G interfaces, FEC is not supported and the option is disabled.
- For 25G and 100G interfaces, FEC is automatically set to `cl91-rs-fec` by default.

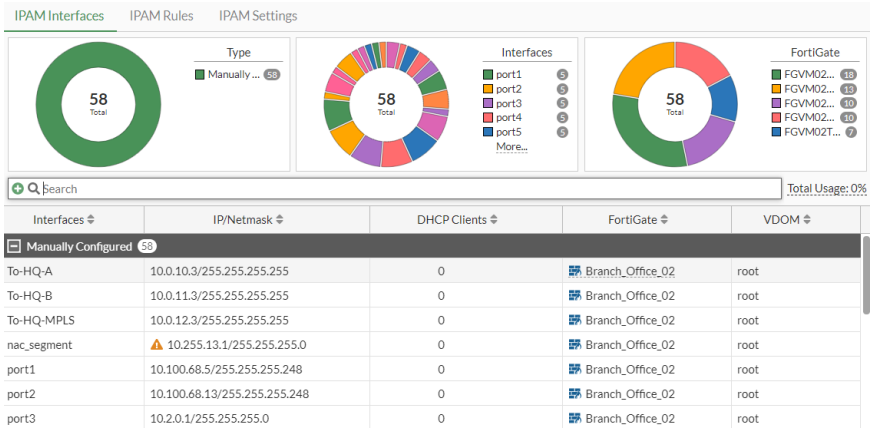
To configure an interface for FEC:

```
config system interface
    edit <name>
        set speed {10000full | 1000full | 100Gauto | 100Gfull | 25000auto | 25000full |
40000full}
        set mediatype {sr4 | lr4 | cr4}
        set forward-error-correction {disable | cl91-rs-fec | cl74-fc-fec}
    next
end
```

`speed {10000full | 1000full | 100Gauto | 100Gfull | 25000auto | 25000full | 40000full}`	Set the interface speed: • 10000full: 10G full-duplex • 1000full: 1000M full-duplex • 100Gauto: 100G auto-negotiation • 100Gfull: 100G full-duplex • 25000auto: 25G auto-negotiation • 25000full: 25G full-duplex • 40000full: 40G full-duplex
`mediatype {sr4 | lr4 | cr4}`	Set the media type to use: • sr4: short-range transceiver (4-lane) • lr4: long-range transceiver (4-lane) • cr4: copper transceiver (4-lane)
`forward-error-correction {disable | cl91-rs-fec | cl74-fc-fec}`	Set the forward error correction type: • disable: disable forward error correction • cl91-rs-fec: Reed-Solomon (FEC CL91) • cl74-fc-fec: Firecode (FEC CL74)

To change the interface speed from 40G to 100G:

```
config system interface
    edit port26
        set speed 100Gfull
    next
end



The speed/mediatype/FEC of port26 will be changed from 40000full/sr4/disable to
100Gfull/sr4/cl91-rs-fec.
Do you want to continue? (y/n) y
```

Since the speed changed to 1000G, the `mediatype` setting automatically changes to `sr4`, and the `forward-error-correction` setting automatically changes to `cl91-rs-fec`. When the speed was 40G, the `forward-error-correction` setting was disabled.

Configure IPAM locally on the FortiGate

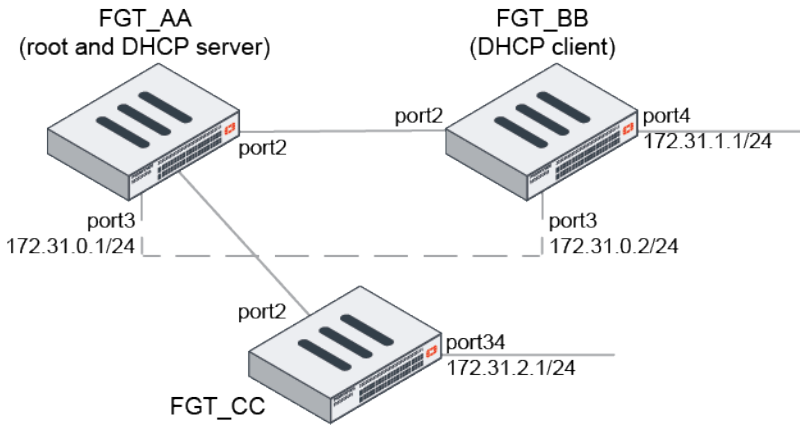
IPAM (IP address management) is available locally on the FortiGate. A standalone FortiGate, or a Fabric root in the Security Fabric, can act as the IPAM server. Interfaces configured to be auto-managed by IPAM will receive an address from the IPAM server's address/subnet pool. *DHCP Server* is automatically enabled in the GUI, and the address range is populated by IPAM. Users can customize the address pool subnet and the size of a subnet that an interface can request.

IPAM can be configured on the *Network* > *IPAM* page using the *IPAM Settings*, *IPAM Rules*, and *IPAM Interfaces* tabs.

To configure IPAM settings:

```
config system ipam
    set pool-subnet <class IP and netmask>
    set status {enable | disable}
    config pools
        edit <pool_name>
            set subnet <IP address/netmask>
        next
    end
    config rules
        edit <rule_name>
            set device {<FortiGate_serial_number> | *}
            set interface {<name> | *}
            set pool <pool_name>
        next
    end
end
```

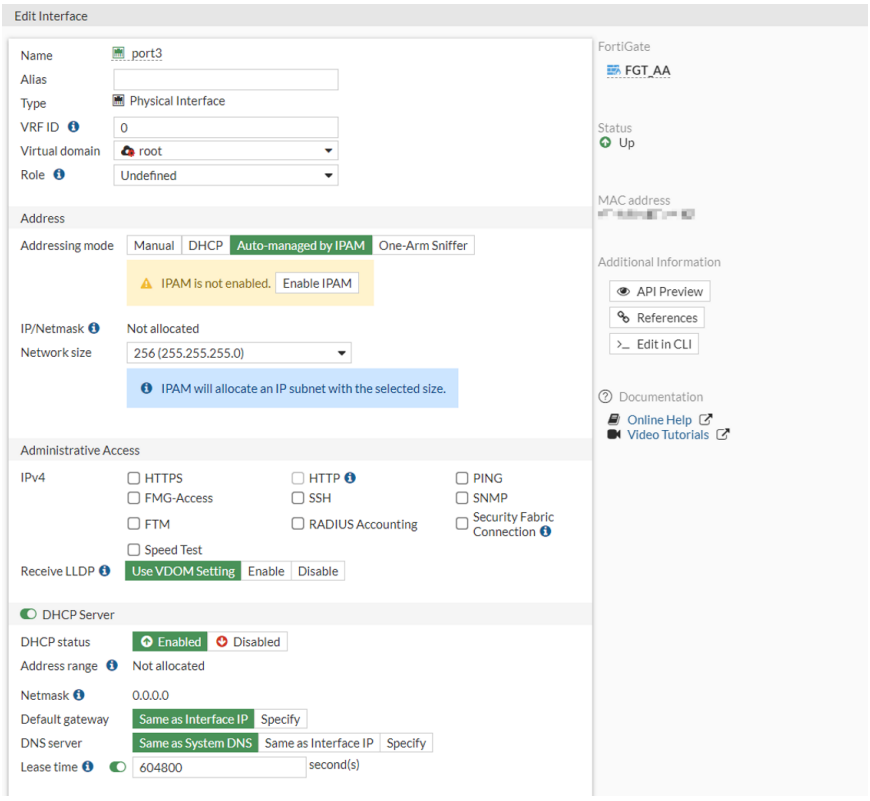
`pool-subnet <class IP and netmask>`	Set the IPAM pool subnet, class A or class B subnet.
`status {enable | disable}`	Enable/disable IP address management services.
`config pools`	Set the subnet for the IP pool.
`config rules`	Set the device, interface, and IP pool for IPAM rules.



In previous FortiOS versions, the `set fortiipam-integration` option was configured under `config system global`.

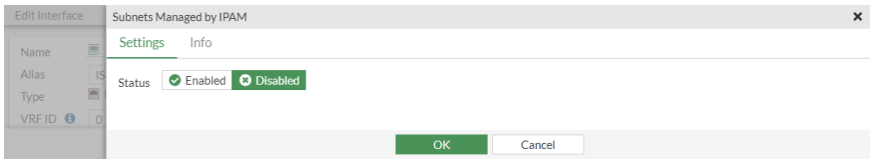
The following options are available for allocating the subnet size:

```
config system interface
    set managed-subnetwork-size {32 | 64 | 128 | 256 |512 | 1024 | 2048 | 4096 | 8192 |
16384 | 32768 | 65536}
end
```

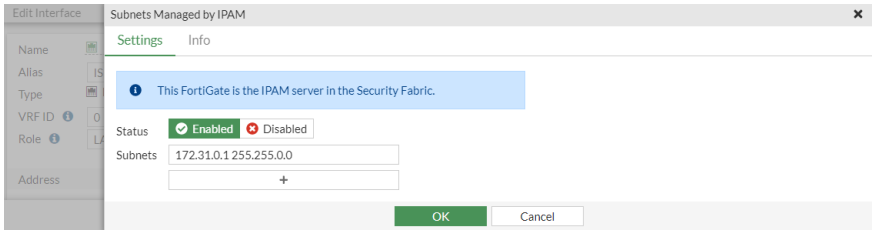


Example

In this example, FGT_AA is the Security Fabric root with IPAM enabled. FGT_BB and FGT_CC are downstream Fabric devices and retrieve IPAM information from FGT_AA. The Fabric interface on all FortiGates is port2. FGT_AA acts as the DHCP server, and FGT_BB acts as the DHCP client.



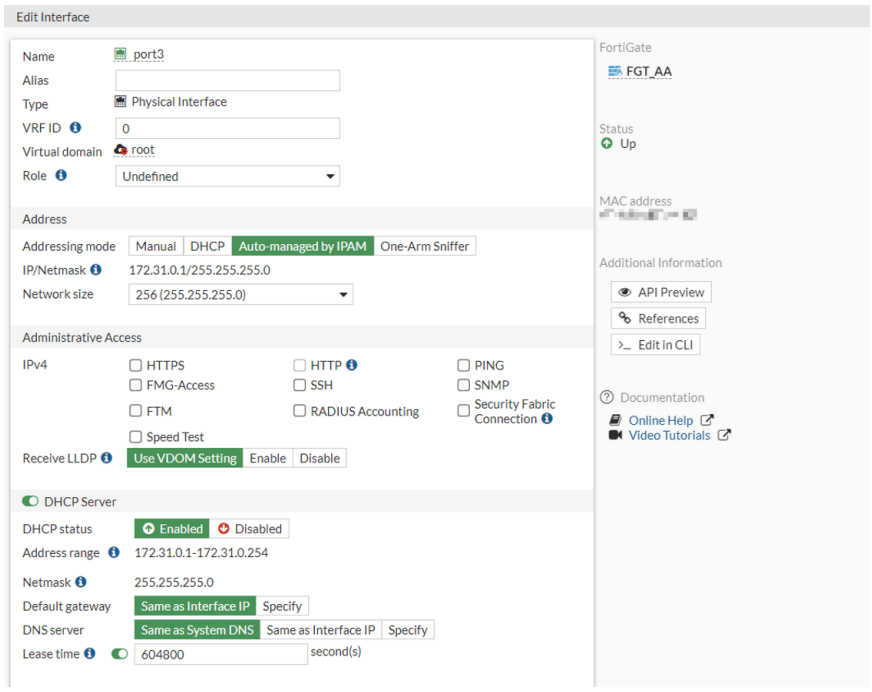
To configure IPAM locally in the Security Fabric:



1. On the root FortiGate, go to *Network* > *Interfaces* and edit port3.
2. For *Addressing Mode*, select *Auto-Managed by IPAM*. *DHCP Server* is automatically enabled.

3. In this example, IPAM is not enabled yet. Click *Enable IPAM*. The *Subnets Managed by IPAM* pane opens.

4. Select *Enabled*, enter the *Pool subnet* (only class A and B are allowed) and click *OK*. The root FortiGate is now the IPAM server in the Security Fabric.



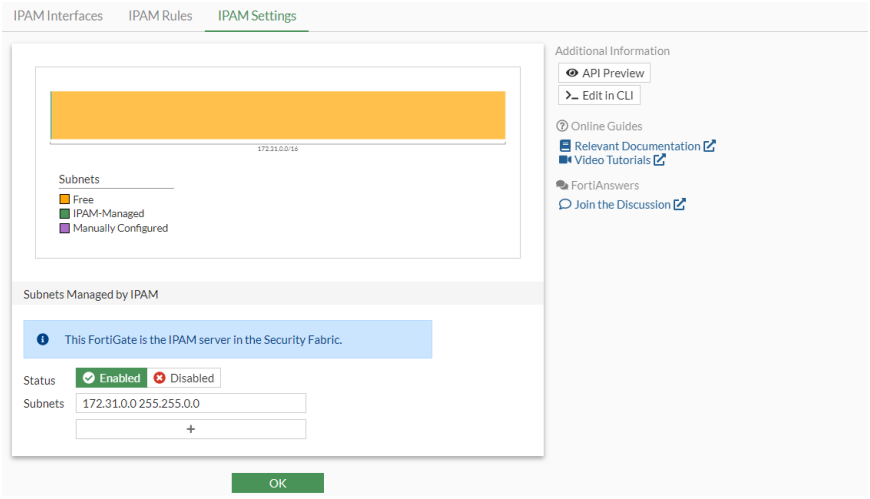
The following is configured in the backend:

```
config system interface
    edit "port3"
        set vdom "root"
        set ip 172.31.0.1 255.255.0.0
        set type physical
        set device-identification enable
        set snmp-index 5
        set ip-managed-by-fortiipam enable
        end
    next
end

config system ipam
    set status enable
end
```

IPAM is managing a 172.31.0.0/16 network and assigned port3 a /24 network by default.

The *IP/Netmask* field in the *Address* section has been automatically assigned a class C IP by IPAM. The *Address range* and *Netmask* fields in the *DHCP Server* section have also been automatically configured by IPAM.



5. Click *OK*.
6. Log in to FGT-BB and set the *Addressing Mode* of port4 to *Auto-Managed by IPAM*. The subnet assigned from the pool on the root is 172.31.1.1/24.
7. Log in to FG_CC and set the *Addressing Mode* of port34 to *Auto-Managed by IPAM*. The subnet assigned from the pool on the root is 172.31.2.1/24.

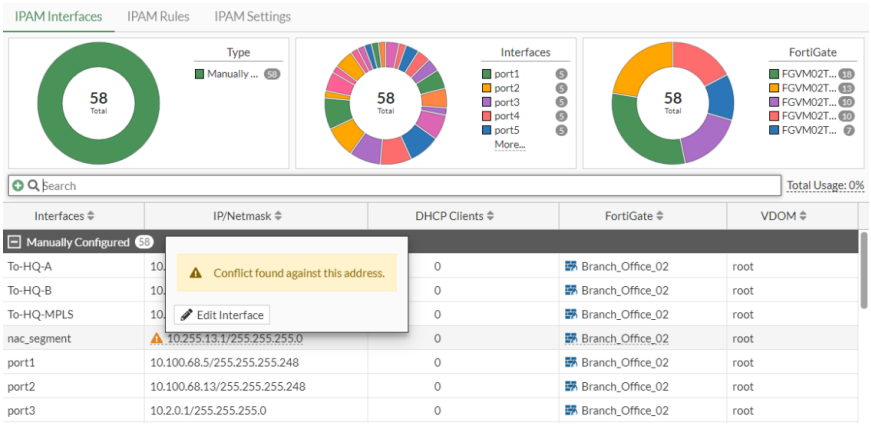
Any interface on a downstream FortiGate can be managed by the IPAM server. The interface does not have to be directly connected to the Fabric root FortiGate.

To edit the IPAM subnet:

1. Go to *Network* > *IPAM* > *IPAM Settings*.
2. Edit the pool subnet if needed.

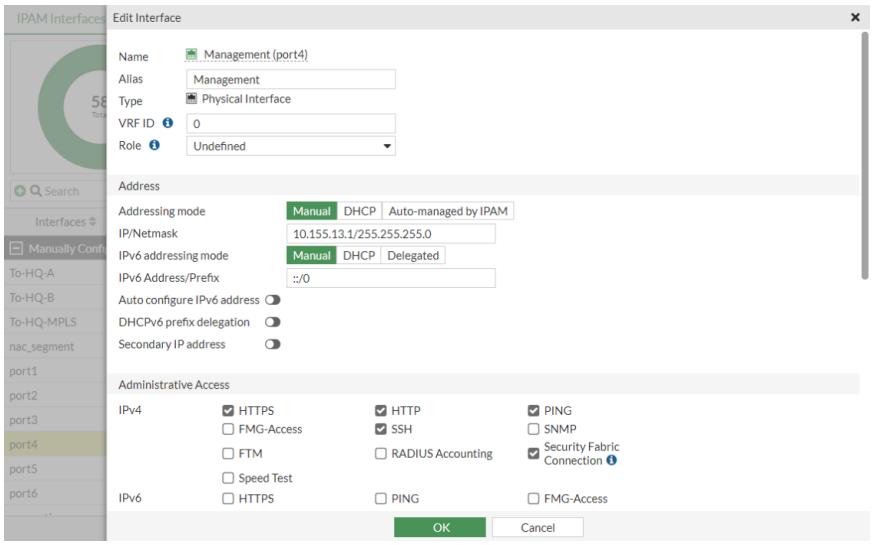
3. Click *OK*.

   On downstream FortiGates, the settings on the *Network* > *IPAM* > *IPAM Settings* tab cannot be changed if IPAM is enabled on the root FortiGate.



Go to *Network* > *IPAM* > *IPAM Interfaces* to view the subnet allocations (port34, port3, and port3) and DHCP lease information. On FGT_BB, port3 is a DHCP client and the DHCP server interface (FGT_AA port3) is managed by IPAM, so it is displayed in the *Manually Configured* section.

IPAM conflict markers



The *IPAM Interfaces* tab displays conflict markers when there are IP pool IP address conflicts with manually configured IP addresses. Administrators can use the *Edit Interface* dialog to manually resolve the conflict.

To resolve conflicts in the GUI:

1. Go to *Network* > *IPAM* > *IPAM Interfaces*.
2. Hover your mouse over the conflict marker. The conflict marker information is displayed.

3. Click *Edit Interface*. The *Edit Interface* pane opens.

4. Enter a new IP address and netmask in the *IP/Netmask* field.
5. Click *OK*. A confirmation message is displayed.
6. Click *OK*.

Diagnostics

Use the following commands to view IPAM related diagnostics.

To view the largest available subnet size:

```
# diagnose sys ipam largest-available-subnet
Largest available subnet is a /17.
```

To verify IPAM allocation information:

```
# diagnose sys ipam dump-ipams-entries
IPAM Entries: (sn, vdom, interface, subnet/mask, flag)
  F140EP4Q17000000 root port34 172.31.2.1/24 0
  FG5H1E5818900001 root port3 172.31.0.1/24 0
  FG5H1E5818900002 root port4 172.31.1.1/24 0
  FG5H1E5818900003 root port3 172.31.0.2/24 1
```

To verify the available subnets:

```
# diagnose sys ipam dump-ipams-free-subnets
IPAM free subnets: (subnet/mask)
  172.31.3.0/24
  172.31.4.0/22
  172.31.8.0/21
  172.31.16.0/20
  172.31.32.0/19
  172.31.64.0/18
  172.31.128.0/17
```

To remove a device from IPAM in the Security Fabric:

```
# diagnose sys ipam delete-device-from-ipams F140EP4Q17000000
Successfully removed device F140EP4Q17000000 from ipam
```

Interface MTU packet size

Changing the maximum transmission unit (MTU) on FortiGate interfaces changes the size of transmitted packets. Most FortiGate device's physical interfaces support jumbo frames that are up to 9216 bytes, but some only support 9000 or 9204 bytes.

To avoid fragmentation, the MTU should be the same as the smallest MTU in all of the networks between the FortiGate and the destination. If the packets sent by the FortiGate are larger than the smallest MTU, then they are fragmented, slowing down the transmission. Packets with the DF flag set in the IPv4 header are dropped and not fragmented .

On many network and endpoint devices, the path MTU is used to determine the smallest MTU and to transmit packets within that size.

- ASIC accelerated FortiGate interfaces, such as NP6, NP7, and SOC4 (np6xlite), support MTU sizes up to 9216 bytes.
- FortiGate VMs can have varying maximum MTU sizes, depending on the underlying interface and driver.
- Virtual interfaces, such as VLAN interfaces, inherit their MTU size from their parent interface.

To verify the supported MTU size:

```
config system interface
    edit <interface>
        set mtu-override enable
        set mtu <integer>
    next
end
```

To change the MTU size:

```
config system interface
    edit <interface>
        set mtu-override enable
        set mtu <max bytes>
    next
end
```

Maximum MTU size on a path

To manually test the maximum MTU size on a path, you can use the ping command on a Windows computer.

For example, you can send ICMP packets of a specific size with a DF flag, and iterate through increasing sizes until the ping fails.

- The `-f` option specifies the Do not Fragment (DF) flag.
- The `-l` option specifies the length, in bytes, of the Data field in the echo Request messages. This does not include the 8 bytes for the ICMP header and 20 bytes for the IP header. Therefore, if the maximum MTU is 1500 bytes, then the maximum supported data size is: 1500 - 8 - 20 = 1472 bytes.

To determine the maximum MTU size on a path:

1. In Windows command prompt, try a likely MTU size:

```
>ping 4.2.2.1 -l 1472 -f
Pinging 4.2.2.1 with 1472 bytes of data:
Reply from 4.2.2.1: bytes=1472 time=41ms TTL=52
Reply from 4.2.2.1: bytes=1472 time=42ms TTL=52
Reply from 4.2.2.1: bytes=1472 time=103ms TTL=52
Reply from 4.2.2.1: bytes=1472 time=38ms TTL=52

Ping statistics for 4.2.2.1:
    Packets: Sent = 4, Received = 4, Lost = 0 (0% loss),
Approximate round trip times in milli-seconds:
    Minimum = 38ms, Maximum = 103ms, Average = 56ms
```

2. Increase the size and try the ping again:

```
>ping 4.2.2.1 -l 1473 -f
Pinging 4.2.2.1 with 1473 bytes of data:
Request timed out.

Ping statistics for 4.2.2.1:
    Packets: Sent = 1, Received = 0, Lost = 1 (100% loss),
```

   The second test fails, so the maximum MTU size on the path is 1472 bytes + 8-byte ICMP header + 20-byte IP header = 1500 bytes

Maximum segment size

The TCP maximum segment size (MSS) is the maximum amount of data that can be sent in a TCP segment. The MSS is the MTU size of the interface minus the 20 byte IP header and 20 byte TCP header. By reducing the TCP MSS, you can effectively reduce the MTU size of the packet.

The TCP MSS can be configured in a firewall policy (see Configurations in the CLI on page 1039), or directly on an interface.

To configure the MSS on an interface:

```
config system interface
    edit "wan2"
        set vdom "root"
        set mode dhcp
        set allowaccess ping fgfm
        set type physical
        set tcp-mss 1448
        set role wan
    next
end
```

One-arm sniffer

You can use a one-arm sniffer to configure a physical interface as a one-arm intrusion detection system (IDS). Traffic sent to the interface is examined for matches to the configured security profile. The matches are logged, and then all received traffic is dropped. Sniffing only reports on attacks; it does not deny or influence traffic.

You can also use the one-arm sniffer to configure the FortiGate to operate as an IDS appliance to sniff network traffic for attacks without actually processing the packets. To configure a one-arm IDS, enable sniffer mode on a physical interface and connect the interface to the SPAN port of a switch or a dedicated network tab that can replicate the traffic to the FortiGate.

If the one-arm sniffer option is not available, this means the interface is in use. Ensure that the interface is not selected in any firewall policies, routes, virtual IPs, or other features where a physical interface is specified. The option also does not appear if the role is set to WAN. Ensure the role is set to LAN, DMZ, or undefined.

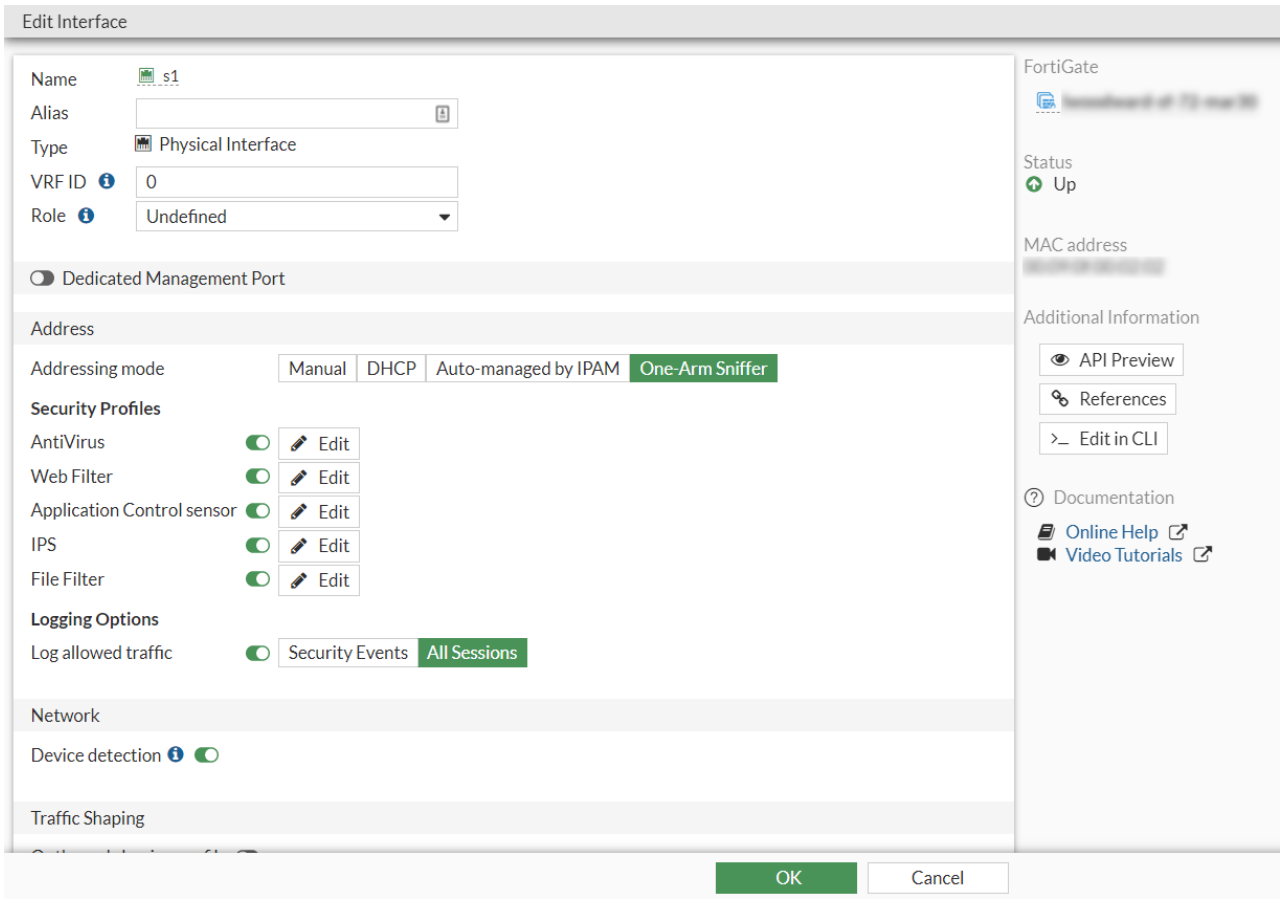
The following table lists some of the one-arm sniffer settings you can configure:

Field	Description
Security Profiles	The following profiles are configurable in the GUI and CLI: • Antivirus • Web filter • Application control • IPS • File filter The following profiles are only configurable in the CLI: • Email filter • DLP • IPS DoS

Each security profile has a predefined profile for *One-Arm Sniffer* called *sniffer-profile*. The *sniffer-profile* can be viewed or edited from the GUI through the *Edit Interface* page only. Please refer to the Example configuration on page 165for a demonstration.

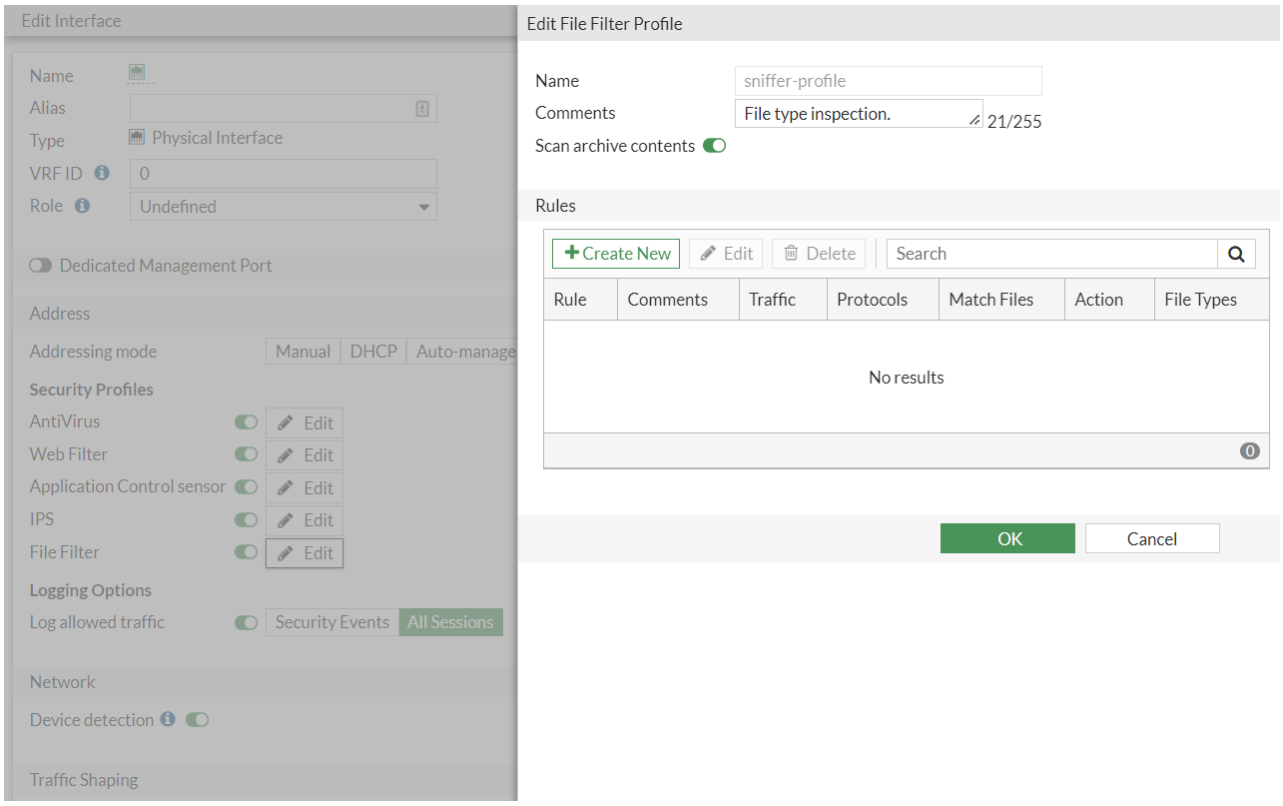
CPU usage and packet loss

Traffic scanned on the one-arm sniffer interface is processed by the CPU, even if there is an SPU, such as NPU or CP, present. The one-arm sniffer may cause higher CPU usage and perform at a lower level than traditional inline scanning, which uses NTurbo or CP to accelerate traffic when present.



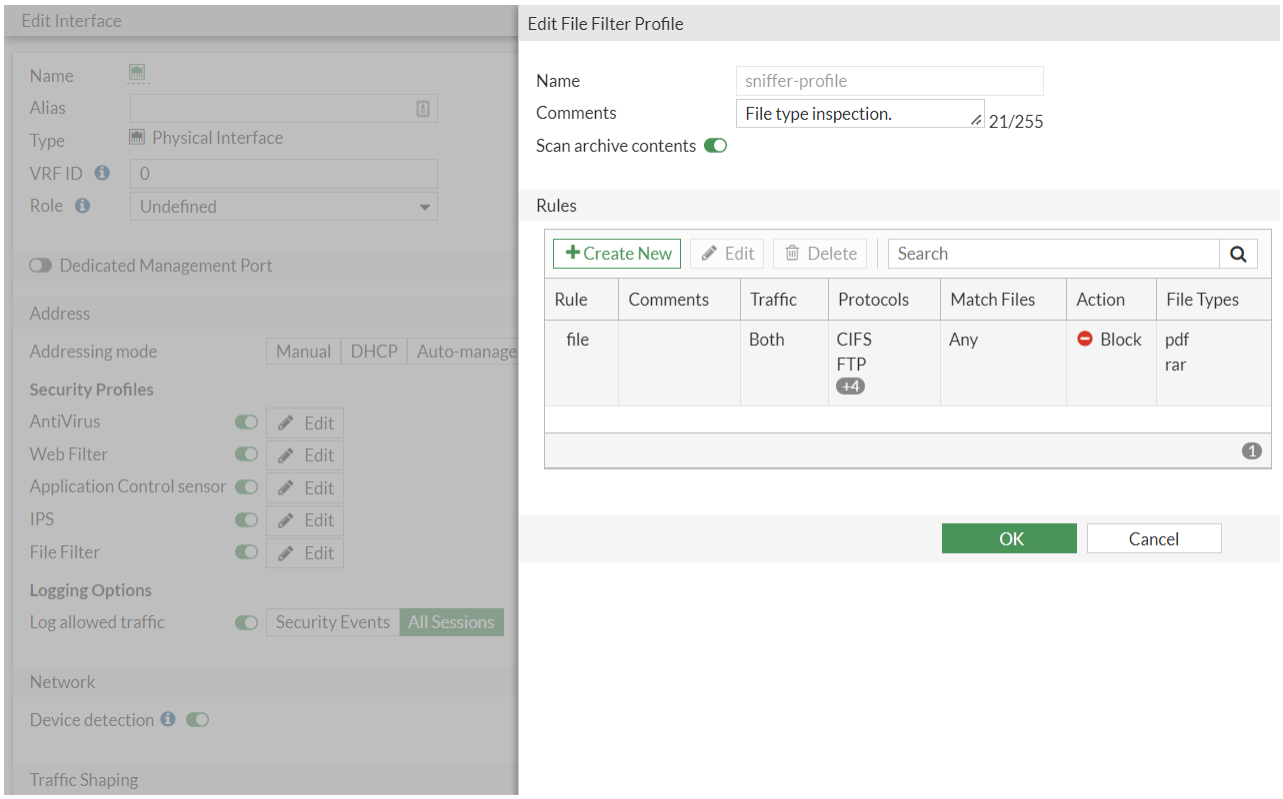
The absence of high CPU usage does not indicate the absence of packet loss. Packet loss may occur due to the capacity of the TAP devices hitting maximum traffic volume during mirroring, or on the FortiGate when the kernel buffer size is exceeded and it is unable to handle bursts of traffic.

Example configuration

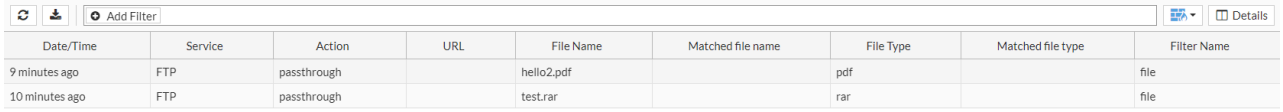


The following example shows how to configure a file filter profile that blocks PDF and RAR files used in a one-arm sniffer policy.

To configure a one-arm sniffer policy in the GUI:



1. Go to *Network* > *Interfaces* and double-click a physical interface to edit it.
2. For *Role*, select either *LAN*, *DMZ*, or *Undefined*.
3. For *Addressing Mode*, select *One-Arm Sniffer*.



4. In the *Security Profiles* section, enable *File Filter* and click *Edit*. The *Edit File Filter Profile* pane opens.
5. In the *Rules* table, click *Create New*.

6. Configure the rule:
   a. For *File types*, click the + and select *pdf* and *rar*.
   b. For *Action*, select *Block*.
   c. Click *OK* to save the rule.
7. Click *OK* to save the file filter profile.

8. Click *OK* to save the interface settings.
9. Go to *Log & Report* > *Security Events* to view the *File Filter* logs.

To configure a one-arm sniffer policy in the CLI:

1. Configure the interface:

```
config system interface
    edit "s1"
        set vdom "root"
        set ips-sniffer-mode enable
        set type physical
        set role undefined
        set snmp-index 31
    next
end
```

2. Configure the file filter profile:

```
config file-filter profile
    edit "sniffer-profile"
        set comment "File type inspection."
        config rules
            edit "1"
                set protocol http ftp smtp imap pop3 cifs
```

```
                set action block
                set file-type "pdf" "rar"
            next
        end
    next
end
```

3. Configure the firewall sniffer policy:

```
config firewall sniffer
    edit 1
        set interface "s1"
        set file-filter-profile-status enable
        set file-filter-profile "sniffer-profile"
    next
end
```

4. View the log:

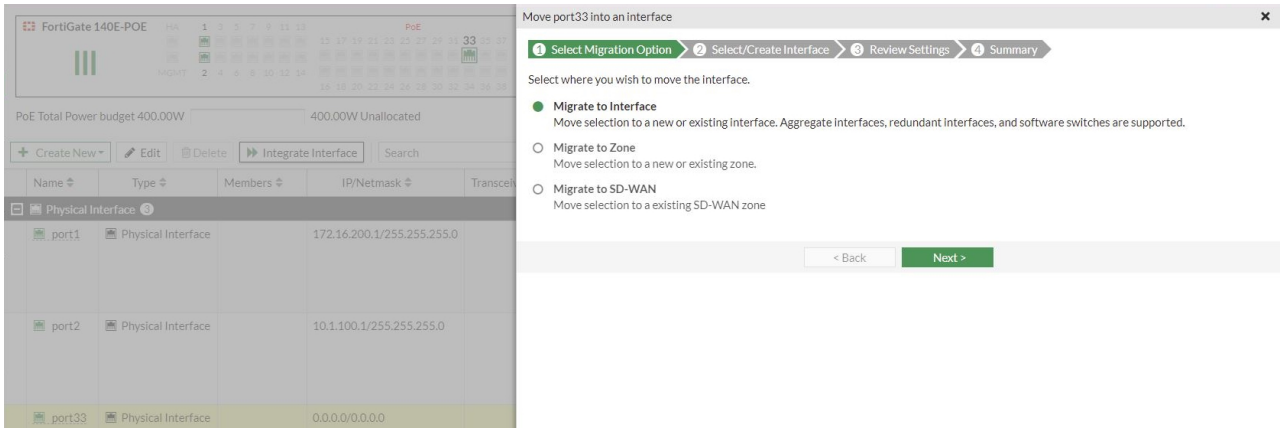
Interface migration wizard

The *Integrate Interface* option on the *Network* > *Interfaces* page helps migrate a physical port into another interface or interface type such as aggregate, software switch, redundant, zone, or SD-WAN zone. The FortiGate will migrate object references either by replacing the existing instance with the new interface, or deleting the existing instance based on the user's choice. Users can also change the VLAN ID of existing VLAN sub-interface or FortiSwitch VLANs.

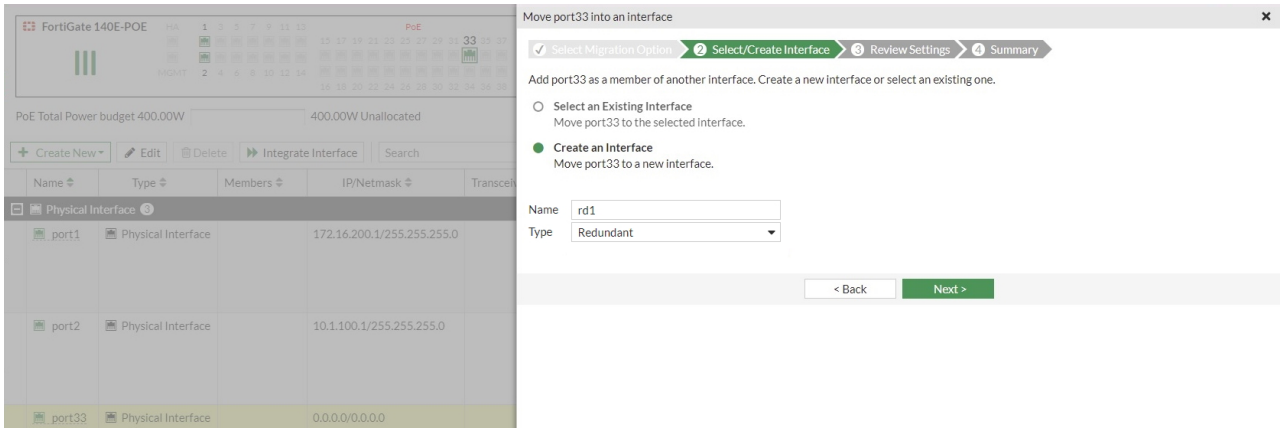
The interface migration wizard does not support turning an aggregate, software switch, redundant, zone, or SD-WAN zone interface back into a physical interface.

Integrating an interface



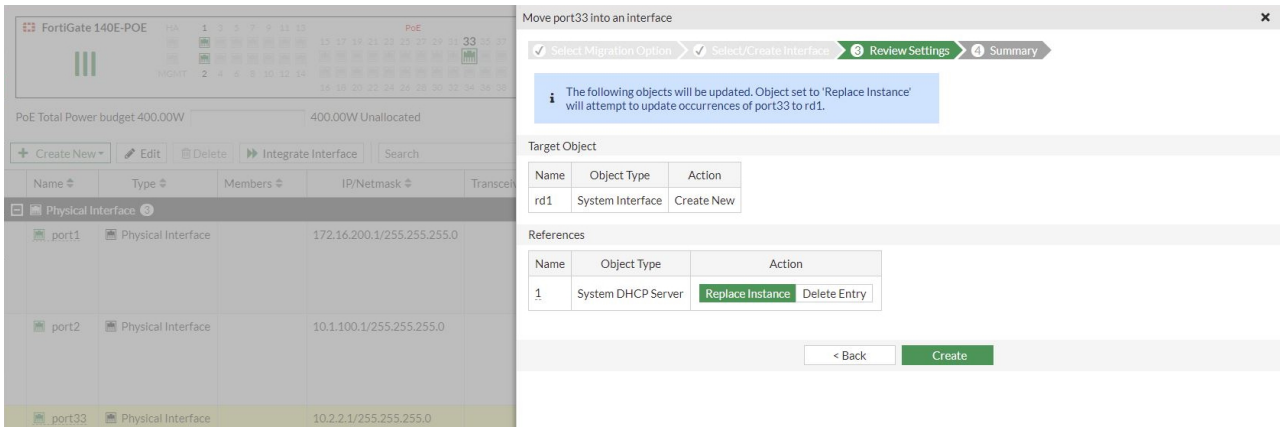
In this example, a DHCP server interface is integrated into a newly created redundant interface, which transfers the DHCP server to a redundant interface.

To integrate an interface:

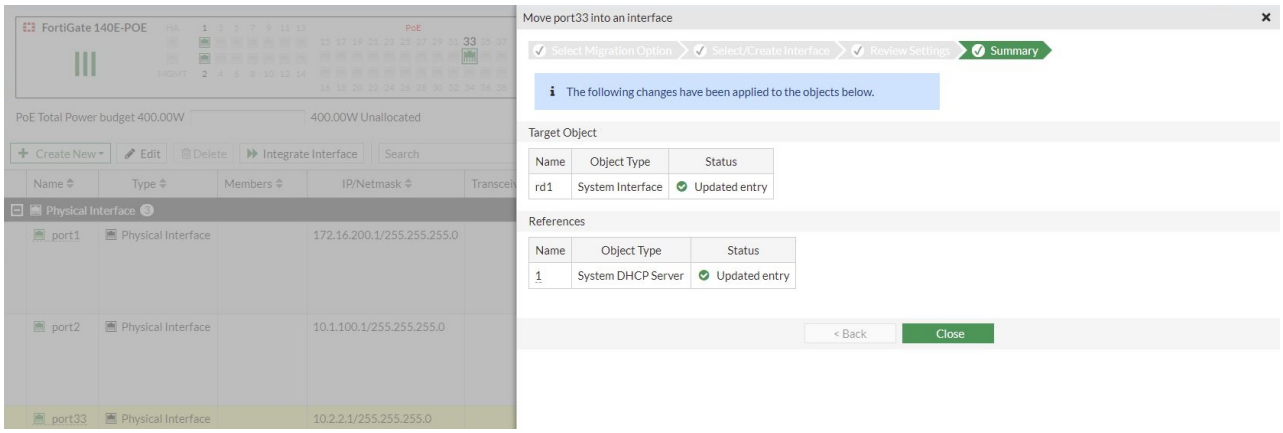


1. Go to *Network* > *Interfaces* and select an interface in the list.
2. Click *Integrate Interface*. The wizard opens.

Alternatively, select an interface in the list. Then right-click and select *Integrate Interface*.



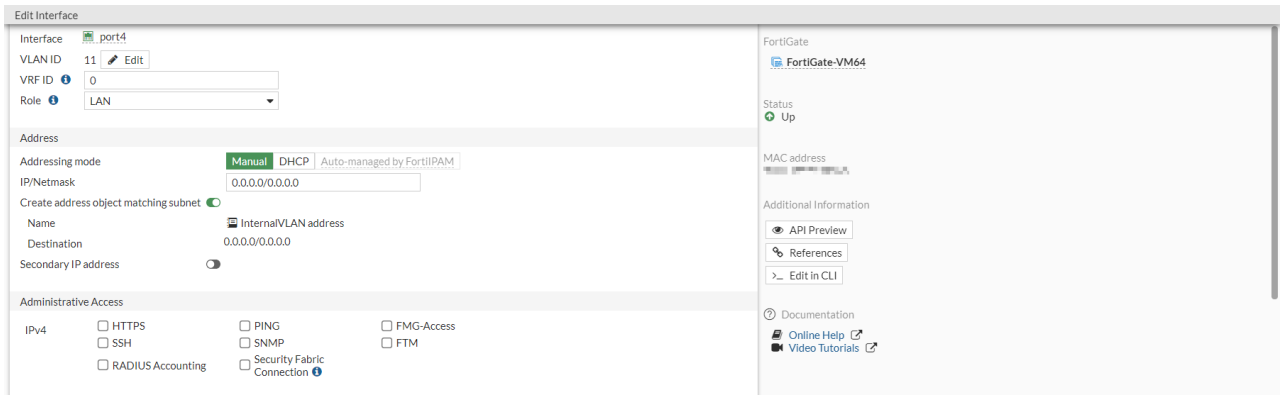
3. Select *Migrate to Interface* and click *Next*.



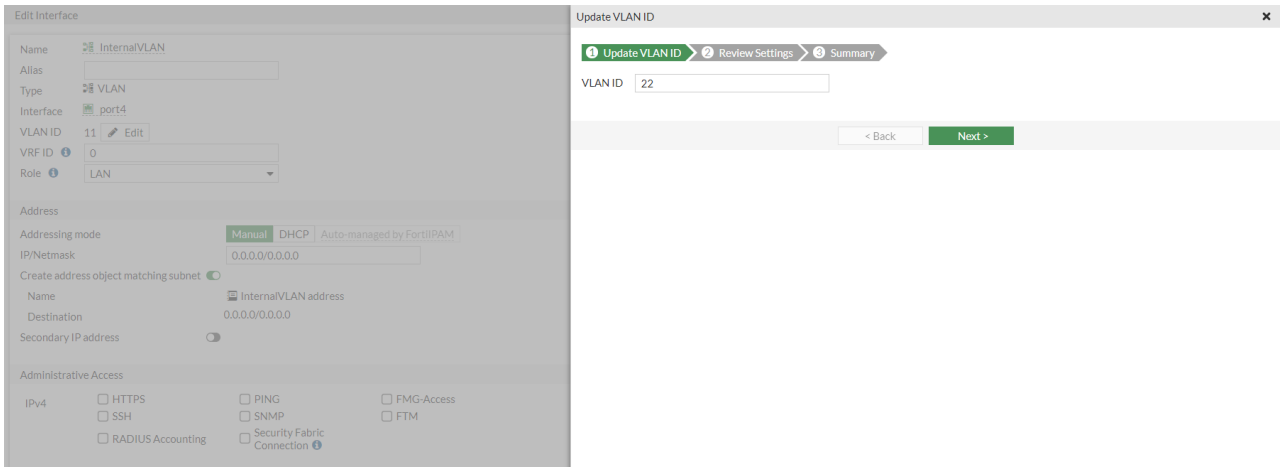
4. Select *Create an Interface*. Enter a name (*rd1*) and set the *Type* to *Redundant*.

5. Click *Next*. The *References* sections lists the associated services with options to *Replace Instance* or *Delete Entry*.
6. For the DHCP server *Action*, select *Replace Instance* and click *Create*.

7. The migration occurs automatically and the statuses for the object and reference change to *Updated entry*. Click *Close*.

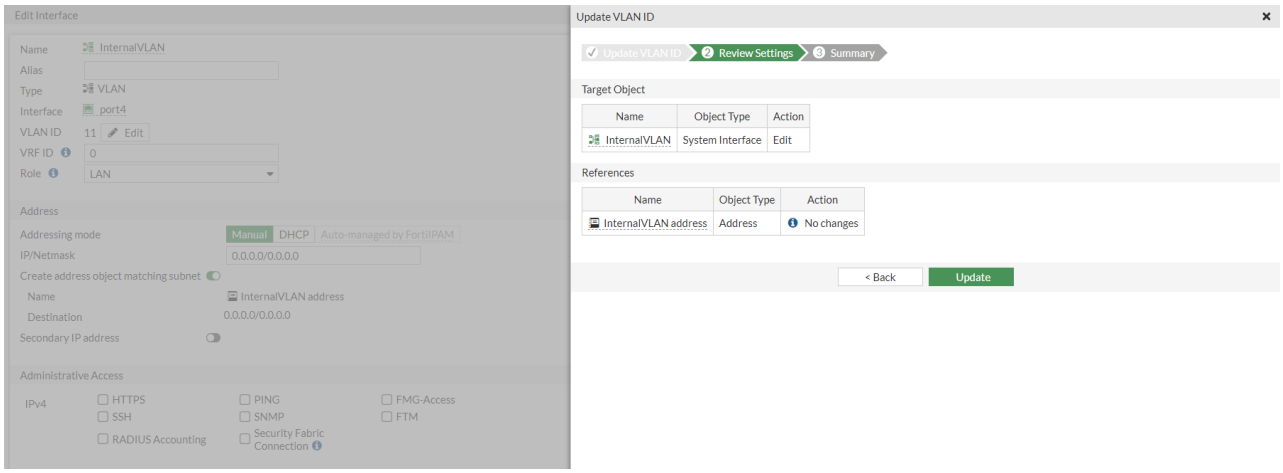


Changing the VLAN ID

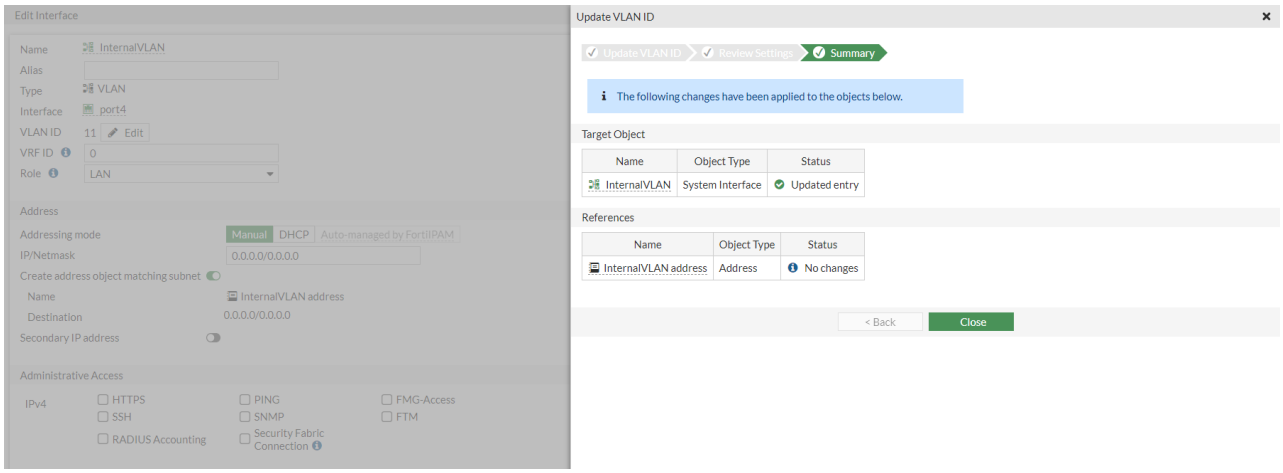


In this example, the VLAN ID of *InternalVLAN* is changed from 11 to 22.

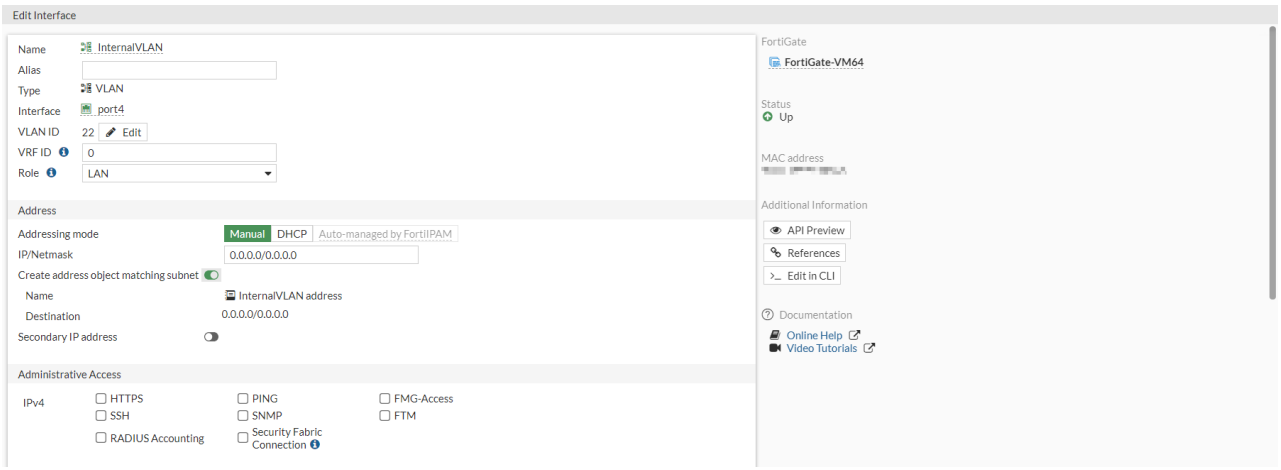
To change the VLAN ID:



1. Go to *Network* > *Interfaces* and edit an existing interface.
2. Beside the *VLAN ID* field, click *Edit*. The *Update VLAN ID* window opens.



3. Enter the new ID (*22*) and click *Next*.

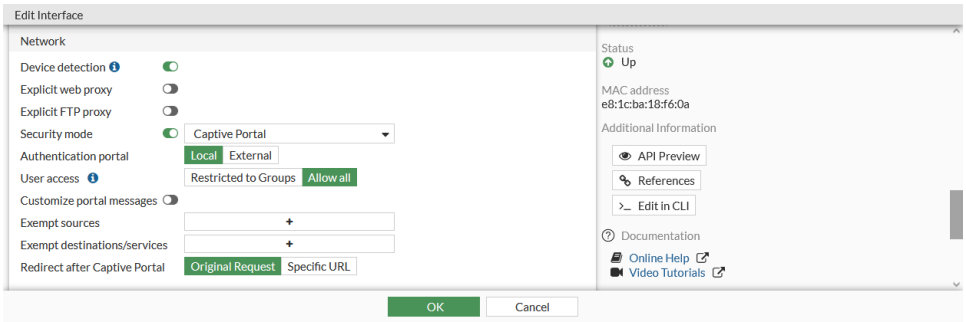


4. Verify the changes, then click *Update* and *OK*.

5. The target object status changes to *Updated entry*. Click *Close*.

In the interface settings, the ID displays as *22*.

Captive portals



A captive portal is used to enforce authentication before web resources can be accessed. Until a user authenticates successfully, any HTTP request returns the authentication page. After successfully authenticating, a user can access the requested URL and other web resources, as permitted by policies. The captive portal can also be configured to only allow access to members of specific user groups.

Captive portals can be hosted on the FortiGate or an external authentication server. They can be configured on any network interface, including VLAN and WiFi interfaces. On a WiFi interface, the access point appears open, and the client can connect to access point with no security credentials, but then sees the captive portal authentication page. See Captive Portal Security, in the FortiWiFi and FortiAP Configuration Guide for more information.

All users on the interface are required to authenticate. Exemption lists can be created for devices that are unable to authenticate, such as a printer that requires access to the internet for firmware upgrades.

To configure a captive portal in the GUI:

1. Go to *Network* > *Interfaces* and edit the interface that the users connect to. The interface *Role* must be *LAN* or *Undefined*.
2. Enable *Security mode*.

3. Configure the following settings, then click *OK*.

Authentication Portal	Configure the location of the portal: • *Local*: the portal is hosted on the FortiGate unit.

	• *External*: enter the FQDN or IP address of external portal.
User access	Select if the portal applies to all users, or selected user groups: • *Restricted to Groups*: restrict access to the selected user groups. The *Login page* is shown when a user tries to log in to the captive portal. • *Allow all*: all users can log in, but access will be defined by relevant policies. The *Disclaimer page* is shown when a user tried to log in to the captive portal.
Customize portal messages	Enable to use custom portal pages, then select a replacement message group. See Custom captive portal pages on page 175.
Exempt sources	Select sources that are exempt from the captive portal. Each exemption is added as a rule in an automatically generated exemption list.
Exempt destinations/services	Select destinations and services that are exempt from the captive portal. Each exemption is added as a rule in an automatically generated exemption list.
Redirect after Captive Portal	Configure website redirection after successful captive portal authentication: • *Original Request*: redirect to the initially browsed to URL . • *Specific URL*: redirect to the specified URL.

To configure a captive portal in the CLI:

1. If required, create a security exemption list:

```
config user security-exempt-list
    edit <list>
        config rule
            edit 1
                set srcaddr <source(s)>
                set dstaddr <source(s)>
                set service <service(s)>
            next
            edit 2
                set srcaddr <source(s)>
                set dstaddr <source(s)>
                set service <service(s)>
            next
        end
    next
end
```

2. Configure captive portal authentication on the interface:

```
config system interface
    edit <interface>
        set security-mode {none | captive-portal}
        set security-external-web <string>
        set replacemsg-override-group <group>
        set security-redirect-url <string>
        set security-exempt-list <list>
        set security-groups <group(s)>
```

```
        next
    end
```

Custom captive portal pages

Portal pages are HTML files that can be customized to meet user requirements.

Most of the text and some of the HTML in the message can be changed. Tags are enclosed by double percent signs (%%); most of them should not be changed because they might carry information that the FortiGate unit needs. For information about customizing replacement messages, see Modifying replacement messages on page 2487.

The images on the pages can be replaced. For example, your organization's logo can replace the Fortinet logo. For information about uploading and using new images in replacement messages, see Replacement message images on page 2488.

The following pages are used by captive portals:

Login Page	Requests user credentials. The *%%QUESTION%%* tag provides the *Please enter the required information to continue.* text. This page is shown to users that are trying to log in when *User access* is set to *Restricted to Groups*.
Login Failed Page	Reports that incorrect credentials were entered, and requests correct credentials. The *%%FAILED_MESSAGE%%* tag provides the *Firewall authentication failed. Please try again.* text.
Disclaimer Page	A statement of the legal responsibilities of the user and the host organization that the user must agree to before proceeding. This page is shown users that are trying to log in when *User access* is set to *Allow all*.
Declined Disclaimer Page	Shown if the user does not agree to the statement on the Disclaimer page. Access is denied until the user agrees to the disclaimer.

Physical interface

A FortiGate has several physical interfaces that can connect to Ethernet or optical cables. Depending on the FortiGate model, it can have a varying combination of Ethernet, small form-factor pluggable (SFP), and enhanced small form-factor pluggable (SFP+) interfaces.

The port names, as labeled on the FortiGate, appear in the interfaces list on the *Network* > *Interfaces* page. Hover the cursor over a port to view information, such as the name and the IP address.

Refer to Configuring an interface for basic GUI and CLI configuration steps.

Displaying transceiver status information for SFP and SFP+ interfaces

Transceiver status information for SFP and SFP+ interfaces installed on the FortiGate can be displayed in the GUI and CLI. For example, the type, vendor name, part number, serial number, and port name. The CLI output includes additional information that can be useful for diagnosing transmission problems, such as the temperature, voltage, and optical transmission power.

To view transceiver status information in the GUI:

1. Go to *Network* > *Interfaces*. The *Transceiver* column is visible in the table, which displays the transceiver vendor name and part number.
2. Hover the cursor over a transceiver to view more information.

To view transceiver status information in the CLI:

```
# get system interface transceiver
Interface port9 - SFP/SFP+
  Vendor Name  :            FINISAR CORP.
  Part No.     :            FCLF-8521-3
  Serial No.   :            PMS***
Interface port10 - Transceiver is not detected.
Interface port11 - SFP/SFP+

  ++ : high alarm, + : high warning, - : low warning, -- : low alarm, ? : suspect.
```

VLAN

Virtual local area networks (VLANs) multiply the capabilities of your FortiGate and can also provide added network security. VLANs use ID tags to logically separate devices on a network into smaller broadcast domains. These smaller

domains forward packets only to devices that are part of that VLAN domain. This reduces traffic and increases network security.

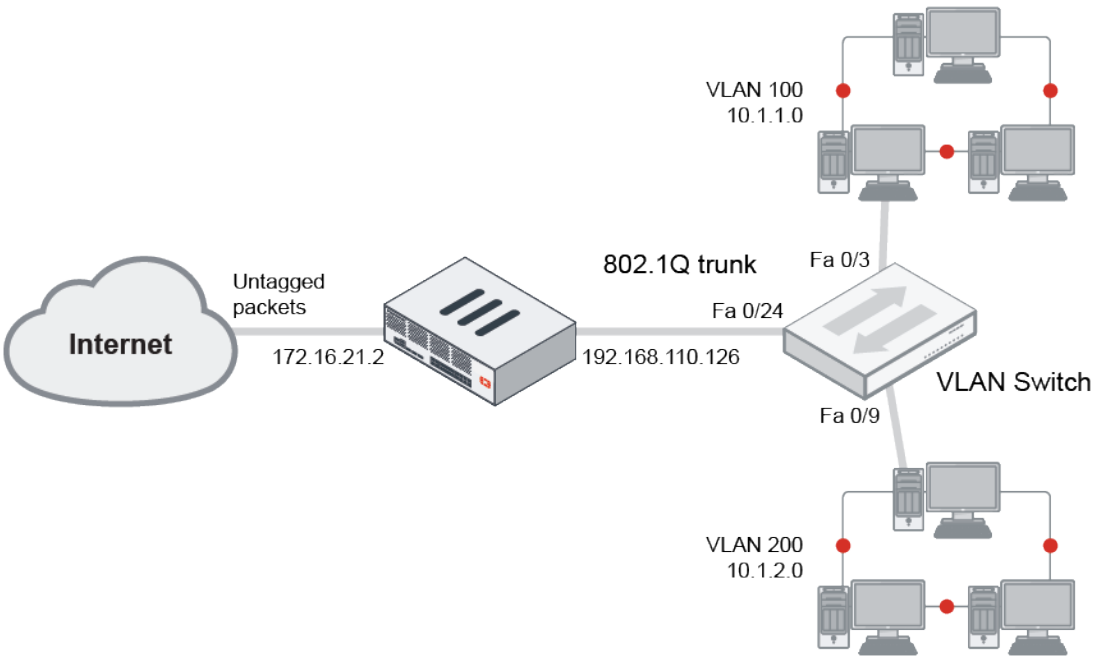
VLANs in NAT mode

In NAT mode, the FortiGate unit functions as a layer-3 device. In this mode, the FortiGate unit controls the flow of packets between VLANs and can also remove VLAN tags from incoming VLAN packets. The FortiGate unit can also forward untagged packets to other networks such as the Internet.

In NAT mode, the FortiGate unit supports VLAN trunk links with IEEE 802.1Q-compliant switches or routers. The trunk link transports VLAN-tagged packets between physical subnets or networks. When you add VLAN subinterfaces to the FortiGate's physical interfaces, the VLANs have IDs that match the VLAN IDs of packets on the trunk link. The FortiGate unit directs packets with VLAN IDs to subinterfaces with matching IDs.

You can define VLAN subinterfaces on all FortiGate physical interfaces. However, if multiple virtual domains are configured on the FortiGate unit, you only have access to the physical interfaces on your virtual domain. The FortiGate unit can tag packets leaving on a VLAN subinterface. It can also remove VLAN tags from incoming packets and add a different VLAN tag to outgoing packets.

Normally in VLAN configurations, the FortiGate unit's internal interface is connected to a VLAN trunk, and the external interface connects to an Internet router that is not configured for VLANs. In this configuration, the FortiGate unit can apply different policies for traffic on each VLAN interface connected to the internal interface, which results in less network traffic and better security.



Sample topology

In this example, two different internal VLAN networks share one interface on the FortiGate unit and share the connection to the Internet. This example shows that two networks can have separate traffic streams while sharing a single interface. This configuration can apply to two departments in a single company or to different companies.

There are two different internal network VLANs in this example. VLAN_100 is on the 10.1.1.0/255.255.255.0 subnet, and VLAN_200 is on the 10.1.2.0/255.255.255.0 subnet. These VLANs are connected to the VLAN switch.

The FortiGate internal interface connects to the VLAN switch through an 802.1Q trunk. The internal interface has an IP address of 192.168.110.126 and is configured with two VLAN subinterfaces (VLAN_100 and VLAN_200). The external interface has an IP address of 172.16.21.2 and connects to the Internet. The external interface has no VLAN subinterfaces.

When the VLAN switch receives packets from VLAN_100 and VLAN_200, it applies VLAN ID tags and forwards the packets of each VLAN both to local ports and to the FortiGate unit across the trunk link. The FortiGate unit has policies that allow traffic to flow between the VLANs, and from the VLANs to the external network.

Sample configuration

In this example, both the FortiGate unit and the Cisco 2950 switch are installed and connected and basic configuration has been completed. On the switch, you need access to the CLI to enter commands. No VDOMs are enabled in this example.

General configuration steps include:

1. Configure the external interface.
2. Add two VLAN subinterfaces to the internal network interface.
3. Add firewall addresses and address ranges for the internal and external networks.
4. Add security policies to allow:
   - the VLAN networks to access each other.
   - the VLAN networks to access the external network.

To configure the external interface:

```
config system interface
    edit external
        set mode static
        set ip 172.16.21.2 255.255.255.0
    next
end
```

To add VLAN subinterfaces:

```
config system interface
    edit VLAN_100
        set vdom root
        set interface internal
        set type vlan
```

```
        set vlanid 100
        set mode static
        set ip 10.1.1.1 255.255.255.0
        set allowaccess https ping
    next
    edit VLAN_200
        set vdom root
        set interface internal
        set type vlan
        set vlanid 200
        set mode static
        set ip 10.1.2.1 255.255.255.0
        set allowaccess https ping
    next
end
```

To add the firewall addresses:

```
config firewall address
    edit VLAN_100_Net
        set type ipmask
        set subnet 10.1.1.0 255.255.255.0
    next
    edit VLAN_200_Net
        set type ipmask
        set subnet 10.1.2.0 255.255.255.0
    next
end
```

To add security policies:

Policies 1 and 2 do not need NAT enabled, but policies 3 and 4 do need NAT enabled.

```
config firewall policy
    edit 1
        set srcintf VLAN_100
        set srcaddr VLAN_100_Net
        set dstintf VLAN_200
        set dstaddr VLAN_200_Net
        set schedule always
        set service ALL
        set action accept
        set nat disable
        set status enable
    next
    edit 2
        set srcintf VLAN_200
        set srcaddr VLAN_200_Net
        set dstintf VLAN_100
        set dstaddr VLAN_100_Net
        set schedule always
        set service ALL
        set action accept
        set nat disable
        set status enable
    next
```

```
    edit 3
        set srcintf VLAN_100
        set srcaddr VLAN_100_Net
        set dstintf external
        set dstaddr all
        set schedule always
        set service ALL
        set action accept
        set nat enable
        set status enable
    next
    edit 4
        set srcintf VLAN_200
        set srcaddr VLAN_200_Net
        set dstintf external
        set dstaddr all
        set schedule always
        set service ALL
        set action accept
        set nat enable
        set status enable
    next
end
```

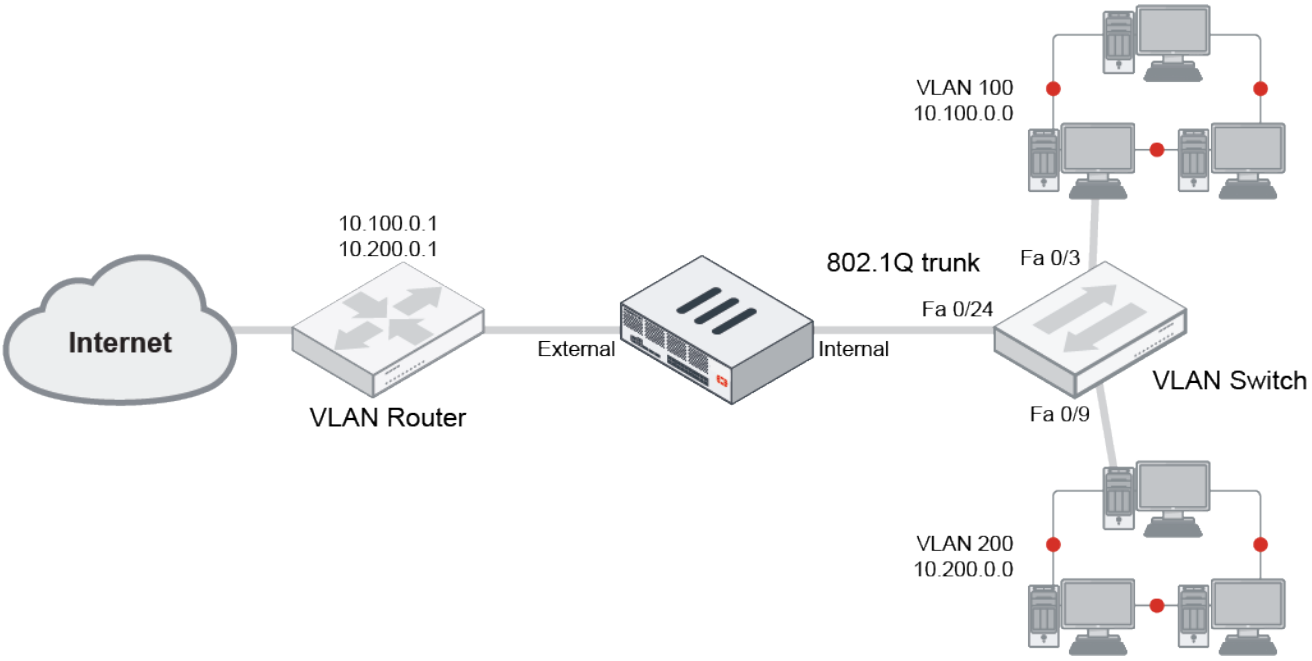
VLANs in transparent mode

In transparent mode, the FortiGate unit behaves like a layer-2 bridge but can still provide services such as antivirus scanning, web filtering, spam filtering, and intrusion protection to traffic. Some limitations of transparent mode is that you cannot use SSL VPN, PPTP/L2TP VPN, DHCP server, or easily perform NAT on traffic. The limits in transparent mode apply to IEEE 802.1Q VLAN trunks passing through the unit.

You can insert the FortiGate unit operating in transparent mode into the VLAN trunk without making changes to your network. In a typical configuration, the FortiGate unit internal interface accepts VLAN packets on a VLAN trunk from a VLAN switch or router connected to internal network VLANs. The FortiGate external interface forwards VLAN-tagged packets through another VLAN trunk to an external VLAN switch or router and on to external networks such as the Internet. You can configure the unit to apply different policies for traffic on each VLAN in the trunk.

To pass VLAN traffic through the FortiGate unit, you add two VLAN subinterfaces with the same VLAN ID, one to the internal interface and the other to the external interface. You then create a security policy to permit packets to flow from the internal VLAN interface to the external VLAN interface. If required, create another security policy to permit packets to flow from the external VLAN interface to the internal VLAN interface. Typically in transparent mode, you do not permit packets to move between different VLANs. Network protection features such as spam filtering, web filtering, and anti-virus scanning, are applied through the UTM profiles specified in each security policy, enabling very detailed control over traffic.

When the FortiGate unit receives a VLAN-tagged packet on a physical interface, it directs the packet to the VLAN subinterface with the matching VLAN ID. The VLAN tag is removed from the packet and the FortiGate unit then applies security policies using the same method it uses for non-VLAN packets. If the packet exits the FortiGate unit through a VLAN subinterface, the VLAN ID for that subinterface is added to the packet and the packet is sent to the corresponding physical interface.



Sample topology

In this example, the FortiGate unit is operating in transparent mode and is configured with two VLANs: one with an ID of 100 and the other with ID 200. The internal and external physical interfaces each have two VLAN subinterfaces, one for VLAN_100 and one for VLAN_200.

The IP range for the internal VLAN_100 network is 10.100.0.0/255.255.0.0, and for the internal VLAN_200 network is 10.200.0.0/255.255.0.0.

The internal networks are connected to a Cisco 2950 VLAN switch which combines traffic from the two VLANs onto one in the FortiGate unit's internal interface. The VLAN traffic leaves the FortiGate unit on the external network interface, goes on to the VLAN switch, and on to the Internet. When the FortiGate units receives a tagged packet, it directs it from the incoming VLAN subinterface to the outgoing VLAN subinterface for that VLAN.

In this example, we create a VLAN subinterface on the internal interface and another one on the external interface, both with the same VLAN ID. Then we create security policies that allow packets to travel between the VLAN_100_int interface and the VLAN_100_ext interface. Two policies are required: one for each direction of traffic. The same is required between the VLAN_200_int interface and the VLAN_200_ext interface, for a total of four security policies.

Sample configuration

There are two main steps to configure your FortiGate unit to work with VLANs in transparent mode:

1. Add VLAN subinterfaces.
2. Add security policies.

You can also configure the protection profiles that manage antivirus scanning, web filtering, and spam filtering.

To add VLAN subinterfaces:

```
config system interface
    edit VLAN_100_int
        set type vlan
```

```
        set interface internal
        set vlanid 100
    next
    edit VLAN_100_ext
        set type vlan
        set interface external
        set vlanid 100
    next
    edit VLAN_200_int
        set type vlan
        set interface internal
        set vlanid 200
    next
    edit VLAN_200_ext
        set type vlan
        set interface external
        set vlanid 200
    next
end
```

To add security policies:

```
config firewall policy
    edit 1
        set srcintf VLAN_100_int
        set srcaddr all
        set dstintf VLAN_100_ext
        set dstaddr all
        set action accept
        set schedule always
        set service ALL
    next
    edit 2
        set srcintf VLAN_100_ext
        set srcaddr all
        set dstintf VLAN_100_int
        set dstaddr all
        set action accept
        set schedule always
        set service ALL
    next
    edit 3
        set srcintf VLAN_200_int
        set srcaddr all
        set dstintf VLAN_200_ext
        set dstaddr all
        set action accept
        set schedule always
        set service ALL
    next
    edit 4
        set srcintf VLAN_200_ext
        set srcaddr all
        set dstintf VLAN_200_int
        set dstaddr all
        set action accept
```

```
        set schedule always
        set service ALL
    next
end
```

Virtual VLAN switch

The hardware switch ports on FortiGate models that support virtual VLAN switches can be used as a layer 2 switch. Virtual VLAN switch mode allows 802.1Q VLANs to be assigned to ports, and the configuration of one interface as a trunk port.

The following FortiGate series are supported in FortiOS 7.2: 60F, 80F, 100E, 100F, 140E, 200F, 300E, 400E, 1100E, 1800F, 2600F, 3500F, 4200F, and 4400F.

The `virtual-switch-vlan` option must be enabled in the CLI to configure VLAN switch mode from the GUI or CLI.

To enable VLAN switches:

```
config system global
    set virtual-switch-vlan enable
end
```

After this setting is enabled, any previously configured hardware switches will appear in the *Network* > *Interfaces* page under *VLAN Switch*.

To enable VLAN switch mode in the GUI:

1. Go to *System* > *Settings*.
2. In the *View Settings* section, enable *VLAN switch mode*.
3. Click *Apply*.

Basic configurations

Hardware switch ports can be configured as either a VLAN switch port or a trunk port. The available interfaces and allowable VLAN IDs that can be used depend on the FortiGate model. It is recommended to remove ports from the default VLAN switch before you begin configurations.

To create a new VLAN and assign ports in the GUI:

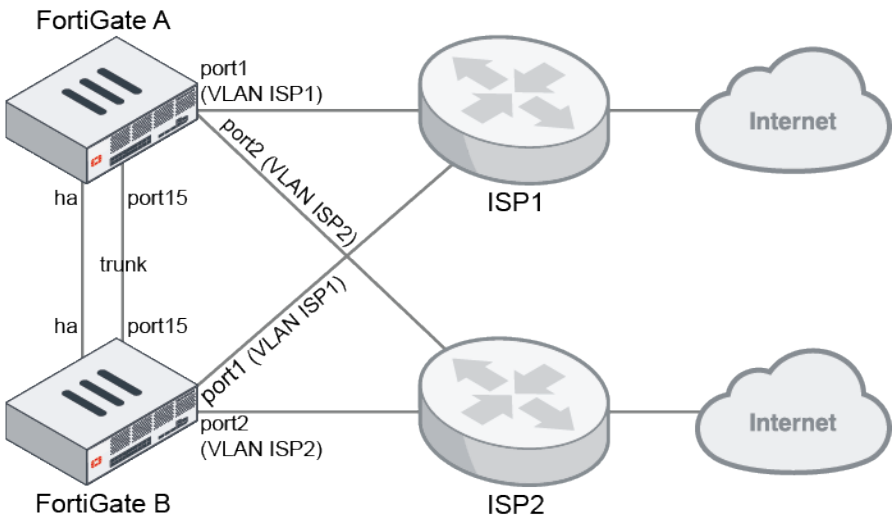
1. Go to *Network* > *Interfaces* and click *Create New* > *Interface*.
2. Enter a name and configure the following:
   a. Set the *Type* to *VLAN Switch*.
   b. Enter a *VLAN ID*.
   c. Click the + and add the *Interface Members*.
   d. Configure the *Address* and *Administrative Access* settings as needed.
3. Click *OK*.

To create a new VLAN and assign ports in the CLI:

1. Configure the VLAN:

```
config system virtual-switch
    edit "VLAN10"
        set physical-switch "sw0"
        set vlan 10
        config port
            edit "internal1"
            next
            edit "internal2"
            next
        end
    next
end
```

2. Configure the VLAN switch interface addressing:



```
config system interface
    edit "VLAN10"
        set vdom "root"
        set ip 192.168.10.99 255.255.255.0
        set allowaccess ping https ssh snmp http fgfm
        set type hard-switch
    next
end
```

To designate an interface as a trunk port:

```
config system interface
    edit internal5
        set trunk enable
    next
end
```

Example 1: HA using a VLAN switch

In this example, two FortiGates in an HA cluster are connected to two ISP routers. Instead of connecting to external L2 switches, each FortiGate connects to each ISP router on the same hardware switch port on the same VLAN. A trunk port connects the two FortiGates to deliver the 802.1Q tagged traffic to the other. A full mesh between the FortiGate cluster and the ISP routers is achieved where no single point of failure will cause traffic disruptions.

This example assumes that the HA settings are already configured. The interface and VLAN switch settings are identical between cluster members and synchronized. See HA using a hardware switch to replace a physical switch on page 2382 for a similar example that does not use a VLAN switch.

To configure the VLAN switches:

1. Configure the ISP interfaces with the corresponding VLAN IDs:

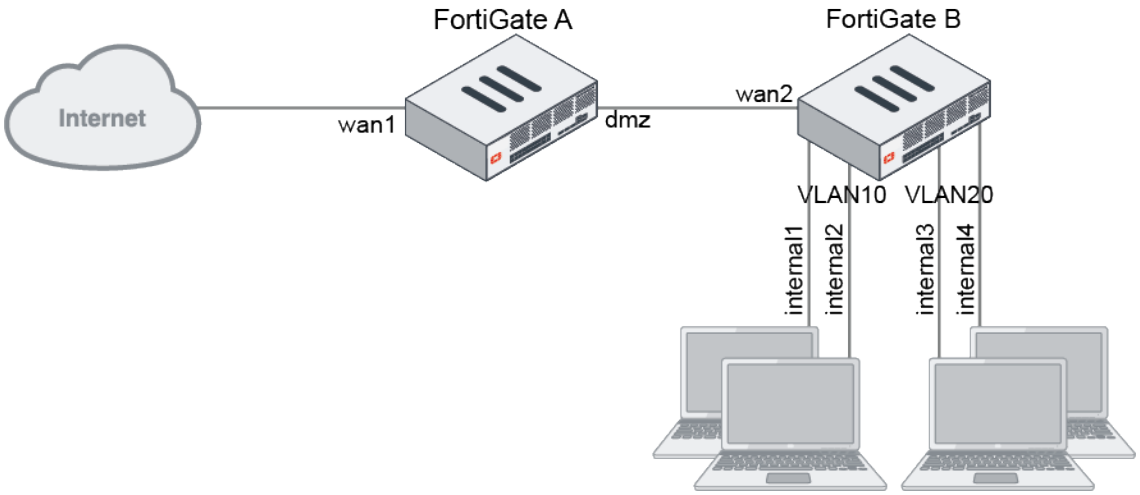
```
config system virtual-switch
    edit "ISP1"
        set physical-switch "sw0"
        set vlan 2951
        config port
            edit "port1"
            next
        end
    next
    edit "ISP2"
        set physical-switch "sw0"
        set vlan 2952
        config port
            edit "port2"
            next
        end
    next
end
```

2. Configure the VLAN switch interface addressing:

```
config system interface
    edit "ISP1"
        set vdom "root"
        set ip 192.168.10.99 255.255.255.0
        set allowaccess ping
        set type hard-switch
    next
    edit "ISP2"
        set vdom "root"
```

```
        set ip 192.168.20.99 255.255.255.0
        set allowaccess ping
        set type hard-switch
    next
end
```

3. Designate port15 as the trunk port:



```
config system interface
    edit port15
        set trunk enable
    next
end
```

4. Configure firewall policies to allow outgoing traffic on the ISP1 and ISP2 interfaces:

```
config firewall policy
    edit 1
        set srcintf "port11"
        set dstintf "ISP1"
        set srcaddr "all"
        set dstaddr "all"
        set action accept
        set schedule "always"
        set service "ALL"
        set nat enable
    next
    edit 2
        set srcintf "port11"
        set dstintf "ISP2"
        set srcaddr "all"
        set dstaddr "all"
        set action accept
        set schedule "always"
        set service "ALL"
        set nat enable
    next
end
```

Example 2: LAN extension

In this example, two hardware switch ports are assigned VLAN10, and two ports are assigned VLAN20 on FortiGate B. The wan2 interface is designated as the trunk port, and is connected to the upstream FortiGate A. The corresponding VLAN subinterfaces VLAN10 and VLAN20 on the upstream FortiGate allow further access to other networks.

The available interfaces and VLAN IDs varies between FortiGate models. The FortiGate B in this example is a 60F model.

To configure FortiGate B:

1. Configure the VLAN interfaces:

```
config system virtual-switch
    edit "VLAN10"
        set physical-switch "sw0"
        set vlan 10
        config port
            edit "internal1"
            next
            edit "internal2"
            next
        end
    next
    edit "VLAN20"
        set physical-switch "sw0"
        set vlan 20
        config port
            edit "internal3"
            next
            edit "internal4"
            next
        end
    next
end
```

2. Configure the VLAN switch interface addressing:

```
config system interface
    edit "VLAN10"
        set vdom "root"
        set ip 192.168.10.99 255.255.255.0
        set allowaccess ping https ssh snmp http fgfm
```

```
        set type hard-switch
    next
    edit "VLAN20"
        set vdom "root"
        set ip 192.168.20.99 255.255.255.0
        set allowaccess ping https ssh snmp http fgfm
        set type hard-switch
    next
end
```

3. Designate wan2 as the trunk port:

```
config system interface
    edit wan2
        set trunk enable
    next
end
```

To configure FortiGate A:

1. Configure the VLAN subinterfaces:

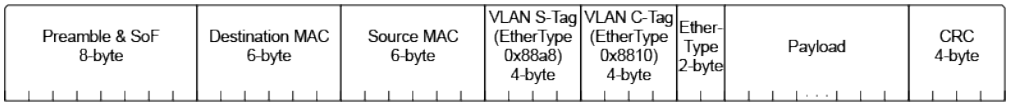
```
config system interface
    edit "VLAN10"
        set ip 192.168.10.98 255.255.255.0
        set allowaccess ping https ssh
        set role lan
        set interface "dmz"
        set vlanid 10
    next
    edit "VLAN20"
        set ip 192.168.20.98 255.255.255.0
        set allowaccess ping https ssh
        set role lan
        set interface "dmz"
        set vlanid 20
    next
end
```

2. Configure the DHCP server on VLAN10:

```
config system dhcp server
    edit 0
        set dns-service default
        set default-gateway 192.168.10.98
        set netmask 255.255.255.0
        set interface "VLAN10 "
        config ip-range
            edit 1
                set start-ip 192.168.10.100
                set end-ip 192.168.10.254
            next
        end
        set timezone-option default
    next
end
```

3. Configure firewall policies that allow traffic from the VLAN10 and VLAN20 interfaces to the internet:

```
config firewall policy
    edit 0
        set name "VLAN10-out"
        set srcintf "VLAN10"
        set dstintf "wan1"
        set srcaddr "all"
        set dstaddr "all"
        set action accept
        set schedule "always"
        set service "ALL"
        set nat enable
    next
    edit 0
        set name "VLAN20-out"
        set srcintf "VLAN20"
        set dstintf "wan1"
        set srcaddr "all"
        set dstaddr "all"
        set action accept
        set schedule "always"
        set service "ALL"
        set nat enable
    next
end
```



To test the connection:

1. Connect a PC to internal1 on FortiGate B.
2. Verify that it receives an IP address from FortiGate A's DHCP server.
3. From the PC, ping FortiGate B on 192.168.10.99.
4. Ping FortiGate A on 192.168.10.98.
5. Connect to the internet. Traffic is allowed by the VLAN10-out policy.

QinQ 802.1Q in 802.1ad

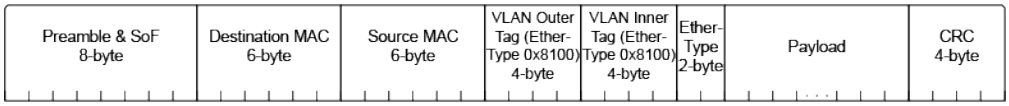
QinQ (802.1ad) allows multiple VLAN tags to be inserted into a single frame, and can be configured on supported FortiGate devices.

In this example, the customer connects to a provider that uses 802.1ad double-tagging to separate their customer VLANs. The FortiGate connecting to the provider double-tags its frames with an outer provider-tag (S-Tag) and an inner customer-tag (C-Tag).

The customer identifies itself with the provider-tag (S-Tag) 232 and uses the customer-tag (C-Tag) 444 for traffic to its VLAN.

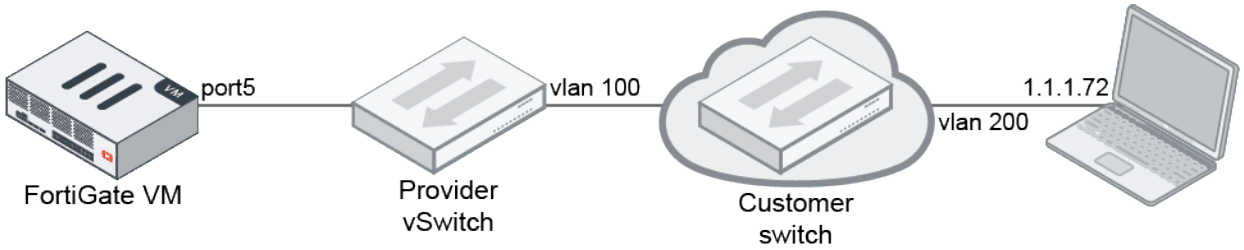
To configure the interfaces:

1. Configure the interface to the provider that uses the outer tag (S-Tag):



```
config system interface
    edit "vlan-8021ad"
        set vdom "root"
        set vlan-protocol 8021ad
        set device-identification enable
        set role lan
        set snmp-index 47
        set interface "PORT"
        set vlanid 232
    next
end
```

2. Configure a dynamic VLAN interface that uses the inner tag (C-Tag):



```
config system interface
    edit "DVLAN"
        set vdom "vdom1"
        set device-identification enable
        set role lan
        set snmp-index 48
        set interface "vlan-8021ad"
        set vlanid 444
    next
end
```

QinQ 802.1Q in 802.1Q

QinQ (802.1Q in 802.1Q) is supported for FortiGate VM models, where multiple VLAN tags can be inserted into a single frame.

In this example, the FortiGate VM is connected to a provider vSwitch and then a customer switch. The FortiGate encapsulates the frame with an outer 802.1Q tag of VLAN 100 and an inner 802.1Q tag of VLAN 200; port5 is used as the physical port. The provider vSwitch strips the outer tag and forwards traffic to the appropriate customer. Then the customer switch strips the inner tag and forwards the packet to the appropriate customer VLAN.

To configure the interfaces:

1. Configure the interface to the provider that uses the outer tag:

```
config system interface
    edit "vlan-8021q"
        set vdom "root"
        set device-identification enable
        set role lan
        set interface "port5"
        set vlan-protocol 8021q
        set vlanid 100
    next
end
```

2. Configure the interface to the provider that uses the inner tag:

```
config system interface
    edit "vlan-qinq8021q"
        set vdom "root"
        set ip 1.1.1.71 255.255.255.0
        set allowaccess ping https ssh snmp http
        set device-identification enable
        set role lan
        set interface "vlan-8021q"
        set vlanid 200
    next
end
```

To verify the traffic:

1. From the FortiGate, ping 1.1.1.72:

```
# execute ping 1.1.1.72
PING 1.1.1.72 (1.1.1.72): 56 data bytes
64 bytes from 1.1.1.72: icmp_seq=0 ttl=255 time=0.2 ms
64 bytes from 1.1.1.72: icmp_seq=1 ttl=255 time=0.1 ms
64 bytes from 1.1.1.72: icmp_seq=2 ttl=255 time=0.1 ms
64 bytes from 1.1.1.72: icmp_seq=3 ttl=255 time=0.1 ms
^C
--- 1.1.1.72 ping statistics ---
4 packets transmitted, 4 packets received, 0% packet loss
round-trip min/avg/max = 0.1/0.1/0.2 ms
```

2. Verify the packet capture frame header output captured from the FortiGate's port5:

```
Frame 2: 106 bytes on wire (848 bits), 106 bytes captured (848 bits)
Ethernet II, Src: VMware_93:ae:8f (00:50:56:93:ae:8f), Dst: VMware_93:e3:72
(00:50:56:93:e3:72)
    Destination: VMware_93:e3:72 (00:50:56:93:e3:72)
    Source: VMware_93:ae:8f (00:50:56:93:ae:8f)
    Type: 802.1Q Virtual LAN (0x8100)
802.1Q Virtual LAN, PRI: 0, DEI: 0, ID: 100
    000. .... .... .... = Priority: Best Effort (default) (0)
    ...0 .... .... .... = DEI: Ineligible
    .... 0000 0110 0100 = ID: 100
    Type: 802.1Q Virtual LAN (0x8100)
802.1Q Virtual LAN, PRI: 0, DEI: 0, ID: 200
```

```
    000. .... .... .... = Priority: Best Effort (default) (0)
    ...0 .... .... .... = DEI: Ineligible
    .... 0000 1100 1000 = ID: 200
    Type: IPv4 (0x0800)
Internet Protocol Version 4, Src: 1.1.1.71, Dst: 1.1.1.72
Internet Control Message Protocol
```

The outer tag (first tag) is an 802.1Q tag with VLAN ID 100. The inner tag (second tag) is also an 802.1Q tag with VLAN ID 200.

Aggregation and redundancy

Link aggregation (IEEE 802.3ad) enables you to bind two or more physical interfaces together to form an aggregated (combined) link. This new link has the bandwidth of all the links combined. If a link in the group fails, traffic is transferred automatically to the remaining interfaces. The only noticeable effect is reduced bandwidth.

This feature is similar to redundant interfaces. The major difference is a redundant interface group only uses one link at a time, where an aggregate link group uses the total bandwidth of the functioning links in the group, up to eight (or more).

An interface is available to be an aggregate interface if:

- It is a physical interface and not a VLAN interface or subinterface.
- It is not already part of an aggregate or redundant interface.
- It is in the same VDOM as the aggregated interface. Aggregate ports cannot span multiple VDOMs.
- It does not have an IP address and is not configured for DHCP or PPPoE.
- It is not referenced in any security policy, VIP, IP Pool, or multicast policy.
- It is not an HA heartbeat interface.
- It is not one of the FortiGate-5000 series backplane interfaces.

When an interface is included in an aggregate interface, it is not listed on the *Network* > *Interfaces* page. Interfaces still appear in the CLI although configuration for those interfaces do not take affect. You cannot configure the interface individually and it is not available for inclusion in security policies, VIPs, IP pools, or routing.

Example configuration

This example creates an aggregate interface on a FortiGate-140D POE using ports 3-5 with an internal IP address of 10.1.1.123, as well as the administrative access to HTTPS and SSH.

To create an aggregate interface in the GUI:

1. Go to *Network* > *Interfaces* and select *Create New* > *Interface*.
2. Set *Name* to *aggregate*.
3. Set *Type* to *802.3ad Aggregate*.
4. Set *Interface members* to *port4*, *port5*, and *port6*.
5. Set *Addressing mode* to *Manual*.
6. Set *IP/Netmask* to *10.1.1.123/24*.
7. For *Administrative Access*, select *HTTPS* and *SSH*.
8. Click *OK*.

To create an aggregate interface in the CLI:

```
config system interface
    edit "aggregate"
        set vdom "root"
        set ip 10.1.1.123 255.255.255.0
        set allowaccess https ssh
        set type aggregate
        set member "port4" "port5" "port6"
        set snmp-index 45
    next
end
```

Redundancy

In a redundant interface, traffic only goes over one interface at any time. This differs from an aggregated interface where traffic goes over all interfaces for increased bandwidth. This difference means redundant interfaces can have more robust configurations with fewer possible points of failure. This is important in a fully-meshed HA configuration.

An interface is available to be in a redundant interface if:

- It is a physical interface and not a VLAN interface.
- It is not already part of an aggregated or redundant interface.
- It is in the same VDOM as the redundant interface.
- It does not have an IP address and is not configured for DHCP or PPPoE.
- It has no DHCP server or relay configured on it.
- It does not have any VLAN subinterfaces.
- It is not referenced in any security policy, VIP, or multicast policy.
- It is not monitored by HA.
- It is not one of the FortiGate-5000 series backplane interfaces.

When an interface is included in a redundant interface, it is not listed on the *Network* > *Interfaces* page. You cannot configure the interface individually and it is not available for inclusion in security policies, VIPs, or routing.

Example configuration

To create a redundant interface in the GUI:

1. Go to *Network* > *Interfaces* and select *Create New* > *Interface*.
2. Set *Name* to *redundant*.
3. Set *Type* to *Redundant Interface*.
4. Set *Interface members* to *port4*, *port5*, and *port6*.
5. Set *Addressing mode* to *Manual*.
6. Set *IP/Netmask* to *10.13.101.100/24*.
7. For *Administrative Access*, select *HTTPS* and *SSH*.
8. Click *OK*.

To create a redundant interface in the CLI:

```
config system interface
    edit "redundant"
```

```
        set vdom "root"
        set ip 10.13.101.100 255.255.255.0
        set allowaccess https http
        set type redundant
        set member "port4" "port5" "port6"
        set snmp-index 9
    next
end
```

Enhanced hashing for LAG member selection

FortiGate models that have an internal switch that supports modifying the distribution algorithm can use enhanced hashing to help distribute traffic evenly, or load balance, across links on the Link Aggregation (LAG) interface.

The enhanced hashing algorithm is based on a 5-tuple of the IP protocol, source IP address, destination IP address, source port, and destination port.

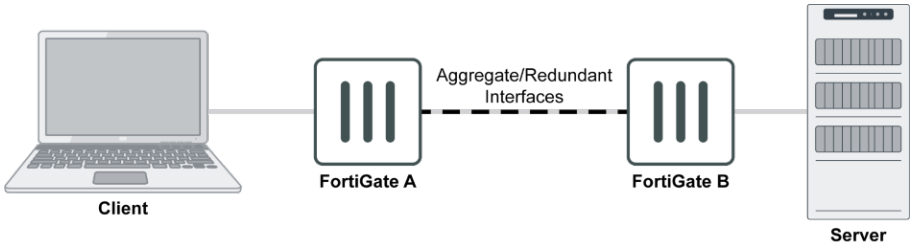
Different computation methods allow for more variation in the load balancing distribution, in case one algorithm does not distribute traffic evenly between links across different XAUIs. The available methods are:

xor16	Use the XOR operator to make a 16 bit hash.
xor8	Use the XOR operator to make an 8 bit hash.
xor4	Use the XOR operator to make a 4 bit hash.
crc16	Use the CRC-16-CCITT polynomial to make a 16 bit hash.

The following NP6 non-service FortiGate models support this feature: 1500D, 1500DT, 3000D, 3100D, 3200D, 3700D, and 5001D.

To configure the enhanced hashing:

```
config system npu
    set lag-out-port-select {enable | disable}
    config sw-eh-hash
        set computation {xor4 | xor8 | xor16 | crc16}
        set ip-protocol {include | exclude}
        set source-ip-upper-16 {include | exclude}
        set source-ip-lower-16 {include | exclude}
        set destination-ip-upper-16 {include | exclude}
        set destination-ip-lower-16 {include | exclude}
        set source-port {include | exclude}
        set destination-port {include | exclude}
        set netmask-length {0 - 32}
    end
end
```



For example, to use XOR16 and include all of the fields in the 5-tuple to compute the link in the LAG interface that the packet is distributed to:

```
config system npu
    set lag-out-port-select enable
```

```
    config sw-eh-hash
        set computation xor16
        set ip-protocol include
        set source-ip-upper-16 include
        set source-ip-lower-16 include
        set destination-ip-upper-16 include
        set destination-ip-lower-16 include
        set source-port include
        set destination-port include
        set netmask-length 32
    end
end
```

Failure detection for aggregate and redundant interfaces

When an aggregate or redundant interface goes down, the corresponding fail-alert interface changes to down. When an aggregate or redundant interface comes up, the corresponding fail-alert interface changes to up.

Fail-detect for aggregate and redundant interfaces can be configured using the CLI.

To configure an aggregate interface so that port3 goes down with it:

```
config system interface
   edit "agg1"
      set vdom "root"
      set fail-detect enable
      set fail-alert-method link-down
      set fail-alert-interfaces "port3"
      set type aggregate
      set member "port1" "port2"
   next
end
```

To configure a redundant interface so that port4 goes down with it:

```
config system interface
   edit "red1"
      set vdom "root"
      set fail-detect enable
      set fail-alert-method link-down
      set fail-alert-interfaces "port4"
      set type redundant
      set member "port1" "port2"
   next
end
```

Loopback interface

A loopback interface is a logical interface that is always up. Its IP address does not depend on one specific physical port, and the attached subnet is always present in the routing table. Therefore, it can be accessed through several physical or VLAN interfaces.

Typically, a loopback interface can be used with management access, BGP peering, PIM rendezvous points, and SD-WAN.

Loopback interfaces require appropriate firewall policies to allow traffic to and from the interfaces. Multiple loopback interfaces can be configured in either non-VDOM mode or in each VDOM.

Dynamic routing protocols can be enabled on loopback interfaces. For example, loopback interfaces are a good practice for OSPF. To make it easier to troubleshoot OSPF, set the OSPF router ID to the same value as the loopback IP address to access a specific FortiGate using that IP address and SSH.

A loopback interface is configured using similar steps as a physical interface (see Configuring an interface).

Software switch

A software switch is a virtual switch that is implemented at the software or firmware level and not at the hardware level. A software switch can be used to simplify communication between devices connected to different FortiGate interfaces. For example, a software switch lets you place the FortiGate interface connected to an internal network on the same subnet as your wireless interfaces. Then devices on the internal network can communicate with devices on the wireless network without any additional configuration on the FortiGate unit, such as additional security policies.

A software switch can also be useful if you require more hardware ports for the switch on a FortiGate unit. For example, if your FortiGate unit has a 4-port switch, WAN1, WAN2, and DMZ interfaces, and you need one more port, you can create a soft switch that can include the four-port switch and the DMZ interface, all on the same subnet. These types of applications also apply to wireless interfaces, virtual wireless interfaces, and physical interfaces such as those in FortiWiFi and FortiAP units.

Similar to a hardware switch, a software switch functions like a single interface. It has one IP address and all the interfaces in the software switch are on the same subnet. Traffic between devices connected to each interface is not regulated by security policies, and traffic passing in and out of the switch is controlled by the same policy.

When setting up a software switch, consider the following:

- Ensure that you have a back up of the configuration.
- Ensure that you have at least one port or connection, such as the console port, to connect to the FortiGate unit. If you accidentally combine too many ports, you need a way to undo errors.
- The ports that you include must not have any link or relation to any other aspect of the FortiGate unit, such as DHCP servers, security policies, and so on.
- Ensure the *Create address object matching subnet* option is disabled, if any port *Role* is set to either *LAN* or *DMZ*.
- For increased security, you can create a captive portal for the switch to allow only specific user groups access to the resources connected to the switch.

Some of the difference between software and hardware switches are:

Feature	Software switch	Hardware switch
Processing	Packets are processed in software by the CPU.	Packets are processed in hardware by the hardware switch controller, or SPU where applicable.
STP	Not Supported	Supported
Wireless SSIDs	Supported	Not Supported
Intra-switch traffic	Allowed by default. Can be explicitly set to require a policy.	Allowed by default.

To create a software switch in the GUI:

1. Go to *Network* > *Interfaces*.
2. Click *Create New* > *Interface*.
3. Set *Type* to *Software Switch*.
4. Configure the *Name*, *Interface members*, and other fields as required.
   To add an interface to a software switch, it cannot be referenced by an existing configuration and its IP address must be set to 0.0.0.0/0.0.0.0.
5. Click *OK*.

To create a software switch in the CLI:

```
config system switch-interface
    edit <interface>
        set vdom <vdom>
        set member <interface_list>
        set type switch
    next
end
config system interface
    edit <interface>
        set vdom <vdom>
        set type switch
        set ip <ip_address>
        set allowaccess https ssh ping
    next
end
```

To add an interface to a software switch, it cannot be referenced by an existing configuration and its IP address must be set to 0.0.0.0/0.0.0.0.

Example

For this example, the wireless interface (WiFi) needs to be on the same subnet as the DMZ1 interface to facilitate wireless synchronization between an iPhone and a local computer. Because synchronization between two subnets is problematic, putting both interfaces on the same subnet allows synchronization to work. The software switch will accomplish this.

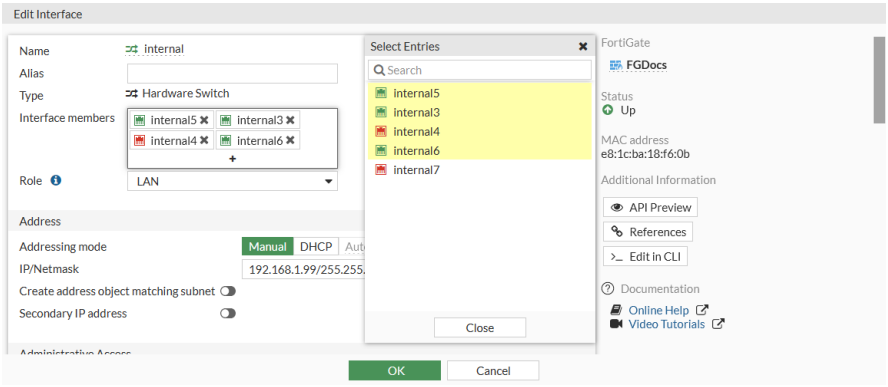
1. Clear the interfaces and back up the configuration:
   a. Ensure the interfaces are not used for other security policy or for other use on the FortiGate unit.
   b. Check the WiFi and DMZ1 ports to ensure that DHCP is not enabled and that there are no other dependencies on these interfaces.
   c. Save the current configuration so that it can be recovered if something goes wrong.
2. Merge the WiFi port and DMZ1 port to create a software switch named `synchro` with an IP address of 10.10.21.12 and administrative access for HTTPS, SSH and PING:

```
config system switch-interface
    edit synchro
        set vdom "root"
        set type switch
        set member dmz1 wifi
    next
end
config system interface
    edit synchro
        set ip 10.10.21.12 255.255.255.0
        set allowaccess https ssh ping
    next
end
```

After the switch is set up, you add security policies, DHCP servers, and any other settings that are required.

Hardware switch

A hardware switch is a virtual switch interface that groups different ports together so that the FortiGate can use the group as a single interface. Supported FortiGate models have a default hardware switch called either *internal* or *lan*. The hardware switch is supported by the chipset at the hardware level.



Ports that are connected to the same hardware switch behave like they are on the same physical switch in the same broadcast domain. Ports can be removed from a hardware switch and assigned to another switch or used as standalone interfaces.

Some of the difference between hardware and software switches are:

Feature	Hardware switch	Software switch
Processing	Packets are processed in hardware by the hardware switch controller, or SPU where applicable.	Packets are processed in software by the CPU.
STP	Supported	Not Supported
Wireless SSIDs	Not Supported	Supported
Intra-switch traffic	Allowed by default.	Allowed by default. Can be explicitly set to require a policy.

To change the ports in a hardware switch in the GUI:

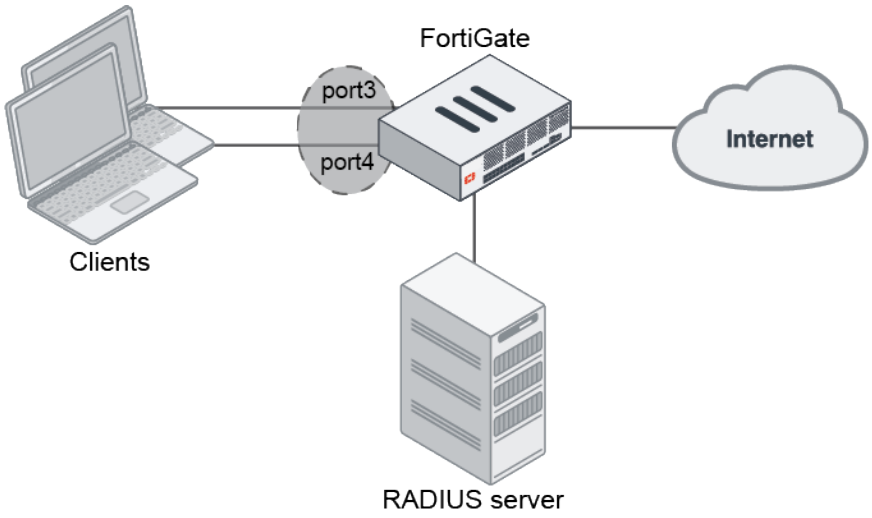
1. Go to *Network* > *Interface* and edit the hardware switch.
2. Click inside the *Interface members* field.

3. Select interfaces to add or remove them from the hardware switch, then click *Close*.
   To add an interface to a hardware switch, it cannot be referenced by an existing configuration and its IP address must be set to 0.0.0.0/0.0.0.0.
4. Click *OK*.
   Removed interfaces will now be listed as standalone interfaces in the *Physical Interface* section.

To remove ports from a hardware switch in the CLI:

```
config system virtual-switch
    edit "internal"
        config port
            delete internal2
            delete internal7
            ...
        end
    next
end
```

To add ports to a hardware switch in the CLI:



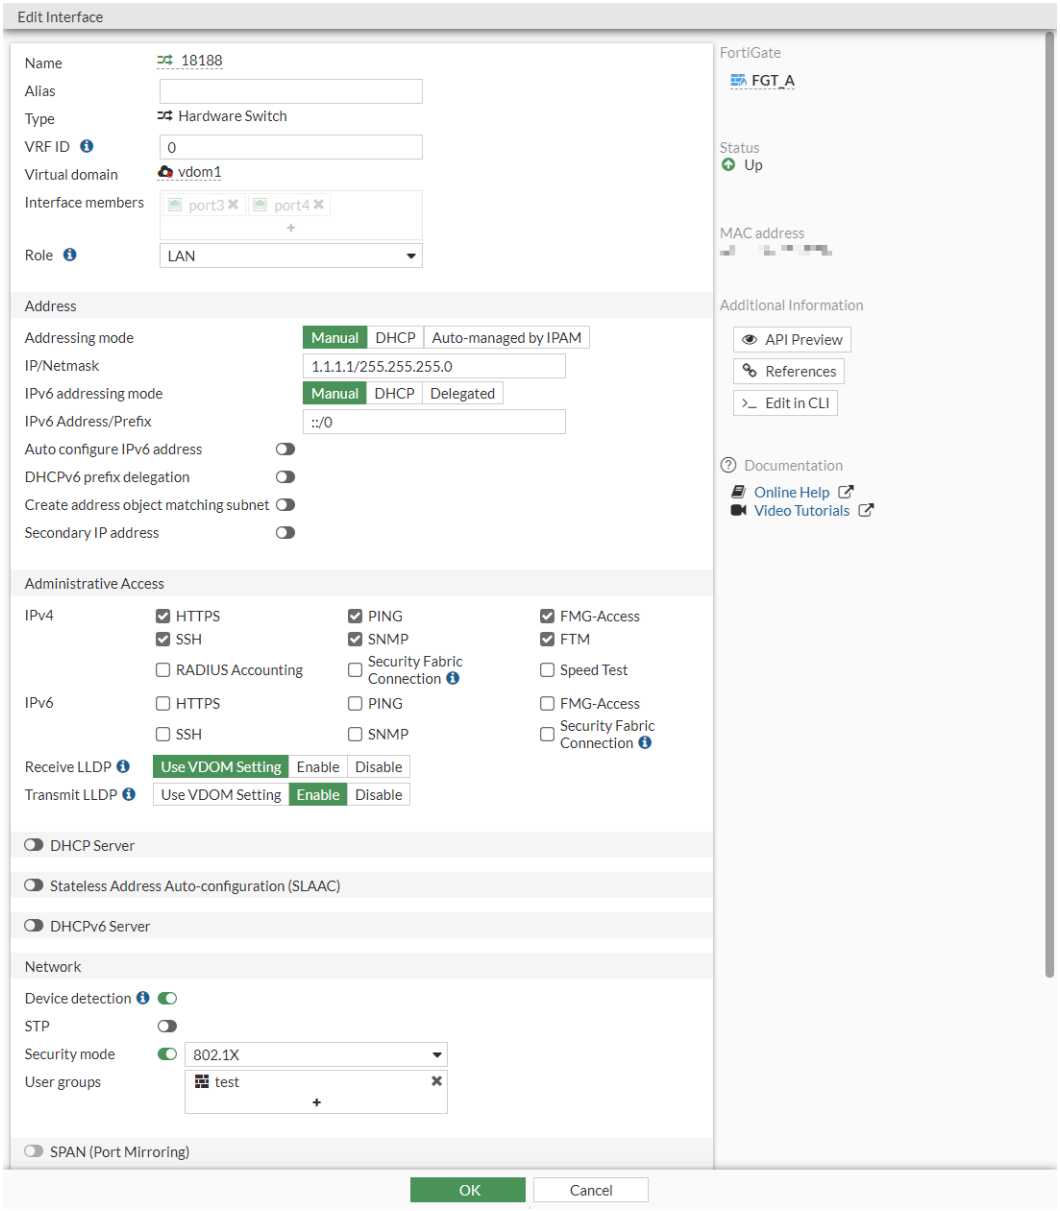
```
config system virtual-switch
    edit "internal"
        set physical-switch "sw0"
        config port
            edit "internal3"
            next
            edit "internal5"
            next
            edit "internal4"
            next
            edit "internal6"
            next
        end
    next
end
```

To add an interface to a hardware switch, it cannot be referenced by an existing configuration and its IP address must be set to 0.0.0.0/0.0.0.0.

Using 802.1X on virtual switches for certain NP6 platforms

802.1X is supported under the hardware switch interface on the following NP6 platforms: FG-30xE, FG-40xE, and FG-110xE.

In this example, port3 and port4 are part of a hardware switch interface. The hardware switch acts as a virtual switch so that devices can connect directly to these ports and perform 802.1X authentication on the port.



Prerequisites:

1. Configure a RADIUS server (see RADIUS servers on page 2094).
2. Define a user group named test to use the remote RADIUS server and for 802.1X authentication (see User definition and groups on page 2065).
3. Configure a hardware switch (named 18188) with port3 and port4 as the members.
4. Configure a firewall policy that allows traffic from the 18188 hardware switch to go to the internet.
5. Enable 802.1X authentication on the client devices.

To configure 802.1X authentication on a hardware switch in the GUI:

1. Go to *Network* > *Interfaces* and edit the hardware switch.
2. In the *Network* section, enable *Security mode* and select *802.1X*.

3. Click the + to add the *User group*.

4. Click *OK*.

To configure 802.1X authentication on a hardware switch in the CLI:

1. Configure the virtual hardware switch interfaces:

```
config system virtual-switch
    edit "18188"
        set physical-switch "sw0"
        config port
            edit "port3"
            next
            edit "port4"
            next
```

```
        end
    next
end
```

2. Configure 802.1X authentication:

```
config system interface
    edit "18188"
        set vdom "vdom1"
        set ip 1.1.1.1 255.255.255.0
        set allowaccess ping https ssh snmp fgfm ftm
        set type hard-switch
        set security-mode 802.1X
        set security-groups "test"
        set device-identification enable
        set lldp-transmission enable
        set role lan
        set snmp-index 52
    next
end
```

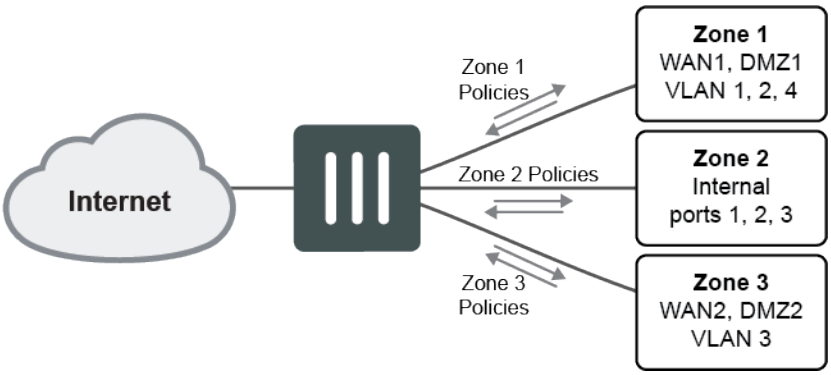
To verify the that the 802.1X authentication was successful:

1. Get a client connected to port3 to authenticate to access the internet.
2. In FortiOS, verify the 802.1X authentication port status:

```
# diagnose sys 802-1x status

Virtual switch '18188' (default mode) 802.1x member status:
  port3: Link up, 802.1X state: authorized
  port4: Link up, 802.1X state: unauthorized
```

Zone



Zones are a group of one or more physical or virtual FortiGate interfaces that you can apply firewall policies to for controlling inbound and outbound traffic. Grouping interfaces and VLAN subinterfaces into zones simplifies creating firewall policies where a number of network segments can use the same policy settings and protection profiles.

When you add a zone, you select the names of the interfaces and VLAN subinterfaces to add to the zone. Each interface still has its own address. Routing is still done between interfaces, that is, routing is not affected by zones. You can use firewall policies to control the flow of intra-zone traffic.

For example, in the sample configuration below, the network includes three separate groups of users representing different entities on the company network. While each group has its own set of ports and VLANs in each area, they can all use the same firewall policy and protection profiles to access the Internet. Rather than the administrator making nine separate firewall policies, he can make administration simpler by adding the required interfaces to a zone and creating three policies.

Example configuration

You can configure policies for connections to and from a zone but not between interfaces in a zone. For this example, you can create a firewall policy to go between zone 1 and zone 3, but not between WAN2 and WAN1, or WAN1 and DMZ1.

To create a zone in the GUI:

1. Go to *Network* > *Interfaces*.

   If VDOMs are enabled, go to the VDOM to create a zone.

2. Click *Create New* > *Zone*.
3. Configure the *Name* and add the *Interface Members*.
4. Enable or disable *Block intra-zone traffic* as required.
5. Click *OK*.

To configure a zone to include the internal interface and a VLAN using the CLI:

```
config system zone
    edit zone_1
        set interface internal VLAN_1
        set intrazone {deny | allow}
    next
end
```

Using zone in a firewall policy

To configure a firewall policy to allow any interface to access the Internet using the CLI:

```
config firewall policy
    edit 2
        set name "2"
        set srcintf "Zone_1"
        set dstintf "port15"
        set srcaddr "all"
        set dstaddr "all"
        set action accept
        set schedule "always"
        set service "ALL"
        set nat enable
    next
end
```

Intra-zone traffic

In the zone configuration you can `set intrazone deny` to prohibit the different interfaces in the same zone to talk to each other.

For example, if you have ten interfaces in your zone and the `intrazone` setting is `deny`. You now want to allow traffic between a very small number of networks on different interfaces that are part of the zone but you do not want to disable the intra-zone blocking.

In this example, the zone VLANs are defined as: `192.168.1.0/24`, `192.168.2.0/24`, ... `192.168.10.0/24`.

This policy allows traffic from 192.168.1.x to 192.168.2.x even though they are in the same zone and intra-zone blocking is enabled. The intra-zone blocking acts as a default deny rule and you have to specifically override it by creating a policy within the zone.

To enable intra-zone traffic, create the following policy:

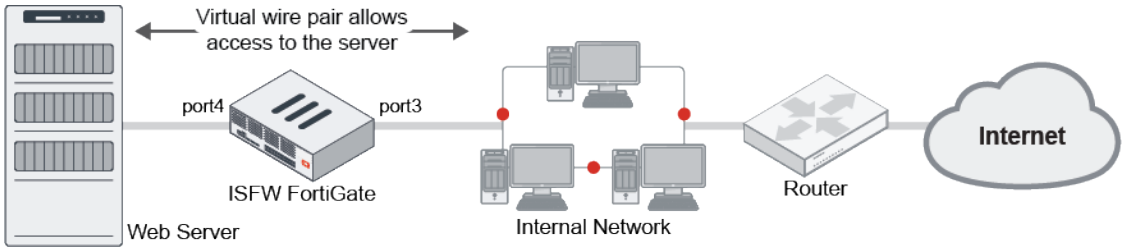
Source Interface	Zone-name, e.g., `Vlans`
Source Address	192.168.1.0/24
Destination	Zone-name (same as Source Interface, i.e., `Vlans`)
Destination Address	192.168.2.0/24

Virtual wire pair

A virtual wire pair consists of two interfaces that do not have IP addressing and are treated like a transparent mode VDOM. All traffic received by one interface in the virtual wire pair can only be forwarded to the other interface, provided a virtual wire pair firewall policy allows this traffic. Traffic from other interfaces cannot be routed to the interfaces in a virtual wire pair. Redundant and 802.3ad aggregate (LACP) interfaces can be included in a virtual wire pair.

Virtual wire pairs are useful for a typical topology where MAC addresses do not behave normally. For example, port pairing can be used in a Direct Server Return (DSR) topology where the response MAC address pair may not match the request's MAC address pair.

When creating a new virtual wire pair, the *Interface members* field displays interfaces without assigned addresses. Interfaces with assigned addresses are not displayed.



Therefore, you cannot add to a virtual wire pair an interface with *Addressing mode* set to *DHCP*. If you change the interface settings to *Manual* with *IP/Netmask* set to *0.0.0.0/0.0.0.0*, you can add the interface to a virtual wire pair.

Example

In this example, a virtual wire pair (port3 and port4) makes it easier to protect a web server that is behind a FortiGate operating as an Internal Segmentation Firewall (ISFW). Users on the internal network access the web server through the ISFW over the virtual wire pair.

Interfaces used in a virtual wire pair cannot be used to access the ISFW FortiGate. Before creating a virtual wire pair, make sure you have a different port configured to allow admin access using your preferred protocol.

To add a virtual wire pair using the GUI:

1. Go to *Network* > *Interfaces*.
2. Click *Create New* > *Virtual Wire Pair*.
3. Enter a name for the virtual wire pair.
4. Select the *Interface Members* to add to the virtual wire pair (*port3* and *port 4*).
   These interfaces cannot be part of a switch, such as the default LAN/internal interface.
5. If required, enable *Wildcard VLAN* and set the *VLAN Filter*.
6. Click *OK*.

To add a virtual wire pair using the CLI:

```
config system virtual-wire-pair
    edit "VWP-name"
        set member "port3" "port4"
        set wildcard-vlan disable
    next
end
```

To create a virtual wire pair policy using the GUI:

1. Go to *Policy & Objects* > *Firewall Virtual Wire Pair Policy*.
2. Click *Create New*.
3. In the *Virtual Wire Pair* field, click the + to add the virtual wire pair.
4. Select the direction (arrows) that traffic is allowed to flow.
5. Configure the other settings as needed.
6. Click *OK*.

To create a virtual wire pair policy using the CLI:

```
config firewall policy
    edit 1
        set name "VWP-Policy"
        set srcintf "port3" "port4"
        set dstintf "port3" "port4"
        set srcaddr "all"
        set dstaddr "all"
        set action accept
        set schedule "always"
        set service "ALL"
        set utm-status enable
        set fsso disable
```

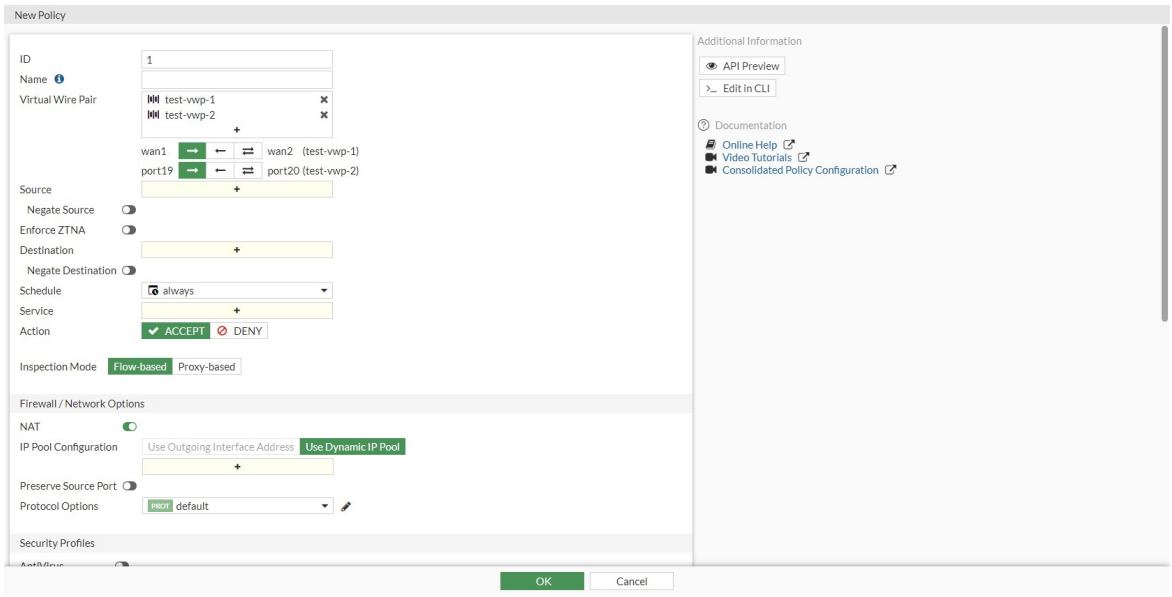
```
    next
end
```

Configuring multiple virtual wire pairs in a virtual wire pair policy

You can create a virtual wire pair policy that includes different virtual wire pairs in NGFW profile and policy mode. This reduces overhead to create multiple similar policies for each VWP. In NGFW policy mode, multiple virtual wire pairs can be configured in a *Security Virtual Wire Pair Policy* and *Virtual Wire Pair SSL Inspection & Authentication* policy.

The virtual wire pair settings must have wildcard VLAN enabled. When configuring a policy in the CLI, the virtual wire pair members must be entered in `srcintf` and `dstintf` as pairs.

To configure multiple virtual wire pairs in a policy in the GUI:



1. Configure the virtual wire pairs:
   a. Go to *Network* > *Interfaces* and click *Create New* > *Virtual Wire Pair*.
   b. Create a pair with the following settings:

Name	test-vwp-1
Interface members	wan1, wan2
Wildcard VLAN	Enable

   c. Click *OK*.
   d. Click *Create New* > *Virtual Wire Pair* and create another pair with the following settings:

Name	test-vwp-2
Interface members	port19, port20
Wildcard VLAN	Enable

   e. Click *OK*.
2. Configure the policy:
   a. Go to *Policy & Objects* > *Firewall Virtual Wire Pair Policy* and click *Create New*.
   b. In the *Virtual Wire Pair* field, click the + to add *test-vwp-1* and *test-vwp-2*. Select the direction for each of the selected virtual wire pairs.

c. Configure the other settings as needed.

d. Click *OK*.

To configure multiple virtual wire pairs in a policy in the CLI:

1. Configure the virtual wire pairs:

```
config system virtual-wire-pair
    edit "test-vwp-1"
        set member "wan1" "wan2"
        set wildcard-vlan enable
    next
    edit "test-vwp-2"
        set member "port19" "port20"
        set wildcard-vlan enable
    next
end
```

2. Configure the policy:

```
config firewall policy
    edit 1
        set name "vwp1&2-policy"
        set srcintf "port19" "wan1"
        set dstintf "port20" "wan2"
        set srcaddr "all"
        set dstaddr "all"
        set action accept
        set schedule "always"
        set service "ALL"
        set logtraffic all
    next
end
```

PRP handling in NAT mode with virtual wire pair

PRP (Parallel Redundancy Protocol) is supported in NAT mode for a virtual wire pair. This preserves the PRP RCT (redundancy control trailer) while the packet is processed by the FortiGate.

To configure PRP handling on a device in NAT mode:

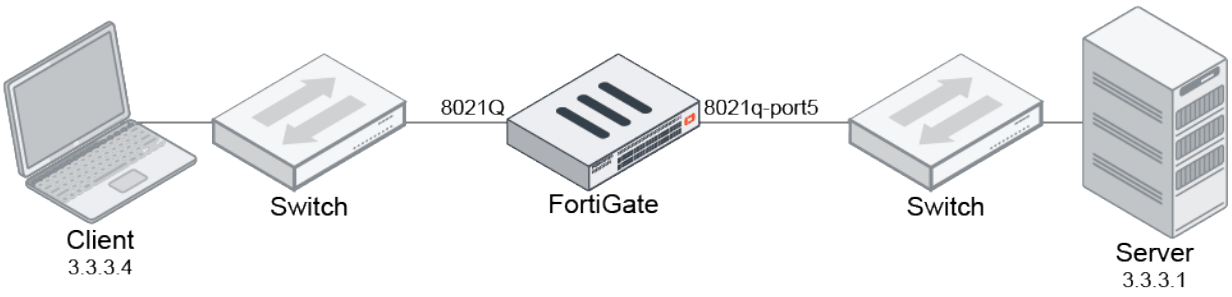
1. Enable PRP in the VDOM settings:

```
(root) # config system settings
    set prp-trailer-action enable
end
```

2. Enable PRP in the NPU attributes:

```
(global) # config system npu
    set prp-port-in "port15"
    set prp-port-out "port16"
end
```

3. Configure the virtual wire pair:



```
(root) # config system virtual-wire-pair
    edit "test-vwp-1"
        set member "port15" "port16"
    next
end
```

Using VLAN sub-interfaces in virtual wire pairs

VLAN sub-interfaces, such as regular 802.1Q and 802.1ad (QinQ), are allowed to be members of a virtual wire pair.

Example

In this example, the FortiGate has two VLAN interfaces. The first interface is a QinQ (802.1ad) interface over the physical interface port3. The second interface is a basic 802.1Q VLAN interface over physical interface port5. These two interfaces are grouped in a virtual wire pair so that bi-directional traffic is allowed. This example demonstrates ICMP from the client (3.3.3.4) sent to the server (3.3.3.1).

To configure VLAN sub-interfaces in a virtual wire pair:

1. Configure the QinQ interfaces:

```
config system interface
    edit "8021ad-port3"
        set vdom "vdom1"
        set vlan-protocol 8021ad
        set device-identification enable
        set role lan
        set snmp-index 31
        set interface "port3"
        set vlanid 3
    next
    edit "8021Q"
        set vdom "vdom1"
        set device-identification enable
        set role lan
        set snmp-index 32
        set interface "8021ad-port3"
        set vlanid 33
    next
end
```

2. Configure the 802.1Q interface:

```
config system interface
    edit "8021q-port5"
        set vdom "vdom1"
        set device-identification enable
        set role lan
        set snmp-index 33
        set interface "port5"
        set vlanid 5
    next
end
```

3. Configure the virtual wire pair:

```
config system virtual-wire-pair
    edit "VWP1"
        set member "8021Q" "8021q-port5"
    next
end
```

4. Configure the firewall policy:

```
config firewall policy
    edit 1
        set name "1"
        set srcintf "8021Q" "8021q-port5"
        set dstintf "8021Q" "8021q-port5"
        set action accept
        set srcaddr "all"
        set dstaddr "all"
        set schedule "always"
        set service "ALL"
```

```
        next
    end
```

To verify that bi-directional traffic passes through the FortiGate:

```
# diagnose sys session filter policy  1
# diagnose sys session list

session info: proto=1 proto_state=00 duration=18 expire=42 timeout=0 flags=00000000
socktype=0 sockport=0 av_idx=0 use=3

total session 1
```

DVLAN QinQ on NP7 platforms over virtual wire pairs - NEW

DVLAN 802.1ad and 802.1Q modes are supported on NP7 platforms over virtual wire pairs, which provides better performance and packet processing.

The default DVLAN mode is 802.1ad, but the DVLAN mode can be changed using `diagnose npu np7 dvlan-mode <dvlan_mode> {<npid> | all}`. The DVLAN mode can be applied to a specific NPID or all NPIDs. For example:

- `diagnose npu np7 dvlan-mode 802.1AD 0` will set NP0 to work in 802.1ad mode.
- `diagnose npu np7 dvlan-mode 802.1Q all` will set all NPUs to work in 802.1Q mode.

A reboot is required for custom DVLAN settings to take effect. To avoid any inconveniences or disruptions, changing the DVLAN settings should be done during a scheduled downtime or maintenance window.

The DVLAN mode should only be changed if you are solely using the virtual wire pair (VWP) and are seeking to enhance performance. Enabling this feature may impact VLAN interfaces within your network.

In the virtual wire pair settings, the `outer-vlan-id` can be set. This is the same value as the outer provider-tag (S-Tag).

To configure the outer VLAN ID:

```
config system virtual-wire-pair
    edit "dvlan-test"
        set member "port33" "port34"
        set wildcard-vlan enable
        set outer-vlan-id 1234
    next
end
```

Enhanced MAC VLAN

The Media Access Control (MAC) Virtual Local Area Network (VLAN) feature in Linux allows you to configure multiple virtual interfaces with different MAC addresses (and therefore different IP addresses) on a physical interface.

FortiGate implements an enhanced MAC VLAN consisting of a MAC VLAN with bridge functionality. Because each MAC VLAN has a unique MAC address, virtual IP addresses (VIPs) and IP pools are supported, and you can disable Source Network Address Translation (SNAT) in policies.

MAC VLAN cannot be used in a transparent mode virtual domain (VDOM). In a transparent mode VDOM, a packet leaves an interface with the MAC address of the original source instead of the interface's MAC address. FortiGate implements an enhanced version of MAC VLAN where it adds a MAC table in the MAC VLAN which learns the MAC addresses when traffic passes through.

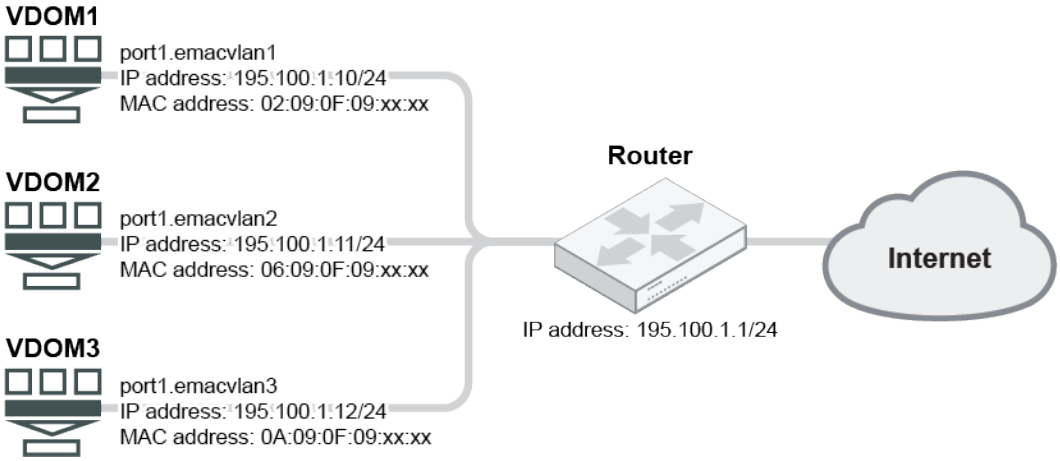
If you configure a VLAN ID for an enhanced MAC VLAN, it won't join the switch of the underlying interface. When a packet is sent to this interface, a VLAN tag is inserted in the packet and the packet is sent to the driver of the underlying interface. When the underlying interface receives a packet, if the VLAN ID doesn't match, it won't deliver the packet to this enhanced MAC VLAN interface.

When using a VLAN ID, the ID and the underlying interface must be a unique pair, even if the belong to different VDOMs. This is because the underlying, physical interface uses the VLAN ID as the identifier to dispatch traffic among the VLAN and enhanced MAC VLAN interfaces.

If you use an interface in an enhanced MAC VLAN, do not use it for other purposes such as a management interface, HA heartbeat interface, or in Transparent VDOMs.

If a physical interface is used by an EMAC VLAN interface, you cannot use it in a Virtual Wire Pair.

In high availability (HA) configurations, enhanced MAC VLAN is treated as a physical interface. It's assigned a unique physical interface ID and the MAC table is synchronized with the secondary devices in the same HA cluster.



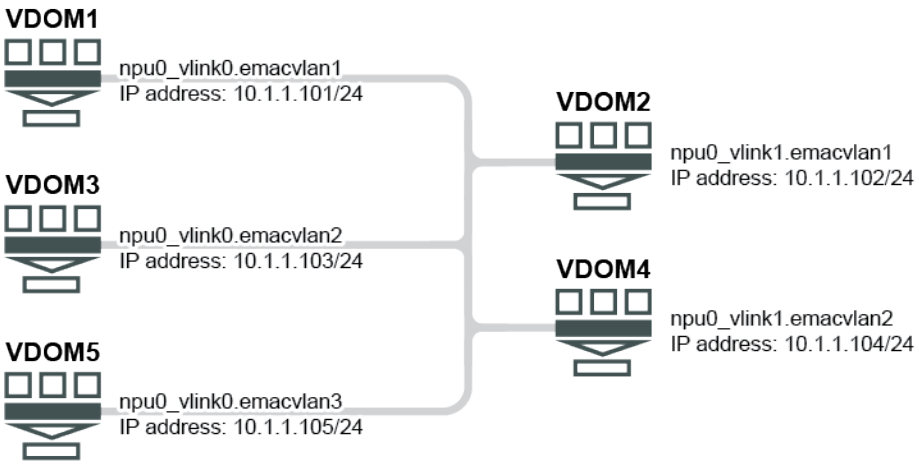
In HA configurations, FortiGate assigns a virtual MAC to each interface. Virtual interfaces, such as EMAC VLAN interfaces with underlying NPU VLINK interface, are an exception and do not get assigned virtual MAC addresses.

Example 1: Enhanced MAC VLAN configuration for multiple VDOMs that use the same interface or VLAN

In this example, a FortiGate is connected, through port 1 to a router that's connected to the Internet. Three VDOMs share the same interface (port 1) which connects to the same router that's connected to the Internet. Three enhanced MAC

VLAN interfaces are configured on port 1 for the three VDOMs. The enhanced MAC VLAN interfaces are in the same IP subnet segment and each have unique MAC addresses.

The underlying interface (port 1) can be a physical interface, an aggregate interface, or a VLAN interface on a physical or aggregate interface.



To configure enhanced MAC VLAN for this example in the CLI:

```
config system interface
    edit port1.emacvlan1
        set vdom VDOM1
        set type emac-vlan
        set interface port1
    next
    edit port 1.emacvlan2
        set vdom VDOM2
        set type emac-vlan
        set interface port1
    next
    edit port1.emacvlan3
        set vdom VDOM3
        set type emac-vlan
        set interface port1
    next
end
```

Example 2: Enhanced MAC VLAN configuration for shared VDOM links among multiple VDOMs

In this example, multiple VDOMs can connect to each other using enhanced MAC VLAN on network processing unit (NPU) virtual link (Vlink) interfaces.

FortiGate VDOM links (NPU-Vlink) are designed to be peer-to-peer connections and VLAN interfaces on NPU Vlink ports use the same MAC address. Connecting more than two VDOMs using NPU Vlinks and VLAN interfaces is not recommended as the VLAN interfaces share the same MAC address. To avoid overlapping MAC addresses on the same NPU Vlink, use EMAC VLANs instead.

To configure enhanced MAC VLAN for this example in the CLI:

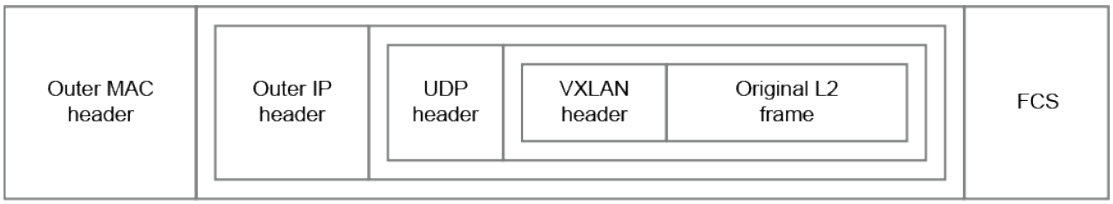
```
config system interface
    edit npu0_vlink0.emacvlan1
        set vdom VDOM1
        set type emac-vlan
        set interface npu0_vlink0
    next
    edit npu0_vlink0.emacvlan2
        set vdom VDOM3
        set type emac-vlan
        set interface npu0_vlink0
    next
    edit npu0_vlink1.emacvlan1
        set vdom VDOM2
        set type emac-vlan
        set interface npu0_vlink1
    next
end
```

Example 3: Enhanced MAC VLAN configuration for unique MAC addresses for each VLAN interface on the same physical port

Some networks require a unique MAC address for each VLAN interface when the VLAN interfaces share the same physical port. In this case, the enhanced MAC VLAN interface is used the same way as normal VLAN interfaces.

To configure this, use the `set vlanid` command for the VLAN tag. The VLAN ID and interface must be a unique pair, even if they belong to different VDOMs.

To configure enhanced MAC VLAN:



```
config system interface
    edit <interface-name>
        set type emac-vlan
        set vlanid <VLAN-ID>
        set interface <physical-interface>
    next
end
```

FortiGate supports a maximum of 512 EMAC VLAN interfaces per underlying interface, and a maximum of 600 MAC addresses including EMAC VLAN interfaces.

VXLAN

Virtual Extensible LAN (VXLAN) is a network virtualization technology used in large cloud computing deployments. It encapsulates layer 2 Ethernet frames within layer 3 IP packets using the UDP transport protocol on port 4789. VXLAN endpoints that terminate VXLAN tunnels can be virtual or physical switch ports, and are known as VXLAN tunnel endpoints (VTEPs).

Sample VXLAN packet

A VXLAN packet encapsulation occurs by first inserting a VXLAN header in front of the original layer 2 frame. This VXLAN header uses 3 B for the VNID that is used to identify the VXLAN segment, meaning that there are 16,777,215 different possible VNIDs. This allows for more unique LAN segments than possible VLANs. The original frame and the VXLAN header are then encapsulated into the UDP payload. The outer IP header allows it to be routed and transported over a layer 3 network, thus providing a layer 2 overlay scheme over a layer 3 network.

This equates to 50 B of overhead over the original frame: 14 B (Ethernet) + 20 B (IPv4) + 8 B (UDP) + 8 B (VXLAN headers). Since fragmenting a VXLAN packet is not recommended, it is advisable to increase the MTU size to 1550 B or above if possible, or to decrease the TCP MSS size inside a firewall policy.

For more information about VXLAN, see RFC 7348.

The following topics provide information about VXLAN:

- General VXLAN configuration and topologies on page 214
- VLAN inside VXLAN on page 219
- Virtual wire pair with VXLAN on page 221
- VXLAN over IPsec tunnel with virtual wire pair on page 223
- VXLAN over IPsec using a VXLAN tunnel endpoint on page 227
- VXLAN troubleshooting on page 232

General VXLAN configuration and topologies

This topic describes general VXLAN configurations and commonly used topologies. In the most basic configuration, a FortiGate is configured as a VXLAN tunnel endpoint (VTEP).

To configure a FortiGate as a VTEP:

1. Configure the local interface:

```
config system vxlan
    edit <name>
        set interface <string>
        set vni <integer>
        set ip-version {ipv4-unicast | ipv6-unicast | ipv4-multicast | ipv6-multicast}
        set dstport <integer>
        set remote-ip <IP_address>
        set remote-ip6 <IP_address>
    next
end
```

`interface <string>`	Set the local outgoing interface for the VXLAN encapsulated traffic.
`vni <integer>`	Set the VXLAN network ID.
`ip-version {ipv4-unicast | ipv6-unicast | ipv4-multicast | ipv6-multicast}`	Set the IP version to use for the VXLAN device and communication over VXLAN (default = ipv4-unicast).
`dstport <integer>`	Set the VXLAN destination port (default = 4789).
`remote-ip <IP_address>`	Set the IPv4 address of the remote VXLAN endpoint.
`remote-ip6 <IP_address>`	Set the IPv6 address of the remote VXLAN endpoint.

The VXLAN system interface is automatically created with a `vxlan` type.

2. Configure the VXLAN interface settings:

```
config system interface
    edit <name>
        set vdom <string>
        set type vxlan
        set ip <IP_address>
        set allowaccess {ping https ssh http telnet fgfm radius-acct probe-response
fabric ftm speed-test}
    next
end
```

3. Connect the internal interface and VXLAN interface to the same L2 network.
   - Connect using a software switch:

```
config system switch-interface
    edit <name>
        set vdom <string>
        set member <member_1> <member_2> ... <member_n>
        set intra-switch-policy {implicit | explicit}
    next
end
```

`member <member_1> <member_2> ... <member_n>`	Enter the VXLAN interface and other physical or virtual interfaces that will share the L2 network.

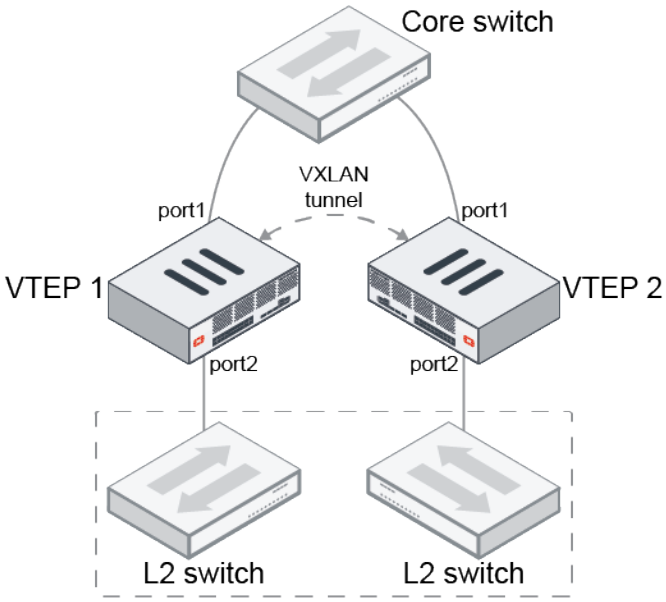
	When adding an interface member to a software switch, it cannot have an IP address or be referenced in any other settings. For newly created VLAN interfaces, it is advised to change the role from LAN to undefined so that an address is not automatically assigned.
`intra-switch-policy {implicit | explicit}`	Allow any traffic between switch interfaces or require firewall policies to allow traffic between switch interfaces: • implicit: traffic between switch members is implicitly allowed. • explicit: traffic between switch members must match firewall policies (explicit firewall policies are required to allow traffic between members).

- Connect using a virtual wire pair:

```
config system virtual-wire-pair
    edit <name>
        set member <member_1> <member_2>
        set wildcard-vlan {enable | disable}
        set vlan-filter <filter>
    next
end
```

`member <member_1> <member_2>`	Enter the VXLAN interface and other physical or virtual interface that will share the L2 network.
`wildcard-vlan {enable | disable}`	Enable/disable wildcard VLAN. Disable to prevent VLAN-tagged traffic between the members of the virtual wire pair (default). Enable for VLAN tags to be allowed between the members.
`vlan-filter <filter>`	When wildcard-vlan is enabled, set the VLAN filter to specify which VLANs are allowed. By default, an empty vlan-filter allows all VLANs.

4. If using a virtual wire pair, configure a firewall policy that allows bi-directional traffic between the members of the virtual wire pair and inspection between them:

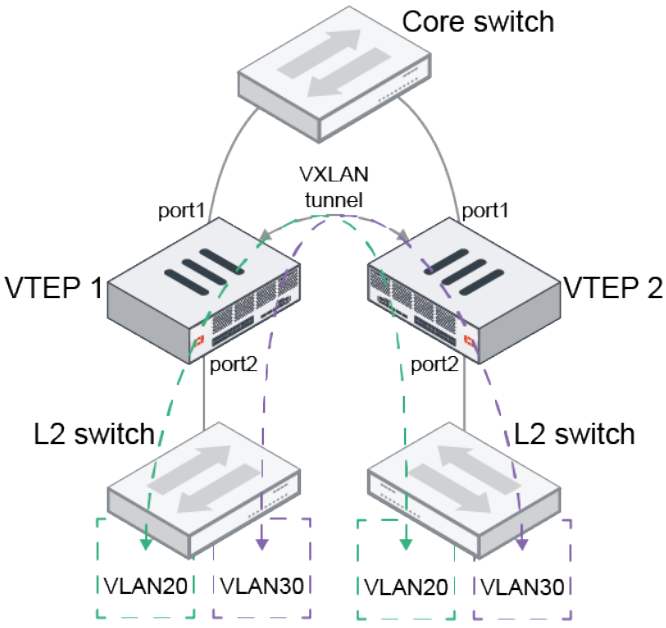


```
config firewall policy
    edit <id>
        set name <name>
        set srcintf <member_1> <member_2>
        set dstintf <member_1> <member_2>
        set srcaddr "all"
        set dstaddr "all"
        set action accept
        set schedule "always"
        set service "ALL"
    next
end
```

Topologies

Many topologies can be deployed with VXLAN. A FortiGate can connect to VXLAN endpoints that are Fortinet devices or devices from other vendors. In the following topologies, it is assumed that at least one of the VTEPs is a FortiGate. The second VTEP can be any vendor.

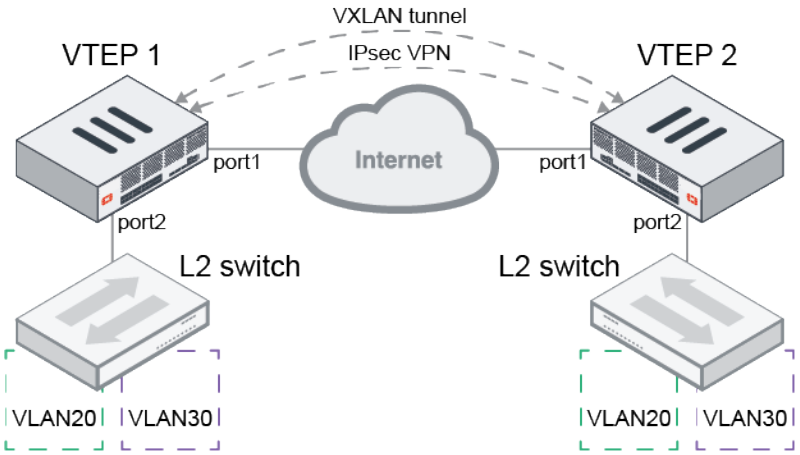
Basic VXLAN between two VTEPs



In this topology, a FortiGate (VTEP 1) is configured with a VXLAN interface over port1 where the `remote-ip` points to port1 of VTEP 2. The VXLAN interface and port2 can be associated with the same L2 network by making them members of either a software switch or a virtual wire pair. Devices under the L2 switches are part of the same L2 network.

See Virtual wire pair with VXLAN on page 221 for an example configuration.

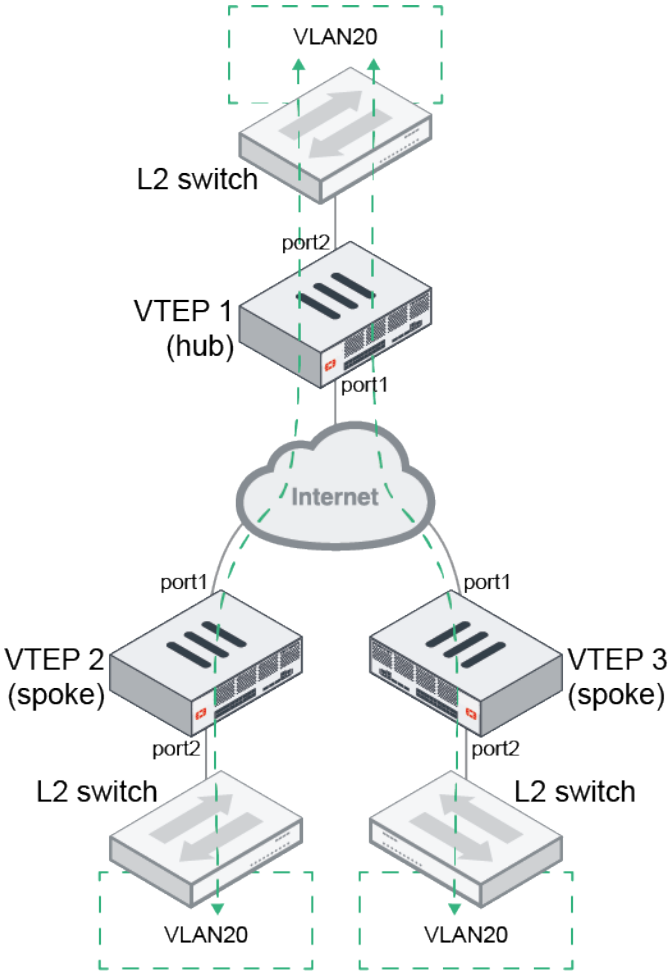
VXLAN between two VTEPs with wildcard VLANs



In this topology, a FortiGate (VTEP 1) is configured with a VXLAN interface over port1 where the `remote-ip` points to port1 of VTEP 2. The VXLAN interface is combined with port2 into the same L2 network using a virtual wire pair. The virtual wire pair allows wildcard VLANs to pass, which allows VLAN tags to be encapsulated over VXLAN. As a result, VLANs can span different switches over VXLAN.

Variations of these two scenarios can also be found in FortiGate to FortiSwitch FortiLink connections over VXLAN. See Deployment procedures in the FortiSwitch VXLAN Deployment Guide for example configurations.

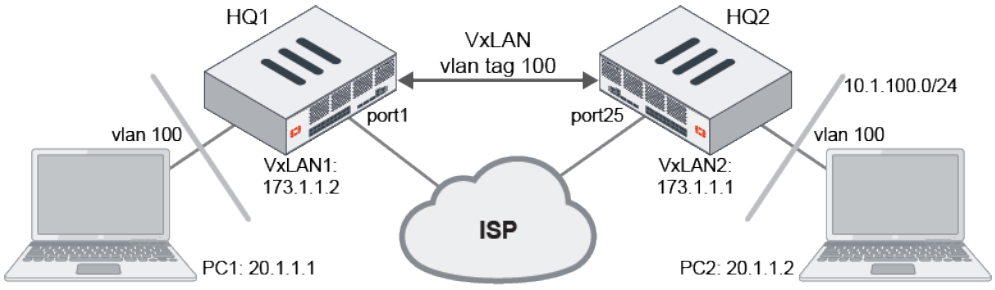
VXLAN between two VTEPs over IPsec



In scenarios where VTEPs are located in different sites and traffic must be secured between the sites, VXLAN will need to be encrypted over IPsec. The VXLAN interface must use the IPsec interface as its outgoing interface. The `remote-ip` must be configured as the IP of the remote IPsec gateway. The VXLAN interface can be combined with port2 into the same L2 network using a software switch or virtual wire pair. Devices under the L2 switches can communicate with each other.

See VXLAN over IPsec tunnel with virtual wire pair on page 223 for an example configuration. A variation of this scenario is explained in FortiGate LAN extension on page 613 and in FortiExtender as FortiGate LAN extension (FortiExtender FortiGate-Managed Administration Guide).

VXLAN between multiple VTEPs in an IPsec hub and spoke topology



In this topology, an IPsec VPN hub and spoke overlay network is already configured between sites. To allow networks behind the hub and spokes to be connected together, each spoke has a VXLAN connection to the hub, and the hub allows interconnection between its private network and each of the VXLAN interfaces to the spokes. In this scenario, the private networks behind each spoke are actually on the same L2 network as the private network behind the hub.

See VXLAN over IPsec using a VXLAN tunnel endpoint on page 227 for an example configuration.

VLAN inside VXLAN

VLANs can be assigned to VXLAN interfaces. In a data center network where VXLAN is used to create an L2 overlay network and for multitenant environments, a customer VLAN tag can be assigned to VXLAN interface. This allows the VLAN tag from VLAN traffic to be encapsulated within the VXLAN packet.

To configure VLAN inside VXLAN on HQ1:

1. Configure VXLAN:

```
config system vxlan
   edit "vxlan1"
      set interface port1
      set vni 1000
      set remote-ip 173.1.1.1

   next
end
```

2. Configure system interface:

```
config system interface
   edit vlan100
     set vdom root
     set vlanid 100
     set interface dmz
   next
   edit vxlan100
     set type vlan
     set vlanid 100
     set vdom root
     set interface vxlan1
   next
end
```

3. Configure software-switch:

```
config system switch-interface
   edit sw1
      set vdom root
      set member vlan100 vxlan100
      set intra-switch-policy implicit
   next
end
```

The default `intra-switch-policy implicit` behavior allows traffic between member interfaces within the switch. Therefore, it is not necessary to create firewall policies to allow this traffic.

Instead of creating a software-switch, it is possible to use a virtual-wire-pair as well. See Virtual wire pair with VXLAN on page 221.

To configure VLAN inside VXLAN on HQ2:

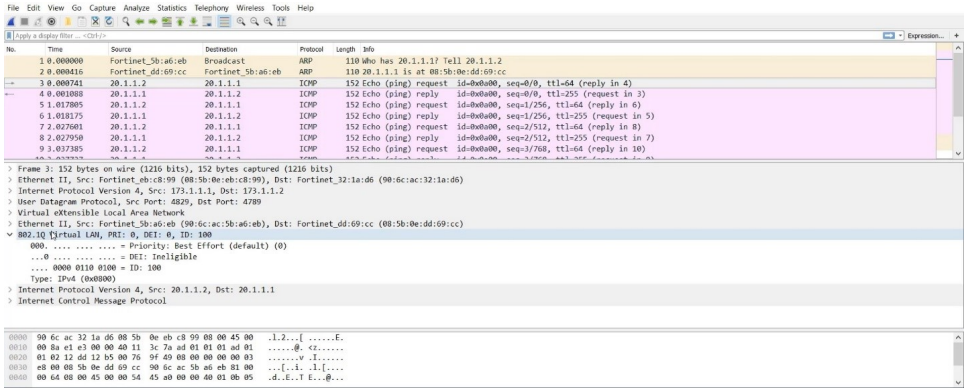
1. Configure VXLAN:

```
config system vxlan
   edit "vxlan2"
      set interface port25
      set vni 1000
      set remote-ip 173.1.1.2
   next
```

```
end
```

2. Configure system interface:

```
config system interface
      edit vlan100
      set vdom root
      set vlanid 100
      set interface port20
   next
   edit vxlan100
      set type vlan
      set vlanid 100
      set vdom root
      set interface vxlan2
   next
end
```



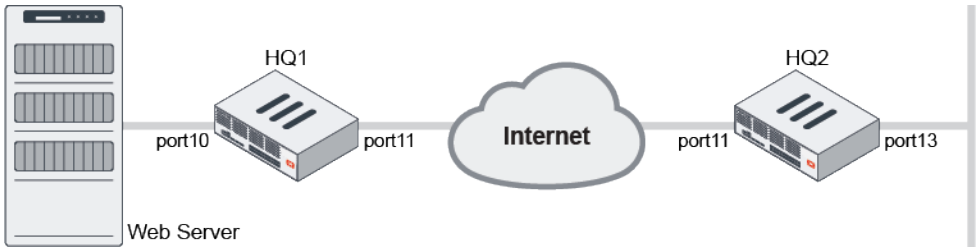
3. Configure software-switch:

```
config system switch-interface
   edit sw1
      set vdom root
      set member vlan100 vxlan100
   next
end
```

To verify the configuration:

Ping PC1 from PC2.

The following is captured on HQ2:



This captures the VXLAN traffic between 172.1.1.1 and 172.1.1.2 with the VLAN 100 tag inside.

Virtual wire pair with VXLAN

Virtual wire pairs can be used with VXLAN interfaces.

In this examples, VXLAN interfaces are added between FortiGate HQ1 and FortiGate HQ2, a virtual wire pair is added in HQ1, and firewall policies are created on both HQ1 and HQ2.

To create VXLAN interface on HQ1:

```
config system interface
    edit "port11"
        set vdom "root"
        set ip 10.2.2.1 255.255.255.0
        set allowaccess ping https ssh snmp telnet
    next
end
config system vxlan
    edit "vxlan1"
        set interface "port11"
        set vni 1000
        set remote-ip "10.2.2.2"
    next
end
```

To create VXLAN interface on HQ2:

```
config system interface
    edit "port11"
        set vdom "root"
        set ip 10.2.2.2 255.255.255.0
        set allowaccess ping https ssh snmp http
    next
end
config system vxlan
    edit "vxlan1"
        set interface "port11"
        set vni 1000
        set remote-ip "10.2.2.1"
    next
end
config system interface
    edit "vxlan1"
        set vdom "root"
        set ip 10.1.100.2 255.255.255.0
        set allowaccess ping https ssh snmp
    next
end
```

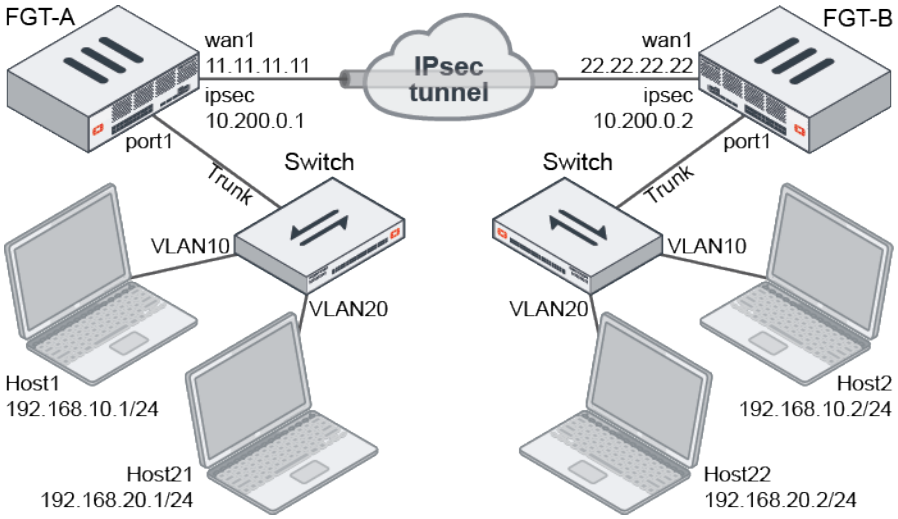
To create a virtual wire pair on HQ1:

```
config system virtual-wire-pair
    edit "vwp1"
        set member "port10" "vxlan1"
```

```
    next
end
```

To create a firewall policy on HQ1:

```
config firewall policy
    edit 5
        set name "vxlan-policy"
        set srcintf "port10" "vxlan1"
        set dstintf "port10" "vxlan1"
        set srcaddr "all"
        set dstaddr "all"
        set action accept
        set schedule "always"
        set service "ALL"
        set utm-status enable
        set ssl-ssh-profile "certificate-inspection"
        set av-profile "default"
        set webfilter-profile "default"
        set dnsfilter-profile "default"
        set ips-sensor "default"
        set application-list "default"
        set fsso disable
    next
end
```



To create a firewall policy on HQ2:

```
config firewall policy
    edit 5
        set name "1"
        set srcintf "port13"
        set dstintf "vxlan1"
        set srcaddr "all"
        set dstaddr "all"
        set action accept
        set schedule "always"
        set service "ALL"
        set fsso disable
        set nat enable
    next
end
```

VXLAN over IPsec tunnel with virtual wire pair

VXLAN can be used to encapsulate VLAN traffic over a Layer 3 network. Using IPsec VPN tunnels to secure a connection between two sites, VXLAN can encapsulate VLAN traffic over the VPN tunnel to extend the VLANs between the two sites.

In this example, a site-to-site VPN tunnel is formed between two FortiGates. A VXLAN is configured over the IPsec interface. Multiple VLANs are connected to a switch behind each FortiGate. Host1 and Host2 are connected to VLAN10 on the switches on each site, and Host21 and Host22 are connected to VLAN20. Using virtual wire pairs, the internal interface (port1) will be paired with the VXLAN interface (vxlan) to allow VLAN traffic to pass through in either direction.

To configure FGT-A:

1. Configure the WAN interface:

```
config system interface
    edit "wan1"
        set vdom "root"
        set ip 11.11.11.11 255.255.255.0
        set allowaccess ping https ssh http fgfm
        set type physical
        set role wan
        set snmp-index 1
    next
end
```

2. Configure a static route to send all traffic out the WAN interface:

```
config router static
    edit 1
        set gateway 11.11.11.1
        set device "wan1"
    next
end
```

3. Configure the IPsec tunnel:

```
config vpn ipsec phase1-interface
    edit "ipsec"
        set interface "wan1"
        set peertype any
        set proposal aes256-sha1
        set remote-gw 22.22.22.22
        set psksecret **********
    next
end
config vpn ipsec phase2-interface
    edit "ipsec"
        set phase1name "ipsec"
        set proposal aes256-sha1
```

```
        set auto-negotiate enable
    next
end
```

4. Configure local and remote IP addresses for the IPsec interface:

```
config system interface
    edit "ipsec"
        set ip 10.200.0.1 255.255.255.255
        set remote-ip 10.200.0.2 255.255.255.252
    next
end
```

5. Configure the VXLAN interface and bind it to the IPsec interface:

```
config system vxlan
    edit "vxlan"
        set interface "ipsec"
        set vni 10
        set remote-ip "10.200.0.2"
    next
end
```

   The remote IP address is the address of the remote IPsec peer.

6. Configure a virtual wire pair with the port1 and vxlan interfaces as members:

```
config system virtual-wire-pair
    edit "vwp"
        set member "port1" "vxlan"
        set wildcard-vlan enable
    next
end
```

   The interfaces added to the virtual wire pair cannot be part of a switch, such as the default internal interface.

   By enabling wildcard VLANs on the virtual wire pair, all VLAN tagged traffic that is allowed by the virtual wire pair firewall policies passes through the pair.

7. Configure a virtual wire pair firewall policy to allow traffic between the port1 and vxlan interfaces:

```
config firewall policy
    edit 4
        set name "vwp-pol"
        set srcintf "port1" "vxlan"
        set dstintf "port1" "vxlan"
        set srcaddr "all"
        set dstaddr "all"
        set action accept
        set schedule "always"
        set service "ALL"
    next
end
```

To configure FGT-B

1. Configure the WAN interface:

```
config system interface
    edit "wan1"
        set vdom "root"
```

```
        set ip 22.22.22.22 255.255.255.0 255.255.255.0
        set allowaccess ping https ssh http fgfm
        set type physical
        set role wan
        set snmp-index 1
    next
end
```

2. Configure a static route to send all traffic out the WAN interface:

```
config router static
    edit 1
        set gateway 22.22.22.2
        set device "wan1"
    next
end
```

3. Configure the IPsec tunnel:

```
config vpn ipsec phase1-interface
    edit "ipsec"
        set interface "wan1"
        set peertype any
        set proposal aes256-sha1
        set remote-gw 11.11.11.11
        set psksecret **********
    next
end
config vpn ipsec phase2-interface
    edit "ipsec"
        set phase1name "ipsec"
        set proposal aes256-sha1
        set auto-negotiate enable
    next
end
```

4. Configure local and remote IP addresses for the IPsec interface:

```
config system interface
    edit "ipsec"
        set ip 10.200.0.2 255.255.255.255
        set remote-ip 10.200.0.1 255.255.255.252
    next
end
```

5. Configure the VXLAN interface and bind it to the IPsec interface:

```
config system vxlan
    edit "vxlan"
        set interface "ipsec"
        set vni 10
        set remote-ip "10.200.0.1"
    next
end
```

   The remote IP address is the address of the remote IPsec peer.

6. Configure a virtual wire pair with the port1 and vxlan interfaces as members:

```
config system virtual-wire-pair
    edit "vwp"
        set member "port1" "vxlan"
        set wildcard-vlan enable
    next
end
```

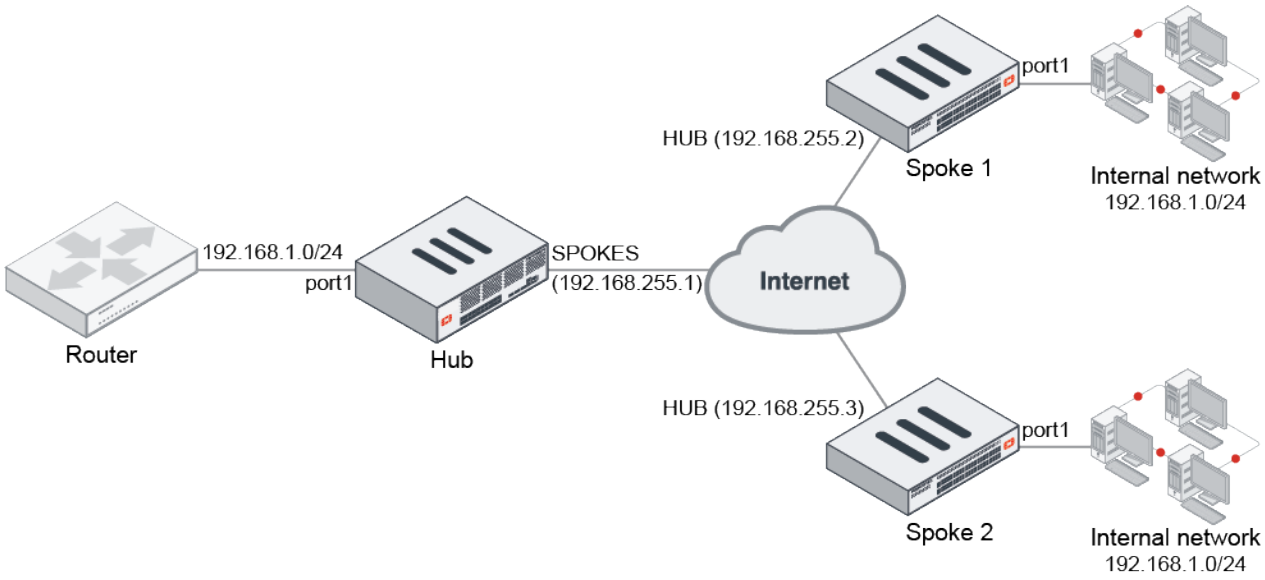
7. Configure a firewall policy to allow traffic between the port1 and vxlan interfaces:

```
config firewall policy
    edit 4
        set name "vwp-pol"
        set srcintf "port1" "vxlan"
        set dstintf "port1" "vxlan"
        set srcaddr "all"
        set dstaddr "all"
        set action accept
        set schedule "always"
        set service "ALL"
    next
end
```

Test the configuration

To test the configuration, ping Host2 (VLAN10: 192.168.10.2/24) from Host1 (VLAN10: 192.168.10.1/24):

```
C:\>ping 192.168.10.2



Pinging 192.168.10.2 with 32 bytes of data:
Reply from 192.168.10.2: bytes=32 time=8ms TTL=56
Reply from 192.168.10.2: bytes=32 time=8ms TTL=56
Reply from 192.168.10.2: bytes=32 time=8ms TTL=56
Reply from 192.168.10.2: bytes=32 time=11ms TTL=56

Ping statistics for 192.168.10.2:
    Packets: Sent = 4, Received = 4, Lost = 0 (0% loss),
Approximate round trip times in milli-seconds:
    Minimum = 8ms, Maximum = 11ms, Average = 8ms
```

Host21 should also be able to ping Host22.

VXLAN over IPsec using a VXLAN tunnel endpoint

This example describes how to implement VXLAN over IPsec VPN using a VXLAN tunnel endpoint (VTEP).

This example uses a hub and spoke topology. Dialup VPN is used because it allows a single phase 1 dialup definition on the hub FortiGate. Additional spoke tunnels are added with minimal changes to the hub by adding a user account and VXLAN interface for each spoke. Spoke-to-spoke communication is established through the hub. This example assumes that the authentication users and user groups have already been created. While this topology demonstrates hub and spoke with dialup tunnels with XAuth authentication, the same logic can be applied to a static VPN with or without XAuth.

IPsec tunnel interfaces are used to support VXLAN tunnel termination. An IP address is set for each tunnel interface. Ping access is allowed for troubleshooting purposes.

VTEPs are created on the hub and each spoke to forward VXLAN traffic through the IPsec tunnels. VXLAN encapsulates OSI layer 2 Ethernet frames within layer 3 IP packets. You will need to either combine the internal port1 and VXLAN interface into a soft switch, or create a virtual wire pair so that devices behind port1 have direct layer 2 access to remote peers over the VXLAN tunnel. This example uses a switch interface on the hub and a virtual wire pair on the spokes to demonstrate the two different methods.

In order to apply an IPsec VPN interface on the VXLAN interface setting, `net-device` must be disabled in the IPsec VPN phase 1 settings.

To configure the hub FortiGate:

1. Configure the IPsec phase 1 interface:

```
config vpn ipsec phase1-interface
    edit "SPOKES"
        set type dynamic
        set interface "port2"
        set mode aggressive
        set peertype one
        set net-device disable
        set proposal aes256-sha256
        set xauthtype auto
        set authusrgrp "SPOKES"
        set peerid "SPOKES"
        set psksecret <secret>
    next
end
```

2. Configure the IPsec phase 2 interface:

```
config vpn ipsec phase2-interface
    edit "SPOKES"
        set phase1name "SPOKES"
        set proposal aes128-sha1 aes256-sha1 aes128-sha256 aes256-sha256 aes128gcm
aes256gcm chacha20poly1305
    next
end
```

3. Configure the IPsec VPN policy that allows VXLAN traffic between the spokes:

```
config firewall policy
    edit 1
        set name "VXLAN_SPOKE_to_SPOKE"
        set srcintf "SPOKES"
        set dstintf "SPOKES"
        set srcaddr "NET_192.168.255.0"
        set dstaddr "NET_192.168.255.0"
        set action accept
        set schedule "always"
        set service "UDP_4789"
        set logtraffic all
        set fsso disable
    next
end
```

4. Configure the IPsec tunnel interfaces (the remote IP address is not used, but it is necessary for this configuration):

```
config system interface
    edit "SPOKES"
        set vdom "root"
        set ip 192.168.255.1 255.255.255.255
        set allowaccess ping
        set type tunnel
        set remote-ip 192.168.255.254 255.255.255.0
        set snmp-index 12
        set interface "port2"
    next
end
```

5. Configure the VXLAN interfaces. Each spoke requires a VXLAN interface with a different VNI. The remote IP is the tunnel interfaces IP of the spokes.

   a. Spoke 1:

```
config system VXLAN
    edit "SPOKES_VXLAN1"
        set interface "SPOKES"
        set vni 1
        set remote-ip "192.168.255.2"
    next
end
```

   b. Spoke 2:

```
config system VXLAN
    edit "SPOKES_VXLAN2"
        set interface "SPOKES"
        set vni 2
```

```
            set remote-ip "192.168.255.3"
        next
    end
```

To configure the spoke FortiGates:

1. Configure the IPsec phase 1 interface:

```
config vpn ipsec phase1-interface
    edit "HUB"
        set interface "port2"
        set mode aggressive
        set peertype any
        set net-device disable
        set proposal aes256-sha256
        set localid "SPOKES"
        set xauthtype client
        set authusr "SPOKE1"
        set authpasswd <secret>
        set remote-gw <hub public IP>
        set psksecret <secret>
    next
end
```

2. Configure the IPsec phase 2 interface:

```
config vpn ipsec phase2-interface
    edit "HUB"
        set phase1name "HUB"
        set proposal aes128-sha1 aes256-sha1 aes128-sha256 aes256-sha256 aes128gcm
aes256gcm chacha20poly1305
        set auto-negotiate enable
        set src-subnet 192.168.255.2 255.255.255.255
    next
end
```

The hub FortiGate inserts a reverse route pointing to newly established tunnel interfaces for any of the subnets that the spoke FortiGate's source quick mode selectors provides. This is why you should set the tunnel IP address here.

3. Configure the IPsec VPN policy:

```
config firewall policy
    edit 1
        set name "VTEP_IPSEC_POLICY"
        set srcintf "HUB"
        set dstintf "HUB"
        set srcaddr "none"
        set dstaddr "none"
        set action accept
        set schedule "always"
        set service "PING"
        set logtraffic disable
        set fsso disable
    next
end
```

4. Configure the IPsec tunnel interface:

```
config system interface
    edit "HUB"
        set vdom "root"
        set ip 192.168.255.2 255.255.255.255
        set allowaccess ping
        set type tunnel
        set remote-ip 192.168.255.1 255.255.255.0
        set snmp-index 12
        set interface "port2"
    next
end
```

5. Configure the VXLAN interfaces (the remote IP is the tunnel interface IP of the hub):
   a. Spoke 1:

```
config system VXLAN
    edit "HUB_VXLAN"
        set interface "HUB"
        set vni 1
        set remote-ip "192.168.255.1"
    next
end
```

   b. Spoke 2:

```
config system VXLAN
    edit "HUB_VXLAN"
        set interface "HUB"
        set vni 2
        set remote-ip "192.168.255.1"
    next
end
```

To bind the VXLAN interface to the internal interface:

1. Configure a switch interface on the hub:

```
config system switch-interface
    edit "SW"
        set vdom "root"
        set member "port1" "SPOKES_VXLAN1" "SPOKES_VXLAN2"
        set intra-switch-policy {implicit | explicit}
    next
end
```

Allowing intra-switch traffic is implicitly allowed by default. Use `set intra-switch-policy explicit` to require firewall policies to allow traffic between switch interfaces.

2. Configure a virtual wire pair on the spokes:

```
config system virtual-wire-pair
    edit "VWP"
        set member "HUB_VXLAN" "port1"
```

```
    next
end
```

The virtual wire pair requires an explicit policy to allow traffic between interfaces.

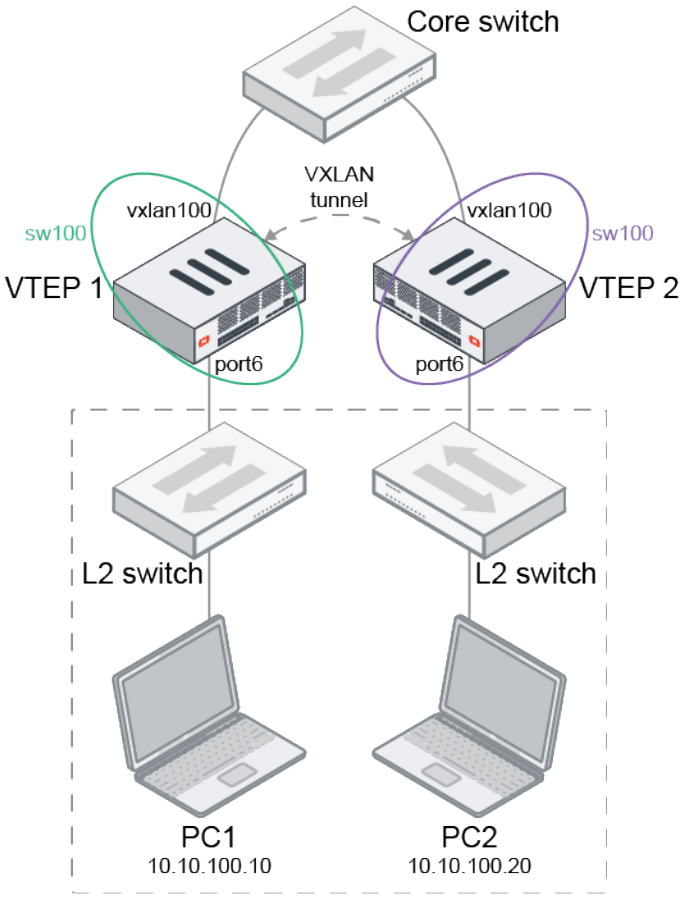
To test the configuration:

1. Ping the hub FortiGate from the spoke FortiGate:

```
user@pc-spoke1:~$ ping 192.168.1.1 -c 3
PING 192.168.1.1 (192.168.1.1) 56(84) bytes of data.
64 bytes from 192.168.1.1: icmp_seq=1 ttl=64 time=1.24 ms
64 bytes from 192.168.1.1: icmp_seq=2 ttl=64 time=0.672 ms
64 bytes from 192.168.1.1: icmp_seq=3 ttl=64 time=0.855 ms
--- 192.168.1.1 ping statistics ---
3 packets transmitted, 3 received, 0% packet loss, time 2002 ms
rtt min/avg/max/mdev = 0.672/0.923/1.243/0.239 ms
```

2. Sniff traffic on the hub FortiGate:

```
# diagnose sniffer packet any 'icmp or (udp and port 4789)' 4 0
interfaces=[any] filters=[icmp or (udp and port 4789)]
15:00:01.438230 SPOKES in 192.168.255.2.4790 -&gt; 192.168.255.1.4789: udp 106
15:00:01.438256 SPOKES_VXLAN1 in 192.168.1.2 -&gt; 192.168.1.1: icmp: echo request
15:00:01.438260 port1 out 192.168.1.2 -&gt; 192.168.1.1: icmp: echo request
15:00:01.438532 port1 in 192.168.1.1 -&gt; 192.168.1.2: icmp: echo reply
15:00:01.438536 SPOKES_VXLAN1 out 192.168.1.1 -&gt; 192.168.1.2: icmp: echo reply
15:00:01.438546 SPOKES out 192.168.255.1.4851 -&gt; 192.168.255.2.4789: udp 106
```



VXLAN troubleshooting

The following commands can be used to troubleshoot VXLAN connectivity:

- `diagnose sys vxlan fdb list <VXLAN_interface>`
- `diagnose sys vxlan fdb stat <VXLAN_interface>`
- `diagnose netlink brctl name host <switch_interface>`
- `diagnose debug sniffer packet any 'udp and port 4789' 4 0 l`
- `diagnose debug enable`
- `diagnose debug flow filter port 4789`
- `diagnose debug flow trace start <repeat_#>`

Topology

The following topology is used as an example configuration to demonstrate VXLAN troubleshooting steps.

In this example, two FortiGates are configured as VXLAN tunnel endpoints (VTEPs). A VXLAN is configured to allow L2 connectivity between the networks behind each FortiGate. The VXLAN interface and port6 are placed on the same L2 network using a software switch (sw100). An L2 network is formed between PC1 and PC2.

The VTEPs have the following MAC address tables:

Interface/endpoint	VTEP 1	VTEP 2
vxlan100	7e:f2:d1:84:75:0f	ca:fa:31:23:8d:c1
port6	00:0c:29:4e:5c:1c	00:0c:29:d0:3e:0d
sw100	00:0c:29:4e:5c:1c	00:0c:29:d0:3e:0d

The MAC address of PC1 is 00:0c:29:90:4f:bf. The MAC address of PC2 is 00:0c:29:f0:88:2c.

To configure the VTEP 1 FortiGate:

1. Configure the local interface:

```
config system vxlan
    edit "vxlan100"
        set interface "port2"
        set vni 100
        set remote-ip "192.168.2.87"
```

```
    next
end
```

2. Configure the interface settings:

```
config system interface
    edit "port2"
        set vdom "root"
        set ip 192.168.2.86 255.255.255.0
        set allowaccess ping https ssh http fabric
    next
    edit "vxlan100"
        set vdom "root"
        set type vxlan
        set interface "port2"
    next
end
```

3. Configure the software switch:

```
config system switch-interface
    edit "sw100"
        set vdom "root"
        set member "port6" "vxlan100"
    next
end
```

4. Configure the software switch interface settings:

```
config system interface
    edit "sw100"
        set vdom "root"
        set ip 10.10.100.86 255.255.255.0
        set allowaccess ping
        set type switch
        set device-identification enable
        set lldp-transmission enable
        set role lan
    next
end
```

To configure the VTEP 2 FortiGate:

1. Configure the local interface:

```
config system vxlan
    edit "vxlan100"
        set interface "port2"
        set vni 100
        set remote-ip "192.168.2.86"
    next
end
```

2. Configure the interface settings:

```
config system interface
    edit "port2"
        set vdom "root"
        set ip 192.168.2.87 255.255.255.0
```

```
        set allowaccess ping https ssh snmp http
    next
    edit "vxlan100"
        set vdom "root"
        set type vxlan
        set interface "port2"
    next
end
```

3. Configure the software switch:

```
config system switch-interface
    edit "sw100"
        set vdom "root"
        set member "port6" "vxlan100"
    next
end
```

4. Configure the software switch interface settings:

```
config system interface
    edit "sw100"
        set vdom "root"
        set ip 10.10.100.87 255.255.255.0
        set allowaccess ping
        set type switch
        set device-identification enable
        set lldp-transmission enable
        set role lan
        set snmp-index 42
    next
end
```

To run diagnostics and debugs:

1. Start a ping from PC1 10.10.100.10 to PC2 10.10.100.20:

```
C:\Users\fortidocs>ping 10.10.100.20

Pinging 10.10.100.20 with 32 bytes of data:
Reply from 10.10.100.20: bytes=32 time=2ms TTL=128
Reply from 10.10.100.20: bytes=32 time=1ms TTL=128
Reply from 10.10.100.20: bytes=32 time=1ms TTL=128
Reply from 10.10.100.20: bytes=32 time<1ms TTL=128

Ping statistics for 10.10.100.20:
    Packets: Sent = 4, Received = 4, Lost = 0 (0% loss),
Approximate round trip times in milli-seconds:
    Minimum = 0ms, Maximum = 2ms, Average = 1ms
```

2. Verify the ARP table:

```
C:\Users\fortidocs>arp /a

Interface: 10.10.100.10 --- 0x21
  Internet Address      Physical Address      Type
  10.10.100.20          00-0c-29-f0-88-2c     dynamic
  10.10.100.86          00-0c-29-4e-5c-1c     dynamic
```

```
10.10.100.255         ff-ff-ff-ff-ff-ff     static
224.0.0.22            01-00-5e-00-00-16     static
224.0.0.252           01-00-5e-00-00-fc     static
```

3. Run diagnostics on the VTEP 1 FortiGate.
   a. Verify the forwarding database of VXLAN interface vxlan100:

```
# diagnose sys vxlan fdb list vxlan100
mac=00:00:00:00:00:00 state=0x0082 remote_ip=192.168.2.87 port=4789 vni=100 ifindex=6
mac=00:0c:29:f0:88:2c state=0x0002 remote_ip=192.168.2.87 port=4789 vni=100 ifindex=6

total fdb num: 2
```

   The MAC address 00:0c:29:f0:88:2c is learned from PC2 10.10.100.20.

   b. Verify the summary of statistics from the VXLAN's forwarding database:

```
# diagnose sys vxlan fdb stat vxlan100
fdb_table_size=256 fdb_table_used=2 fdb_entry=2 fdb_max_depth=1 cleanup_idx=0
cleanup_timer=252
```

   c. Verify the software switch's forwarding table:

```
# diagnose netlink brctl name host sw100
show bridge control interface sw100 host.
fdb: hash size=32768, used=6, num=6, depth=1, gc_time=4, ageing_time=3, simple=switch
Bridge sw100 host table
port no device  devname mac addr                ttl     attributes
  1     7       port6   00:0c:29:4e:5c:1c       0       Local Static
  2     33      vxlan100        7e:f2:d1:84:75:0f       0       Local Static
  2     33      vxlan100        00:00:00:00:00:00       26       Hit(26)
  1     7       port6   00:0c:29:90:4f:bf       0        Hit(0)
  1     7       port6   00:0c:29:d0:3e:ef       7        Hit(7)
  2     33      vxlan100        00:0c:29:f0:88:2c       0        Hit(0)
```

   The MAC address of port6 is 00:0c:29:4e:5c:1c. The MAC address of vxlan100 is 7e:f2:d1:84:75:0f. The MAC address 00:0c:29:f0:88:2c of PC2 is learned from the remote network.

4. Run diagnostics on the VTEP 2 FortiGate.
   a. Verify the forwarding database of VXLAN interface vxlan100:

```
# diagnose sys vxlan fdb list vxlan100
mac=00:00:00:00:00:00 state=0x0082 remote_ip=192.168.2.86 port=4789 vni=100 ifindex=6
mac=00:0c:29:90:4f:bf state=0x0002 remote_ip=192.168.2.86 port=4789 vni=100 ifindex=6

total fdb num: 2
```

   The MAC address 00:0c:29:90:4f:bf is learned from PC1 10.10.100.10.

   b. Verify the summary of statistics from the VXLAN's forwarding database:

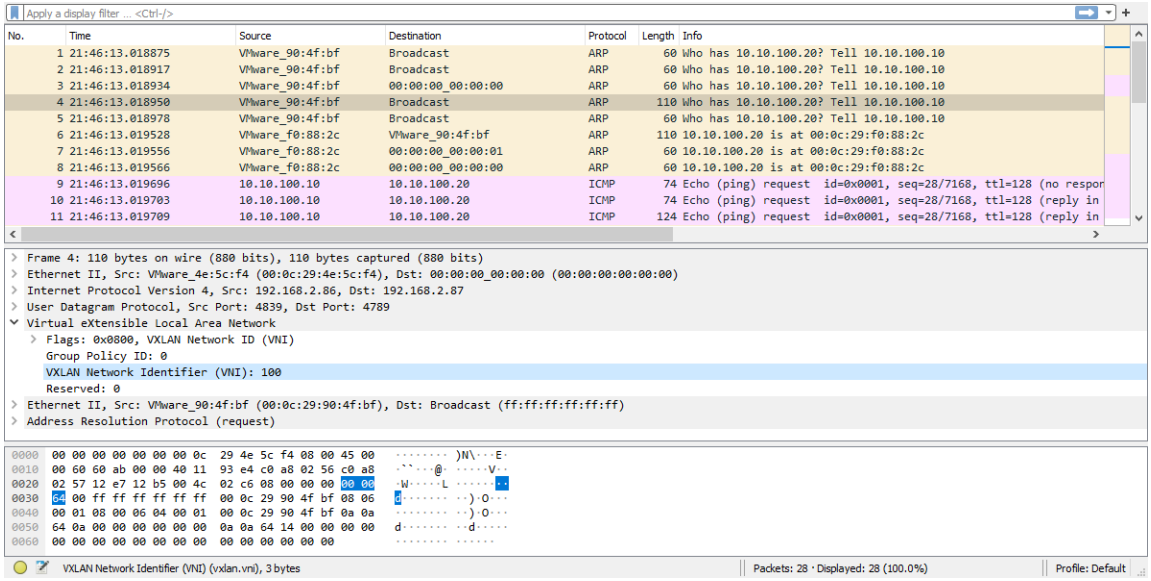
```
# diagnose sys vxlan fdb stat vxlan100
fdb_table_size=256 fdb_table_used=2 fdb_entry=2 fdb_max_depth=1 cleanup_idx=0
cleanup_timer=304
```

   c. Verify the software switch's forwarding table:

```
# diagnose netlink brctl name host sw100
show bridge control interface sw100 host.
fdb: hash size=32768, used=5, num=5, depth=1, gc_time=4, ageing_time=3, simple=switch
Bridge sw100 host table
```

```
port no device  devname mac addr                ttl     attributes
  2     50      vxlan100        00:00:00:00:00:00       10       Hit(10)
  2     50      vxlan100        00:0c:29:90:4f:bf       2        Hit(2)
  1     7       port6   00:0c:29:d0:3e:0d       0       Local Static
  2     50      vxlan100        ca:fa:31:23:8d:c1       0       Local Static
  1     7       port6   00:0c:29:f0:88:2c       0        Hit(0)
```

The MAC address of port6 is 00:0c:29:d0:3e:0d. The MAC address of vxlan100 is ca:fa:31:23:8d:c1. The MAC address 00:0c:29:90:4f:bf of PC1 is learned from the remote network.



5. Perform a sniffer trace on the VTEP 1 FortiGate to view the life of the packets as they pass through the FortiGate:

```
# diagnose sniffer packet any 'host 10.10.100.20 or (udp and host 192.168.2.87)' 4 0 l
Using Original Sniffing Mode
interfaces=[any]
filters=[host 10.10.100.20 or (udp and host 192.168.2.87)]
2022-11-04 14:35:18.567602 port6 in arp who-has 10.10.100.20 tell 10.10.100.10
2022-11-04 14:35:18.567629 vxlan100 out arp who-has 10.10.100.20 tell 10.10.100.10
2022-11-04 14:35:18.567642 port2 out 192.168.2.86.4804 -> 192.168.2.87.4789: udp 68

2022-11-04 14:35:18.568263 vxlan100 in arp reply 10.10.100.20 is-at 00:0c:29:f0:88:2c
2022-11-04 14:35:18.568272 port6 out arp reply 10.10.100.20 is-at 00:0c:29:f0:88:2c
2022-11-04 14:35:18.568425 port6 in 10.10.100.10 -> 10.10.100.20: icmp: echo request
2022-11-04 14:35:18.568435 vxlan100 out 10.10.100.10 -> 10.10.100.20: icmp: echo request
2022-11-04 14:35:18.568443 port2 out 192.168.2.86.4805 -> 192.168.2.87.4789: udp 82
2022-11-04 14:35:18.568912 port2 in 192.168.2.87.4789 -> 192.168.2.86.4789: udp 68
2022-11-04 14:35:18.568925 vxlan100 in arp who-has 10.10.100.10 tell 10.10.100.20
2022-11-04 14:35:18.568935 port6 out arp who-has 10.10.100.10 tell 10.10.100.20
2022-11-04 14:35:18.568945 sw100 in arp who-has 10.10.100.10 tell 10.10.100.20
2022-11-04 14:35:18.569070 port6 in arp reply 10.10.100.10 is-at 00:0c:29:90:4f:bf
2022-11-04 14:35:18.569076 vxlan100 out arp reply 10.10.100.10 is-at 00:0c:29:90:4f:bf
2022-11-04 14:35:18.569081 port2 out 192.168.2.86.4806 -> 192.168.2.87.4789: udp 68
2022-11-04 14:35:18.569417 port2 in 192.168.2.87.4789 -> 192.168.2.86.4789: udp 82
2022-11-04 14:35:18.569427 vxlan100 in 10.10.100.20 -> 10.10.100.10: icmp: echo reply
2022-11-04 14:35:18.569431 port6 out 10.10.100.20 -> 10.10.100.10: icmp: echo reply
```

In the output, the following packet sequence is seen on the FortiGate:

a. The FortiGate receives an ARP request from PC1 10.10.100.10 on port6.
b. The ARP request is forwarded to vxlan100 on the same software switch, where it gets encapsulated and sent out as a UDP port 4789 packet on port2.
c. A reply is received on port2 from the remote VTEP with the ARP response encapsulated in UDP port 4789 again.
d. The ARP reply is forwarded back out of port6 to PC1.
e. PC1 sends the ICMP request using the same steps.

6. Perform the same sniffer trace filter with a level 6 verbose level. In this example, the packet capture is converted into a Wireshark file.

The packet that leaves the physical port2 is encapsulated in UDP and has a VXLAN header with VNI 100 as the identifier. There is an additional 50 B overhead of the UDP encapsulated VXLAN packets as opposed to the unencapsulated packets (for example, packet 4 versus packets 1 and 2).

DNS

Domain name system (DNS) is used by devices to locate websites by mapping a domain name to a website's IP address.

A FortiGate can serve different roles based on user requirements:

- A FortiGate can control what DNS server a network uses.
- A FortiGate can function as a DNS server.

FortiGuard Dynamic DNS (DDNS) allows a remote administrator to access a FortiGate's Internet-facing interface using a domain name that remains constant even when its IP address changes.

FortiOS supports DNS configuration for both IPv4 and IPv6 addressing. When a user requests a website, the FortiGate looks to the configured DNS servers to provide the IP address of the website in order to know which server to contact to complete the transaction.

The FortiGate queries the DNS servers whenever it needs to resolve a domain name into an IP address, such as for NTP or web servers defined by their domain names.

The following topics provide information about DNS:

- Important DNS CLI commands on page 239
- DNS domain list on page 242
- FortiGate DNS server on page 243
- DDNS on page 246
- DNS latency information on page 249
- DNS over TLS and HTTPS on page 251
- DNS troubleshooting on page 256

Important DNS CLI commands

DNS settings can be configured with the following CLI command:

```
config system dns
    set primary <ip_address>
    set secondary <ip_address>
    set protocol {cleartext dot doh}
    set ssl-certificate <string>
    set server-hostname <hostname>
    set domain <domains>
    set ip6-primary <ip6_address>
    set ip6-secondary <ip6_address>
    set timeout <integer>
    set retry <integer>
    set dns-cache-limit <integer>
    set dns-cache-ttl <integer>
    set cache-notfound-responses {enable | disable}
    set interface-select-method {auto | sdwan | specify}
    set interface <interface>
    set source-ip <class_ip>
    set server-select-method {least-rtt | failover}
    set alt-primary <ip_address>
    set alt-secondary <ip_address>
    set log {disable |error | all}
    set fqdn-cache-ttl <integer>
    set fqdn-min-refresh <integer>

end
```

For a FortiGate with multiple logical CPUs, you can set the DNS process number from 1 to the number of logical CPUs. The default DNS process number is 1.

```
config system global
    set dnsproxy-worker-count <integer>
end
```

DNS protocols

The following DNS protocols can be enabled:

- `cleartext`: Enable clear text DNS over port 53 (default).
- `dot`: Enable DNS over TLS.
- `doh`: Enable DNS over HTTPS.

For more information, see DNS over TLS and HTTPS on page 251.

cache-notfound-responses

When enabled, any DNS requests that are returned with `NOT FOUND` can be stored in the cache. The DNS server is not asked to resolve the host name for `NOT FOUND` entries. By default, this option is disabled.

dns-cache-limit

Set the number of DNS entries that are stored in the cache (0 to 4294967295, default = 5000). Entries that remain in the cache provide a quicker response to requests than going out to the Internet to get the same information.

dns-cache-ttl

The duration that the DNS cache retains information, in seconds (60 to 86400 (1 day), default = 1800).

fqdn-cache-ttl

FQDN cache time to live (TTL), in seconds (0 - 86400, default = 0).

This is the amount of time an FQDN's address record can live if not refreshed. This setting applies globally, across all VDOMs, to FQDNs that have unspecified firewall address `cache-ttl` settings. If the `cache-ttl` value is configured for an FQDN address, it will supersede the `fqdn-cache-ttl` setting for that address.

For example, configure the FQDN cache TTL on the global VDOM:

```
config system dns
    set fqdn-cache-ttl 2000
end
```

```
# diagnose test application dnsproxy 6

...
vfid=0 name=test.bb.com ver=IPv4 wait_list=0 timer=985 min_refresh=20 min_ttl=1000 cache_
ttl=2000 slot=-1 num=1 wildcard=0
         1.1.1.1 (ttl=1000:991:1991)
vfid=0 name=*.google.com ver=IPv4 wait_list=0 timer=0 min_refresh=20 min_ttl=0 cache_
ttl=2000 slot=-1 num=0 wildcard=
...
```

Change the cache TTL in a VDOM for a specific address:

```
config firewall address
    edit "test.bb.com"
        set cache-ttl 1000
    next
end
```

```
# sudo global diagnose test application dnsproxy 6
...
vfid=0 name=test.bb.com ver=IPv4 wait_list=0 timer=864 min_refresh=20 min_ttl=1000 cache_
ttl=1000 slot=-1 num=1 wildcard=0
1.1.1.1 (ttl=1000:870:1870)
vfid=0 name=*.google.com ver=IPv4 wait_list=0 timer=0 min_refresh=20 min_ttl=0 cache_
ttl=2000 slot=-1 num=0 wildcard=1
...
```

fqdn-min-refresh

FQDN cache minimum refresh time, in seconds (10 - 3600, default = 60).

An FQDN normally requeries for updates according to the lowest TTL interval returned from all the DNS records in a DNS response. The FortiGate has a default minimum refresh interval of 60 seconds; if a TTL interval is shorter than 60 seconds, it still requires a minimum of 60 seconds for the FortiGate to requery for new addresses. The `fqdn-min-refresh` setting changes the interval. The settings could be shortened if there are FQDNs that require fast resolutions based on a short TTL interval.

For example, if `fqdn_min_refresh` is unspecified:

```
# diagnose test application dnsproxy 6
worker idx: 0
vfid=0 name=www.aa.com ver=IPv4 wait_list=0 timer=29 min_refresh=60 min_ttl=20 cache_ttl=0
slot=-1 num=1 wildcard=0
         104.103.122.96 (ttl=20:0:0)
...
```

The `min_refresh` is the default values of 60 seconds. Although the `min_ttl` (TTL returned) value is shorter, the FortiGate only requeries for updates based on the `min_refresh` value. the `timer` value is the countdown until the next refresh is triggered. The FortiGate triggers a refresh slightly earlier than the larger of the `min_refresh` or `min_ttl` value.

If `fqdn_min_refresh` is configured:

```
config system dns
    set fqdn-min-refresh 20
end
```

```
# diagnose test application dnsproxy 6
worker idx: 0
vfid=0 name=www.aa.com ver=IPv4 wait_list=0 timer=12 min_refresh=20 min_ttl=20 cache_ttl=0
slot=-1 num=1 wildcard=0
         104.103.122.96 (ttl=20:18:18)
```

This setting can be used in combination with `fqdn-cache-ttl` and `cache-ttl` to send more frequent queries and store more resolved addresses in cache. This is useful in scenarios where the FQDN has many resolutions and changes very frequently.

VDOM DNS

When the FortiGate is in multi-vdom mode, DNS is handled by the management VDOM. However in some cases, administrators may want to configure custom DNS settings on a non-management VDOM. For example, in a multi-tenant scenario, each VDOM might be occupied by a different tenant, and each tenant might require its own DNS server.

To configure a custom VDOM within a non-management VDOM:

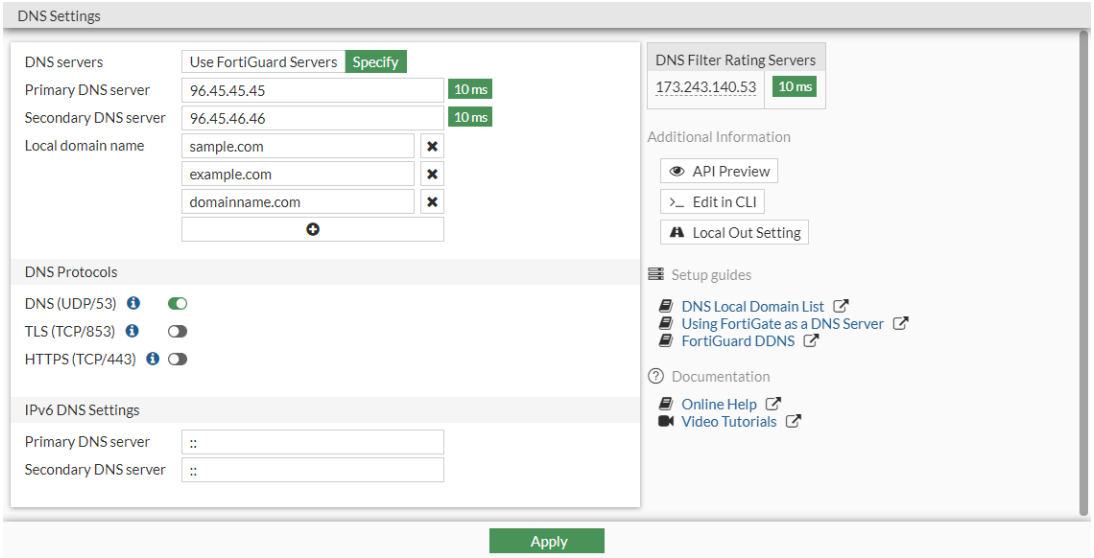
```
config vdom
edit <vdom>
config system vdom-dns
    set vdom-dns enable
    set primary <primary_DNS>
    set secondary <secondary_DNS>
    set protocol {cleartext dot doh}
    set ip6-primary <primary_IPv6_DNS>
    set ip6-secondary <secondary_IPv6_DNS>
    set source-ip <IP_address>
```

```
    set interface-select-method {auto | sdwan | specify}
end
```

DNS domain list

You can configure up to eight domains in the DNS settings using the GUI or the CLI.

When a FortiGate requests a URL that does not include an FQDN, FortiOS resolves the URL by traversing through the DNS domain list and performing a query for each domain until the first match is found.



By default, FortiGates use FortiGuard's DNS servers:

- Primary: 96.45.45.45
- Secondary: 96.45.46.46

You can also customize the DNS timeout time and the number of retry attempts.

To configure a DNS domain list in the GUI:

1. Go to *Network* > *DNS*.
2. Set *DNS Servers* to *Specify*.
3. Configure the primary and secondary DNS servers as needed.
4. In the *Local Domain Name* field, enter the first domain (`sample.com` in this example).
5. Click the + to add more domains (`example.com` and `domainname.com` in this example). You can enter up to eight domains.
6. Configure additional DNS protocol and IPv6 settings as needed.

7. Click *Apply*.

To configure a DNS domain list in the CLI:

```
config system dns
    set primary 96.45.45.45
    set secondary 96.45.46.46
```

```
    set domain "sample.com" "example.com" "domainname.com"
end
```

Verify the DNS configuration

In the following example, the local DNS server has the entry for *host1* mapped to the FQDN of *host1.sample.com*, and the entry for *host2* is mapped to the FQDN of *host2.example.com*.

To verify that the DNS domain list is configured:

1. Open the FortiGate CLI.
2. Enter `execute ping host1`.
   The system returns the following response:
   ```
   PING host1.sample.com (1.1.1.1): 56 data bytes
   ```
   As the request does not include an FQDN, FortiOS traverses the configured DNS domain list to find a match. Because *host1* is mapped to the *host1.sample.com*, FortiOS resolves *host1* to *sample.com*, the first entry in the domain list.
3. Enter `execute ping host2`.
   The system returns the following response:
   ```
   PING host2.example.com (2.2.2.2): 56 data bytes
   ```
   FortiOS traverses the domain list to find a match. It first queries sample.com, the first entry in the domain list, but does not find a match. It then queries the second entry in the domain list, example.com. Because *host2* is mapped to the FQDN of *host2.example.com*, FortiOS resolves *host2* to *example.com*.

DNS timeout and retry settings

The DNS timeout and retry settings can be customized using the CLI.

```
config system dns
    set timeout <integer>
    set retry <integer>
end
```

`timeout <integer>`	The DNS query timeout interval, in seconds (1 - 10, default = 5).
`retry <integer>`	The number of times to retry the DNS query (0 - 5, default - 2).

FortiGate DNS server

You can create local DNS servers for your network. Depending on your requirements, you can either manually maintain your entries (primary DNS server), or use it to refer to an outside source (secondary DNS server).

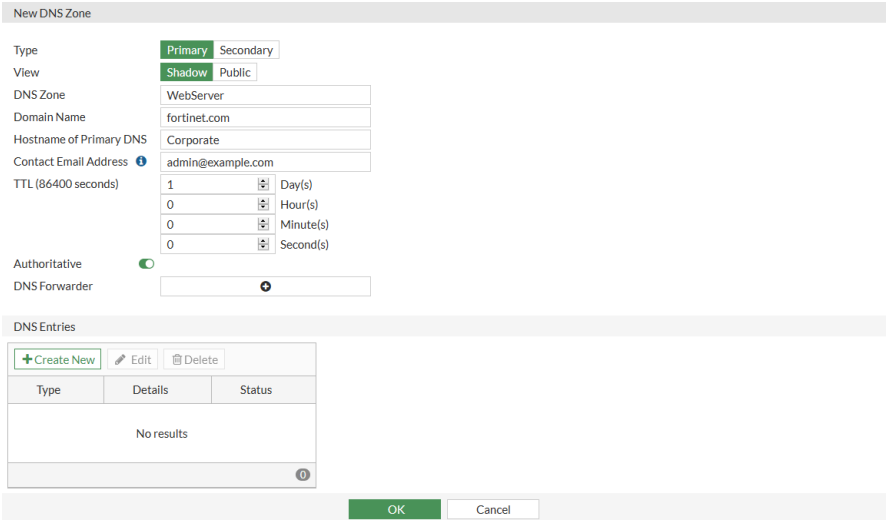
A local, primary DNS server requires that you to manually add all URL and IP address combinations. Using a primary DNS server for local services can minimize inbound and outbound traffic, and access time. Making it authoritative is not recommended, because IP addresses can change, and maintaining the list can become labor intensive.

A secondary DNS server refers to an alternate source to obtain URL and IP address combinations. This is useful when there is a primary DNS server where the entry list is maintained.

FortiGate as a DNS server also supports TLS and HTTPS connections to a DNS client. See DNS over TLS and HTTPS on page 251 for details.

By default, DNS server options are not available in the FortiGate GUI.

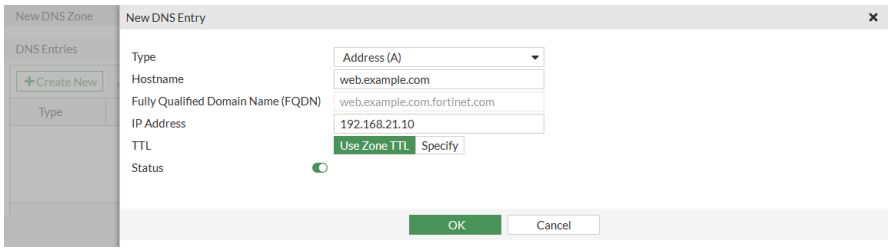
To enable DNS server options in the GUI:



1. Go to *System* > *Feature Visibility*.
2. Enable *DNS Database* in the *Additional Features* section.
3. Click *Apply*.

Example configuration

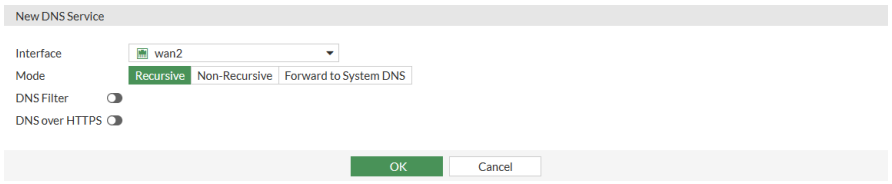
This section describes how to create an unauthoritative primary DNS server. The interface mode is recursive so that, if the request cannot be fulfilled, the external DNS servers will be queried.



To configure FortiGate as a primary DNS server in the GUI:

1. Go to *Network* > *DNS Servers*.
2. In the *DNS Database* table, click *Create New*.
3. Set *Type* to *Primary*.
4. Set *View* to *Shadow*.
   The *View* setting controls the accessibility of the DNS server. If you select *Public*, external users can access or use the DNS server. If you select *Shadow*, only internal users can use it.
5. Enter a *DNS Zone*, for example, *WebServer*.
6. Enter the *Domain Name* of the zone, for example, *fortinet.com*.
7. Enter the *Hostname* of the DNS server, for example, *Corporate*.
8. Enter the *Contact Email Address* for the administrator, for example, *admin@example.com*.
9. Disable *Authoritative*.

10. Add DNS entries:
    a. In the *DNS Entries* table, click *Create New*.
    b. Select a *Type*, for example *Address (A)*.



c. Set the *Hostname*, for example *web.example.com*.

d. Configure the remaining settings as needed. The options vary depending on the selected *Type*.

e. Click *OK*.

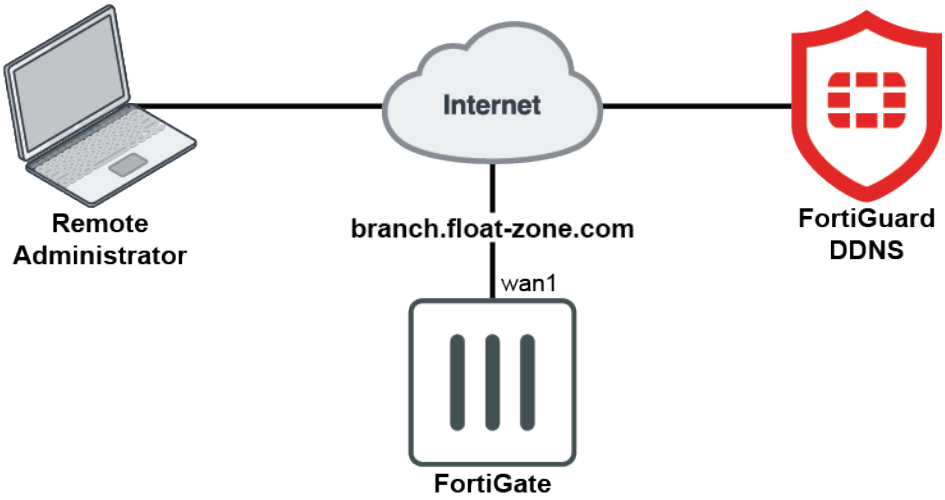
11. Add more DNS entries as needed.
12. Click *OK*.
13. Enable DNS services on an interface:
    a. Go to *Network* > *DNS Servers*.
    b. In the *DNS Service on Interface* table, click *Create New*.
    c. Select the *Interface* for the DNS server, such as *wan2*.
    d. Set the *Mode* to *Recursive*.

    e. Click *OK*.

To configure FortiGate as a primary DNS server in the CLI:

```
config system dns-database
    edit WebServer
        set domain example.com
        set type master
        set view shadow
        set ttl 86400
        set primary-name corporate
        set contact admin@example.com
        set authoritative disable
        config dns-entry
            edit 1
                set status enable
                set hostname web.example.com
                set type A
                set ip 192.168.21.12
            next
        end
    next
end
config system dns-server
    edit wan2
        set mode recursive
    next
end
```

DDNS



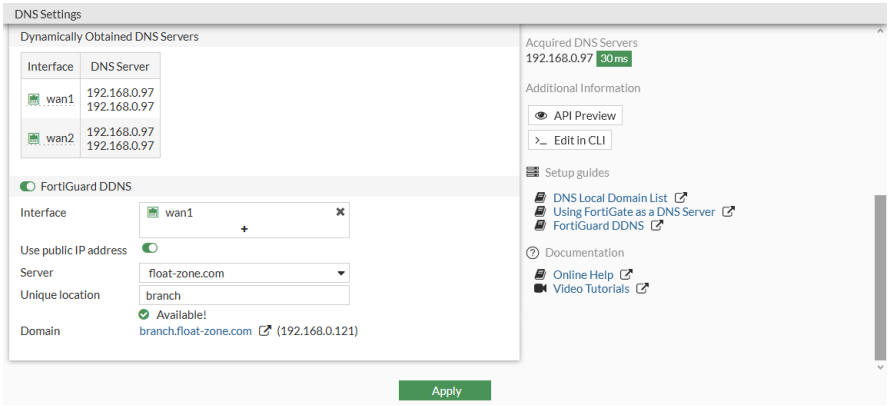
If your external IP address changes regularly and you want a static domain name, you can configure the external interface to use a dynamic DNS (DDNS) service. This ensures that external users and customers can always connect to your company firewall. You can configure FortiGuard as the DDNS server using the GUI or CLI.

A license or subscription is not required to use the DDNS service, but configuring DDNS in the GUI is not supported if:

- The FortiGate model is a 1000-series or higher.
- The FortiGate is a VM.
- The DNS server is not using FortiGuard as the DNS.

FortiGate does not support DDNS when in transparent mode.

Sample topology



In this example, FortiGuard DDNS is enabled and the DDNS server is set to *float-zone.com*. Other DDNS server options include *fortiddns.com* and *fortidyndns.com*.

To configure FortiGuard DDNS service as a DDNS server in the GUI:

1. Go to *Network* > *DNS*
2. Enable *FortiGuard DDNS*.
3. Select the *Interface* with the dynamic connection.
4. Select the *Server* that you have an account with.

5. Enter your *Unique Location*.

6. Click *Apply*.

To configure the FortiGuard DDNS service as an IPv4 DDNS server in the CLI:

```
config system ddns
    edit 1
        set ddns-server FortiGuardDDNS
        set server-type ipv4
        set ddns-domain "branch.float-zone.com"
        set addr-type ipv4
        set use-public-ip enable
        set monitor-interface "wan1"
    next
end
```

To configure the FortiGuard DDNS service as an IPv6 DDNS server in the CLI:

```
config system ddns
    edit 1
        set ddns-server FortiGuardDDNS
        set server-type ipv6
        set ddns-domain "fgtatest001.float-zone.com"
        set addr-type ipv6
        set monitor-interface "wan1"
    next
end
```

DDNS servers other than FortiGuard

If you do not have a FortiGuard subscription, or want to use a different DDNS server, you can configure a DDNS server for each interface. Only the first configure port appears in the GUI.

The available commands vary depending on the selected DDNS server.

To configure DDNS servers other than FortiGuard in the CLI:

```
config system ddns
    edit <DDNS_ID>
        set monitor-interface <external_interface>
```

```
        set ddns-server <ddns_server_selection>
        set server-type {ipv4 | ipv6}
        set ddns-server-addr <address>
        set addr-type ipv6 {ipv4 | ipv6}
    next
end
```

To configure an IPv6 DDNS client with generic DDNS on port 3 in the CLI:

```
config system ddns
    edit 1
        set ddns-server genericDDNS
        set server-type ipv6
        set ddns-server-addr "2004:16:16:16::2" "16.16.16.2" "ddns.genericddns.com"
        set ddns-domain "test.com"
        set addr-type ipv6
        set monitor-interface "port3"
    next
end
```

Refresh DDNS IP addresses

When using a public IP that is not assigned to the FortiGate, the FortiGate cannot trigger an update when the IP address changes. The FortiGate can be configured to refresh DDNS IP addresses by periodically checking the DDNS server at an update interval.

To configure FortiGate to refresh DDNS IP addresses in the CLI:

```
config system ddns
    edit 1
        set use-public-ip enable
        set update-interval <seconds>
    next
end
```

When `update-interval` is set to `0`:

- For FortiGuard DDNS, the interval is 300 seconds.
- For third part DDNS servers, the interval is assigned by the DDNS server.

Disable cleartext

When `clear-text` is disabled, FortiGate uses the SSL connection to send and receive DDNS updates.

To disable cleartext and set the SSL certificate in the CLI:

```
config system ddns
    edit 2
        set clear-text disable
        set ssl-certificate <cert_name>
    next
end
```

DDNS update override

A DHCP server has an override command option that allows DHCP server communications to go through DDNS to perform updates for the DHCP client. This enforces a DDNS update of the A field every time even if the DHCP client does not request it. This allows support for the `allow`, `ignore`, and `deny client-updates` options.

To enable DDNS update override in the CLI:

```
config system dhcp server
    edit 1
        set ddns-update enable
        set ddns-update-override enable
        set ddns-server-ip <ddns_server_ip>
        set ddns-zone <ddns_zone>
    next
end
```

Troubleshooting

To debug DDNS:

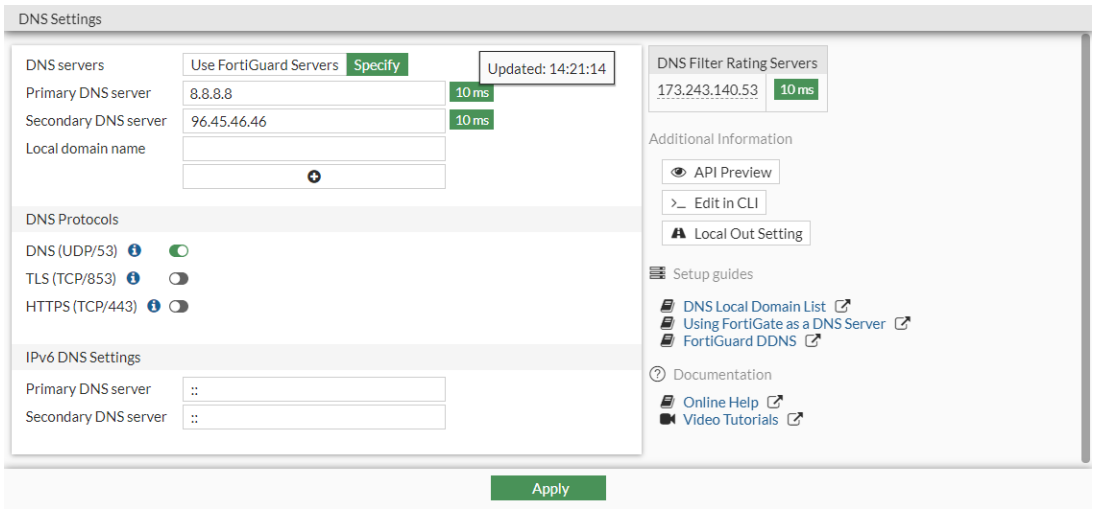
```
# diagnose debug application ddnscd -1
# diagnose debug enable
```

To check if a DDNS server is available:

```
# diagnose test application ddnscd 3
```

Not available:

```
FortiDDNS status:
ddns_ip=0.0.0.0, ddns_ip6=::, ddns_port=443 svr_num=0 domain_num=0
```



Available:

```
FortiDDNS status:
ddns_ip=208.91.113.230, ddns_ip6=::, ddns_port=443 svr_num=1 domain_num=3
svr[0]= 208.91.113.230
domain[0]= fortiddns.com
domain[1]= fortidyndns.com
domain[2]= float-zone.com
```

DNS latency information

High latency in DNS traffic can result in an overall sluggish experience for end-users. In the *DNS Settings* pane, you can quickly identify DNS latency issues in your configuration.

Go to *Network* > *DNS* to view DNS latency information in the right side bar. If you use FortiGuard DNS, latency information for DNS, DNS filter, web filter, and outbreak prevention servers is also visible. Hover your pointer over a latency value to see when it was last updated.

To view DNS latency information using the CLI:

```
# diagnose test application dnsproxy 2
worker idx: 0
worker: count=1 idx=0
retry_interval=500 query_timeout=1495
DNS latency info:
vfid=0 server=2001::1 latency=1494 updated=73311
vfid=0 server=96.45.46.46 latency=1405 updated=2547
vfid=0 server=8.8.8.8 latency=19 updated=91
SDNS latency info:
vfid=0 server=173.243.140.53 latency=1 updated=707681
DNS_CACHE: alloc=35, hit=26
RATING_CACHE: alloc=1, hit=49
DNS UDP: req=66769 res=63438 fwd=83526 alloc=0 cmp=0 retrans=16855 to=3233
          cur=111 switched=8823467 num_switched=294 v6_cur=80 v6_switched=7689041 num_v6_
switched=6
         ftg_res=8 ftg_fwd=8 ftg_retrans=0
DNS TCP: req=0, res=0, fwd=0, retrans=0 alloc=0, to=0
FQDN: alloc=45 nl_write_cnt=9498 nl_send_cnt=21606 nl_cur_cnt=0
Botnet: searched=57 hit=0 filtered=57 false_positive=0
```

To view the latency from web filter and outbreak protection servers using the CLI:

```
# diagnose debug rating
Locale   : english

Service  : Web-filter
Status   : Enable
License  : Contract

Service  : Antispam
Status   : Disable

Service  : Virus Outbreak Prevention
Status   : Disable

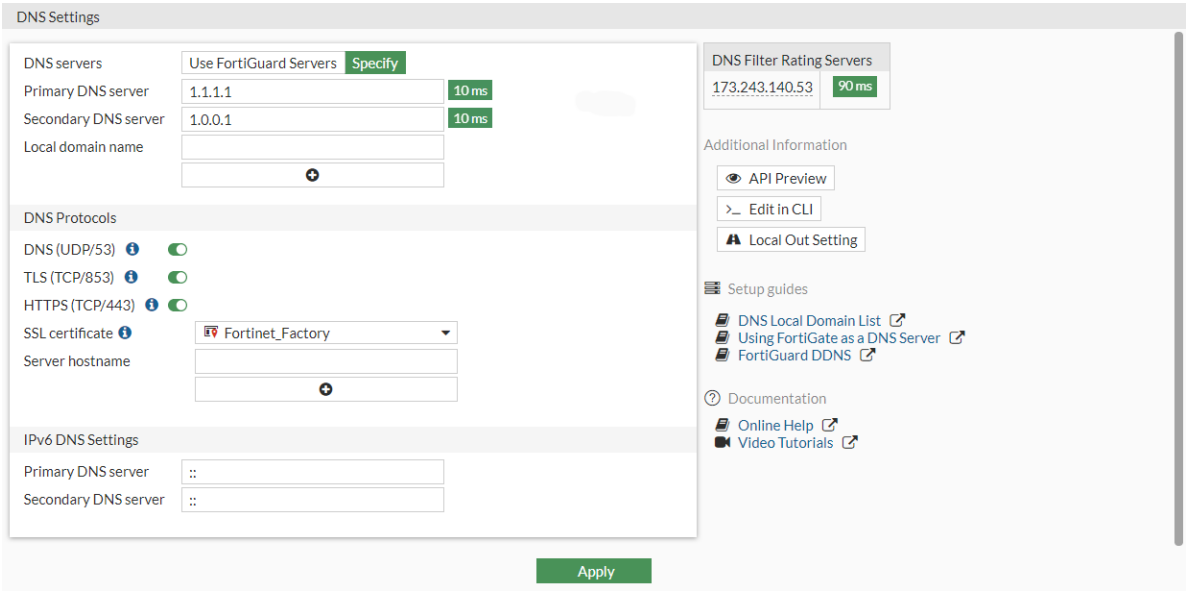
DNS over TLS and HTTPS

DNS over TLS (DoT) is a security protocol for encrypting and encapsulating DNS queries and responses over the TLS protocol. DoT increases user privacy and security by preventing eavesdropping and manipulation of DNS data via man-in-the-middle attacks. Similarly, DNS over HTTPS (DoH) provides a method of performing DNS resolution over a secure HTTPS connection. DoT and DoH are supported in explicit mode where the FortiGate acts as an explicit DNS server that listens for DoT and DoH requests. Local-out DNS traffic over TLS and HTTPS is also supported.



Basic configurations for enabling DoT and DoH for local-out DNS queries

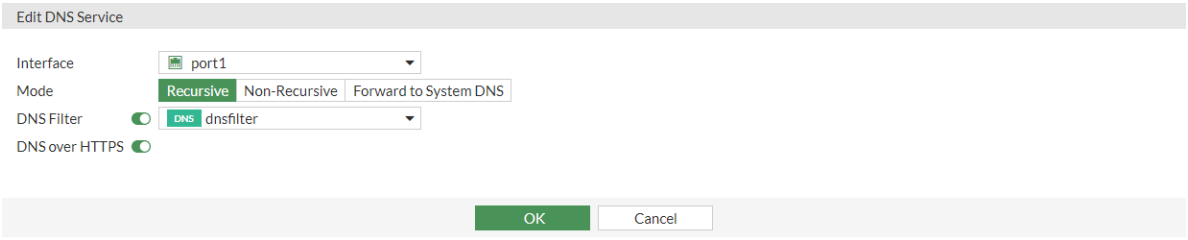
Before enabling DoT or DoH, ensure that they are supported by the DNS servers. The legacy FortiGuard DNS servers (208.91.112.53 and 208.91.112.52) do not support DoT or DoH queries, and will drop these packets. At times, the latency status of the DNS servers might also appear high or unreachable.

Disabling DoT and DoH is recommended when they are not supported by the DNS servers.

To enable DoT and DoH DNS in the GUI:

1. Go to *Network* > *DNS*.
2. Enter the primary and secondary DNS server addresses.
3. In the *DNS Protocols* section, enable *TLS (TCP/853)* and *HTTPS (TCP/443)*.

4. Configure the other settings as needed.
5. Click *Apply*.



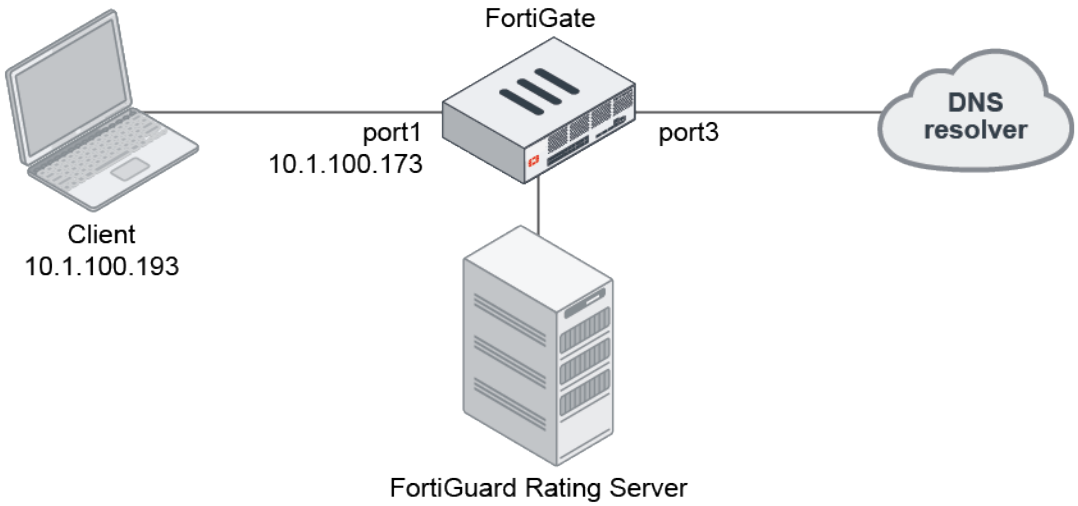
To enable DoT and DoH DNS in the CLI:

```
config system dns
    set primary 1.1.1.1
    set secondary 1.0.0.1
    set protocol {cleartext dot doh}
end
```

To enable DoH on the DNS server in the GUI:

1. Go to *Network* > *DNS Servers*.
2. In the *DNS Service on Interface* section, edit an existing interface, or create a new one.
3. Select a *Mode*, and *DNS Filter* profile.

4. Enable *DNS over HTTPS*.



5. Click *OK*.

To enable DoH on the DNS server in the CLI:

```
config system dns-server
    edit "port1"
        set dnsfilter-profile "dnsfilter"
        set doh enable
    next
end
```

Examples

The following examples demonstrate how configure DNS settings to support DoT and DoH queries made to the FortiGate.

DoT

The following example uses a DNS filter profile where the education category is blocked.

To enable scanning DoT traffic in explicit mode with a DNS filter:

1. Configure the DNS settings:

```
config system dns
    set primary 1.1.1.1
```

```
    set secondary 1.0.0.1
    set protocol dot
end
```

2. Configure the DNS filter profile:

```
config dnsfilter profile
    edit "dnsfilter"
        config ftgd-dns
            config filters
                edit 1
                    set category 30
                    set action block
                next
            end
        end
    next
end
```

3. Configure the DNS server settings:

```
config system dns-server
    edit "port1"
        set dnsfilter-profile "dnsfilter"
    next
end
```

4. Send a DNS query over TLS (this example uses kdig on an Ubuntu client) using the FortiGate as the DNS server. The www.ubc.ca domain belongs to the education category:

```
root@client:/tmp# kdig -d @10.1.100.173 +tls +header +all www.ubc.ca
;; DEBUG: Querying for owner(www.ubc.ca.), class(1), type(1), server(10.1.100.173), port
(853), protocol(TCP)
;; DEBUG: TLS, received certificate hierarchy:
;; DEBUG:  #1,
C=US,ST=California,L=Sunnyvale,O=Fortinet,OU=FortiGate,CN=FG3H1E5818903681,EMAIL=support
@fortinet.com
;; DEBUG:      SHA-256 PIN: Xhkpv9ABEhxDLtWG+lGEndNrBR7B1xjRYlGn2ltlkb8=
;; DEBUG:  #2, C=US,ST=California,L=Sunnyvale,O=Fortinet,OU=Certificate
Authority,CN=fortinet-subca2001,EMAIL=support@fortinet.com
;; DEBUG:      SHA-256 PIN: 3T8EqFBjpRSkxQNPFagjUNeEUghXOEYp904ROlJM8yo=

Authority,CN=fortinet-ca2,EMAIL=support@fortinet.com
;; DEBUG:      SHA-256 PIN: /QfV4N3k5oxQR5RHtW/rbn/HrHgKpMLN0DEaeXY5yPg=
;; DEBUG: TLS, skipping certificate PIN check
;; DEBUG: TLS, skipping certificate verification
;; TLS session (TLS1.2)-(ECDHE-RSA-SECP256R1)-(AES-256-GCM)
;; ->>HEADER<<- opcode: QUERY; status: NOERROR; id: 56719
;; Flags: qr rd; QUERY: 1; ANSWER: 1; AUTHORITY: 0; ADDITIONAL: 0

;; QUESTION SECTION:
;; www.ubc.ca.                  IN      A

;; ANSWER SECTION:
www.ubc.ca.             60      IN      A       208.91.112.55

;; Received 44 B
;; Time 2021-03-12 23:11:27 PST
```

```
;; From 10.1.100.173@853(TCP) in 0.2 ms
root@client:/tmp#
```

The IP returned by the FortiGate for ubc.ca belongs to the FortiGuard block page, so the query was blocked successfully.

DoH

The following example uses a DNS filter profile where the education category is blocked.

To configure scanning DoH traffic in explicit mode with a DNS filter:

1. Configure the DNS settings:

```
config system dns
    set primary 1.1.1.1
    set secondary 1.0.0.1
    set protocol doh
end
```

2. Configure the DNS filter profile:

```
config dnsfilter profile
    edit "dnsfilter"
        config ftgd-dns
            config filters
                edit 1
                    set category 30
                    set action block
                next
            end
        end
    next
end
```

3. Configure the DNS server settings:

```
config system dns-server
    edit "port1"
        set dnsfilter-profile "dnsfilter"
        set doh enable
    next
end
```

4. In your browser, enable DNS over HTTPS.
5. On your computer, edit the TCP/IP settings to use the FortiGate interface address as the DNS server.
6. In your browser, go to a website in the education category (www.ubc.ca). The website is redirected to the block page.

DNS troubleshooting

The following diagnose command can be used to collect DNS debug information. If you do not specify worker ID, the default worker ID is `0`.

```
# diagnose test application dnsproxy
worker idx: 0
1. Clear DNS cache
2. Show stats
3. Dump DNS setting
4. Reload FQDN
5. Requery FQDN
6. Dump FQDN
7. Dump DNS cache
8. Dump DNS DB
9. Reload DNS DB
10. Dump secure DNS policy/profile
11. Dump Botnet domain
12. Reload Secure DNS setting
13. Show Hostname cache
14. Clear Hostname cache
15. Show SDNS rating cache
16. Clear SDNS rating cache
17. DNS debug bit mask
18. DNS debug obj mem
99. Restart dnsproxy worker
```

To view useful information about the ongoing DNS connection:

```
# diagnose test application dnsproxy 3
worker idx: 0
vdom: root, index=0, is primary, vdom dns is disabled, mip-169.254.0.1 dns_log=1 tls=0 cert=
dns64 is disabled
vdom: vdom1, index=1, is primary, vdom dns is enabled, mip-169.254.0.1 dns_log=1 tls=0 cert=
dns64 is disabled

FGD_CATEGORY_VERSION:8
SERVER_LDB: gid=eb19, tz=-480, error_allow=0
FGD_REDIR_V4:208.91.112.55 FGD_REDIR_V6:
```

Important fields include:

`tls`	1 if the connection is TLS, 0 if the connection is not TLS.
`rt`	The round trip time of the DNS latency.
`probe`	The number of probes sent.

To dump the second DNS worker's cache:

```
diagnose test application dnsproxy 7 1
```

To enable debug on the second worker:

```
diagnose debug application dnsproxy -1 1
```

To enable debug on all workers by specifying -1 as worker ID:

```
diagnose debug application dnsproxy -1 -1
```

Explicit and transparent proxies

This section contains instructions for configuring explicit and transparent proxies.

- Explicit web proxy on page 258
- Transparent proxy on page 264
- FTP proxy on page 262
- Proxy policy addresses on page 267
- Proxy policy security profiles on page 274
- Explicit proxy authentication on page 278
- Transparent web proxy forwarding on page 284
- Upstream proxy authentication in transparent proxy mode on page 288
- Multiple dynamic header count on page 289
- Restricted SaaS access on page 292
- Explicit proxy and FortiGate Cloud Sandbox on page 300
- Proxy chaining on page 302
- WAN optimization SSL proxy chaining on page 307
- Agentless NTLM authentication for web proxy on page 315
- Multiple LDAP servers in Kerberos keytabs and agentless NTLM domain controllers on page 318
- Learn client IP addresses on page 319
- Explicit proxy authentication over HTTPS on page 320
- mTLS client certificate authentication on page 322

- CORS protocol in explicit web proxy when using session-based, cookie-enabled, and captive portal-enabled SAML authentication on page 327
- HTTP connection coalescing and concurrent multiplexing for explicit proxy on page 331

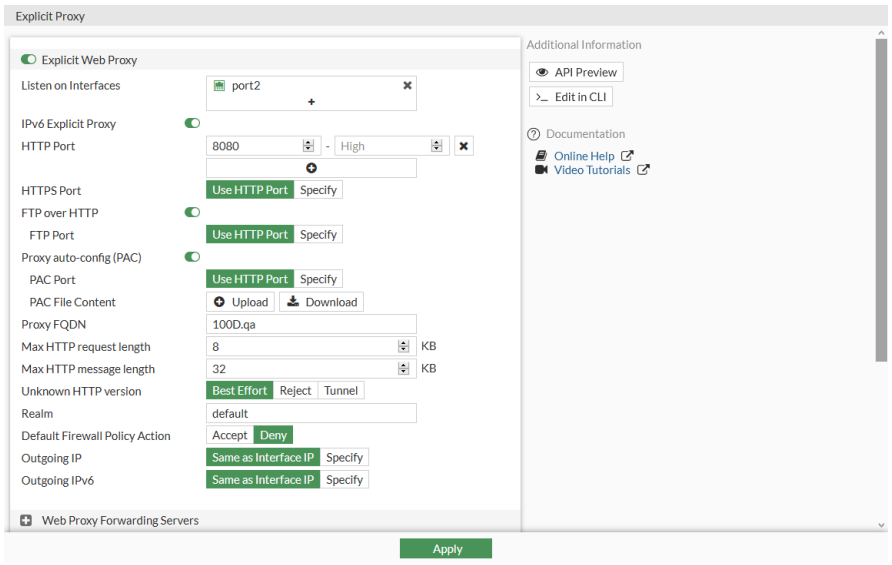
Explicit web proxy

Explicit web proxy can be configured on FortiGate for proxying HTTP and HTTPS traffic.

To deploy explicit proxy, individual client browsers can be manually configured to send requests directly to the proxy, or they can be configured to download proxy configuration instructions from a Proxy Auto-Configuration (PAC) file.

When explicit proxy is configured on an interface, the interface IP address can be used by client browsers to forward requests directly to the FortiGate. FortiGate also supports PAC file configuration.

For FortiOS 7.0.1 and above, SSL VPN web mode and explicit web proxy features will not work with the following configuration:



1. An IP pool with ARP reply enabled is configured.
2. This IP pool is configured as the source IP address in either a firewall policy for SSL VPN web mode or in a proxy policy for explicit web proxy.
3. A matching blackhole route is configured for IP pool reply traffic.

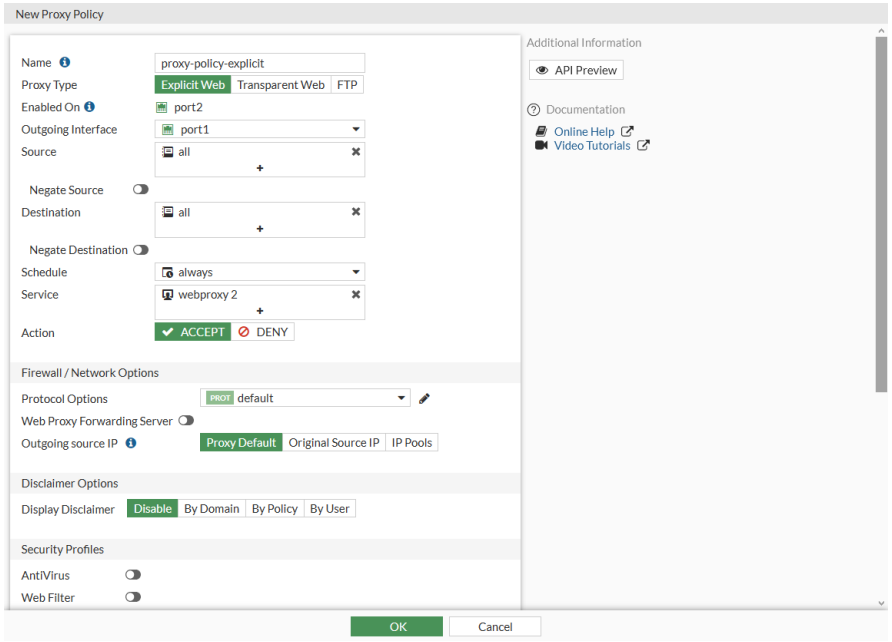
Configuring an IP pool as the source NAT IP address in a regular firewall policy works as before.

See IP pools and blackhole route configuration on page 1082 for details.

To configure explicit web proxy in the GUI:

1. Enable and configure explicit web proxy:
   a. Go to *Network* > *Explicit Proxy*.
   b. Enable *Explicit Web Proxy*.
   c. Select *port2* as the *Listen on Interfaces* and set the *HTTP Port* to *8080*.
   d. Configure the remaining settings as needed.

e. Click *Apply*.



2. Create an explicit web proxy policy:

a. Go to *Policy & Objects* > *Proxy Policy*.

b. Click *Create New*.

c. Set *Proxy Type* to *Explicit Web* and *Outgoing Interface* to *port1*.

d. Also set *Source* and *Destination* to *all*, *Schedule* to *always*, *Service* to *webproxy*, and *Action* to *ACCEPT*.

e. Click *OK* to create the policy.

This example creates a basic policy. If required, security profiles can be enabled, and deep SSL inspection can be selected to inspect HTTPS traffic.

3. Configure a client to use the FortiGate explicit proxy:
   Set the FortiGate IP address as the proxy IP address in the browser, or use an automatic configuration script for the PAC file.

To configure explicit web proxy in the CLI:

1. Enable and configure explicit web proxy:

```
config web-proxy explicit
    set status enable
    set ftp-over-http enable
    set socks enable
    set http-incoming-port 8080
    set ipv6-status enable
    set unknown-http-version best-effort
end
config system interface
    edit "port2"
        set vdom "vdom1"
        set ip 10.1.100.1 255.255.255.0
        set allowaccess ping https ssh snmp http telnet
        set type physical
        set explicit-web-proxy enable
        set snmp-index 12
        end
    next
end
```

2. Create an explicit web proxy policy:

```
config firewall proxy-policy
    edit 1
        set name "proxy-policy-explicit"
        set proxy explicit-web
        set dstintf "port1"
        set srcaddr "all"
        set dstaddr "all"
        set service "webproxy"
        set action accept
        set schedule "always"
        set logtraffic all
    next
end
```

This example creates a basic policy. If required, security profiles can be enabled, and deep SSL inspection can be selected to inspect HTTPS traffic.

3. Configure a client to use the FortiGate explicit web proxy:
   Set the FortiGate IP address as the proxy IP address in the browser, or use an automatic configuration script for the PAC file.

Downloading a PAC file using HTTPS

PAC files can be downloaded for an explicit proxy through the FortiGate's captive portal using HTTPS to ensure a secure download.

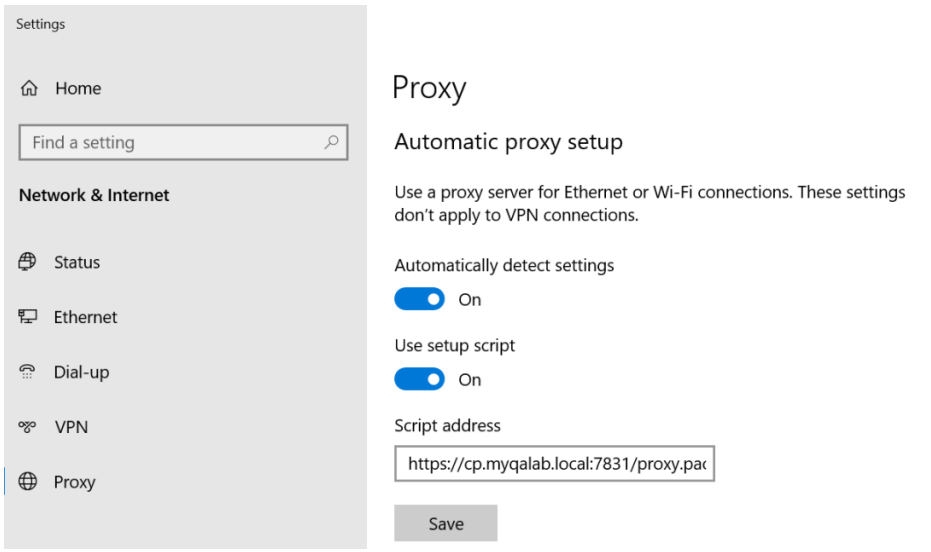
In this example, a Windows PC has an HTTPS URL configured in its proxy settings to download a PAC file from a FortiGate by using a download link, https://cp.myqalab.local:7831/proxy.pac, through a captive portal. Once the PAC file is securely downloaded using HTTPS, browsers installed on the PC can use the proxy in the PAC file to visit a website.

The global web proxy settings must be configured to use a customized SSL certificate because the default Fortinet_Factory certificate will not be accepted by Windows due to security restrictions. The customized SSL certificate is used as the HTTPS server's certificate on the FortiGate. All CA certificates in the server certificate must be installed and trusted on the Windows PC.

To download a PAC file using HTTPS:

1. Configure the explicit web proxy to get a PAC file through HTTPS:

```
config web-proxy explicit
    set pac-file-server-status enable
    unset pac-file-server-port
    set pac-file-name "proxy.pac"
    set pac-file-data "function FindProxyForURL(url, host) {
   // testtest
   return \"PROXY 10.1.100.1:8080\";
}
"
    set pac-file-through-https enable
end
```



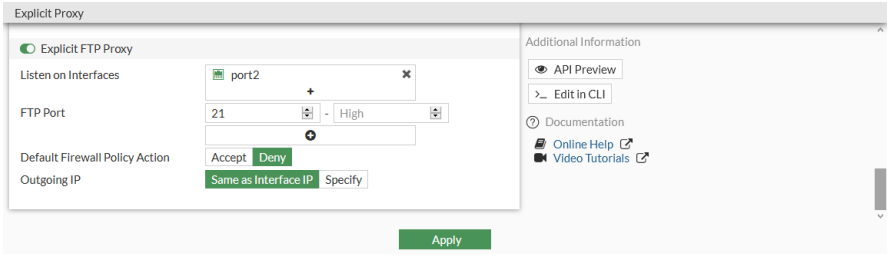
2. Configure the captive portal to be used as an HTTPS server to provide the service to download the PAC file:

```
config authentication setting
    set captive-portal-type ip
    set captive-portal-ip 10.1.100.1
    set captive-portal-ssl-port 7831
end
```

3. Configure the global web proxy settings to use a customized SSL certificate:

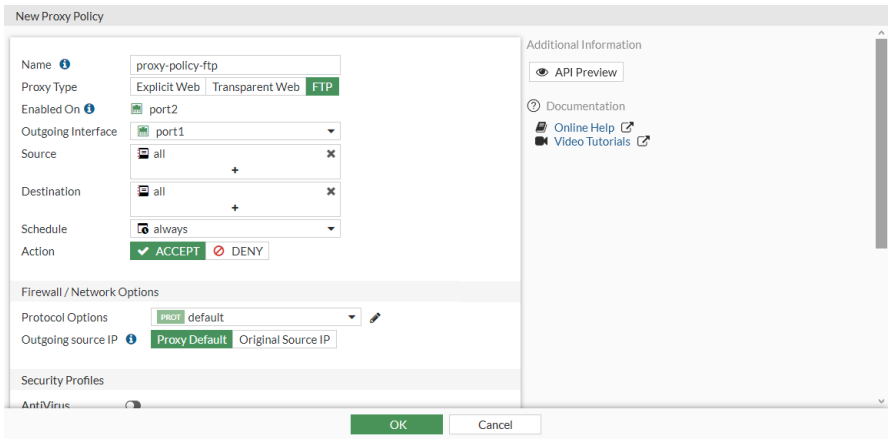
```
config web-proxy global
    set ssl-cert "server_cert"
end
```

4. On the Windows PC, go to *Settings* > *Network & Internet* > *Proxy*.



5. In the *Automatic proxy setup* section, click *Save* to trigger the PAC file download from the HTTPS URL.

FTP proxy



FTP proxies can be configured on the FortiGate so that FTP traffic can be proxied. When the FortiGate is configured as an FTP proxy, FTP client applications should be configured to send FTP requests to the FortiGate.

To configure explicit FTP proxy in the GUI:

1. Enable and configure explicit FTP proxy:
   a. Go to *Network* > *Explicit Proxy*.
   b. Enable *Explicit FTP Proxy*.
   c. Select *port2* as the *Listen on Interfaces* and set the *HTTP Port* to *21*.
   d. Configure the *Default Firewall Policy Action* as needed.

   e. Click *Apply*.
2. Create an explicit FTP proxy policy:
   a. Go to *Policy & Objects* > *Proxy Policy*.
   b. Click *Create New*.
   c. Set *Proxy Type* to *FTP* and *Outgoing Interface* to *port1*.
   d. Also set *Source* and *Destination* to *all*, *Schedule* to *always*, and *Action* to *ACCEPT*.

e. Click *OK* to create the policy.

This example creates a basic policy. If required, security profiles can be enabled.

3. Configure the FTP client application to use the FortiGate IP address.

To configure explicit FTP proxy in the CLI:

1. Enable and configure explicit FTP proxy:

```
config ftp-proxy explicit
    set status enable
    set incoming-port 21
end
config system interface
    edit "port2"
        set vdom "vdom1"
        set ip 10.1.100.1 255.255.255.0
        set allowaccess ping https ssh snmp http telnet
        set type physical
        set explicit-ftp-proxy enable
        set snmp-index 12
    next
end
```

2. Create an explicit FTP proxy policy:

```
config firewall proxy-policy
    edit 4
        set name "proxy-policy-ftp"
        set proxy ftp
        set dstintf "port1"
        set srcaddr "all"
        set dstaddr "all"
        set action accept
        set schedule "always"
    next
```

```
end
```

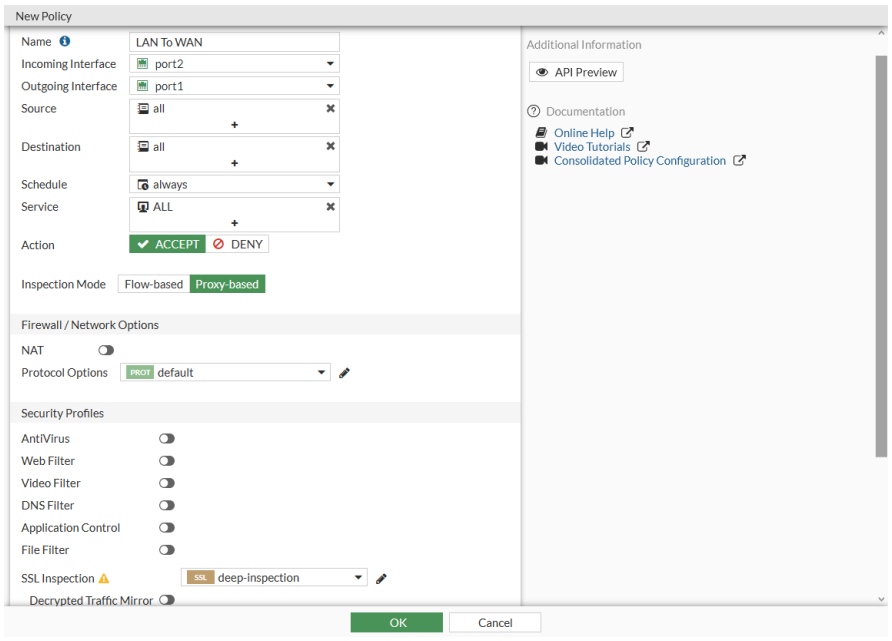
This example creates a basic policy. If required, security profiles can be enabled.

3. Configure the FTP client application to use the FortiGate IP address.

Transparent proxy

In a transparent proxy deployment, the user's client software, such as a browser, is unaware that it is communicating with a proxy.

Users request internet content as usual, without any special client configuration, and the proxy serves their requests. FortiGate also allows users to configure in transparent proxy mode.



To redirect HTTPS traffic, SSL inspection is required.

If the base firewall policy successfully redirects to the proxy policy then antivirus and web filter profiles configured on the firewall policy will not be applied. Security profiles should be configured on the proxy policy.

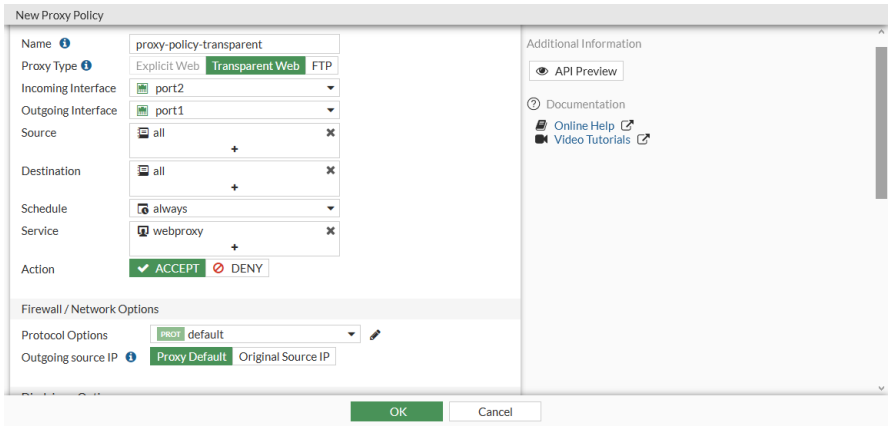
To configure transparent proxy in the GUI:

1. Configure a regular firewall policy with HTTP redirect:
   a. Go to *Policy & Objects* > *Firewall Policy*.
   b. Click *Create New*.
   c. Name the policy appropriately, set the *Incoming Interface* to *port2*, and set the *Outgoing Interface* to *port1*.
   d. Also set *Source* and *Destination* to *all*, *Schedule* to *always*, *Service* to *ALL*, and *Action* to *ACCEPT*.
   e. Set *Inspection Mode* to *Proxy-based* and *SSL Inspection* to *deep-inspection*.

f. Configure the remaining settings as needed.

g. Click *OK*.

By default, HTTP redirect can only be enabled in the CLI. Enable *Policy Advanced Options* in *Feature Visibility* to configure it in the GUI. See Feature visibility on page 2517 on page 1 for more information.



2. Configure a transparent proxy policy:

a. Go to *Policy & Objects* > *Proxy Policy*.

b. Click *Create New*.

c. Set *Proxy Type* to *Transparent Web*, set the *Incoming Interface* to *port2*, and set the *Outgoing Interface* to *port1*.

d. Also set *Source* and *Destination* to *all*, *Schedule*to *always*, *Service* to *webproxy*, and *Action* to *ACCEPT*.

e. Configure the remaining settings as needed.

f. Click *OK* to create the policy.

This example creates a basic policy. If required, security profiles can be enabled, and deep SSL inspection can be selected to inspect HTTPS traffic.

3. No special configuration is required on the client to use FortiGate transparent proxy. As the client is using the FortiGate as its default gateway, requests will first hit the regular firewall policy, and then be redirected to the transparent proxy policy.

To configure transparent proxy in the CLI:

1. Configure a regular firewall policy with HTTP redirect:

```
config firewall policy
    edit 1
        set name "LAN To WAN"
        set srcintf "port2"
        set dstintf "port1"
        set srcaddr "all"
        set dstaddr "all"
        set action accept
        set schedule "always"
        set service "ALL"
        set inspection-mode proxy
        set http-policy-redirect enable
        set fsso disable
        set ssl-ssh-profile "deep-inspection"
        set nat enable
    next
end
```

2. Configure a transparent proxy policy:

```
config firewall proxy-policy
    edit 5
        set name "proxy-policy-transparent"
        set proxy transparent-web
        set srcintf "port2"
        set dstintf "port1"
        set srcaddr "all"
        set dstaddr "all"
        set service "webproxy"
        set action accept
        set schedule "always"
    next
end
```

This example creates a basic policy. If required, security profiles can be enabled, and deep SSL inspection can be selected to inspect HTTPS traffic.

3. No special configuration is required on the client to use FortiGate transparent proxy. As the client is using the FortiGate as its default gateway, requests will first hit the regular firewall policy, and then be redirected to the transparent proxy policy.

Proxy policy addresses

Proxy addresses are designed to be used only by proxy policies. The following address types are available:

- Host regex match on page 267
- URL pattern on page 268
- URL category on page 269
- HTTP method on page 270
- HTTP header on page 270
- User agent on page 271
- Advanced (source) on page 272
- Advanced (destination) on page 273

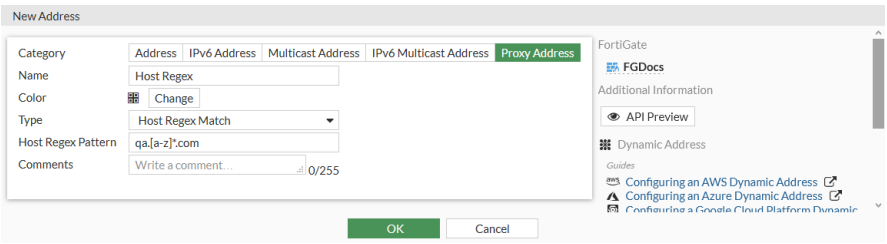
Fast policy match

The fast policy match function improves the performance of IPv4 explicit and transparent web proxies on FortiGate devices.

When enabled, after the proxy policies are configured, the FortiGate builds a fast searching table based on the different proxy policy matching criteria. When fast policy matching is disabled, web proxy traffic is compared to the policies one at a time from the beginning of the policy list.

Fast policy matching is enabled by default, and can be configured with the following CLI command:

```
config web-proxy global
    set fast-policy-match {enable | disable}
end
```



Host regex match

In this address type, a user can create a hostname as a regular expression. Once created, the hostname address can be selected as a destination of a proxy policy. This means that a policy will only allow or block requests that match the regular expression.

This example creates a host regex match address with the pattern *qa.[a-z]*.com*.

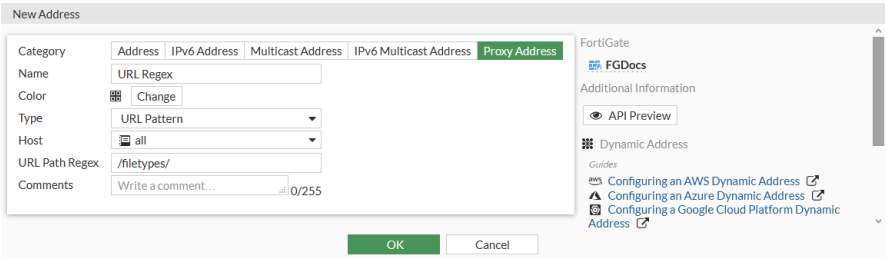
To create a host regex match address in the GUI:

1. Go to *Policy & Objects* > *Addresses*.
2. Click *Create New* > *Address*.
3. Set the following:
   - *Category* to *Proxy Address*,
   - *Name* to *Host Regex*,
   - *Type* to *Host Regex Match*, and
   - *Host Regex Pattern* to *qa.[a-z]*.com*.

4. Click *OK*.

To create a host regex match address in the CLI:

```
config firewall proxy-address
    edit "Host Regex"
        set type host-regex
        set host-regex "qa.[a-z]*.com"
    next
end
```



URL pattern

In this address type, a user can create a URL path as a regular expression. Once created, the path address can be selected as a destination of a proxy policy. This means that a policy will only allow or block requests that match the regular expression.

This example creates a URL pattern address with the pattern */filetypes/*.

To create a URL pattern address in the GUI:

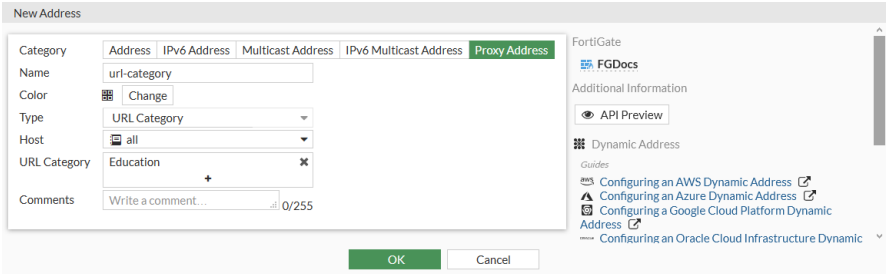
1. Go to *Policy & Objects* > *Addresses*.
2. Click *Create New* > *Address*.
3. Set the following:
   - *Category* to *Proxy Address*,
   - *Name* to *URL Regex*,
   - *Type* to *URL Pattern*,
   - *Host* to *all*, and
   - *URL Path Regex* to */filetypes/*.

4. Click *OK*.

To create a URL pattern address in the CLI:

```
config firewall proxy-address
    edit "URL Regex"
        set type url
        set host "all"
        set path "/filetypes/"
    next
end
```

URL category



In this address type, a user can create a URL category based on a FortiGuard URL ID. Once created, the address can be selected as a destination of a proxy policy. This means that a policy will only allow or block requests that match the URL category.

The example creates a URL category address for URLs in the *Education* category. For more information about categories, see https://fortiguard.com/webfilter/categories.

For information about creating and using custom local and remote categories, see Web rating override on page 1558, Using local and remote categories on page 1566, and Threat feeds on page 2923.

To create a URL category address in the GUI:

1. Go to *Policy & Objects* > *Addresses*.
2. Click *Create New* > *Address*.
3. Set the following:
   - *Category* to *Proxy Address*,
   - *Name* to *url-category*,
   - *Type* to *URL Category*,
   - *Host* to *all*, and
   - *URL Category* to *Education*.

4. Click *OK*.

To create a URL category address in the CLI:

```
config firewall proxy-address
    edit "url-category"
        set type category
        set host "all"
        set category 30
    next
end
```

To see a list of all the categories and their numbers, when editing the address, enter `set category ?`.

HTTP method

In this address type, a user can create an address based on the HTTP request methods that are used. Multiple method options are supported, including: *CONNECT*, *DELETE*, *GET*, *HEAD*, *OPTIONS*, *POST*, *PUT*, and *TRACE*. Once created, the address can be selected as a source of a proxy policy. This means that a policy will only allow or block requests that match the selected HTTP method.

The example creates a HTTP method address that uses the GET method.

To create a HTTP method address in the GUI:

1. Go to *Policy & Objects* > *Addresses*.
2. Click *Create New* > *Address*.
3. Set the following:
   - *Category* to *Proxy Address*,
   - *Name* to *method_get*,
   - *Type* to *HTTP Method*,
   - *Host* to *all*, and
   - *Request Method* to *GET*.
4. Click *OK*.

To create a HTTP method address in the CLI:

```
config firewall proxy-address
    edit "method_get"
        set type method
        set host "all"
        set method get
    next
end
```

HTTP header

In this address type, a user can create a HTTP header as a regular expression. Once created, the header address can be selected as a source of a proxy policy. This means that a policy will only allow or block requests where the HTTP header matches the regular expression.

This example creates a HTTP header address with the pattern *Q[A-B]*.

To create a HTTP header address in the GUI:

1. Go to *Policy & Objects* > *Addresses*.
2. Click *Create New* > *Address*.
3. Set the following:
   - *Category* to *Proxy Address*,
   - *Name* to *HTTP-header*,

- *Type* to *HTTP Header*,
- *Host* to *all*,
- *Header Name* to *Header_Test*, and
- *Header Regex* to *Q[A-B]*.

4. Click *OK*.

To create a HTTP header address in the CLI:

```
config firewall proxy-address
    edit "method_get"
        set type header
        set host "all"
        set header-name "Header_Test"
        set header "Q[A-B]"
    next
end
```

User agent

In this address type, a user can create an address based on the names of the browsers that are used as user agents. Multiple browsers are supported, such as Chrome, Firefox, Internet Explorer, and others. Once created, the address can be selected as a source of a proxy policy. This means that a policy will only allow or block requests from the specified user agent.

This example creates a user agent address for Google Chrome.

To create a user agent address in the GUI:

1. Go to *Policy & Objects* > *Addresses*.
2. Click *Create New* > *Address*.
3. Set the following:
   - *Category* to *Proxy Address*,
   - *Name* to *UA-Chrome*,
   - *Type* to *User Agent*,
   - *Host* to *all*, and
   - *User Agent* to *Google Chrome*.
4. Click *OK*.

To create a user agent address in the CLI:

```
config firewall proxy-address
    edit "UA-Chrome"
        set type ua
        set host "all"
        set ua chrome
    next
end
```

Browser version control

For security reasons, the user can restrict the browser version by specifying a range of the supported versions which can be set from the CLI using `set ua-min-ver` and `set ua-max-ver`. This option is available when the address *Type* is either *User Agent* or *Advanced (Source)*.

To restrict the browser version:

```
config firewall proxy-address
    edit "ua-ver"
        set type ua
        set ua firefox
        set ua-min-ver "100.0.1"
        set ua-max-ver "160"
    next
end
```

Advanced (source)

In this address type, a user can create an address based on multiple parameters, including HTTP method, User Agent, and HTTP header. Once created, the address can be selected as a source of a proxy policy. This means that a policy will only allow or block requests that match the selected address.

This example creates an address that uses the get method, a user agent for Google Chrome, and an HTTP header with the pattern *Q[A-B]*.

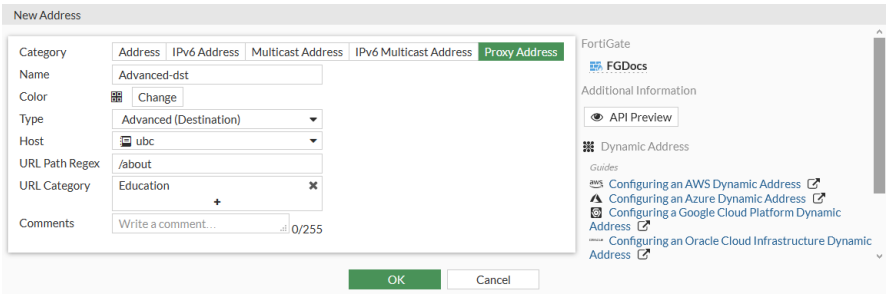
To create an advanced (source) address in the GUI:

1. Go to *Policy & Objects* > *Addresses*.
2. Click *Create New* > *Address*.
3. Set the following:
   - *Category* to *Proxy Address*,
   - *Name* to *advanced_src*,
   - *Type* to *Advanced (Source)*,
   - *Host* to *all*,
   - *Request Method* to *GET*,
   - *User Agent* to *Google Chrome*, and
   - *HTTP header* to *Header_Test* : *Q[A-B]*.
4. Click *OK*.

To create an advanced (source) address in the CLI:

```
config firewall proxy-address
    edit "advance_src"
        set type src-advanced
        set host "all"
        set method get
        set ua chrome
        config header-group
            edit 1
```

```
                set header-name "Header_Test"
                set header "Q[A-B]"
            next
        end
    next
end
```



Advanced (destination)

In this address type, a user can create an address based on URL pattern and URL category parameters. Once created, the address can be selected as a destination of a proxy policy. This means that a policy will only allow or block requests that match the selected address.

This example creates an address with the URL pattern */about* that are in the *Education* category. For more information about categories, see https://fortiguard.com/webfilter/categories.

To create an advanced (destination) address in the GUI:

1. Go to *Policy & Objects* > *Addresses*.
2. Click *Create New* > *Address*.
3. Set the following:
   - *Category* to *Proxy Address*,
   - *Name* to *Advanced-dst*,
   - *Type* to *Advanced (Destination)*,
   - *Host* to *all*,
   - *URL Path Regex* to */about*, and
   - *URL Category* to *Education*.

4. Click *OK*.

To create an advanced (destination) address in the CLI:

```
config firewall proxy-address
    edit "Advanced-dst"
        set type dst-advanced
        set host "ubc"
        set path "/about"
        set category 30
    next
end
```

Proxy policy security profiles

Web proxy policies support most security profile types.

Security profiles must be created before they can be used in a policy, see Security Profiles on page 1265 for information.

Explicit web proxy policy

The security profiles supported by explicit web proxy policies are:

- *AntiVirus*
- *Web Filter*
- *Video Filter*
- *Application Control*
- *IPS*
- *DLP Profile*
- *ICAP*
- *Web Application Firewall*
- *File Filter*
- *SSL Inspection*

To configure security profiles on an explicit web proxy policy in the GUI:

1. Go to *Policy & Objects* > *Proxy Policy*.
2. Click *Create New*.
3. Set the following:

Proxy Type	Explicit Web
Outgoing Interface	port1
Source	all
Destination	all
Schedule	always
Service	webproxy
Action	ACCEPT

4. In the *Firewall / Network Options* section, set *Protocol Options* to *default*.
5. In the *Security Profiles* section, make the following selections (for this example, these profiles have all already been created):

AntiVirus	av
Web Filter	urlfiler

Application Control	app
IPS	Sensor-1
DLP Profile	dlp
ICAP	default
Web Application Firewall	default
SSL Inspection	deep-inspection

6. Click *OK* to create the policy.

To configure security profiles on an explicit web proxy policy in the CLI:

```
config firewall proxy-policy
    edit 1
        set proxy explicit-web
        set dstintf "port1"
        set srcaddr "all"
        set dstaddr "all"
        set service "web"
        set action accept
        set schedule "always"
        set utm-status enable
        set av-profile "av"
        set webfilter-profile "urlfilter"
        set dlp-profile "dlp"
        set ips-sensor "sensor-1"
        set application-list "app"
        set icap-profile "default"
        set waf-profile "default"
        set ssl-ssh-profile "deep-inspection"
    next
end
```

Transparent proxy

The security profiles supported by transparent proxy policies are:

- *AntiVirus*
- *Web Filter*
- *Video Filter*
- *Application Control*
- *IPS*
- *DLP Profile*
- *ICAP*
- *Web Application Firewall*
- *File Filter*
- *SSL Inspection*

To configure security profiles on a transparent proxy policy in the GUI:

1. Go to *Policy & Objects* > *Proxy Policy*.
2. Click *Create New*.
3. Set the following:

Proxy Type	Transparent Web
Incoming Interfae	port2
Outgoing Interface	port1
Source	all
Destination	all
Schedule	always
Service	webproxy
Action	ACCEPT

4. In the *Firewall / Network Options* section, set *Protocol Options* to *default*.
5. In the *Security Profiles* section, make the following selections (for this example, these profiles have all already been created):

AntiVirus	av
Web Filter	urlfiler
Application Control	app
IPS	Sensor-1
DLP Profile	dlp
ICAP	default
Web Application Firewall	default
SSL Inspection	deep-inspection

6. Click *OK* to create the policy.

To configure security profiles on a transparent proxy policy in the CLI:

```
config firewall proxy-policy
    edit 2
        set proxy transparent-web
        set srcintf "port2"
        set dstintf "port1"
        set srcaddr "all"
        set dstaddr "all"
        set service "webproxy"
        set action accept
        set schedule "always"
        set utm-status enable
        set av-profile "av"
        set webfilter-profile "urlfilter"
```

```
        set dlp-profile "dlp"
        set ips-sensor "sensor-1"
        set application-list "app"
        set icap-profile "default"
        set waf-profile "default"
        set ssl-ssh-profile "certificate-inspection"
    next
end
```

FTP proxy

The security profiles supported by FTP proxy policies are:

- *AntiVirus*
- *Application Control*
- *IPS*
- *File Filter*
- *DLP Profile*

To configure security profiles on an FTP proxy policy in the GUI:

1. Go to *Policy & Objects* > *Proxy Policy*.
2. Click *Create New*.
3. Set the following:

Proxy Type	FTP
Outgoing Interface	port1
Source	all
Destination	all
Schedule	always
Action	ACCEPT

4. In the *Firewall / Network Options* section, set *Protocol Options* to *default*.
5. In the *Security Profiles* section, make the following selections (for this example, these profiles have all already been created):

AntiVirus	av
Application Control	app
IPS	Sensor-1
DLP Profile	dlp

6. Click *OK* to create the policy.

To configure security profiles on an FTP proxy policy in the CLI:

```
config firewall proxy-policy
    edit 3
```

```
        set proxy ftp
        set dstintf "port1"
        set srcaddr "all"
        set dstaddr "all"
        set action accept
        set schedule "always"
        set utm-status enable
        set av-profile "av"
        set dlp-profile "dlp"
        set ips-sensor "sensor-1"
        set application-list "app"
    next
end
```

Explicit proxy authentication

FortiGate supports multiple authentication methods. This topic explains using an external authentication server with Kerberos as the primary and NTLM as the fallback.

To configure Explicit Proxy with authentication:

1. Enable and configure the explicit proxy on page 278.
2. Configure the authentication server and create user groups on page 279.
3. Create an authentication scheme and rules on page 281.
4. Create an explicit proxy policy and assign a user group to the policy on page 282.
5. Verify the configuration on page 283.

Enable and configure the explicit proxy

To enable and configure explicit web proxy in the GUI:

1. Go to *Network* > *Explicit Proxy*.
2. Enable *Explicit Web Proxy*.
3. Select *port2* as the *Listen on Interfaces* and set the *HTTP Port* to *8080*.
4. Configure the remaining settings as needed.
5. Click *Apply*.

To enable and configure explicit web proxy in the CLI:

```
config web-proxy explicit
    set status enable
    set ftp-over-http enable
    set socks enable
    set http-incoming-port 8080
    set ipv6-status enable
    set unknown-http-version best-effort
end
config system interface
    edit "port2"
        set vdom "vdom1"
```

```
        set ip 10.1.100.1 255.255.255.0
        set allowaccess ping https ssh snmp http telnet
        set type physical
        set explicit-web-proxy enable
        set snmp-index 12
        end
    next
end
```

Configure the authentication server and create user groups

Since we are using an external authentication server with Kerberos authentication as the primary and NTLM as the fallback, Kerberos authentication is configured first and then FSSO NTLM authentication is configured.

For successful authorization, the FortiGate checks if user belongs to one of the groups that is permitted in the security policy.

When configuring an LDAP connection to an Active Directory server, an administrator must provide Active Directory user credentials.

- To secure this connection, use LDAPS on both the Active Directory server and FortiGate. See Configuring an LDAP server on page 2078 and Configuring client certificate authentication on the LDAP server on page 2092.
- Apply the principle of least privilege. For the LDAP regular bind operation, do not use credentials that provide full administrative access to the Windows server when using credentials. See Configuring least privileges for LDAP admin account authentication in Active Directory on page 2085.

To configure an authentication server and create user groups in the GUI:

1. Configure Kerberos authentication:
   a. Go to *User & Authentication* > *LDAP Servers*.
   b. Click *Create New*.
   c. Set the following:

Name	ldap-kerberos
Server IP	172.18.62.220
Server Port	389
Common Name Identifier	cn
Distinguished Name	dc=fortinetqa,dc=local

   d. Click *OK*
2. Define Kerberos as an authentication service. This option is only available in the CLI. For information on generating a keytab, see Generating a keytab on a Windows server on page 283.
3. Configure FSSO NTLM authentication:

   FSSO NTLM authentication is supported in a Windows AD network. FSSO can also provide NTLM authentication service to the FortiGate unit. When a user makes a request that requires authentication, the FortiGate initiates

NTLM negotiation with the client browser, but does not process the NTLM packets itself. Instead, it forwards all the NTLM packets to the FSSO service for processing.

   a. Go to *Security Fabric* > *External Connectors*.
   b. Click *Create New* and select *FSSO Agent on Windows AD* from the *Endpoint/Identity* category.
   c. Set the *Name* to *FSSO*, *Primary FSSO Agent* to *172.16.200.220*, and enter a password.
   d. Click *OK*.

4. Create a user group for Kerberos authentication:
   a. Go to *User & Authentication* > *User Groups*.
   b. Click *Create New*.
   c. Set the *Name* to *Ldap-Group*, and *Type* to *Firewall*.
   d. In the *Remote Groups* table, click *Add*, and set the *Remote Server* to the previously created *ldap-kerberos* server.
   e. Click *OK*.
5. Create a user group for NTLM authentication:
   a. Go to *User & Authentication* > *User Groups*.
   b. Click *Create New*.
   c. Set the *Name* to *NTLM-FSSO-Group*, *Type* to *Fortinet Single Sign-On (FSSO)*, and add *FORTINETQA/FSSO* as a member.
   d. Click *OK*.

To configure an authentication server and create user groups in the CLI:

1. Configure Kerberos authentication:

```
config user ldap
    edit "ldap-kerberos"
        set server "172.18.62.220"
        set cnid "cn"
        set dn "dc=fortinetqa,dc=local"
        set type regular
        set username "CN=root,CN=Users,DC=fortinetqa,DC=local"
        set password *********
    next
end
```

2. Define Kerberos as an authentication service:

```
config user krb-keytab
    edit "http_service"
        set pac-data disable
        set principal "HTTP/FGT.FORTINETQA.LOCAL@FORTINETQA.LOCAL"
        set ldap-server "ldap-kerberos"
        set keytab
"BQIAAABFAAIAEEZPUlRJTkVUUUEuTE9DQUwABEhUVFAAFEZHVC5GT1JUSU5FVFFBLkxPQ0FMAAAAAQAAAAAEAAE
ACKLCMonpitnVAAAARQACABBGT1JUSU5FVFFBLkxPQ0FMAARIVFRQABRGR1QuRk9SVElORVRRQS5MT0NBTAAAAAE
AAAAABAADAAiiwjKJ6YrZ1QAAAE0AAgAQRk9SVElORVRRQS5MT0NBTAAESFRUUAAURkdULkZPUlRJTkVUUUEuTE9
DQUwAAAABAAAAAAQAFwAQUHo9uqR9cSkzyxdzKCEXdwAAAF0AAgAQRk9SVElORVRRQS5MT0NBTAAESFRUUAAURkd
ULkZPUlRJTkVUUUEuTE9DQUwAAAABAAAAAAQAEgAgzee854Aq1HhQiKJZvV4tL2Poy7hMIARQpK8MCB//BIAAAAB
NAAIAEEZPUlRJTkVUUUEuTE9DQUwABEhUVFAAFEZHVC5GT1JUSU5FVFFBLkxPQ0FMAAAAAQAAAAAEABEAEG49vHE
iiBghr63Z/lnwYrU="
```

```
    next
end
```

For information on generating a keytab, see Generating a keytab on a Windows server on page 283.

3. Configure FSSO NTLM authentication:

```
config user fsso
    edit "1"
        set server "172.18.62.220"
        set password *********
    next
end
```

4. Create a user group for Kerberos authentication:

```
config user group
    edit "Ldap-Group"
        set member "ldap" "ldap-kerberos"
    next
end
```

5. Create a user group for NTLM authentication:

```
config user group
    edit "NTLM-FSSO-Group"
        set group-type fsso-service
        set member "FORTINETQA/FSSO"
    next
end
```

Create an authentication scheme and rules

Explicit proxy authentication is managed by authentication schemes and rules. An authentication scheme must be created first, and then the authentication rule.

To create an authentication scheme and rules in the GUI:

1. Create an authentication scheme:
   a. Go to *Policy & Objects* > *Authentication Rules*.
   b. Click *Create New* > *Authentication Schemes*.
   c. Set the *Name* to *Auth-scheme-Negotiate* and select *Negotiate* as the *Method*.
   d. Click *OK*.
2. Create an authentication rule:
   a. Go to *Policy & Objects* > *Authentication Rules*.
   b. Click *Create New* > *Authentication Rules*.
   c. Set the *Name* to *Auth-Rule*, *Source Address* to *all*, and *Protocol* to *HTTP*.
   d. Enable *Authentication Scheme*, and select the just created *Auth-scheme-Negotiate* scheme.
   e. Click *OK*.

To create an authentication scheme and rules in the CLI:

1. Create an authentication scheme:

```
config authentication scheme
    edit "Auth-scheme-Negotiate"
        set method negotiate       <<< Accepts both Kerberos and NTLM as fallback
    next
end
```

2. Create an authentication rule:

```
config authentication rule
    edit "Auth-Rule"
        set status enable
        set protocol http
        set srcaddr "all"
        set ip-based enable
        set active-auth-method "Auth-scheme-Negotiate"
        set comments "Testing"
    next
end
```

Create an explicit proxy policy and assign a user group to the policy

To create an explicit proxy policy and assign a user group to it in the GUI:

1. Go to *Policy & Objects* > *Proxy Policy*.
2. Click *Create New*.
3. Set *Proxy Type* to *Explicit Web* and *Outgoing Interface* to *port1*.
4. Set *Source* to *all*, and the just created user groups *NTLM-FSSO-Group* and *Ldap-Group*.
5. Also set *Destination* to *all*, *Schedule* to *always*, *Service* to *webproxy*, and *Action* to *ACCEPT*.
6. Click *OK*.

To create an explicit proxy policy and assign a user group to it in the CLI:

```
config firewall proxy-policy
    edit 1
        set proxy explicit-web
        set dstintf "port1"
        set srcaddr "all"
        set dstaddr "all"
        set service "web"
        set action accept
        set schedule "always"
        set logtraffic all
        set groups "NTLM-FSSO-Group" "Ldap-Group"
        set av-profile "av"
        set ssl-ssh-profile "deep-custom"
    next
end
```

Verify the configuration

Log in using a domain and system that would be authenticated using the Kerberos server, then enter the `diagnose wad user list` CLI command to verify:

```
# diagnose wad user list
ID: 8, IP: 10.1.100.71, VDOM: vdom1
  user name    : test1@FORTINETQA.LOCAL
  duration     : 389
  auth_type    : IP
  auth_method : Negotiate
  pol_id       : 1
  g_id         : 1
  user_based   : 0
  expire       : no
  LAN:
    bytes_in=4862 bytes_out=11893
  WAN:
    bytes_in=7844 bytes_out=1023
```

Log in using a system that is not part of the domain. The NTLM fallback server should be used:

```
# diagnose wad user list
ID: 2, IP: 10.1.100.202, VDOM: vdom1
  user name    : TEST31@FORTINETQA
  duration     : 7
  auth_type    : IP
  auth_method : NTLM
  pol_id       : 1
  g_id         : 5
  user_based   : 0
  expire       : no
  LAN:
    bytes_in=6156 bytes_out=16149
  WAN:
    bytes_in=7618 bytes_out=1917
```

Generating a keytab on a Windows server

A keytab is used to allow services that are not running Windows to be configured with service instance accounts in the Active Directory Domain Service (AD DS). This allows Kerberos clients to authenticate to the service through Windows Key Distribution Centers (KDCs).

For an explanation of the process, see https://docs.microsoft.com/en-us/windows-server/administration/windows-commands/ktpass.

To generate a keytab on a Windows server:

1. On the server, create a user for the FortiGate:
   - The service name is the FQDN for the explicit proxy interface, such as the hostname in the client browser proxy configuration. In this example, the service name is *FGT*.
   - The account only requires *domain users* membership.

- The password must be very strong.
- The password is set to never expire.

2. Add the FortiGate FQDN in to the Windows DNS domain, as well as in-addr.arpa.
3. Generate the Kerberos keytab using the `ktpass` command on Windows servers and many domain workstations:

```
# ktpass -princ HTTP/<domain name of test fgt>@realm -mapuser <user> -pass <password> -
crypto all -ptype KRB5_NT_PRINCIPAL -out fgt.keytab
```

For example:

```
ktpass -princ HTTP/FGT.FORTINETQA.LOCAL@FORTINETQA.LOCAL -mapuser FGT -pass **********
-crypto all -ptype KRB5_NT_PRINCIPAL -out fgt.keytab
```

If the FortiGate is handling multiple keytabs in Kerberos authentication, use different passwords when generating each keytab.

4. Encode the keytab to base64 in a text file:
   - On Windows: `certutil -encode fgt.keytab tmp.b64 && findstr /v /c:- tmp.b64 > fgt.txt`
   - On Linux: `base64 fgt.keytab > fgt.txt`
   - On MacOS: `base64 -i fgt.keytab -o fgt.txt`
5. Use the code in `fgt.txt` as the keytab parameter when configuring the FortiGate.

Transparent web proxy forwarding

In FortiOS, there is an option to enable proxy forwarding for transparent web proxy policies and regular firewall policies for HTTP and HTTPS.

In previous versions of FortiOS, you could forward proxy traffic to another proxy server (proxy chaining) with explicit proxy. Now, you can forward web traffic to the upstream proxy without having to reconfigure your browsers or publish a proxy auto-reconfiguration (PAC) file.

Once configured, the FortiGate forwards traffic generated by a client to the upstream proxy. The upstream proxy then forwards it to the server.

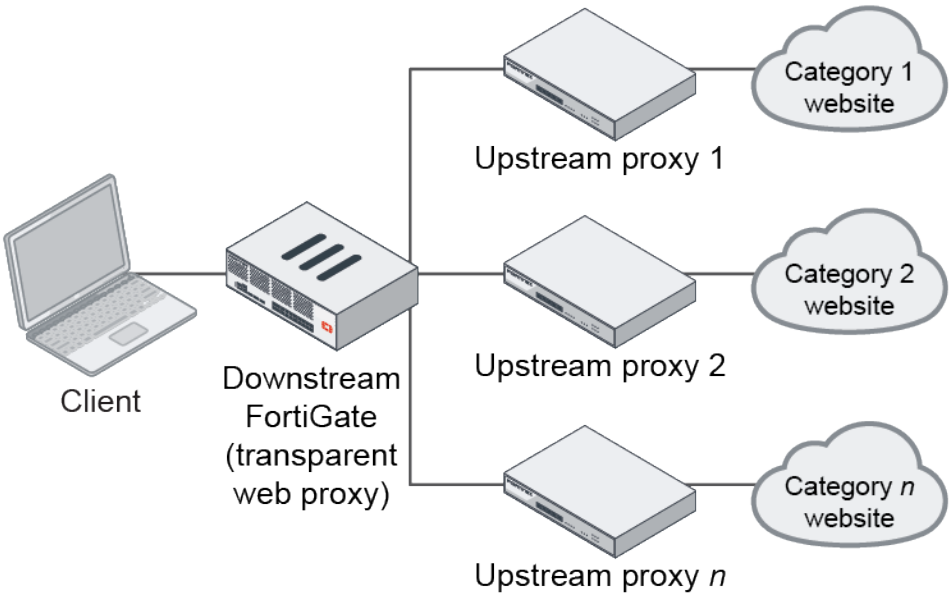
To configure proxy forwarding:

1. Configure the web proxy forwarding server:

```
config web-proxy forward-server
    edit "upStream_proxy_1"
        set ip 172.16.200.20
        set healthcheck enable
        set monitor "http://www.google.ca"
    next
end
```

2. Append the web proxy forwarding server to a firewall policy:

```
config firewall policy
    edit 1
        set name "LAN To WAN"
```



```
        set srcintf "port10"
        set dstintf "port9"
        set srcaddr "all"
        set dstaddr "all"
        set action accept
        set schedule "always"
        set service "ALL"
        set utm-status enable
        set logtraffic all
        set webproxy-forward-server "upStream_proxy_1"
        set fsso disable
        set av-profile "av"
        set ssl-ssh-profile "deep-custom"
        set nat enable
    next
end
```

Selectively forward web requests to a transparent web proxy

Web traffic over HTTP/HTTPS can be forwarded selectively by the FortiGate's transparent web proxy to an upstream web proxy to avoid overwhelming the proxy server. Traffic can be selected by specifying the proxy address, which can be based on a FortiGuard URL category.

The FortiGuard web filter service must be enabled on the downstream FortiGate.

Topology

Forwarding behavior

The forward server will be ignored if the proxy policy matching for a particular session needs the FortiGate to see authentication information inside the HTTP (plain text) message. For example, assume that user authentication is required and a forward server is configured in the transparent web proxy, and the authentication method is an active method (such as basic). When the user or client sends the HTTP request over SSL with authentication information to the FortiGate, the request cannot be forwarded to the upstream proxy. Instead, it will be forwarded directly to the original web server (assuming deep inspection and `http-policy-redirect` are enabled in the firewall policy).

The FortiGate will close the session before the client request can be forwarded if all of the following conditions are met:

- The certificate inspection is configured in the firewall policy that has the `http-policy-redirect` option enabled.
- A previously authenticated IP-based user record cannot be found by the FortiGate's memory during the SSL handshake.
- Proxy policy matching needs the FortiGate to see the HTTP request authentication information.

This means that in order to enable user authentication and use `webproxy-forward-server` in the transparent web proxy policy at the same time, the following best practices should be followed:

- In the firewall policy that has the `http-policy-redirect` option enabled, set `ssl-ssh-profile` to use the `deep-inspection` profile.
- Use IP-based authentication rules; otherwise, the `webproxy-forward-server` setting in the transparent web proxy policy will be ignored.
- Use a passive authentication method such as FSSO. With FSSO, once the user is authenticated as a domain user by a successful login, the web traffic from the user's client will always be forwarded to the upstream proxy as long as the authenticated user remains unexpired. If the authentication method is an active authentication method (such as basic, digest, NTLM, negotiate, form, and so on), the first session containing authentication information will bypass the forward server, but the following sessions will be connected through the upstream proxy.

Sample configuration

On the downstream FortiGate proxy, there are two category proxy addresses used in two separate transparent web proxy policies as the destination address:

- In the policy with `upstream_proxy_1` as the forward server, the proxy address `category_infotech` is used to match URLs in the information technology category.
- In the policy with `upstream_proxy_2` as the forward server, the proxy address `category_social` is used to match URLs in the social media category.

To configure forwarding requests to transparent web proxies:

1. Configure the proxy forward servers:

```
config web-proxy forward-server
    edit "upStream_proxy_1"
        set ip 172.16.200.20
    next
    edit "upStream_proxy_2"
        set ip 172.16.200.46
    next
end
```

2. Configure the web proxy addresses:

```
config firewall proxy-address
    edit "category_infotech"
        set type category
        set host "all"
        set category 52
    next
    edit "category_social"
        set type category
        set host "all"
        set category 37
    next
end
```

3. Configure the firewall policy:

```
config firewall policy
    edit 1
        set srcintf "port10"
        set dstintf "port9"
        set srcaddr "all"
        set dstaddr "all"
        set action accept
        set schedule "always"
        set service "ALL"
        set utm-status enable
        set inspection-mode proxy
        set http-policy-redirect enable
        set ssl-ssh-profile "deep-inspection"
        set av-profile "av"
        set nat enable
    next
end
```

4. Configure the proxy policies:

```
config firewall proxy-policy
    edit 1
        set proxy transparent-web
        set srcintf "port10"
        set dstintf "port9"
        set srcaddr "all"
        set dstaddr "category_infotech"
        set service "webproxy"
        set action accept
        set schedule "always"
        set logtraffic all
        set webproxy-forward-server "upStream_proxy_1"
        set utm-status enable
        set ssl-ssh-profile "deep-inspection"
        set av-profile "av"
    next
    edit 2
        set proxy transparent-web
        set srcintf "port10"
        set dstintf "port9"
        set srcaddr "all"
```

```
            set dstaddr "category_social"
            set service "webproxy"
            set action accept
            set schedule "always"
            set logtraffic all
            set webproxy-forward-server "upStream_proxy_2"
            set utm-status enable
            set ssl-ssh-profile "deep-inspection"
            set av-profile "av"
        next
    end
```

Upstream proxy authentication in transparent proxy mode

A downstream proxy FortiGate that needs to be authenticated by the upstream web proxy can use the basic authentication method to send its username and password, in the base64 format, to the upstream web proxy for authentication. If the authentication succeeds, web traffic that is forwarded from the downstream proxy FortiGate to the upstream proxy can be accepted and forwarded to its destinations.

In this example, a school has a FortiGate acting as a downstream proxy that is configured with firewall policies for each user group (students and staff). In each policy, a forwarding server is configured to forward the web traffic to the upstream web proxy.

The username and password that the upstream web proxy uses to authenticate the downstream proxy are configured on the forwarding server, and are sent to the upstream web proxy with the forwarded HTTP requests.

	Username	Password
student.proxy.local:8080	students	ABC123
staff.proxy.local:8081	staff	123456

On the downstream FortiGate, configure forwarding servers with the usernames and passwords for authentication on the upstream web proxy, then apply those servers to firewall policies for transparent proxy. For explicit web proxy, the forwarding servers can be applied to proxy policies.

When the transparent proxy is configured, clients can access websites without configuring a web proxy in their browser. The downstream proxy sends the username and password to the upstream proxy with forwarded HTTP requests to be authenticated.

To configure the forwarding server on the downstream FortiGate:

```
config web-proxy forward-server
    edit "Student_Upstream_WebProxy"
        set addr-type fqdn
        set fqdn "student.proxy.local"
        set port 8080
        set username "student"
        set password ABC123
    next
    edit "Staff_Upstream_WebProxy"
        set addr-type fqdn
        set fqdn "staff.proxy.local"
        set port 8081
```

```
        set username "staff"
        set password 123456
    next
end
```

To configure firewall policies for transparent proxy:

```
config firewall policy
    edit 1
        set srcintf "Vlan_Student"
        set dstintf "port9"
        set srcaddr "Student_Subnet"
        set dstaddr "all"
        set action accept
        set schedule "always"
        set service "ALL"
        set utm-status enable
        set inspection-mode proxy
        set ssl-ssh-profile "deep-inspection"
        set av-profile "av"
        set webproxy-forward-server "Student_Upstream_WebProxy"
        set nat enable
    next
    edit 2
        set srcintf "Vlan_Staff"
        set dstintf "port9"
        set srcaddr "Staff_Subnet"
        set dstaddr "all"
        set action accept
        set schedule "always"
        set service "ALL"
        set utm-status enable
        set inspection-mode proxy
        set ssl-ssh-profile "deep-inspection"
        set av-profile "av"
        set webproxy-forward-server "Staff_Upstream_WebProxy"
        set nat enable
    next
end
```

Multiple dynamic header count

Multiple dynamic headers are supported for web proxy profiles, as well as Base64 encoding and the append/new options.

Administrators only have to select the dynamic header in the profile. The FortiGate will automatically display the corresponding static value. For example, if the administrator selects the `$client-ip` header, the FortiGate will display the actual client IP address.

The supported headers are:

`$client-ip`	Client IP address
`$user`	Authentication user name

$domain	User domain name
$local_grp	Firewall group name
$remote_grp	Group name from authentication server
$proxy_name	Proxy realm name

To configure dynamic headers using the CLI:

Since authentication is required, FSSO NTLM authentication is configured in this example.

1. Configure LDAP:

```
config user ldap
    edit "ldap-kerberos"
        set server "172.18.62.220"
        set cnid "cn"a
        set dn "dc=fortinetqa,dc=local"
        set type regular
        set username "CN=root,CN=Users,DC=fortinetqa,DC=local"
        set password *********
    next
end
```

2. Configure FSSO:

```
config user fsso
    edit "1"
        set server "172.18.62.220"
        set password *********
    next
end
```

3. Configure a user group:

```
config user group
    edit "NTLM-FSSO"
        set group-type fsso-service
        set member "FORTINETQA/FSSO"
    next
end
```

4. Configure an authentication scheme:

```
config authentication scheme
    edit "au-sch-ntlm"
        set method ntlm
    next
end
```

5. Configure an authentication rule:

```
config authentication rule
    edit "au-rule-fsso"
        set srcaddr "all"
        set active-auth-method "au-sch-ntlm"
    next
end
```

6. Create a web proxy profile that adds a new dynamic and custom `Via` header:

```
config web-proxy profile
    edit "test"
        set log-header-change enable
        config headers
            edit 1
                set name "client-ip"
                set content "$client-ip"
            next
            edit 2
                set name "Proxy-Name"
                set content "$proxy_name"
            next
            edit 3
                set name "user"
                set content "$user"
            next
            edit 4
                set name "domain"
                set content "$domain"
            next
            edit 5
                set name "local_grp"
                set content "$local_grp"
            next
            edit 6
                set name "remote_grp"
                set content "$remote_grp"
            next
            edit 7
                set name "Via"
                set content "Fortigate-Proxy"
            next
        end
    next
end
```

7. In the proxy policy, append the web proxy profile created in the previous step:

```
config firewall proxy-policy
    edit 1
        set proxy explicit-web
        set dstintf "port1"
        set srcaddr "all"
        set dstaddr "all"
        set service "web"
        set action accept
        set schedule "always"
        set logtraffic all
        set groups "NTLM-FSSO"
        set webproxy-profile "test"
        set utm-status enable
        set av-profile "av"
        set webfilter-profile "content"
        set ssl-ssh-profile "deep-custom"
```

```
    next
end
```

8. Once traffic is being generated from the client, look at the web filter logs to verify that it is working.

   The corresponding values for all the added header fields are shown in the *Web Filter* card at *Log & Report* > *Security Events*, in the *Change headers* section at the bottom of the *Log Details* pane.

```
1: date=2019-02-07 time=13:57:24 logid="0344013632" type="utm" subtype="webfilter"
eventtype="http_header_change" level="notice" vd="vdom1" eventtime=1549576642 policyid=1
transid=50331689 sessionid=1712788383 user="TEST21@FORTINETQA" group="NTLM-FSSO"
profile="test" srcip=10.1.100.116 srcport=53278 dstip=172.16.200.46 dstport=80
srcintf="port2" srcintfrole="undefined" dstintf="port1" dstintfrole="undefined" proto=6
service="HTTP" url="http://172.16.200.46/" agent="curl/7.22.0" chgheaders="Added=client-
ip: 10.1.100.116|Proxy-Name: 1.1 100D.qa|user: TEST21|domain: FORTINETQA|local_grp:
NTLM-FSSO|remote_grp: FORTINETQA/FSSO|Via: Fortigate-Proxy"
```

Restricted SaaS access

Large organizations may want to restrict SaaS access to resources like Microsoft Office 365, Google Workspace, and Dropbox by tenant to block non-company login attempts and secure the users from accessing non-approved cloud resources. Many cloud vendors enable this by applying tenant restrictions for access control. For example, users accessing Microsoft 365 applications with tenant restrictions through the corporate proxy will only be allowed to log in as the company's tenant and access the organization's applications.

To implement this, access requests from the clients pass through the company's web proxy, which inserts headers to notify the SaaS service to apply tenant restrictions with the permitted tenant list. Users are redirected the SaaS service login page, and are only allowed to log in if they belong to the permitted tenant list.

For more information, refer to the vendor-specific documentation:

- Office 365: Restrict access to a tenant
- Google Workspace: Block access to consumer accounts
- Dropbox: Network control

Basic configuration

A web proxy profile can specify access permissions for Microsoft Office 365, Google Workspace, and Dropbox by inserting vendor-defined headers that restrict access to the specific accounts. Custom headers can also be inserted for any destination. The web proxy profile can then be applied to a firewall policy to control the header's insertion.

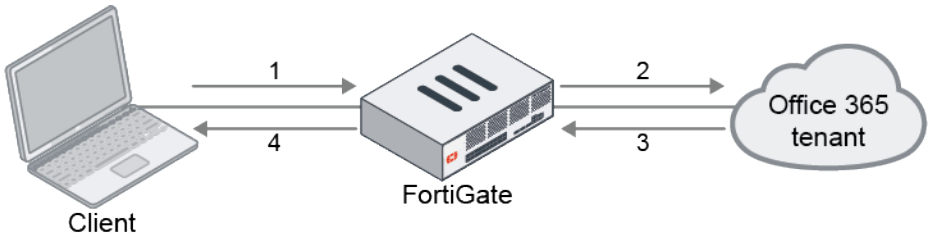
To implement Office 365 tenant restriction, Google Workspace account access control, and Dropbox network access control:

1. Configure a web proxy profile according to the vendors' specifications:
   a. Set the header name (defined by the service provider).
   b. Set the traffic destination (the service provider).
   c. Set the HTTP header content to be inserted into the traffic (defined by your settings).

```
config web-proxy profile
    edit <name>
        config headers
            edit <id>
```

```
                set name <string>
                set dstaddr <address>
                set action add-to-request
                set base64-encoding disable
                set add-option new
                set protocol https http
                set content <string>
            next
        end
    next
end
```

2. Apply the web proxy profile to a policy. SSL deep inspection must be used in the firewall policy:



The following table lists the vendor-specific `config headers` settings that must be configured in the web proxy profile (`config web-proxy profile`):

Setting	Vendor specification		
	Microsoft Office 365	Google Workspace	Dropbox
`name <string>`	• `Restrict-Access-To-Tenants` • `Restrict-Access-Context`	• `X-GoogApps-Allowed-Domains`	• `X-Dropbox-allowed-Team-Ids`
`dstaddr <address>`	• Use the built-in `Microsoft Office 365` address.	• Use the built-in `G Suite` address.	• Use the built-in `wildcard.dropbox.com` address.
`content <string>`	• Enter the domain for `Restrict-Access-To-Tenants`. • Enter the directory ID for `Restrict-Access-Context`.	• Enter the domain.	• Enter the Dropbox team ID.

Due to vendors' changing requirements, these settings may no longer comply with the vendors' official guidelines. See the vendor documentation for more details.

Microsoft Office 365 example

In this example, a web proxy profile is created to control permissions for Microsoft Office 365 to allow corporate domains and deny personal accounts, such as Hotmail and Outlook that are accessed through login.live.com.

1. When a user attempts to access login.microsoftonline.com, login.microsoft.com, or login.windows.net, the traffic will match a proxy inspection mode firewall policy with the assigned web proxy profile.
2. The web proxy profile adds new headers to the customer tenant, indicating the allowed domain and restricted access for personal accounts. Next, the FortiGate starts a new connection with the Microsoft Office 365 domain controller including the new headers.
3. The Microsoft Office 365 domain controller assesses this data and will allow or deny this access, then sends a reply to the FortiGate.
4. The FortiGate sends a reply to the client.

The FortiGate will only indicate the correct domains to be allowed or denied through the headers to Microsoft. The custom sign-in portal in the browser is generated by Microsoft.

Configuration summary

The following must be configured in FortiOS:

- An FQDN address for login.live.com
- An SSL inspection profile that uses deep inspection with an exemption for login.live.com

Ensure that the firewall certificate is installed on the client machines. A company certificate signed by an internal CA is recommended.

- A web filter profile in proxy mode with static URL filters for the SNI URLs
- A web proxy profile that adds new headers to the customer tenant
- A firewall policy using proxy mode inspection that applies the configured SSL SSL inspection, web filter, and web proxy profiles

The `Restrict-Access-To-Tenants` and `Restrict-Access-Context` headers are inserted for incoming requests to: login.microsoftonline.com, login.microsoft.com, and login.windows.net, which are part of the `Microsoft Office 365` address group.

To restrict access to personal accounts using the login.live.com domain, the `sec-Restrict-Tenant-Access-Policy` header is inserted and uses `restrict-msa` as the header content.

Before configuring the FortiGate, collect the information related to the company domain in the Office 365 contract.

- `Restrict-Access-To-Tenants`: your <domain.com>
- `Restrict-Access-Context`: Directory ID

To find the Directory ID related to the domain, locate it in the Azure portal, or use the whatismytenantid.com open tool.

To configure the FortiGate:

1. Add the FQDN address for login.live.com:

```
config firewall address
    edit "login.live.com"
        set type fqdn
        set fqdn "login.live.com"
    next
end
```

2. Configure the SSL inspection profile. In this example, the `deep-inspection` profile is cloned, and the `live.com` FQDN is removed from the exemption list.
   a. Clone the `deep-inspection` profile:

```
config firewall ssl-ssh-profile
    clone "deep-inspection" to "Tenant"
end
```

   b. Edit the `Tenant` profile and remove `live.com` from the `config ssl-exempt` list.
3. Configure the URL filter list:

```
config webfilter urlfilter
    edit 1
        set name "Auto-webfilter-urlfilter"
        config entries
            edit 1
                set url "login.microsoftonline.com"
                set action allow
            next
            edit 2
                set url "login.microsoft.com"
                set action allow
            next
            edit 3
                set url "login.windows.net"
                set action allow
            next
            edit 4
                set url "login.live.com"
                set action allow
            next
        end
    next
end
```

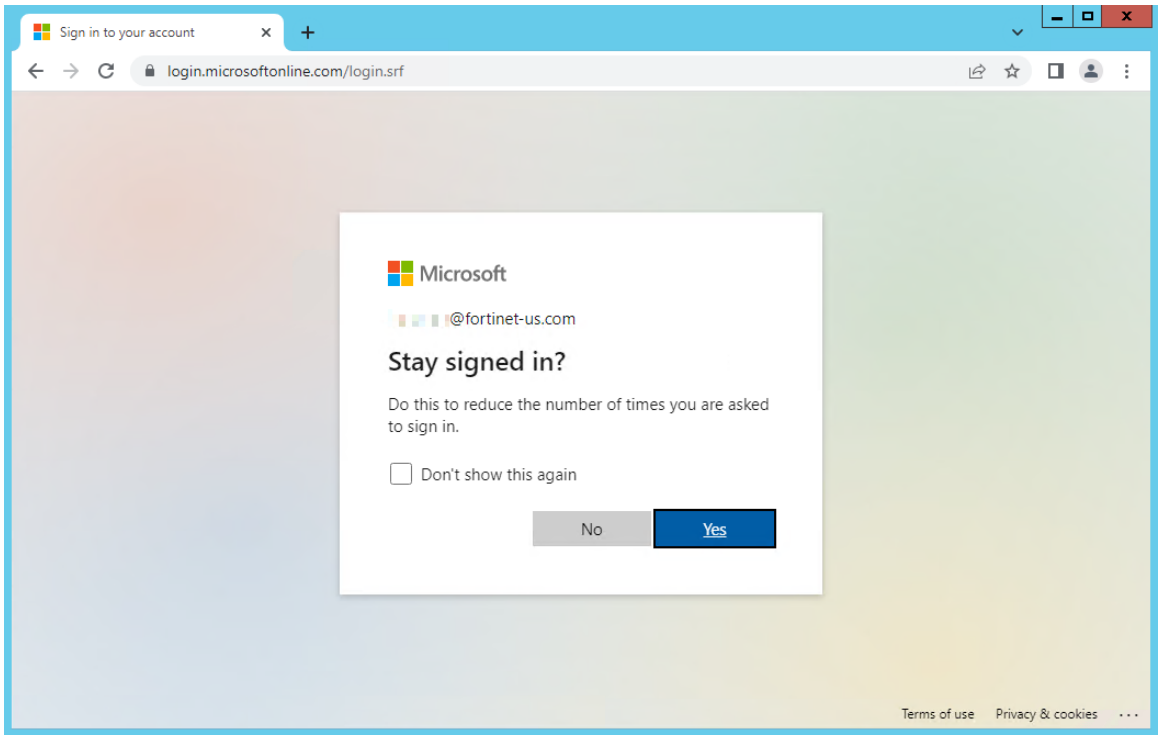
4. Configure the web filter profile:

```
config webfilter profile
    edit "Tenant"
        set comment "Office 365"
        set feature-set proxy
        config web
            set urlfilter-table 1
        end
    next
end
```

5. Configure the web proxy profile (enter the header names exactly as shown):

```
config web-proxy profile
    edit "SaaS-Tenant-Restriction"
        set header-client-ip pass
        set header-via-request pass
        set header-via-response pass
        set header-x-forwarded-for pass
        set header-x-forwarded-client-cert pass
        set header-front-end-https pass
        set header-x-authenticated-user pass
        set header-x-authenticated-groups pass
        set strip-encoding disable
        set log-header-change disable
        config headers
            edit 1
                set name "Restrict-Access-To-Tenants"
                set dstaddr "login.microsoft.com" "login.microsoftonline.com"
"login.windows.net"
                set action add-to-request
                set base64-encoding disable
                set add-option new
                set protocol https http
                set content <domain>
            next
            edit 2
                set name "Restrict-Access-Context"
                set dstaddr "login.microsoftonline.com" "login.microsoft.com"
"login.windows.net"
                set action add-to-request
                set base64-encoding disable
                set add-option new
                set protocol https http
                set content <directory_ID>
            next
            edit 3
                set name "sec-Restrict-Tenant-Access-Policy"
                set dstaddr "login.live.com"
                set action add-to-request
                set base64-encoding disable
                set add-option new
                set protocol https http
                set content "restrict-msa"
            next
        end
    next
end
```

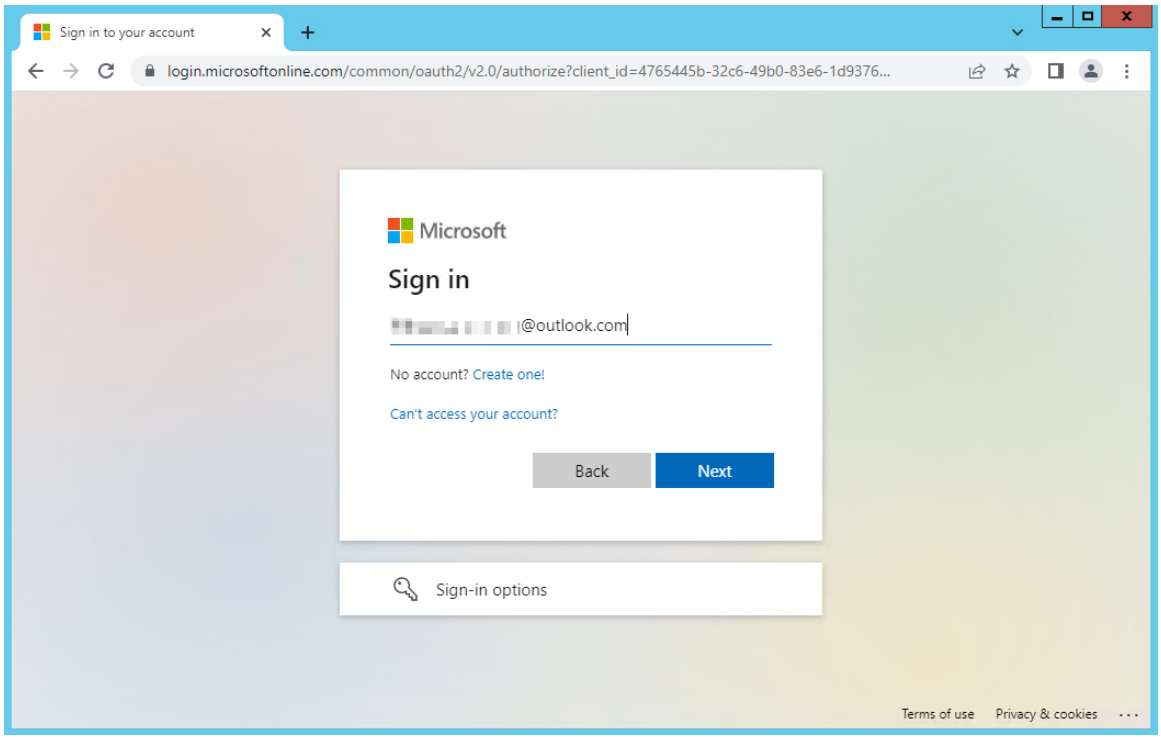
6. Configure the firewall policy:



```
config firewall policy
    edit 10
        set name "Tenant"
        set srcintf "port2"
        set dstintf "port1"
        set action accept
        set srcaddr "users-lan"
```

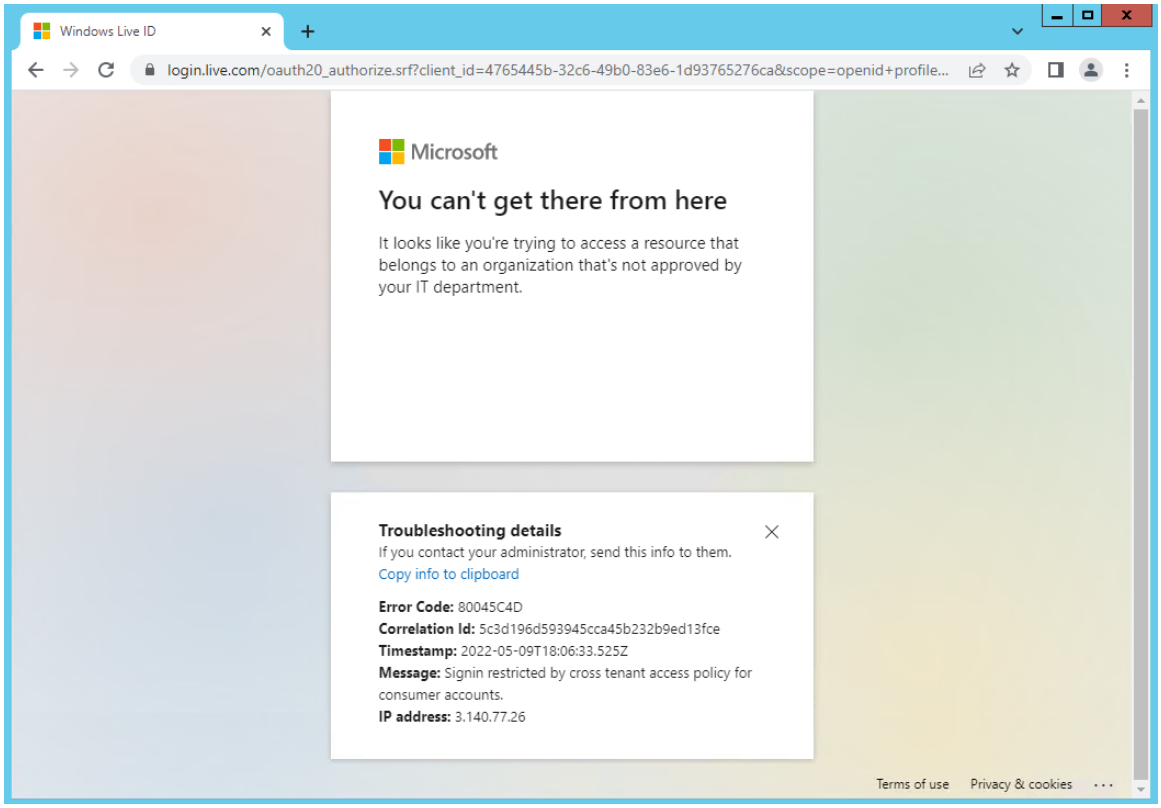
```
        set dstaddr "login.microsoft.com" "login.microsoftonline.com"
"login.windows.net" "login.live.com"
        set schedule "always"
        set service "HTTP" "HTTPS"
        set utm-status enable
        set inspection-mode proxy
        set webproxy-profile "SaaS-Tenant-Restriction"
        set ssl-ssh-profile "Tenant"
        set webfilter-profile "Tenant"
        set logtraffic all
        set nat enable
    next
end
```

Testing the access



To test the access to corporate domains and personal accounts:

1. Get a client to log in with their corporate email using the login.microsoftonline.com domain.



2. The client is able to enter their credentials and log in successfully.

3. Get a client to log in to their personal Outlook account.

4. After the client enters their credentials, a message appears that they cannot access this resource because it is restricted by the cross-tenant access policy.

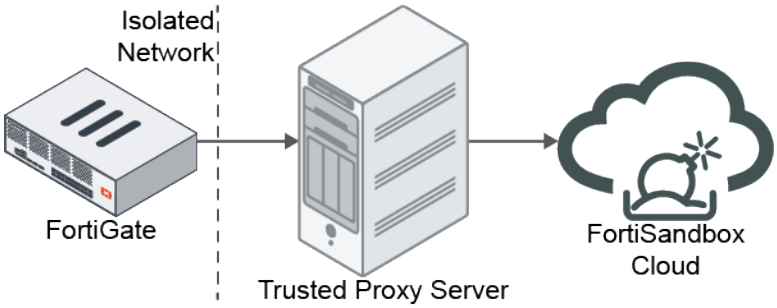
Verifying the header insertion

To verify the header insertion for corporate domains and personal accounts:

1. On the FortiGate, start running the WAD debugs:

```
# diagnose wad debug enable category http
# diagnose wad debug enable level info
# diagnose debug enable
```

2. After a client attempts to access corporate domains, verify that the header information is sent to the Microsoft Active Directory:



```
[I][p:234][s:2481][r:33] wad_dump_fwd_http_req            :2567  hreq=0x7fc75f0cd468
Forward request to server:

Explicit proxy and FortiGate Cloud Sandbox

Explicit proxy connections can leverage FortiGate Cloud Sandbox for advanced threat scanning and updates. This allows FortiGates behind isolated networks to connect to FortiCloud services.

To configure FortiGuard services to communicate with an explicit proxy server:

```
config system fortiguard
    set proxy-server-ip 172.16.200.44
    set proxy-server-port 3128
    set proxy-username "test1"
    set proxy-password *********
end
```

To verify the explicit proxy connection to FortiGate Cloud Sandbox:

```
# diagnose debug application forticldd -1
Debug messages will be on for 30 minutes.
# diagnose debug enable
[2942] fds_handle_request: Received cmd 23 from pid-2526, len 0

Proxy chaining

For the explicit web proxy you can configure web proxy forwarding servers to use proxy chaining to redirect web proxy sessions to other proxy servers. Proxy chaining can be used to forward web proxy sessions from the FortiGate unit to one or more other proxy servers on your network or on a remote network. You can use proxy chaining to integrate the FortiGate explicit web proxy with a web proxy solution that you already have in place.

A FortiGate unit can forward sessions to most web proxy servers including a remote FortiGate unit with the explicit web proxy enabled. No special configuration of the explicit web proxy on the remote FortiGate unit is required.

You can deploy the explicit web proxy with proxy chaining in an enterprise environment consisting of small satellite offices and a main office. If each office has a FortiGate unit, users at each of the satellite offices can use their local FortiGate unit as an explicit web proxy server. The satellite office FortiGate units can forward explicit web proxy sessions to an explicit web proxy server at the central office. From here the sessions can connect to web servers on the Internet.

FortiGate proxy chaining does not support web proxies in the proxy chain authenticating each other.

The following examples assume explicit web proxy has been enabled.

To enable explicit web proxy in the GUI:

1. Go to *System* > *Feature Visibility*.
2. In the *Security Features* column, enable *Explicit Proxy*.
3. Configure the explicit web proxy settings. See Explicit web proxy on page 258.

To add a web proxy forwarding server in the GUI:

1. Go to *Network* > *Explicit Proxy*. The *Explicit Proxy* page opens.
2. In the *Web Proxy Forwarding Servers* section, click *Create New*.
3. Configure the server settings:

Name	Enter the name of the forwarding server.
Proxy Address Type	Select the type of IP address of the forwarding server. A forwarding server can have an *FQDN* or *IP* address.
Proxy Address	Enter the IP address of the forwarding server.
Port	Enter the port number on which the proxy receives connections. Traffic leaving the FortiGate explicit web proxy for this server has its destination port number changed to this number.
Server Down Action	Select the action the explicit web proxy will take if the forwarding server is down. • *Block*: Blocks the traffic if the remote server is down. • *Use Original Server*: Forwards the traffic from the FortiGate to its destination as if no forwarding server is configured.
Health Monitor	Select to enable health check monitoring.
Health Check Monitor Site	Enter the address of a remote site.

4. Click *OK*.

Example

The following example adds a web proxy forwarding server named `fwd-srv` at address `proxy.example.com` and port `8080`.

To add a web proxy forwarding server in the CLI:

```
config web-proxy forward-server
    edit fwd-srv
        set addr-type fqdn
        set fqdn proxy.example.com
        set port 8080
    next
end
```

Web proxy forwarding server monitoring and health checking

By default, a FortiGate unit monitors a web proxy forwarding server by forwarding a connection to the remote server every 10 seconds. The remote server is assumed to be down if it does not respond to the connection. FortiGate continues checking the server. The server is assumed to be back up when the server sends a response. If you enable health checking, the FortiGate unit attempts to get a response from a web server every 10 seconds by connecting through the remote forwarding server.

You can configure health checking for each remote server and specify a different website to check for each one.

If the remote server is found to be down you can configure the FortiGate unit to block sessions until the server comes back up or to allow sessions to connect to their destination, bypassing the remote forwarding server. You cannot configure the FortiGate unit to fail over to another remote forwarding server.

To configure proxy server monitor and health checking in the GUI:

1. Go to *Network* > *Explicit Proxy*. The *Explicit Proxy* page opens.
2. In the *Web Proxy Forwarding Servers* section, edit a server.
3. Configure the *Server Down Action* and *Health Monitor* settings.

Server Down Action	Select the action the explicit web proxy will take if the forwarding server is down. • *Block*: Blocks the traffic if the remote server is down. • *Use Original Server*: Forwards the traffic from the FortiGate to its destination as if no forwarding server configured.
Health Monitor	Select to enable health check monitoring.
Health Check Monitor Site	Enter the address of a remote site.

4. Click *OK*.

Example

The following example enables health checking for a web proxy forwarding server and sets the server down option to bypass the forwarding server if it is down.

To configure proxy server monitor and health checking in the CLI:

```
config web-proxy forward-server
    edit fwd-srv
        set healthcheck enable
        set monitor http://example.com
        set server-down-option pass
    next
end
```

Grouping forwarding servers and load balancing traffic to the servers

You can add multiple web proxy forwarding servers to a forwarding server group and then add the server group to an explicit web proxy policy instead of adding a single server. Forwarding server groups are created from the FortiGate CLI but can be added to policies from the web-based manager (or from the CLI).

When you create a forwarding server group you can select a load balancing method to control how sessions are load balanced to the forwarding servers in the server group. Two load balancing methods are available:

- *Weighted* load balancing sends more sessions to the servers with higher weights. You can configure the weight for each server when you add it to the group.
- *Least-session* load balancing sends new sessions to the forwarding server that is processing the fewest sessions.

When you create a forwarding server group you can also enable *affinity*. Enable affinity to have requests from the same client processed by the same server. This can reduce delays caused by using multiple servers for a single multi-step client operation. Affinity takes precedence over load balancing.

You can also configure the behavior of the group if all of the servers in the group are down. You can select to block traffic or you can select to have the traffic pass through the FortiGate explicit proxy directly to its destination instead of being sent to one of the forwarding servers.

Example

The following example adds a forwarding server group that uses weighted load balancing to load balance traffic to three forwarding servers. Server weights are configured to send most traffic to `server2`. The group has `affinity` enabled and blocks traffic if all of the forward servers are down.

To configure load balancing in the CLI:

```
config web-proxy forward-server
    edit server_1
        set ip 172.20.120.12
        set port 8080
    next
    edit server_2
        set ip 172.20.120.13
        set port 8000
    next
    edit server_3
        set ip 172.20.120.14
        set port 8090
    next
end
config web-proxy forward-server-group
    edit New-fwd-group
        set affinity enable
        set ldb-method weighted
        set group-down-option block
        config server-list
            edit server_1
                set weight 10
            next
            edit server_2
                set weight 40
            next
            edit server_3
                set weight 10
            next
        end
    next
end
```

Adding proxy chaining to an explicit web proxy policy

You can enable proxy chaining for web proxy sessions by adding a web proxy forwarding server or server group to an explicit web proxy policy. In a policy you can select one web proxy forwarding server or server group. All explicit web proxy traffic accepted by this security policy is forwarded to the specified web proxy forwarding server or server group.

To add an explicit web proxy forwarding server in the GUI:

1. Go to *Policy & Objects* > *Proxy Policy* and click *Create New*.
2. Configure the policy settings:

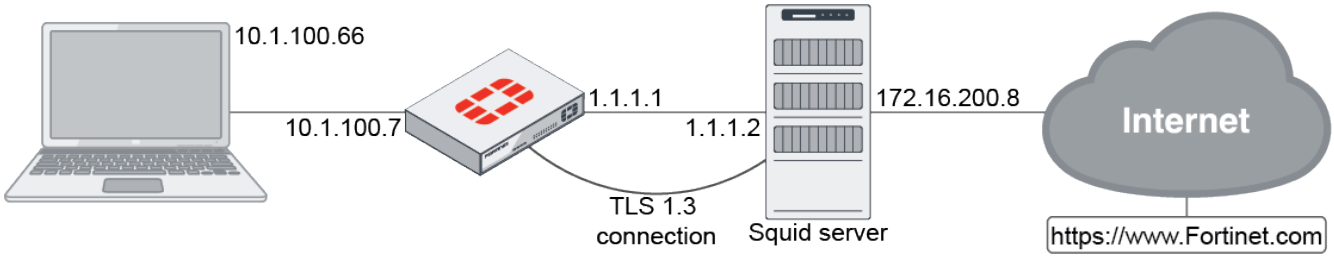
Proxy Type	Explicit Web
Outgoing Interface	wan1
Source	Internal_subnet
Destination	all
Schedule	always
Service	webproxy
Action	Accept

3. Enable *Web Proxy Forwarding Server* and select the forwarding server, (for example,*fwd-srv*).
4. Click *OK*.

Example

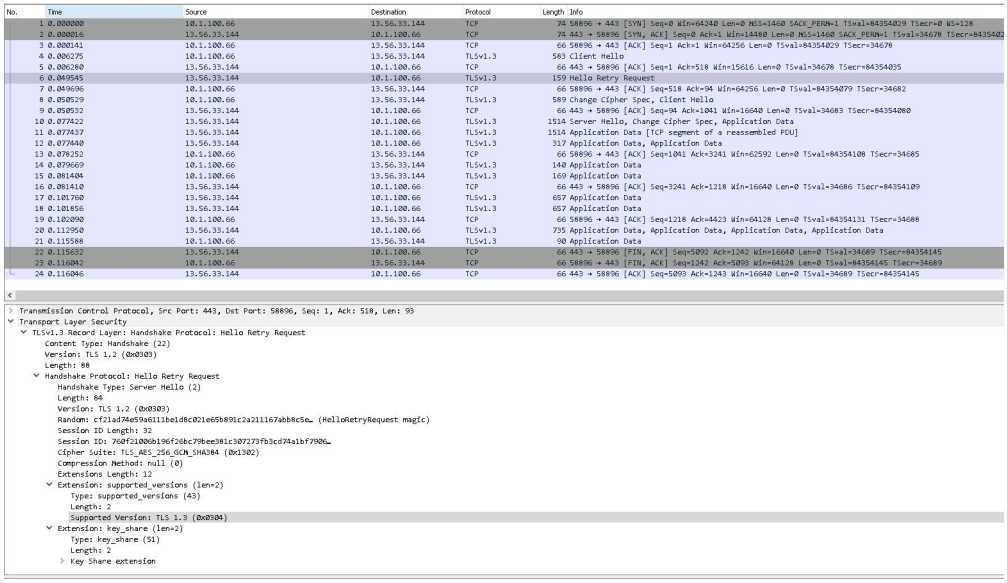
The following example adds a security policy that allows all users on the `10.31.101.0` subnet to use the explicit web proxy for connections through the `wan1` interface to the Internet. The policy forwards web proxy sessions to a remote forwarding server named *fwd-srv*.

To add an explicit web proxy forwarding server in the CLI:



```
config firewall proxy-policy
    edit 0
        set proxy explicit-web
        set dstintf "wan1"
        set srcaddr "Internal_subnet"
        set dstaddr "all"
        set service "webproxy"
        set action accept
        set schedule "always"
        set webproxy-forward-server "fwd-srv"
    next
end
```

Using TLS 1.3 with web proxy forward servers



A FortiGate can handle TLS 1.3 traffic in both deep and certificate inspection modes.

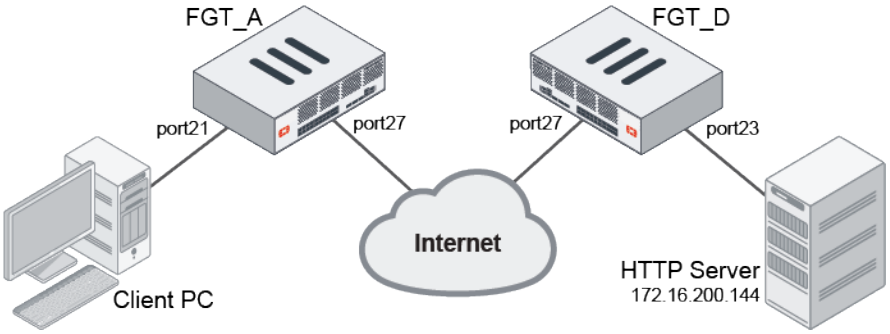
Example

The following example demonstrates that the Squid server and the FortiGate can handle TLS 1.3 traffic.

The following output from the Squid server demonstrates that the FortiGate supports TLS 1.3 traffic and forwards the hello retry request back to the client PC. The client PC then sends the client hello again, and the connection is successfully established.

WAN optimization SSL proxy chaining

An SSL server does not need to be defined for WAN optimization (WANOpt) SSL traffic offloading (traffic acceleration). The server side FortiGate uses an SSL profile to resign the HTTP server's certificate, both with and without an external proxy, without an SSL server configured. GCM and ChaCha ciphers can also be used in the SSL connection.



Examples

In these examples, HTTPS traffic is accelerated without configuring an SSL server, including with a proxy in between, and when the GCM or ChaCha ciphers are used.

Example 1

In this example, the server certificate is resigned by the server side FortiGate, and HTTPS traffic is accelerated without configuring an SSL server.

HTTPS traffic with the GCM or ChaCha cipher can pass though WANOpt tunnel.

To configure FGT_A:

1. Configure the hard disk to perform WANOpt:

```
config system storage
    edit "HDD2"
        set status enable
        set usage wanopt
        set wanopt-mode mix
    next
end
```

2. Configure the WANOpt peer and profile:

```
config wanopt peer
    edit "FGT-D"
        set ip 120.120.120.172
    next
end
```

```
config wanopt profile
    edit "test"
        config http
            set status enable
            set ssl enable
        end
    next
end
```

3. Create an SSL profile with deep inspection on HTTPS port 443:

```
config firewall ssl-ssh-profile
    edit "ssl"
        config https
            set ports 443
            set status deep-inspection
        end
    next
end
```

4. Configure a firewall policy in proxy mode with WANOpt enabled and the WANOpt profile selected:

```
config firewall policy
    edit 1
        set name "WANOPT-A"
```

```
        set srcintf "port21"
        set dstintf "port27"
        set action accept
        set srcaddr "all"
        set dstaddr "all"
        set schedule "always"
        set service "ALL"
        set utm-status enable
        set inspection-mode proxy
        set profile-protocol-options "protocol"
        set ssl-ssh-profile "ssl"
        set wanopt enable
        set wanopt-profile "test"
        set nat enable
    next
end
```

To configure FGT_D:

1. Configure the hard disk to perform WANOpt:

```
config system storage
    edit "HDD2"
        set status enable
        set usage wanopt
        set wanopt-mode mix
    next
end
```

2. Configure the WANOpt peer:

```
config wanopt peer
    edit "FGT-A"
        set ip 110.110.110.171
    next
end
```

3. Create an SSL profile with deep inspection on HTTPS port 443. The default *Fortinet_CA_SSL* certificate is used to resign the server certificate:

```
config firewall ssl-ssh-profile
    edit "ssl"
        config https
            set ports 443
            set status deep-inspection
        end
    next
end
```

4. Configure a firewall policy in proxy mode with WANOpt enabled and passive WANOpt detection:

```
config firewall policy
    edit 1
        set name "WANOPT-B"
        set srcintf "port27"
        set dstintf "port23"
        set action accept
        set srcaddr "all"
```

```
        set dstaddr "all"
        set schedule "always"
        set service "ALL"
        set utm-status enable
        set inspection-mode proxy
        set wanopt enable
        set wanopt-detection passive
        set nat enable
    next
end
```

5. Configure a proxy policy to apply the SSL profile:

```
config firewall proxy-policy
    edit 100
        set proxy wanopt
        set dstintf "port23"
        set srcaddr "all"
        set dstaddr "all"
        set service "ALL"
        set action accept
        set schedule "always"
        set utm-status enable
        set profile-protocol-options "protocol"
        set ssl-ssh-profile "ssl"
    next
end
```

To confirm that traffic is accelerated:

1. On the client PC, curl a 10MB test sample for the first time:

```
root@client:/tmp# curl -k https://172.16.200.144/test_10M.pdf -O
  % Total    % Received % Xferd  Average Speed   Time    Time     Time  Current
                                 Dload  Upload   Total   Spent    Left  Speed
100 9865k  100 9865k    0     0   663k      0  0:00:14  0:00:15 --:--:-- 1526k
```

   It takes 15 seconds to finish the download.

2. On FGT_A, check the WAD statistics:

```
# diagnose wad stats worker.tunnel
comp.n_in_raw_bytes                  10155840
comp.n_in_comp_bytes                 4548728
comp.n_out_raw_bytes                 29624
comp.n_out_comp_bytes                31623

# diagnose wad stats worker.protos.http
wan.bytes_in                         0
wan.bytes_out                        0
lan.bytes_in                         760
lan.bytes_out                        10140606
tunnel.bytes_in                      4548728
tunnel.bytes_out                     31623
```

3. Curl the same test sample a second time:

```
root@client:/tmp# curl -k https://172.16.200.144/test_10M.pdf -O
  % Total    % Received % Xferd  Average Speed   Time    Time     Time  Current
```

```
                                 Dload  Upload   Total   Spent    Left  Speed
100 9865k  100 9865k    0     0   663k      0  0:00:01  0:00:01 --:--:-- 1526k
```

It now takes less than one second to finish the download.

4. On FGT_A, check the WAD statistics again:

```
# diagnose wad stats worker.tunnel
comp.n_in_raw_bytes                  10181157
comp.n_in_comp_bytes                 4570331
comp.n_out_raw_bytes                 31627
comp.n_out_comp_bytes                34702

# diagnose wad stats worker.protos.http
wan.bytes_in                         0
wan.bytes_out                        0
lan.bytes_in                         1607
lan.bytes_out                        20286841
tunnel.bytes_in                      4570331
tunnel.bytes_out                     34702
```

The tunnel bytes are mostly unchanged, but the LAN bytes are doubled. This means that the bytes of the second curl come from the cache, showing that the traffic is accelerated.

To confirm that a curl using the GCM cipher is accepted and accelerated:

1. On the client PC, curl a 10MB test sample with the GCM cipher:

```
root@client:/tmp# curl -v -k --ciphers DHE-RSA-AES128-GCM-SHA256
https://172.16.200.144/test_10M.pdf -O
*   Trying 172.16.200.144...
* TCP_NODELAY set
  % Total    % Received % Xferd  Average Speed   Time    Time     Time  Current
                                 Dload  Upload   Total   Spent    Left  Speed
  0     0    0     0    0     0      0      0 --:--:-- --:--:-- --:--:--     0*
Connected to 172.16.200.144 (172.16.200.144) port 443 (#0)

* Closing connection 0
```

Example 2

In this example, an external proxy is added to the configuration in Example 1.

To reconfigure FGT_A:

```
config firewall profile-protocol-options
    edit "protocol"
        config http
            set ports 80 8080
            unset options
            unset post-lang
        end
    next
end
```

To reconfigure FGT_D:

1. Configure a new firewall policy for traffic passing from port27 to port29:

```
config firewall policy
    edit 1
        set name "WANOPT-B"
        set srcintf "port27"
        set dstintf "port29"
        set action accept
        set srcaddr "all"
        set dstaddr "all"
        set schedule "always"
        set service "ALL"
        set utm-status enable
        set inspection-mode proxy
        set wanopt enable
        set wanopt-detection passive
        set nat enable
    next
end
```

2. Configure a proxy policy for traffic on destination interface port29:

```
config firewall proxy-policy
    edit 100
        set proxy wanopt
        set dstintf "port29"
        set srcaddr "all"
        set dstaddr "all"
        set service "ALL"
        set action accept
```

```
        set schedule "always"
        set profile-protocol-options "protocol"
        set ssl-ssh-profile "ssl"
    next
end
```

To confirm that HTTPS traffic is still being accelerated:

1. On the client PC, curl the same 10MB test sample through the explicit proxy:

```
root@client:/tmp# curl -x 100.100.100.174:8080 -v -k https://172.16.200.144/test_10M.pdf
-O
  % Total    % Received % Xferd  Average Speed   Time    Time     Time  Current
                                 Dload  Upload   Total   Spent    Left  Speed
100 9865k  100 9865k    0     0   663k      0  0:00:01  0:00:01 --:--:-- 1526k
```

   It takes less than a second to finish the download.

Agentless NTLM authentication for web proxy

Agentless Windows NT LAN Manager (NTLM) authentication includes support for the following items:

- Multiple servers
- Individual users

You can use multiple domain controller servers for the agentless NTLM. They can be used for load balancing and high service stability.

You can also use user-based matching in groups for Kerberos and agentless NTLM. In these scenarios, FortiOS matches the user's group information from an LDAP server.

To support multiple domain controllers for agentless NTLM using the CLI:

1. Configure an LDAP server:

```
config user ldap
    edit "ldap-kerberos"
        set server "172.18.62.177"
        set cnid "cn"
        set dn "dc=fortinetqa,dc=local"
        set type regular
        set username "CN=root,CN=Users,DC=fortinetqa,DC=local"
        set password *********
    next
end
```

2. Configure multiple domain controllers:

```
config user domain-controller
    edit "dc1"
        set ip-address 172.18.62.177
        config extra-server
            edit 1
                set ip-address 172.18.62.220
            next
        end
```

```
        set ldap-server "ldap-kerberos"
    next
end
```

3. Create an authentication scheme and rule:

```
config authentication scheme
    edit "au-ntlm"
        set method ntlm
        set domain-controller "dc1"
    next
end
config authentication rule
    edit "ru-ntlm"
        set srcaddr "all"
        set ip-based disable
        set active-auth-method "au-ntlm"
    next
end
```

4. In the proxy policy, append the user group for authorization:

```
config firewall proxy-policy
    edit 1
        set proxy explicit-web
        set dstintf "port1"
        set srcaddr "all"
        set dstaddr "all"
        set service "web"
        set action accept
        set schedule "always"
        set groups "ldap-group"
        set utm-status enable
        set av-profile "av"
        set ssl-ssh-profile "deep-custom"
    next
end
```

   This configuration uses a round-robin method. When the first user logs in, the FortiGate sends the authentication request to the first domain controller. Later when another user logs in, the FortiGate sends the authentication request to another domain controller.

5. Verify the behavior after the user successfully logs in:

```
# diagnose wad user list
ID: 1825, IP: 10.1.100.71, VDOM: vdom1
    user name   : test1
    duration    : 497
    auth_type   : Session
    auth_method : NTLM
    pol_id      : 1   g_id        : 5
    user_based  : 0   e
    xpire      : 103
    LAN:
        bytes_in=2167 bytes_out=7657
    WAN:
        bytes_in=3718 bytes_out=270
```

To support individual users for agentless NTLM using the CLI:

1. Configure an LDAP server:

```
config user ldap
    edit "ldap-kerberos"
        set server "172.18.62.177"
        set cnid "cn"
        set dn "dc=fortinetqa,dc=local"
        set type regular
        set username "CN=root,CN=Users,DC=fortinetqa,DC=local"
        set password *********
    next
end
```

2. Configure the user group and allow user-based matching:

```
config user group
    edit "ldap-group"
        set member "ldap" "ldap-kerberos"
        config match
            edit 1
                set server-name "ldap-kerberos"
                set group-name "test1"
            next
        end
    next
end
```

3. Create an authentication scheme and rule:

```
config authentication scheme
    edit "au-ntlm"
        set method ntlm
        set domain-controller "dc1"
    next
end

config authentication rule
    edit "ru-ntlm"
        set srcaddr "all"
        set ip-based disable
        set active-auth-method "au-ntlm"
    next
end
```

4. In the proxy policy, append the user group for authorization:

```
config firewall proxy-policy
    edit 1
        set proxy explicit-web
        set dstintf "port1"
        set srcaddr "all"
        set dstaddr "all"
        set service "web"
        set action accept
        set schedule "always"
        set groups "ldap-group"
        set utm-status enable
```

```
        set av-profile "av"
        set ssl-ssh-profile "deep-custom"
    next
end
```

This implementation lets you configure a single user instead of a whole group. The FortiGate will now allow the user named `test1`.

To verify the configuration using the CLI:

```
diagnose wad user list
    ID: 1827, IP: 10.1.15.25, VDOM: vdom1
    user name   : test1
    duration    : 161
    auth_type   : Session
    auth_method : NTLM
    pol_id      : 1
    g_id        : 5
    user_based  : 0
    expire      : 439
    LAN:
            bytes_in=1309 bytes_out=4410
      WAN:

```

Multiple LDAP servers in Kerberos keytabs and agentless NTLM domain controllers

Multiple LDAP servers can be configured in Kerberos keytabs and agentless NTLM domain controllers for multi-forest deployments.

To use multiple LDAP servers in Kerberos keytabs and agentless NTLM domain controllers:

1. Add multiple LDAP servers:

```
config user ldap
    edit "ldap-kerberos"
        set server "172.16.200.98"
        set cnid "cn"
        set dn "dc=fortinetqa,dc=local"
        set type regular
        set username "CN=root,CN=Users,DC=fortinetqa,DC=local"
        set password xxxxxxxxx
    next
    edit "ldap-two"
        set server "172.16.106.128"
        set cnid "cn"
        set dn "OU=Testing,DC=ad864r2,DC=com"
        set type regular
        set username "cn=Testadmin,cn=users,dc=AD864R2,dc=com"
        set password xxxxxxxxx
    next
end
```

2. Configure a Kerberos keytab entry that uses both LDAP servers:

```
config user krb-keytab
    edit "http_service"
        set pac-data disable
        set principal "HTTP/FGT.FORTINETQA.LOCAL@FORTINETQA.LOCAL"
        set ldap-server "ldap-kerberos" "ldap-two"
        set keytab xxxxxxxxx
    next
end
```

3. Configure a domain controller that uses both LDAP servers:

```
config user domain-controller
    edit "dc1"
        set ip-address 172.16.200.98
        set ldap-server "ldap-two" "ldap-kerberos"
    next
end
```

Learn client IP addresses

Learning the actual client IP addresses is imperative for authorization. This function identifies the real client IP address when there is a NATing device between the FortiGate and the client.

```
config web-proxy global
    set learn-client-ip {enable | disable}
    set learn-client-ip-from-header {true-client-ip | x-real-ip | x-forwarded-for}
    set learn-client-ip-srcaddr <address> ... <address>
end
```

`learn-client-ip {enable | disable}`	Enable/disable learning the client's IP address from headers.
`learn-client-ip-from-header {true-client-ip | x-real-ip | x-forwarded-for}`	Learn client IP addresses from the specified headers.
`learn-client-ip-srcaddr <address> ... <address>`	The source address names.

Example

In this example, the real client IP address is used to match a policy for FSSO authentication.

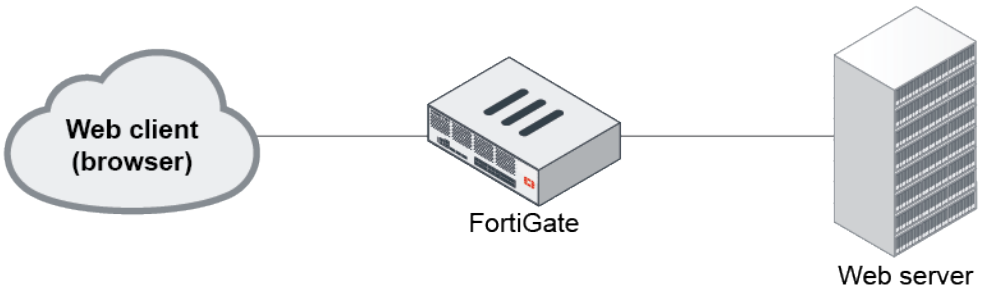
To enable learning the client IP address:

```
config web-proxy global
    set proxy-fqdn "default.fqdn"
    set webproxy-profile "default"
    set learn-client-ip enable
       set learn-client-ip-from-header x-forwarded-for
    set learn-client-ip-srcaddr "all"
end
```

To configure the proxy policy:

```
config firewall proxy-policy
    edit 1
        set proxy explicit-web
        set dstintf "mgmt1"
        set srcaddr "all"
        set dstaddr "all"
        set service "w"
        set action accept
        set schedule "always"
        set groups "fsso1"
        set utm-status enable
        set av-profile "default"
        set dlp-profile "default"
        set profile-protocol-options "default"
        set ssl-ssh-profile "deep-inspection"
    next
end
```

To configure the authentication scheme and rule:



```
config authentication scheme
    edit "scheme1"
        set method fsso
    next
end
config authentication rule
    edit "rule1"
        set srcaddr "all"
        set sso-auth-method "scheme1"
    next
end
```

Explicit proxy authentication over HTTPS

When a HTTP request requires authentication in an explicit proxy, the authentication can be redirected to a secure HTTPS captive portal. Once authentication is complete, the client can be redirected back to the original destination over HTTP.

Example

A user visits a website via HTTP through the explicit web proxy on a FortiGate. The user is required to authenticate by either basic or form IP-based authentication for the explicit web proxy service. The user credentials need to be transmitted over the networks in a secured method over HTTPS rather than in plain text. The user credentials are protected by redirecting the client to a captive portal of the FortiGate over HTTPS for authentication where the user credentials are encrypted and transmitted over HTTPS.

In this example, explicit proxy authentication over HTTPS is configured with form IP-based authentication. Once configured, you can enable authorization for an explicit web proxy by configuring users or groups in the firewall proxy policy.

To configure explicit proxy authentication over HTTPS:

1. Configure the authentication settings:

```
config authentication setting
    set captive-portal-type fqdn
    set captive-portal "fgt-cp"
    set auth-https enable
end
```

2. Configure the authentication scheme:

```
config authentication scheme
    edit "form"
        set method form
        set user-database "local-user-db"
    next
end
```

3. Configure the authentication rule:

```
config authentication rule
    edit "form"
        set srcaddr "all"
        set active-auth-method "form"
    next
end
```

If a session-based basic authentication method is used, enable `web-auth-cookie`.

4. Configure the firewall address:

```
config firewall address
    edit "fgt-cp"
        set type fqdn
        set fqdn "fgt.fortinetqa.local"
    next
end
```

5. Configure the interface:

```
config system interface
    edit "port10"
        set ip 10.1.100.1 255.255.255.0
        set explicit-web-proxy enable
        set proxy-captive-portal enable
    next
end
```

6. Configure a firewall proxy policy with users or groups (see Explicit web proxy on page 258).

Verification

When a client visits a HTTP website, the client will be redirected to the captive portal for authentication by HTTPS. For example, the client could be redirected to a URL by a HTTP 303 message similar to the following:

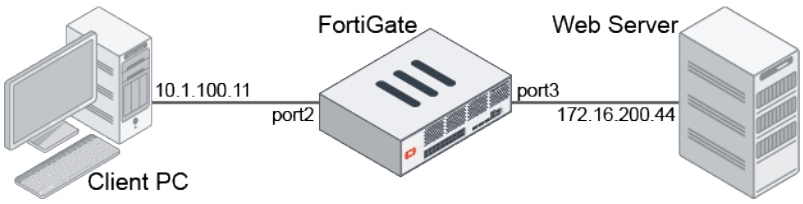
HTTP/1.1 303 See Other

Connection: close

Content-Type: text/html

Cache-Control: no-cache

Location: https://fgt.fortinetqa.local:7831/XX/YY/ZZ/cpauth?scheme=http&4Tmthd=0&host=172.16.200.46&port=80&rule=75&uri=Lw==&



Content-Length: 0

The captive portal URL used for authentication is *https://fgt.fortinetqa.local:7831/...*. Once the authentication is complete with all user credentials protected by HTTPS, the client is redirected to the original HTTP website they intended to visit.

mTLS client certificate authentication

FortiGate supports client certificate authentication used in mutual Transport Layer Security (mTLS) communication between a client and server. Clients are issued certificates by the CA, and an access proxy configured on the FortiGate uses the new certificate method in the authentication scheme to identify and approve the certificate provided by the client when they try to connect to the access proxy. The FortiGate can also add the HTTP header X-Forwarded-Client-Cert to forward the certificate information to the server.

Examples

In these examples, the access proxy VIP IP address is 10.1.100.200.

Example 1

In this example, clients are issued unique client certificates from your CA. The FortiGate authenticates the clients by their user certificate before allowing them to connect to the access proxy. The access server acts as a reverse proxy for the web server that is behind the FortiGate.

This example assumes that you have already obtained the public CA certificate from your CA, the root CA of the client certificate has been imported (`CA_Cert_1`), and the client certificate has been distributed to the endpoints.

To configure the FortiGate:

1. Configure user authentication. Both an authentication scheme and rule must be configured, as the authentication is applied on the access proxy:

```
config authentication scheme
    edit "mtls"
        set method cert
        set user-cert enable
    next
end

config authentication rule
    edit "mtls"
        set srcintf "port2"
        set srcaddr "all"
        set dstaddr "all"
        set active-auth-method "mtls"
    next
end
```

2. Select the CA or CAs used to verify the client certificate:

```
config authentication setting
    set user-cert-ca "CA_Cert_1"
end
```

3. Configure the users. Users can be matched based on either the common-name on the certificate or the trusted issuer.
   - Verify the user based on the common name on the certificate:

```
config user certificate
    edit "single-certificate"
        set type single-certificate
        set common-name "client.fortinet.com"
    next
end
```

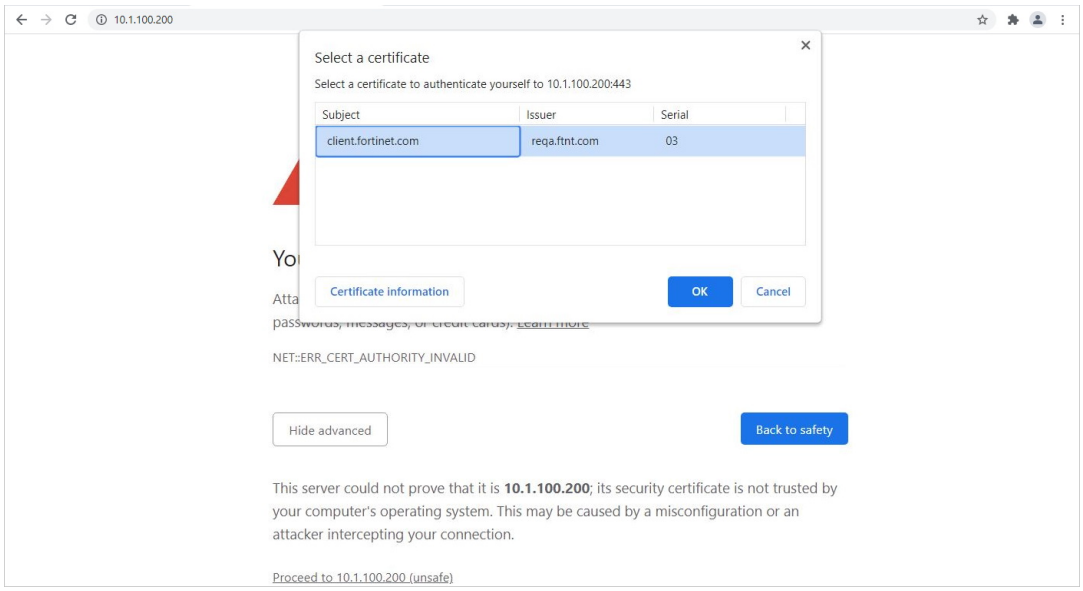
   - Verify the user based on the CA issuer:

```
config user certificate
    edit "trusted-issuer"
        set type trusted-issuer
        set issuer "CA_Cert_1"
    next
end
```

4. Configure the access proxy VIP. The SSL certificate is the server certificate that is presented to the user as they connect:

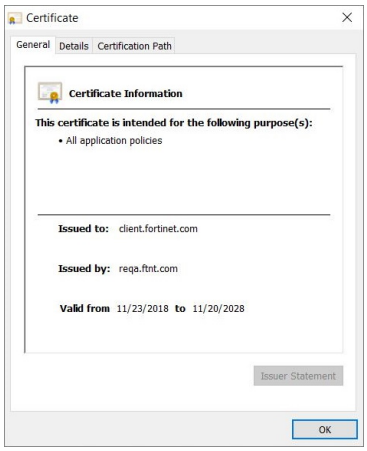
```
config firewall vip
    edit "mTLS"
        set type access-proxy
        set extip 10.1.100.200
        set extintf "port2"
        set server-type https
        set extport 443
        set ssl-certificate "Fortinet_CA_SSL"
    next
end
```

5. Configure the access proxy policy, including the real server to be mapped. To request the client certificate for authentication, `client-cert` is enabled:



```
config firewall access-proxy
    edit "mTLS-access-proxy"
        set vip "mTLS"
        set client-cert enable
        set empty-cert-action accept
        config api-gateway
            edit 1
                config realservers
                    edit 1
                        set ip 172.16.200.44
                    next
                end
            next
        end
    next
end
```

6. Configure the proxy policy to apply authentication and the security profile, selecting the appropriate user object depending on the user type:



```
config firewall proxy-policy
    edit 3
        set proxy access-proxy
        set access-proxy "mTLS-access-proxy"
        set srcintf "port2"
        set srcaddr "all"
        set dstaddr "all"
        set action accept
        set schedule "always"
        set users {"single-certificate" | "trusted-issuer"}
        set utm-status enable
        set ssl-ssh-profile "deep-inspection-clone"
        set av-profile "av"
    next
end
```

To verify the results:

1. In a web browser, access the VIP address. This example uses Chrome.
2. When prompted, select the client certificate, then click *OK*.

3. Click *Certificate information* to view details about the certificate.

4. On the FortiGate, check the traffic logs.
   - If client certificate authentication passes:

     ```
     1: date=2021-06-03 time=15:48:36 eventtime=1622760516866635697 tz="-0700"
     logid="0000000010" type="traffic" subtype="forward" level="notice" vd="vdom1"
     srcip=10.1.100.11 srcport=45532 srcintf="port2" srcintfrole="undefined"
     dstcountry="Reserved" srccountry="Reserved" dstip=172.16.200.44 dstport=443
     dstintf="vdom1" dstintfrole="undefined" sessionid=154900 service="HTTPS"
     wanoptapptype="web-proxy" proto=6 action="accept" policyid=3 policytype="proxy-
     policy" poluuid="af5e2df2-c321-51eb-7d5d-42fa58868dcb" duration=0 user="single-
     certificate" wanin=2550 rcvdbyte=2550 wanout=627 lanin=4113 sentbyte=4113 lanout=2310
     appcat="unscanned"
     ```

   - If the CA issuer is used to verify the client:

     ```
     1: date=2021-06-03 time=15:43:02 eventtime=1622760182384776037 tz="-0700"
     logid="0000000010" type="traffic" subtype="forward" level="notice" vd="vdom1"
     srcip=10.1.100.11 srcport=45514 srcintf="port2" srcintfrole="undefined"
     dstcountry="Reserved" srccountry="Reserved" dstip=10.1.100.200 dstport=443
     dstintf="vdom1" dstintfrole="undefined" sessionid=153884 service="HTTPS"
     ```

```
wanoptapptype="web-proxy" proto=6 action="accept" policyid=3 policytype="proxy-
policy" poluuid="af5e2df2-c321-51eb-7d5d-42fa58868dcb" duration=0 user="trusted-
issuer" wanin=0 rcvdbyte=0 wanout=0 lanin=4089 sentbyte=4089 lanout=7517
appcat="unscanned" utmaction="block" countweb=1 crscore=30 craction=8 utmref=65535-0
```

- If the client certificate authentication fails, and the traffic is blocked:

```
1: date=2021-06-03 time=15:45:53 eventtime=1622760353789703671 tz="-0700"
logid="0000000013" type="traffic" subtype="forward" level="notice" vd="vdom1"
srcip=10.1.100.11 srcport=45518 srcintf="port2" srcintfrole="undefined"
dstip=172.16.200.44 dstport=443 dstintf="vdom1" dstintfrole="undefined"
srccountry="Reserved" dstcountry="Reserved" sessionid=154431 proto=6 action="deny"
policyid=0 policytype="proxy-policy" user="single-certificate" service="HTTPS"
trandisp="noop" url="https://10.1.100.200/" agent="curl/7.68.0" duration=0 sentbyte=0
rcvdbyte=0 sentpkt=0 rcvdpkt=0 appcat="unscanned" crscore=30 craction=131072
crlevel="high" msg="Traffic denied because of explicit proxy policy"
```

Example 2

In this example, the same configuration as in Example 1 is used, with a web proxy profile added to enable adding the client certificate to the HTTP header X-Forwarded-Client-Cert. The header is then forwarded to the server.

To configure the FortiGate:

1. Repeat steps 1 to 6 of Example 1, using the common name on the certificate to verify the user.
2. Configure a web proxy profile that adds the HTTP x-forwarded-client-cert header in forwarded requests:

```
config web-proxy profile
    edit "mtls"
        set header-x-forwarded-client-cert add
    next
end
```

3. Configure the proxy policy to apply authentication, the security profile, and web proxy profile:

```
config firewall proxy-policy
    edit 3
        set uuid af5e2df2-c321-51eb-7d5d-42fa58868dcb
        set proxy access-proxy
        set access-proxy "mTLS-access-proxy"
        set srcintf "port2"
        set srcaddr "all"
        set dstaddr "all"
        set action accept
        set schedule "always"
        set logtraffic all
        set users "single-certificate"
        set webproxy-profile "mtls"
        set utm-status enable
        set ssl-ssh-profile "deep-inspection-clone"
        set av-profile "av"
    next
end
```

To verify the results:

The WAD debug shows that the FortiGate adds the client certificate information to the HTTP header. The added header cannot be checked using the sniffer, because the FortiGate encrypts the HTTP header to forward it to the server.

1. Enable WAD debug on all categories:

```
# diagnose wad debug enable category all
```

2. Set the WAD debug level to verbose:

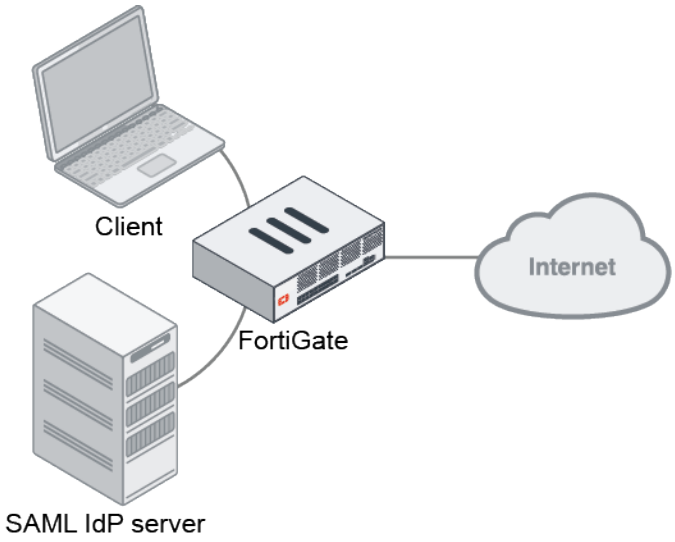
```
# diagnose wad debug enable level verbose
```

3. Enable debug output:

```
# diagnose debug enable
```

4. Check the debug output.
   - When the FortiGate receives the client HTTP request:

```
[0x7fc8d4bc4910] Received request from client: 10.1.100.11:45544



GET / HTTP/1.1
Host: 10.1.100.200
User-Agent: curl/7.68.0
Accept: */*
```

   - When the FortiGate adds the client certificate in to the HTTP header and forwards the client HTTP request:

```
[0x7fc8d4bc4910] Forward request to server:
GET / HTTP/1.1
Host: 172.16.200.44
User-Agent: curl/7.68.0
Accept: */*
X-Forwarded-Client-Cert: -----BEGIN CERTIFICATE-----
MIIFXzCCA0egAwI...aCFHDHlR+wb39s=
-----END CERTIFICATE-----
-----BEGIN CERTIFICATE-----
MIIFpTCCA42gAwI...OtDtetkNoFLbvb
-----END CERTIFICATE-----
```

CORS protocol in explicit web proxy when using session-based, cookie-enabled, and captive portal-enabled SAML authentication

The FortiGate explicit web proxy supports the Cross-Origin Resource Sharing (CORS) protocol, which allows the FortiGate to process a CORS preflight request and an actual CORS request properly, in addition to a simple CORS request when using session-based, cookie-enabled, and captive portal-enabled SAML authentication. This allows a FortiGate explicit web proxy user with this specific configuration to properly view a web page requiring CORS with domains embedded in it other than its own domain.

To configure the FortiGate:

1. Configure the authentication rule:

```
config authentication rule
    edit "saml"
        set srcaddr "all"
        set ip-based disable
        set active-auth-method "saml"
        set web-auth-cookie enable
    next
end
```

2. Configure the captive portal:

```
config authentication setting
    set captive-portal "fgt9.myqalab.local"
end
```

3. Configure the proxy policy

```
config firewall proxy-policy
    edit 3
        set proxy explicit-web
        set dstintf "port9"
        set srcaddr "all"
        set dstaddr "all"
        set service "webproxy"
        set action accept
        set schedule "always"
        set logtraffic all
        set groups "ldap-group-saml"
        set utm-status enable
        set profile-protocol-options "protocol"
        set ssl-ssh-profile "deep-custom"
        set av-profile "av"
        set application-list "fff"
```

```
        next
    end
```

CORS request scenarios

Preflight CORS request

The client sends the initial CORS preflight request (`OPTIONS` with the origin header) to the web server through FortiGate's web proxy and receives a CORS `200 OK` response (with headers, such as `Access-Control-Allow-Origin`). The FortiGate will not redirect the client to the captive capital for authentication:

```
> OPTIONS /bidRequest HTTP/1.1
> Host: c2shb.pubgw.yahoo.com
> User-Agent: curl/7.61.1
> Accept: */*
> Access-Control-Request-Method: GET
> Access-Control-Request-Headers: content-type,x-openrtb-version
> Origin: https://www.cnn.com
...
< HTTP/1.1 200 OK
< Date: Thu, 19 May 2022 01:49:17 GMT
< Content-Length: 0
< Server: ATS/9.1.0.46
< Access-Control-Allow-Origin: https://www.cnn.com
< Access-Control-Allow-Methods: GET,POST,OPTIONS
< Access-Control-Allow-Headers: X-Requested-With,Content-Type,X-Openrtb-Version
< Access-Control-Allow-Credentials: true
< Access-Control-Max-Age: 600
< Age: 0
< Connection: keep-alive
< Set-Cookie: A3=d=AQABBB2ihWICEIUyD_Du5ol8tMdKKWxspR8FEgEBAQHzhmKPYgAAAAAA_
eMAAA&S=AQAAAlU0dAheQx6euvcPs8ErK4I; Expires=Fri, 19 May 2023 07:49:17 GMT; Max-
Age=31557600; Domain=.yahoo.com; Path=/; SameSite=None; Secure; HttpOnly
```

Real CORS request

Once the initial preflight request for the client is successful, the client sends the real CORS request (`GET` request with origin header) to the FortiGate, The FortiGate then replies with a 30x response to redirect the client to the captive portal. The 30x response includes CORS headers such as `Access-Control-Allow-Origin`:

```
> GET /bidRequest HTTP/1.1
> Host: c2shb.pubgw.yahoo.com
> User-Agent: curl/7.61.1
> Accept: */*
> Origin: https://www.cnn.com
...
< HTTP/1.1 303 See Other
< Access-Control-Max-Age: 1
< Access-Control-Allow-Origin: https://www.cnn.com
< Access-Control-Allow-Credentials: true
< Set-Cookie: FTNT-EP-
FG900D3915800054=pqWlpdswdcCnpaWli6WlpcjEwszGmJbGksbBwMCVwcPBlpKRnMGTl52QxJeUwYPW18aYlJWLlIu
UlZWLlJalpQ==; Path=/; Domain=.pubgw.yahoo.com; HttpOnly; SameSite=None; Secure
< Connection: close
< Content-Type: text/html
```

```
< Cache-Control: no-cache
< Location:
https://fgt9.myqalab.local:7831/test/saml/login/?cptype=ckauth&scheme=https&4Tmthd=0&host=c2
shb.pubgw.yahoo.com&port=443&rule=98&uri=L2JpZFJlcXVlc3Q=&cdata=pqWlpdswdcCnpaWli6WlpcjEwszG
mJbGksbBwMCVwcPBlpKRnMGTl52QxJeUwYPW18aYlJWLlIuUlZWLlJalpQ==
< Content-Length: 0
```

Redirection to captive portal

Once the client's real CORS request is redirected to the captive portal, the client senda another preflight to the captive portal. The captive portal then replies with a 20x response, which includes CORS headers such as `Access-Control-Allow-Origin`:

```
> OPTIONS
/test/saml/login/?cptype=ckauth&scheme=https&4Tmthd=1&host=gql.reddit.com&port=443&rule=98&u
ri=Lw==&cdata=pqWlpQM5dcCnpaWliqWlpcjEwszGmJbGksbAk5WTl8aTwJDGnJ2Tl52QxpHDkYPW18aYlJWLlIuUlZ
WLlJGWpQ== HTTP/1.1
> Host: fgt9.myqalab.local:7831
> Connection: keep-alive
> Accept: */*
> Access-Control-Request-Method: GET
> Access-Control-Request-Headers: authorization,content-type,x-reddit-compression,x-reddit-
loid,x-reddit-session
> Origin: null
> User-Agent: Mozilla/5.0 (Windows NT 10.0; Win64; x64) AppleWebKit/537.36 (KHTML, like
Gecko) Chrome/100.0.4896.75 Safari/537.36 Edg/100.0.1185.36
> Sec-Fetch-Mode: cors
> Sec-Fetch-Site: cross-site
> Sec-Fetch-Dest: empty
> Referer: https://www.reddit.com/
> Accept-Encoding: gzip, deflate, br
> Accept-Language: en-US,en;q=0.9
...
< HTTP/1.1 204 No Content
< Access-Control-Max-Age: 86400
< Access-Control-Allow-Methods: GET
< Access-Control-Allow-Headers: authorization,content-type,x-reddit-compression,x-reddit-
loid,x-reddit-session
< Access-Control-Allow-Origin: null
< Access-Control-Allow-Credentials: true
```

Simple CORS request

If a simple CORS request (no preflight request sent before it) is used, when the FortiGate receives the simple request, it replies with a 30x response that includes CORS headers, such as `Access-Control-Allow-Origin`:

```
> Host: www.yahoo.com
> User-Agent: curl/7.61.1
> Accept: */*
> Origin: https://www.cnn.com
...
< HTTP/1.1 303 See Other
< Access-Control-Max-Age: 1
< Access-Control-Allow-Origin: https://www.cnn.com
< Access-Control-Allow-Credentials: true
< Set-Cookie: FTNT-EP-
```

```
FG900D3915800000=pqWlpaw7dcCnpaWli6WlpcjEwszGmJbGksbAkpOcxMDDlpbGlMSTl52QwcGcl4PW18aYlJWLlIu
UlZWLlJalpQ==; Path=/; Domain=.yahoo.com; HttpOnly; SameSite=None; Secure
< Connection: close
< Content-Type: text/html

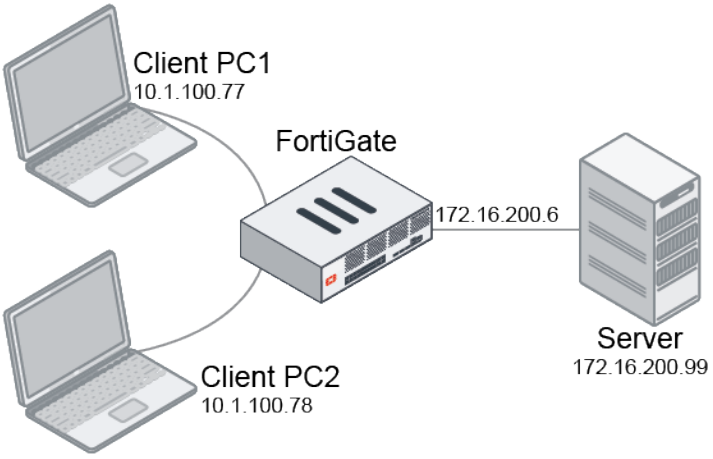
```

HTTP connection coalescing and concurrent multiplexing for explicit proxy

HTTP connection coalescing and concurrent multiplexing allows multiple HTTP requests to share the same TCP three-way handshake when the destination IP is the same.



To configure the explicit web proxy:

```
config web-proxy explicit
    set http-connection-mode {static | multiplex | serverpool}
end
```

`http-connection-mode {static | multiplex | serverpool}`	Set the HTTP connection mode: • static: only one server connection exists during the proxy session (default). • multiplex: hold established connections until the proxy session ends. • serverpool: share established connections with other proxy sessions.

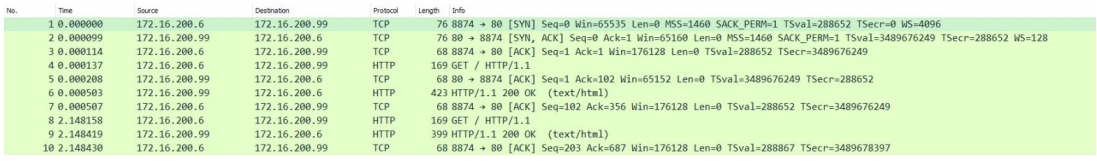
Example

In this example, multiple clients submit requests in HTTP. The requests hit the VIP address, and then FortiGate opens a session between itself (172.16.200.6) and the server (172.16.200.99). The coalescing occurs in this session as the multiple streams share the same session to connect to the same destination server.

To configure connection coalescing and concurrent multiplexing with an explicit proxy:

1. Configure the explicit web proxy:

```
config web-proxy explicit
    set status enable
    set http-incoming-port 8080
    set http-connection-mode serverpool
end
```



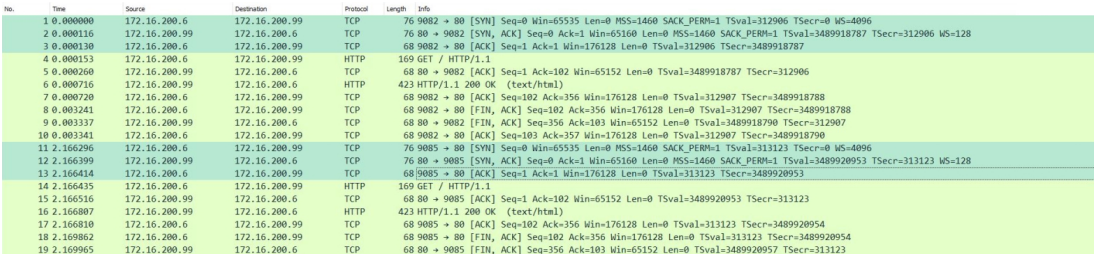
2. Enable explicit web proxy on port2:

```
config system interface
    edit "port2"
        set ip 10.1.100.6 255.255.255.0
        set explicit-web-proxy enable
    next
end
```

3. Configure the proxy policy:

```
config firewall proxy-policy
    edit 1
        set proxy explicit-web
        set dstintf "port3"
        set srcaddr "all"
        set dstaddr "all"
        set service "web"
        set action accept
        set schedule "always"
        set srcaddr6 "all"
        set dstaddr6 "all"
        set utm-status enable
        set profile-protocol-options "default-clone"
        set ssl-ssh-profile "deep-inspection-clone"
    next
end
```

4. Get the clients to access the server through the explicit web proxy (10.1.100.6:8080). The FortiGate shares the first connection TCP three-way handshake with later connections that connect to same destination address.
5. Verify the sniffer packet capture on the FortiGate server side. There is one TCP three-way handshake, but there are two HTTP connections.



No.	Time	Source	Destination	Protocol	Length	Info
1	0.000000	172.16.200.6	172.16.200.99	TCP	76	8874 → 80 [SYN] Seq=0 Win=65535 Len=0 MSS=1460 SACK_PERM=1 TSval=288652 TSecr=0 WS=4096
2	0.000099	172.16.200.99	172.16.200.6	TCP	76	80 → 8874 [SYN, ACK] Seq=0 Ack=1 Win=65160 Len=0 MSS=1460 SACK_PERM=1 TSval=3489676249 TSecr=288652 WS=128
3	0.000114	172.16.200.6	172.16.200.99	TCP	68	8874 → 80 [ACK] Seq=1 Ack=1 Win=176128 Len=0 TSval=288652 TSecr=3489676249
4	0.000137	172.16.200.6	172.16.200.99	HTTP	169	GET / HTTP/1.1
5	0.000208	172.16.200.99	172.16.200.6	TCP	68	80 → 8874 [ACK] Seq=1 Ack=102 Win=65152 Len=0 TSval=3489676249 TSecr=288652
6	0.000503	172.16.200.99	172.16.200.6	HTTP	423	HTTP/1.1 200 OK (text/html)
7	0.000507	172.16.200.6	172.16.200.99	TCP	68	8874 → 80 [ACK] Seq=102 Ack=356 Win=176128 Len=0 TSval=288652 TSecr=3489676249
8	2.148158	172.16.200.6	172.16.200.99	HTTP	169	GET / HTTP/1.1
9	2.148419	172.16.200.99	172.16.200.6	HTTP	399	HTTP/1.1 200 OK (text/html)
10	2.148430	172.16.200.6	172.16.200.99	TCP	68	8874 → 80 [ACK] Seq=203 Ack=687 Win=176128 Len=0 TSval=288867 TSecr=3489678397

6. Change the HTTP connection mode to static:

```
config web-proxy explicit
    set status enable
    set http-incoming-port 8080
    set http-connection-mode static
end
```

7. Verify the sniffer packet capture. This time, the FortiGate establishes a TCP connection for each client.

No.	Time	Source	Destination	Protocol	Length	Info
1	0.000000	172.16.200.6	172.16.200.99	TCP	76	9082 → 80 [SYN] Seq=0 Win=65535 Len=0 MSS=1460 SACK_PERM=1 TSval=312906 TSecr=0 WS=4096
2	0.000116	172.16.200.99	172.16.200.6	TCP	76	80 → 9082 [SYN, ACK] Seq=0 Ack=1 Win=65160 Len=0 MSS=1460 SACK_PERM=1 TSval=3489918787 TSecr=312906 WS=128

DHCP servers and relays

A DHCP server dynamically assigns IP addresses to hosts on the network connected to the interface. The host computers must be configured to obtain their IP addresses using DHCP. You can configure one or more DHCP servers on any FortiGate interface.

A DHCP server can be in server or relay mode. In server mode, you can define up to ten address ranges to assign addresses from, and options such as the default gateway, DNS server, lease time, and other advanced settings. In relay mode, the interface forwards DHCP requests from DHCP clients to an external DHCP server and returns the responses to the DHCP clients. The DHCP server must have appropriate routing so that its response packets to the DHCP clients arrive at the unit.

If an interface is connected to multiple networks through routers, you can add a DHCP server for each network. The IP range of each DHCP server must match the network address range. The routers must be configured for DHCP relay.

Default DHCP server for low-end FortiGates

On low-end FortiGate units, a DHCP server is configured on the internal interface, by default, with the following values:

Field	Value
Address Range	192.168.1.110 to 192.168.1.210
Netmask	255.255.255.0
Default Gateway	192.168.1.99
Lease Time	7 days
DNS Server 1	192.168.1.99

These settings are appropriate for the default internal interface IP address of 192.168.1.99. If you change this address to a different network, you need to change the DHCP server settings to match.

- Basic configuration on page 334
- DHCP options on page 337
- DHCP addressing mode on an interface on page 344
- VCI pattern matching for DHCP assignment on page 347
- FortiGate DHCP works with DDNS to allow FQDN connectivity to leased IP addresses on page 349

Basic configuration

The following contains information on basic configurations.

Configure a DHCP server on an interface

A DHCP server can be configured on an interface in the GUI from *Network* > *Interfaces*.

To configure a DHCP server in the GUI:

1. Go to *Network* > *Interfaces*.
2. Edit an interface.
3. Enable the *DHCP Server* option and configure the settings.
4. Click *OK*.

Field	Description
Address Range	By default, the FortiGate unit assigns an address range based on the address of the interface for the complete scope of the address. For example, if the interface address is 172.20.120.230, the default range created is 172.20.120.231 to 172.20.120.254. Select the range and select *Edit* to adjust the range or select *Create New* to add a different range.
Netmask	Enter the netmask of the addresses that the DHCP server assigns.
Default Gateway	Select this to use either *Same as Interface IP* or select *Specify* and enter the IP address of the default gateway that the DHCP server assigns to DHCP clients.
DNS Server	Select this to use *Same as system DNS*, *Same as Interface IP* or select *Specify* and enter the IP address of the DNS server.
Mode	Select the type of DHCP server FortiGate will be. By default, it is a *Server*. Select *Relay* if needed. When *Relay* is selected, the above configuration is replaced by a field to enter the *DHCP Server IP* address.
DHCP Server IP	This appears only when *Mode* is *Relay*. Enter the IP address of the DHCP server where FortiGate obtains the requested IP address.
Type	Select this to use the DHCP in *Regular* or *IPsec* mode.
Additional DHCP Options	Use this to create new DHCP options.
Add from DHCP Client List	If the client is currently connected and using an IP address from the DHCP server, you can select this option to select the client from the list.

To configure a DHCP server in the CLI:

```
config system dhcp server
    edit 1
        set dns-service default
        set default-gateway 192.168.1.2
        set netmask 255.255.255.0
```

```
        set interface "port1"
        config ip-range
            edit 1
                set start-ip 192.168.1.1
                set end-ip 192.168.1.1
            next
            edit 2
                set start-ip 192.168.1.3
                set end-ip 192.168.1.254
            next
        end
        set timezone-option default
        set tftp-server "172.16.1.2"
    next
end
```

Configure a DHCP relay on an interface

To configure a DHCP relay in the GUI:

1. Go to *Network* > *Interfaces*.
2. Edit an interface.
3. Expand the *Advanced* section and set *Mode* to *Relay*.
4. Enter the *DHCP Server IP*.
5. Click *OK*.

To configure a DHCP relay in the CLI:

1. Configure the interface, making sure to configure set `dhcp-relay-ip`:

```
config system interface
    edit "port2"
        set vdom "root"
        set dhcp-relay-service enable
        set ip 10.1.1.5 255.255.255.0
        set allowaccess ping https ssh fabric
        set type physical
        set snmp-index 4
        set dhcp-relay-ip "192.168.20.10"
    next
end
```

Configure a DHCP server and relay on an interface

A FortiGate interface can be configured to work in DHCP server mode to lease out addresses, and at the same time relay the DHCP packets to another device, such as a FortiNAC to perform device profiling.

The DHCP message to be forwarded to the relay server under the following conditions:

- `dhcp-relay-request-all-server` is enabled
- Message type is either DHCPDISCOVER or DHCPINFORM
- Client IP address in client message is 0
- Server ID is NULL in the client message

- Server address is a broadcast address (255.255.255.255)
- Server address is 0

Configuring a DHCP server and relay on the same interface is currently only supported in the CLI.

To configure a DHCP server and relay in the CLI:

1. Configure the interface:

```
config system interface
    edit "port2"
        set vdom "root"
        set dhcp-relay-service enable
        set ip 10.1.1.5 255.255.255.0
        set allowaccess ping https ssh fabric
        set type physical
        set snmp-index 4
        set dhcp-relay-ip "192.168.20.10"
        set dhcp-relay-request-all-server enable
    next
end
```

2. Configure the DHCP server settings:

```
config system dhcp server
    edit 17
        set status enable
        set dns-service default
        set default-gateway 10.1.1.5
        set netmask 255.255.255.0
        set interface "port2"
        config ip-range
            edit 1
                set start-ip 10.1.1.6
                set end-ip 10.1.1.254
            next
        end
    next
end
```

Excluding addresses in DHCP

If you have a large address range for the DHCP server, you can block a range of addresses that will not be included in the available addresses for the connecting users using the `config exclude-range` subcommand.

To exclude addresses in DHCP:

```
config system dhcp server
    edit <id>
        config exclude-range
            edit <sequence_number>
```

```
                set start-ip <address>
                set end-ip <address>
            next
        end
    next
end
```

Viewing information about DHCP server connections

To view information about DHCP server connections, go to *Dashboard* > *Network* and expand the *DHCP* monitor widget. On this page, you can also add IP addresses to the reserved IP address list.

DHCP options

When adding a DHCP server, you can include DHCP options. The DHCP options are BOOTP vendor information fields that provide additional vendor-independent configuration parameters to manage the DHCP server. For example, you might need to configure a FortiGate DHCP server that gives out a separate option as well as an IP address, such as an environment that needs to support PXE boot with Windows images. The *Option code* is specific to the application. The documentation for the application indicates the values to use. The *Option code* is a value between 1 and 255.

For detailed information about DHCP options, see RFC 2132, DHCP Options and BOOTP Vendor Extensions.

The FortiOS DHCP server supports up to a maximum of 30 options per DHCP server. These optional fields can be set in either the GUI or CLI.

DHCP server options are not available in transparent mode.

The DHCP options include:

- Common DHCP options on page 337
- Additional DHCP options on page 340
- IP address assignment with relay agent information option on page 342

Common DHCP options

All FortiGate models come with predefined DHCP options. These DHCP options are widely used and required in most scenarios. The following DHCP options can be set straight from the *DHCP server* section of the *Edit Interface* dialog:

Option Code	Option Name	Purpose
***1**	*Netmask*	Assign subnet mask to the DHCP client.
***3**	*Default Gateway*	Assign default gateway to the DHCP client.
6	*DNS server*	Assign DNS server to the DHCP client.
42	*NTP server*	Assign NTP server to the DHCP client.
***51**	*Lease time*	Lease time for the DHCP client.

Option Code	Option Name	Purpose
138	*Wireless controllers*	Assign CAPWAP Access Controller addresses to the DHCP client.
150	*TFTP server(s)*	Assign TFTP server to the DHCP client.

The parameter marked with an asterisk (*) are mandatory and must be filled in.

Configuring the lease time

This configuration implements DHCP option code 51. The global lease time (measured in seconds, 300 - 864000) determines the length of time an IP address remains assigned to a client. Once the lease expires, the address is released for allocation to the next client that requests an IP address.

To configure the global lease time:

```
config system dhcp server
    edit <id>
        set interface <interface>
        set netmask <netmask>
        set lease-time <integer>
    next
end
```

The default lease time is seven days (604800 seconds). To have an unlimited lease time, set the value to zero.

The lease time can also be configured in the GUI in the *Lease time* field within the *DHCP server* section of the *Edit Interface* dialog.

Configuring the lease time for IP ranges

The lease time can be also be configured for an IP range. Measured in seconds, the range is similar to the global lease time (300 - 864000), but the default value is zero (0). If the default (0) is used for an IP range, it applies the global DHCP server lease time value.

To configure the lease time for an IP range:

```
config system dhcp server
    edit <id>
        config ip-range
            edit <id>
                set lease-time <integer>
            next
        end
    next
end
```

This setting can only be configured in the CLI.

Breaking an address lease

If you need to end an IP address lease, you can break the lease. This is useful if you have limited addresses and longer lease times when some leases are no longer necessary, for example, with corporate visitors.

To break a lease:

```
# execute dhcp lease-clear <ip_address>
```

To break a lease for all IP addresses for the DHCP servers in the current VDOM:

```
# execute dhcp lease-clear all
```

Configuring NTP servers

This configuration implements DHCP option code 42. NTP server can be used by the client to synchronize their time which is very important as for many features to work, including scheduling, logging, and SSL-dependent features, the FortiOS system time must be accurate. This option specifies a list of the NTP servers available to the client by IP address.

To configure NTP servers:

```
config system dhcp server
    edit 2
        set ntp-service {local | default | specify}
        set ntp-server1 <class_ip>
        set ntp-server2 <class_ip>
        set ntp-server3 <class_ip>
    next
end
```

NTP servers can also be configured in the GUI in the *NTP server* field within the *DHCP server* > *Advanced* section of the *Edit Interface* dialog.

`ntp-service {local | default | specify}`	Set the option for assigning NTP servers to DHCP clients: • `local`: the IP address of the interface that the DHCP server is added to becomes the client's NTP server IP address. • `default`: clients are assigned the FortiGate's configured NTP servers. • `specify`: specify up to three NTP servers in the DHCP server configuration.

Configuring TFTP servers

This configuration implements DHCP option code 150. TFTP server are used by VoIP phones to obtain the VoIP Configuration. You can configure multiple TFTP servers for a DHCP server. For example, you may want to configure a main TFTP server and a backup TFTP server.

The `tftp-server` command allows you to configure the TFTP servers, using either their hostnames or IP addresses. Separate multiple server entries with spaces.

To configure TFTP servers:

```
config system dhcp server
    edit <id>
        set interface <interface>
        set netmask <netmask>
        set tftp-server <hostname/IP address> <hostname/IP address>
    next
end
```

TFTP servers can also be configured in the GUI in the *TFTP server(s)* field within the *DHCP server* > *Advanced* section of the *Edit Interface* dialog.

Additional DHCP options

The FortiGate can be used to provide additional DHCP options that can be useful for different scenarios.

A few of the options are explained below:

- Option 82 on page 341
- Option 77 on page 341

To configure the DHCP options in the GUI:

1. Go to *Network* > *Interfaces*, click *Create New* or *Edit* the existing interface.
2. Enable *DHCP Server*.
3. Expand the *Advanced* section and select *Create New* under *Additional DHCP options*.
4. Select a predefined *Option code* from the list or select *Specify* to enter a custom *Option code*.
5. Configure the rest of the parameters as required and click *OK* to save the options.
6. Click *OK* to save the setting.

To configure the DHCP options in the CLI:

```
config system dhcp server
    edit <id>
        config options
            edit <integer>
                set code <integer>
                set type {hex | string | ip | fqdn}
                set value <string>
            next
        end
    next
end
```

Variable	Description
`code <integer>`	DHCP client option code (0 - 255, default = 0). See Dynamic Host Configuration Protocol (DHCP) and Bootstrap Protocol (BOOTP) Parameters for a list of possible options.
`type {hex | string | ip | fqdn}`	DHCP server option type (default = hex).
`value <string>`	DHCP server option value.
`ip <ip address>`	DHCP server option IP address. This option is only available when `type` is `ip`.

Example

To configure option 252 with value http://192.168.1.1/wpad.dat:

```
config system dhcp server
    edit <id>
        config options
            edit <id>
                set code 252
                set type hex
                set value 687474703a2f2f3139322e3136382e312e312f777061642e646174
            next
        end
    next
end
```

In the example above, `687474703a2f2f3139322e3136382e312e312f777061642e646174` is the hexadecimal equivalent of the ASCII text `http://192.168.1.1/wpad.dat`.

Option 82

The DHCP relay agent information option (option 82 in RFC 3046) helps protect the FortiGate against attacks such as spoofing (forging) of IP addresses and MAC addresses, and DHCP IP address starvation.

This option is disabled by default. However, when `dhcp-relay-service` is enabled, `dhcp-relay-agent-option` becomes enabled.

To configure the DHCP relay agent option:

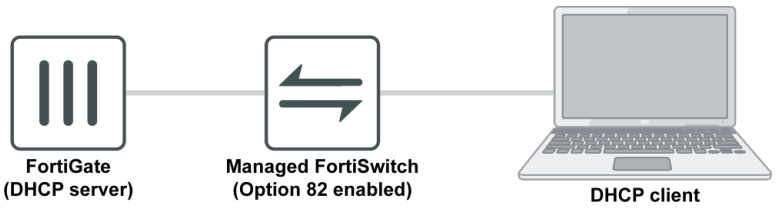
```
config system interface
    edit <interface>
        set vdom root
        set dhcp-relay-service enable
        set dhcp-relay-ip <ip>
        set dhcp-relay-agent-option enable
        set vlanid <id>
    next
end
```

See IP address assignment with relay agent information option on page 342 for an example.

Option 77

This option can be used for User Class information (UCI) matching. When enabled, only DHCP requests with a matching UCI are served with the specified range.

To configure UCI matching:



```
config system dhcp server
    edit <id>
        config ip-range
            edit <id>
```

```
                set uci-match {enable | disable}
                set uci-string <string>
            next
        end
        config options
            edit <id>
                set uci-match {enable | disable}
                set uci-string <string>
            next
        end
    next
end
```

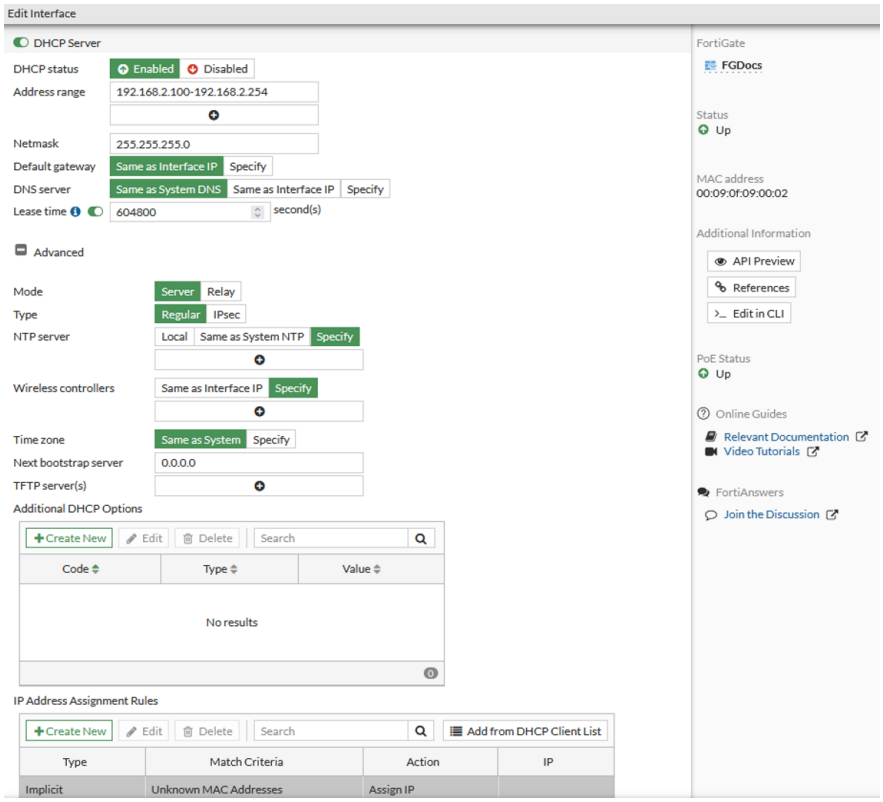
`uci-match {enable | disable}`	Enable/disable User Class information (UCI) matching for option 77.
`uci-string <string>`	Enter one or more UCI strings in quotation marks separated by spaces.

IP address assignment with relay agent information option

Option 82 (DHCP relay information option) helps protect the FortiGate against attacks such as spoofing (or forging) of IP and MAC addresses, and DHCP IP address starvation.

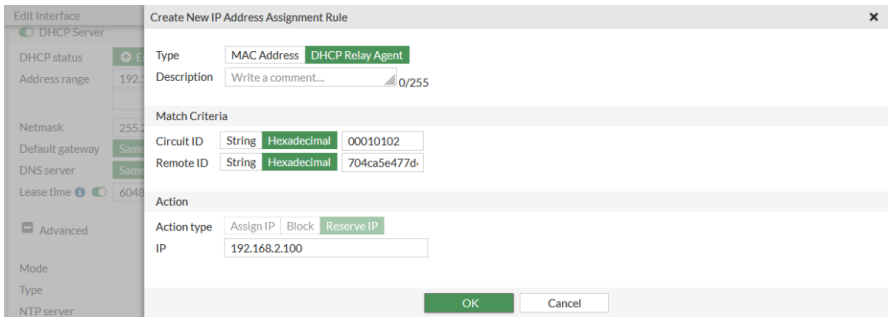
The following CLI variables are included in the `config system dhcp server` > `config reserved-address` command:

`circuit-id-type {hex | string}`	DHCP option type; hex or string (default).
`circuit-id <value>`	Option 82 circuit ID of the client that will get the reserved IP address. Format: *vlan-mod-port* • vlan: VLAN ID (2 bytes) • mod: 1 = snoop, 0 = relay (1 byte) • port: port number (1 byte)
`remote-id-type {hex | string}`	DHCP option type; hex or string (default).
`remote-id <value>`	Option 82 remote ID of the client that will get the reserved IP address. Format: the MAC address of the client.
`type {mac | option82}`	The DHCP reserved address type; mac (default) or option82.



To create an IP address assignment rule using option 82 in the GUI:

1. Go to *Network* > *Interfaces*.
2. Edit an existing port, or create a new one.



The port *Role* must be *LAN* or *Undefined*.

3. Enable *DHCP Server*.
4. Configure the address ranges and other settings as needed.
5. Click + to expand the *Advanced* options.

6. In the *IP Address Assignment Rules* table, click *Create New*.
   The *Create New IP Address Assignment Rule* pane opens.
7. Configure the new rule:
   a. For the *Type*, select *DHCP Relay Agent*.
   b. Enter the *Circuit ID* and *Remote ID*.
   c. Enter the *IP* address that will be reserved.

8. Click *OK*.

To create an IP address assignment rule using option 82 with the CLI:

```
config system dhcp server
    edit 1
        set netmask 255.255.255.0
        set interface "port4"
        config ip-range
            edit 1
                set start-ip 192.168.2.100
                set end-ip 192.168.2.254
            next
        end
        config reserved-address
            edit 1
                set type option82
                set ip 192.168.2.100
                set circuit-id-type hex
                set circuit-id "00010102"
                set remote-id-type hex
                set remote-id "704ca5e477d6"
            next
        end
    next
end
```

DHCP addressing mode on an interface

Any FortiGate interface can be configured to obtain an IP address dynamically using DHCP. If you configure DHCP on an interface on the FortiGate, the FortiGate automatically broadcasts a DHCP request from the interface. The interface is configured with the IP address, any DNS server addresses, and the default gateway address that the DHCP server provides.

Configuring an Interface as a DHCP Client

You can configure interface as a DHCP client.

To configure an interface as a DHCP client in the GUI:

1. Go to *Network* > *Interfaces*.
2. Edit an interface.
3. Select the *DHCP* option in the *Addressing mode*.
4. Configure the rest of the setting as required.
5. Click *OK*.

The following table describes the DHCP status information when DHCP is configured for an interface.

Field	Description
Status	Displays DHCP status messages as the interface connects to the DHCP server and gets addressing information. Status can be one of the following values: • *Initializing*: No activity. • *Connecting*: Interface attempts to connect to the DHCP server. • *Connected*: Interface retrieves an IP address, netmask, and other settings from the DHCP server. • *Failed*: Interface was unable to retrieve an IP address and other settings from the DHCP server.
Obtained IP/Netmask	The IP address and netmask leased from the DHCP server. This is only displayed if the *Status* is *Connected*.
Renew	Select this to renew the DHCP license for this interface. This is only displayed if the *Status* is *Connected*.
Expiry Date	The time and date when the leased IP address and netmask is no longer valid for the interface. The IP address is returned to the pool to be allocated to the next user request for an IP address. This is only displayed if the *Status* is *Connected*.
Default Gateway	The IP address of the gateway defined by the DHCP server. This is displayed only if the *Status* is *Connected*, and if *Retrieve default gateway from server* is enabled.
Acquired DNS	The DNS server IP defined by the DHCP server. This is displayed only if the *Status* is *Connected*.
Retrieve default gateway from server	Enable this to retrieve a default gateway IP address from the DHCP server. The default gateway is added to the static routing table.
Distance	Enter the administrative distance for the default gateway retrieved from the DHCP server. The administrative distance is an integer from 1 to 255, and specifies the relative priority of a route when there are multiple routes to the same destination. A lower administrative distance indicates a more preferred route.
Override internal DNS	Enable this to use the DNS addresses retrieved from the DHCP server instead of the DNS server IP addresses on the DNS page. When VDOMs are enabled, you can override the internal DNS only on the management VDOM.

To configure an interface as a DHCP client in the CLI:

```
config system interface
    edit <name>
        set mode dhcp
        set defaultgw {enable | disable}
        set distance <integer>
        set dns-server-override {enable | disable}
    next
end
```

Configuring the DHCP renew time

You can set a minimum DHCP renew time for an interface acting as a DHCP client. This option is available only when mode is set to DHCP.

To set the DHCP renew time:

```
config system interface
    edit <name>
        set vdom <vdom>
        set interface <interface>
        set mode dhcp
        set dhcp-renew-time <integer>
    next
end
```

The possible values for `dhcp-renew-time` are 300 to 605800 seconds (five minutes to seven days). To use the renew time that the server provides, set this entry to 0.

DHCP client options

When an interface is in DHCP addressing mode, DHCP client options can be configured in the CLI. For example, a vendor class identifier (usually DCHP client option 60) can be specified so that a request can be matched by a specific DHCP offer.

Multiple options can be configured, but any options not recognized by the DHCP server are discarded.

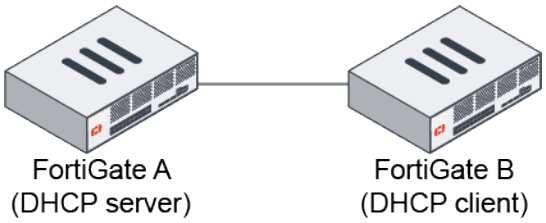
To configure client option 60 - vendor class identifier:

```
config system interface
    edit port1
        set vdom vdom1
        set mode dhcp
        config client-options
            edit 1
                set code 60
                set type hex
                set value aabbccdd
            next
        end
        set type physical
        set snmp-index 4
```

```
    next
end
```

Variable	Description
`code <integer>`	DHCP client option code (0 - 255, default = 0). See Dynamic Host Configuration Protocol (DHCP) and Bootstrap Protocol (BOOTP) Parameters for a list of possible options.
`type {hex | string | ip | fqdn}`	DHCP client option type (default = hex).
`value <string>`	DHCP client option value.
`ip <ip>`	DHCP client option IP address. This option is only available when `type` is `ip`.

VCI pattern matching for DHCP assignment



VCIs (vendor class identifiers) are supported in DHCP to allow VCI pattern matching as a condition for IP or DHCP option assignment. A single IP address, IP ranges of a pool, and dedicated DHCP options can be mapped to a specific VCI string.

```
config system dhcp server
    edit <id>
        config ip-range
            edit <id>
                set vci-match {enable | disable}
                set vci-string <string>
            next
        end
        config options
            edit <id>
                set vci-match {enable | disable}
                set vci-string <string>
            next
        end
    next
end
```

`vci-match {enable | disable}`	Enable/disable VCI matching. When enabled, only DHCP requests with a matching VCI are served with this range.
`vci-string <string>`	Set the VCI string. Enter one or more VCI strings in quotation marks separated by spaces.

Example

In this example, any DHCP client that matches the FortiGate-201F VCI will get their IP from the pool of 10.2.2.133-10.2.2.133, and options 42 (NTP servers) and 150 (TFTP server address). Any DHCP client that matches the FortiGate-101F VCI will get their IP from the default pool (10.2.2.132-10.2.2.132/10.2.2.134-10.2.2.254) and only get the 150 option.

To configure VCI pattern matching on FortiGate A:

```
config system dhcp server
    edit 1
        set dns-service default
        set default-gateway 10.2.2.131
        set netmask 255.255.255.0
        set interface "port3"
        config ip-range
            edit 1
                set start-ip 10.2.2.132
                set end-ip 10.2.2.132
            next
            edit 2
                set start-ip 10.2.2.133
                set end-ip 10.2.2.133
                set vci-match enable
                set vci-string "FortiGate-201F"
            next
            edit 3
                set start-ip 10.2.2.134
                set end-ip 10.2.2.254
            next
        end
        config options
            edit 1
                set code 42
                set type ip
                set vci-match enable
                set vci-string "FortiGate-201F"
                set ip "8.8.8.8"
            next
            edit 2
                set code 150
                set type ip
                set ip "172.16.200.55"
            next
        end
        set vci-match enable
        set vci-string "FortiGate-201F" "FortiGate-101F"
    next
end
```

FortiGate DHCP works with DDNS to allow FQDN connectivity to leased IP addresses

As clients are assigned IP addresses, they send back information that would be found in an A record to the FortiGate DHCP server, which can take this information and pass it back to a corporate DNS server so that even devices using leased IP address can be reached using FQDNs. You can configure the settings for this feature using the `ddns-update` CLI command and some other DDNS related options. Please refer to *DDNS update override* in the DDNS on page 246 topic for further details.

Static routing

Static routing is one of the foundations of firewall configuration. It is a form of routing in which a device uses manually-configured routes. In the most basic setup, a firewall will have a default route to its gateway to provide network access. In a more complex setup with dynamic routing, ADVPN, or SD-WAN involved, you would still likely find static routes being deployed.

This section explores concepts in using static routing and provides examples in common use cases:

- Routing concepts on page 349
- Policy routes on page 363
- Equal cost multi-path on page 365
- Dual internet connections on page 369

The following topics include additional information about static routes:

- Deploying the Security Fabric on page 2679
- Security Fabric over IPsec VPN on page 2701
- Adding a static route on page 634
- IPsec VPN in an HA environment on page 1713
- IPsec VPN to Azure with virtual network gateway on page 1639
- FortiGate as dialup client on page 1659
- ADVPN with BGP as the routing protocol on page 1781
- ADVPN with OSPF as the routing protocol on page 1790
- ADVPN with RIP as the routing protocol on page 1799
- Basic site-to-site VPN with pre-shared key on page 1605
- Site-to-site VPN with digital certificate on page 1610
- Site-to-site VPN with overlapping subnets on page 1617
- Tunneled Internet browsing on page 1687
- Multiple concurrent SDN connectors on page 2900
- Packet distribution and redundancy for aggregate IPsec tunnels on page 1719
- Using BGP tags with SD-WAN rules on page 758

Routing concepts

This section contains the following topics:

- Default route on page 350
- Adding or editing a static route on page 350
- Configuring FQDNs as a destination address in static routes on page 351
- Routing table on page 351
- Viewing the routing database on page 354
- Kernel routing table on page 355
- Route cache on page 356
- Route look-up on page 357
- Blackhole routes on page 357
- Reverse path look-up on page 358
- Asymmetric routing on page 359
- Routing changes on page 361
- Static route tags on page 361

Default route

The default route has a destination of `0.0.0.0/0.0.0.0`, representing the least specific route in the routing table. It is a catch all route in the routing table when traffic cannot match a more specific route. Typically this is configured with a static route with an administrative distance of `10`. In most instances, you will configure the next hop interface and the gateway address pointing to your next hop. If your FortiGate is sitting at the edge of the network, your next hop will be your ISP gateway. This provides internet access for your network.

Sometimes the default route is configured through DHCP. On some desktop models, the WAN interface is preconfigured in DHCP mode. Once the WAN interface is plugged into the network modem, it will receive an IP address, default gateway, and DNS server. FortiGate will add this default route to the routing table with a distance of `5`, by default. This will take precedence over any default static route with a distance of `10`. Therefore, take caution when you are configuring an interface in DHCP mode, where *Retrieve default gateway from server* is enabled. You may disable it and/or change the distance from the *Network* > *Interfaces* page when you edit an interface.

Adding or editing a static route

To add a static route using the GUI:

1. Go to *Network* > *Static Routes* and click *Create New*.
2. Enter the following information:

Dynamic Gateway	When enabled, a selected DHCP/PPPoE interface will automatically retrieve its dynamic gateway.
Destination	• Subnet Enter the destination IP address and netmask. A value of `0.0.0.0/0.0.0.0` creates a default route. • Named Address Select an address or address group object. Only addresses with static route configuration enabled will appear on the list. This means a geography type address cannot be used. • Internet Service

	Select an Internet Service. These are known IP addresses of popular services across the Internet.
Interface	Select the name of the interface that the static route will connect through.
Gateway Address	Enter the gateway IP address. When selecting an IPsec VPN interface or SD-WAN creating a blackhole route, the gateway cannot be specified.
Administrative Distance	Enter the distance value, which will affect which routes are selected first by different protocols for route management or load balancing. The default is 10.
Advanced Options	Optionally, expand *Advanced Options* and enter a *Priority*. When two routes have an equal distance, the route with a lower priority number will take precedence. The default is 1.

3. Click *OK*.

Configuring FQDNs as a destination address in static routes

You can configure FQDN firewall addresses as destination addresses in a static route, using either the GUI or the CLI.

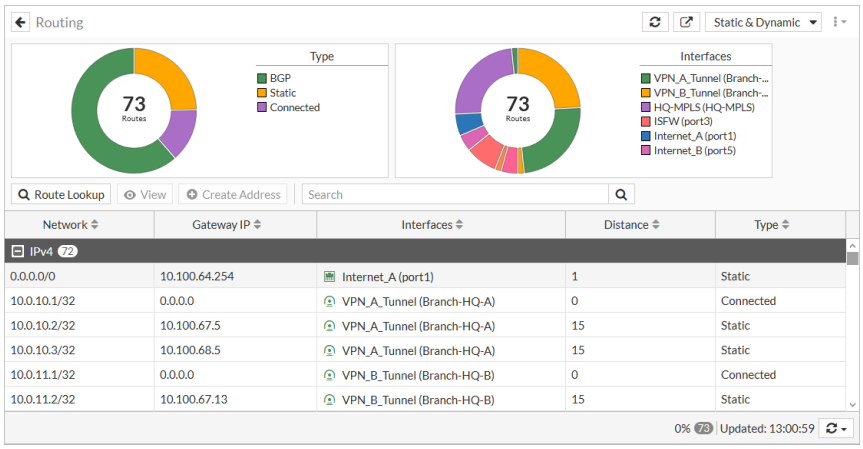
In the GUI, to add an FQDN firewall address to a static route in the firewall address configuration, enable the *Static Route Configuration* option. Then, when you configure the static route, set *Destination* to *Named Address*.

To configure an FQDN as a destination address in a static route using the CLI:

```
config firewall address
    edit 'Fortinet-Documentation-Website'
        set type fqdn
        set fqdn docs.fortinet.com
        set allow-routing enable
    next
end
config router static
    edit 0
        set dstaddr Fortinet-Documentation-Website
        ...
    next
end
```

Routing table

A routing table consists of only the best routes learned from the different routing protocols. The most specific route always takes precedence. If there is a tie, then the route with a lower administrative distance will be injected into the routing table. If administrative distances are also equal, then all the routes are injected into the routing table, and *Cost* and *Priority* become the deciding factors on which a route is preferred. If these are also equal, then FortiGate will use Equal cost multi-path on page 365 to distribute traffic between these routes.



Viewing the routing table in the GUI

You can view routing tables in the FortiGate GUI under *Dashboard* > *Network* > *Static & Dynamic Routing* by default. Expand the widget to see the full page. Additionally, if you want to convert the widget into a dashboard, click on the *Save*

as Monitor icon on the top right of the page.

You can also monitor policy routes by toggling from *Static & Dynamic* to *Policy* on the top right corner of the page. The active policy routes include policy routes that you created, SD-WAN rules, and Internet Service static routes. It also supports downstream devices in the Security Fabric.

The following figure show an example of the static and dynamic routes in the Routing Monitor:

To view more columns, right-click on the column header to select the columns to be displayed:

Field	Description
IP Version	Shows whether the route is IPv4 or IPv6.
Network	The IP addresses and network masks of destination networks that the FortiGate can reach.
Gateway IP	The IP addresses of gateways to the destination networks.
Interfaces	The interface through which packets are forwarded to the gateway of the destination network.
Distance	The administrative distance associated with the route. A lower value means the route is preferable compared to other routes to the same destination.
Type	The type values assigned to FortiGate routes (Static, Connected, RIP, OSPF, or BGP): • *Connected*: All routes associated with direct connections to FortiGate interfaces • *Static*: The static routes that have been added to the routing table manually • *RIP*: All routes learned through RIP • *RIPNG*: All routes learned through RIP version 6 (which enables the sharing of routes through IPv6 networks) • *BGP*: All routes learned through BGP • *OSPF*: All routes learned through OSPF • *OSPF6*: All routes learned through OSPF version 6 (which enables the sharing of routes through IPv6 networks) • *IS-IS*: All routes learned through IS-IS • *HA*: RIP, OSPF, and BGP routes synchronized between the primary unit and the subordinate units of a high availability (HA) cluster. HA routes are maintained on subordinate units and are visible only if you're viewing the router monitor from a virtual domain that is configured as a subordinate virtual domain in a virtual cluster.

Field	Description
Metric	The metric associated with the route type. The metric of a route influences how the FortiGate dynamically adds it to the routing table. The following are types of metrics and the protocols they are applied to: • *Hop count*: Routes learned through RIP • *Relative cost*: Routes learned through OSPF • *Multi-Exit Discriminator (MED)*: Routes learned through BGP. By default, the MED value associated with a BGP route is zero. However, the MED value can be modified dynamically. If the value was changed from the default, the Metric column displays a non-zero value.
Priority	In static routes, priorities are 0 by default. When two routes have an equal distance, the route with the lower priority number will take precedence.
VRF	Virtual routing and forwarding (VRF) allows multiple routing table instances to co-exist. VRF can be assigned to an Interface. Packets are only forwarded between interfaces with the same VRF.
Up Since	The total accumulated amount of time that a route learned through RIP, OSPF, or BGP has been reachable.

Viewing the routing table in the CLI

Viewing the routing table using the CLI displays the same routes as you would see in the GUI.

If VDOMs are enabled on the FortiGate, all routing-related CLI commands must be run within a VDOM and not in the global context.

To view the routing table using the CLI:

```
# get router info routing-table all
Codes: K - kernel, C - connected, S - static, R - RIP, B - BGP
       O - OSPF, IA - OSPF inter area

N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2

E1 - OSPF external type 1, E2 - OSPF external type 2
 i - IS-IS, L1 - IS-IS level-1, L2 - IS-IS level-2, ia - IS-IS inter area
 * - candidate default
Routing table for VRF=0
S*      0.0.0.0/0 [1/0] via 172.31.0.1, MPLS [1/0]via 192.168.2.1, port1 [1/0] via
192.168.122.1, port2
S       1.2.3.4/32 [10/0] via 172.16.100.81, VLAN100
C       10.10.2.0/24 is directly connected, hub
C       10.10.2.1/32 is directly connected, hub
O       10.10.10.0/24 [110/101] via 192.168.2.1, port1, 01:54:18
C       10.253.240.0/20 is directly connected, wqt.root
S       110.2.2.122/32 [22/0] via 2.2.2.2, port2, [3/3]
C       172.16.50.0/24 is directly connected, WAN1-VLAN50
C       172.16.60.0/24 is directly connected, WAN2-VLAN60
C       172.16.100.0/24 is directly connected, VLAN100
C       172.31.0.0/30 is directly connected, MPLS
C       172.31.0.2/32 is directly connected, MPLS
```

```
B       192.168.0.0/24 [20/0] via 172.31.0.1, MPLS, 00:31:43
C       192.168.2.0/24 is directly connected, port1
C       192.168.20.0/24 is directly connected, port3
C       192.168.99.0/24 is directly connected, Port1-VLAN99
C       192.168.122.0/24 is directly connected, port2
Routing table for VRF=10
C       172.16.101.0/24 is directly connected, VLAN101
```

Examining an entry:

```
B       192.168.0.0/24 [20/0] via 172.31.0.1, MPLS, 00:31:43
```

Value	Description
`B`	BGP. The routing protocol used.
`192.168.0.0/24`	The destination of this route, including netmask.
`[20/0]`	`20` indicates an administrative distance of `20` out of a range of `0` to `255`. `0` is an additional metric associated with this route, such as in OSPF.
`172.31.0.1`	The gateway or next hop.
`MPLS`	The interface that the route uses.
`00:31:43`	The age of the route in `HH:MM:SS`.

Viewing the routing database

The routing database consists of all learned routes from all routing protocols before they are injected into the routing table. This likely lists more routes than the routing table as it consists of routes to the same destinations with different distances. Only the best routes are injected into the routing table. However, it is useful to see all learned routes for troubleshooting purposes.

To view the routing database using the CLI:

```
# get router info routing-table database
Codes: K - kernel, C - connected, S - static, R - RIP, B - BGP
       O - OSPF, IA - OSPF inter area

N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
     E1 - OSPF external type 1, E2 - OSPF external type 2
       i - IS-IS, L1 - IS-IS level-1, L2 - IS-IS level-2, ia - IS-IS inter area
       > - selected route, * - FIB route, p - stale info
Routing table for VRF=0
S     *> 0.0.0.0/0 [1/0] via 172.31.0.1, MPLS
      *>           [1/0] via 192.168.2.1, port1
      *>           [1/0] via 192.168.122.1, port2
S     *> 1.2.3.4/32 [10/0] via 172.16.100.81, VLAN100
C     *> 10.10.2.0/24 is directly connected, hub
C     *> 10.10.2.1/32 is directly connected, hub
O     *> 10.10.10.0/24 [110/101] via 192.168.2.1, port1, 02:10:17
C     *> 10.253.240.0/20 is directly connected, wqt.root
S     *> 110.2.2.122/32 [22/0] via 2.2.2.2, port2, [3/3]
```

```
C    *> 172.16.50.0/24 is directly connected, WAN1-VLAN50
C    *> 172.16.60.0/24 is directly connected, WAN2-VLAN60
C    *> 172.16.100.0/24 is directly connected, VLAN100
O       172.31.0.0/30 [110/201] via 192.168.2.1, port1, 00:47:36
C    *> 172.31.0.0/30 is directly connected, MPLS
```

Selected routes are marked by the > symbol. In the above example, the OSPF route to destination `172.31.0.0/30` is not selected.

Kernel routing table

The kernel routing table makes up the actual Forwarding Information Base (FIB) that used to make forwarding decisions for each packet. The routes here are often referred to as kernel routes. Parts of this table are derived from the routing table that is generated by the routing daemon.

To view the kernel routing table using the CLI:

```
# get router info kernel
tab=254 vf=0 scope=0 type=1 proto=11 prio=0 0.0.0.0/0.0.0.0/0->0.0.0.0/0 pref=0.0.0.0
        gwy=172.31.0.1 flag=04 hops=0 oif=31(MPLS)
        gwy=192.168.2.1 flag=04 hops=0 oif=3(port1)
        gwy=192.168.122.1 flag=04 hops=0 oif=4(port2)
tab=254 vf=0 scope=0 type=1 proto=17 prio=0 192.168.122.98/255.255.255.255/0->1.1.1.1/32
pref=0.0.0.0 gwy=192.168.122.1 dev=4(port2)
tab=254 vf=0 scope=0 type=1 proto=17 prio=0 172.31.0.2/255.255.255.255/0->1.1.1.1/32
pref=0.0.0.0 gwy=172.31.0.1 dev=31(MPLS)
tab=254 vf=0 scope=0 type=1 proto=17 prio=0 192.168.2.5/255.255.255.255/0->1.1.1.1/32
pref=0.0.0.0 gwy=192.168.2.1 dev=3(port1)
tab=254 vf=0 scope=0 type=1 proto=11 prio=0 0.0.0.0/0.0.0.0/0->1.2.3.4/32 pref=0.0.0.0
gwy=172.16.100.81 dev=20(VLAN100)
tab=254 vf=0 scope=0 type=1 proto=17 prio=0 192.168.122.98/255.255.255.255/0->8.8.8.8/32
pref=0.0.0.0 gwy=192.168.122.1 dev=4(port2)
```

The kernel routing table entries are:

Value	Description
`tab`	Table number: It will either be `254` (unicast) or `255` (multicast).
`vf`	Virtual domain of the firewall: It is the VDOM index number. If VDOMs are not enabled, this number is `0`.
`type`	Type of routing connection. Valid values include: • `0` - unspecific • `1` - unicast • `2` - local • `3` - broadcast • `4` - anycast • `5` - multicast • `6` - blackhole • `7` - unreachable • `8` - prohibited

Value	Description
proto	Type of installation that indicates where the route came from. Valid values include: • 0 - unspecific • 2 - kernel • 11 - ZebOS routing module • 14 - FortiOS • 15 - HA • 16 - authentication based • 17 - HA1
prio	Priority of the route. Lower priorities are preferred.
->0.0.0.0/0 (->x.x.x.x/mask)	The IP address and subnet mask of the destination.
pref	Preferred next hop along this route.
gwy	Gateway: The address of the gateway this route will use.
dev	Outgoing interface index: This number is associated with the interface for this route. If VDOMs are enabled, the VDOM is also included here. If an interface alias is set for this interface, it is also displayed here.

Route cache

The route cache contains recently used routing entries in a table. It is consulted before the routing table to speed up the route look-up process.

To view the route cache using the CLI:

```
# diagnose ip rtcache list
family=02 tab=254 vrf=0 vf=0 type=01 tos=0 flag=00000200
0.0.0.0@0-&gt;208.91.113.230@3(port1) gwy=192.168.2.1 prefsrc=192.168.2.5
ci: ref=0 lastused=1 expire=0 err=00000000 used=5 br=0 pmtu=1500

family=02 tab=254 vrf=0 vf=0 type=01 tos=0 flag=00000200
192.168.2.5@0-&gt;8.8.8.8@3(port1) gwy=192.168.2.1 prefsrc=0.0.0.0
ci: ref=0 lastused=0 expire=0 err=00000000 used=2 br=0 pmtu=1500

family=02 tab=254 vrf=0 vf=0 type=02 tos=8 flag=80000200
8.8.8.8@31(MPLS)-&gt;172.31.0.2@6(root) gwy=0.0.0.0 prefsrc=172.31.0.2
ci: ref=1 lastused=0 expire=0 err=00000000 used=0 br=0 pmtu=16436

family=02 tab=254 vrf=0 vf=0 type=02 tos=0 flag=84000200
192.168.20.6@5(port3)-&gt;192.168.20.5@6(root) gwy=0.0.0.0 prefsrc=192.168.20.5
ci: ref=2 lastused=0 expire=0 err=00000000 used=1 br=0 pmtu=16436
...
```

The size of the route cache is calculated by the kernel, but can be modified.

To modify the size of the route cache:

```
config system global
    set max-route-cache-size <number_of_cache_entries>
end
```

Route look-up

Route look-up typically occurs twice in the life of a session. Once when the first packet is sent by the originator and once more when the first reply packet is sent from the responder. When a route look-up occurs, the routing information is written to the session table and the route cache. If routing changes occur during the life of a session, additional routing look-ups may occur.

FortiGate performs a route look-up in the following order:

1. Policy-based routes: If a match occurs and the action is to forward, traffic is forwarded based on the policy route.
2. Route Cache: If there are no matches, FortiGate looks for the route in the route cache.
3. Forwarding Information Base, otherwise known as the kernel routing table.
4. If no match occurs, the packet is dropped.

Searching the routing table

When there are many routes in your routing table, you can perform a quick search by using the search bar to specify your criteria, or apply filters on the column header to display only certain routes. For example, if you want to only display static routes, you may use "static" as the search term, or filter by the *Type* field with value *Static*.

Route look-up on the other hand provides a utility for you to enter criteria such as *Destination*, *Destination Port*, *Source*, *Protocol* and/or *Source Interface*, in order to determine the route that a packet will take. Once you click *Search*, the corresponding route will be highlighted.

You can also use the CLI for a route look-up. The CLI provides a basic route look-up tool.

To look-up a route in the CLI:

```
# get router info routing-table details 4.4.4.4
Routing table for VRF=0
Routing entry for 0.0.0.0/0
      Known via "static", distance 1, metric 0, best
      * 172.31.0.1, via MPLS distance 0
      * 192.168.2.1, via port1 distance 0
      * 192.168.122.1, via port2 distance 0
```

Blackhole routes

Sometimes upon routing table changes, it is not desirable for traffic to be routed to a different gateway. For example, you may have traffic destined for a remote office routed through your IPsec VPN interface. When the VPN is down, traffic will try to re-route to another interface. However, this may not be viable and traffic will instead be routed to your default route through your WAN, which is not desirable. Traffic may also be routed to another VPN, which you do not want. For such scenarios, it is good to define a blackhole route so that traffic is dropped when your desired route is down. Upon reconnection, your desired route is once again added to the routing table and your traffic will resume routing to your desired interface. For this reason, blackhole routes are created when you configure an IPsec VPN using the IPsec wizard.

For FortiOS 7.0.1 and above, SSL VPN web mode and explicit web proxy features will not work with the following configuration:

1. An IP pool with ARP reply enabled is configured.
2. This IP pool is configured as the source IP address in either a firewall policy for SSL VPN web mode or in a proxy policy for explicit web proxy.
3. A matching blackhole route is configured for IP pool reply traffic.

Configuring an IP pool as the source NAT IP address in a regular firewall policy works as before.

See IP pools and blackhole route configuration on page 1082 for details.

To create a blackhole route in the GUI:

1. Go to *Network* > *Static Routes*.
2. Click *Create New*. The *New Static Route* screen appears.
3. Specify a *Destination* type.
4. Select *Blackhole* from the *Interface* field.
5. Type the desired *Administrative Distance*.
6. Click *OK*.

Route priority for a *Blackhole* route can only be configured from the CLI.

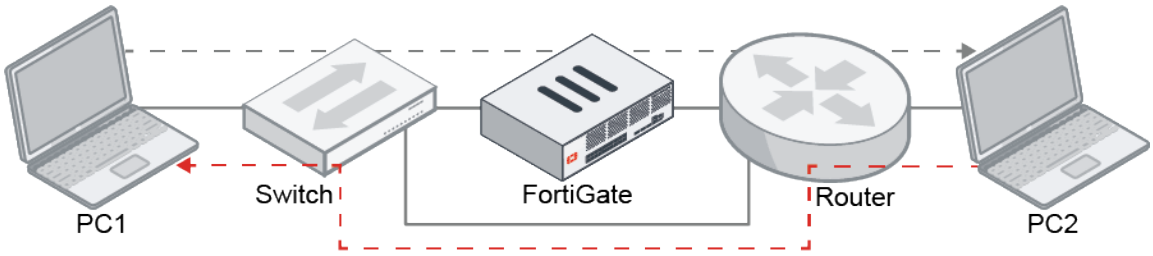
Reverse path look-up

Whenever a packet arrives at one of the interfaces on a FortiGate, the FortiGate determines whether the packet was received on a legitimate interface by doing a reverse look-up using the source IP address in the packet header. This protects against IP spoofing attacks. If the FortiGate does not have a route to the source IP address through the interface on which the packet was received, the FortiGate drops the packet as per Reverse Path Forwarding (RPF) check. There are two modes of RPF – feasible path and strict. The default feasible RPF mode checks only for the existence of at least one active route back to the source using the incoming interface. The strict RPF check ensures the best route back to the source is used as the incoming interface.

To configure a strict Reverse Path Forwarding check in the CLI:

```
config system settings
    set strict-src-check enable
end
```

You can remove RPF state checks without needing to enable asymmetric routing by disabling state checks for traffic received on specific interfaces. Disabling state checks makes a FortiGate less secure and should only be done with caution for troubleshooting purposes.



To remove Reverse Path Forwarding checks from the state evaluation process in the CLI:

```
config system interface
    edit <interface_name>
        set src-check disable
    next
end
```

Asymmetric routing

Asymmetric routing occurs when request and response packets follow different paths that do not cross the same firewall.

In the following topology, traffic between PC1 and PC2 takes two different paths.

Traffic from PC1 to PC2 goes through the FortiGate, while traffic from PC2 to PC1 does not.

In TCP, if the packets in the request and response directions follow different paths, the FortiGate will block the packets, since the TCP three-way handshake is not established through the FortiGate.

Scenario 1: PC1 starts a TCP connection with PC2

1. The TCP SYN is allowed by the FortiGate.
2. The TCP SYN/ACK bypasses the FortiGate.
3. The TCP ACK is blocked by the FortiGate.
4. Subsequent TCP packets are blocked by the FortiGate.

Scenario 2: PC2 starts a TCP connection with PC1

1. The TCP SYN bypasses the FortiGate.
2. The TCP SYN/ACK is blocked by the FortiGate.
3. Subsequent TCP packets are blocked by the FortiGate.

In ICMP, consider the following scenarios.

Scenario 1: PC1 pings PC2

1. The ICMP request passes through the FortiGate. A session is created.
2. The ICMP reply bypasses the FortiGate, but reaches PC1. The ping is successful.
3. The ICMP request passes through the FortiGate, and it matches the previous session.
4. The ICMP reply bypasses the FortiGate, but it reaches PC1. The ping is successful.
5. Subsequent ICMP requests are allowed by the FortiGate.

Scenario 2: PC2 pings PC1

1. The ICMP request bypasses the FortiGate, but it reaches PC1.
2. The ICMP reply passes through the FortiGate. No session is matched, and the packet is dropped.
3. Subsequent ICMP replies are blocked by the FortiGate.

If an ICMP request does not pass through the FortiGate, but the response passes through the FortiGate, then by default it blocks the packet as invalid.

Permitting asymmetric routing

If required, the FortiGate can be configured to permit asymmetric routing.

To permit asymmetric routing:

```
config system settings
    set asymroute enable
end
```

This setting should be used only when the asymmetric routing issue cannot be resolved by ensuring both directions of traffic pass through the FortiGate.

When asymmetric routing is enabled and occurs, the FortiGate cannot inspect all traffic. Potentially malicious traffic may pass through and compromise the security of the network.

Asymmetric routing behaves as follows when it is permitted by the FortiGate:

TCP packets

Scenario 1: PC1 starts a TCP connection with PC2

1. The TCP SYN is allowed by the FortiGate. The FortiGate creates a session, checks the firewall policies, and applies the configuration from the matching policy (UTM inspection, NAT, traffic shaping, and so on).
2. The TCP SYN/ACK bypasses the FortiGate.
3. The TCP ACK is allowed by the FortiGate. The packet matches the previously created session.
4. Subsequent TCP packets are allowed by the FortiGate. The packets in the session can also be offloaded where applicable.

Scenario 2: PC2 starts a TCP connection with PC1

1. The TCP SYN bypasses the FortiGate.
2. The TCP SYN/ACK is allowed by the FortiGate. No session is matched. The packet passes to the CPU and is forwarded based on the routing table.
3. The TCP ACK bypasses the FortiGate.
4. Subsequent TCP packets are allowed by the FortiGate. The FortiGate acts as a router that only makes routing decisions. No security inspection is performed.

ICMP packets

Scenario 1: PC1 pings PC2

1. There is no difference from when asymmetric routing is disabled.

Scenario 2: PC2 pings PC1

1. The ICMP request bypasses the FortiGate, but it reaches PC1.
2. The ICMP reply passes through the FortiGate. No session is matched. The packet passes to the CPU and is forwarded based on the routing table.
3. Subsequent ICMP replies are allowed by the FortiGate. The FortiGate acts as a router that only makes routing decisions. No security inspection is performed.

UDP packets

Asymmetric routing does not affect UDP packets. UDP packets are checked by the session table regardless of asymmetric routing. A policy is required to allow UDP.

Routing changes

When routing changes occur, routing look-up may occur on an existing session depending on certain configurations.

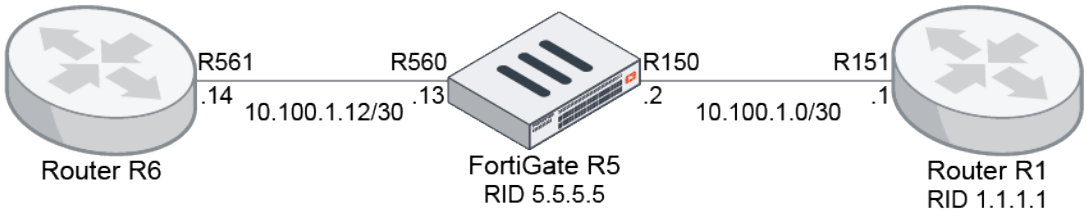
Routing changes without SNAT

When a routing change occurs, FortiGate flushes all routing information from the session table and performs new routing look-up for all new packets on arrival by default. You can modify the default behavior using the following commands:

```
config system interface
    edit <interface>
        set preserve-session-route enable
    next
end
```

By enabling `preserve-session-route`, the FortiGate marks existing session routing information as persistent. Therefore, routing look-up only occurs on new sessions.

Routing changes with SNAT



When SNAT is enabled, the default behavior is opposite to that of when SNAT is not enabled. After a routing change occurs, sessions with SNAT keep using the same outbound interface as long as the old route is still active. This may be the case if the priority of the static route was changed. You can modify this default behavior using the following commands:

```
config system global
    set snat-route-change enable
end
```

By enabling `snat-route-change`, sessions with SNAT will require new route look-up when a routing change occurs. This will apply a new SNAT to the session.

Static route tags

When a static route is configured with a route tag, it is matched in the route map, and then used to set the route's metric and advertise to the BGP neighbor. In the following example, route tag 565 is used, and router R1 receives the advertised route from the FortiGate router R5.

To configure the FortiGate:

1. Configure the static route:

```
config router static
    edit 1
        set dst 77.7.7.7 255.255.255.255
        set distance 2
        set device "R560"
        set tag 565
    next
end
```

2. Configure the route map:

```
config router route-map
    edit "map1"
        config rule
            edit 2
                set match-tag 565
                set set-metric 2301
            next
        end
    next
end
```

3. Configure the BGP neighbor:

```
config router bgp
    config neighbor
        edit "10.100.1.2"
            set route-map-out "map1"
        next
    end
end
```

On its neighbor side, router R1 receives the advertised route from the FortiGate router R5.

4. Verify the BGP routing table:

```
# get router info routing-table bgp
Routing table for VRF=0
B       77.7.7.7/32 [20/2301] via 10.100.1.1 (recursive is directly connected, R150),
03:18:53, [1/0]
```

5. Verify the network community:

```
# get router info bgp network 77.7.7.7/32
VRF 0 BGP routing table entry for 77.7.7.7/32
Paths: (1 available, best #1, table Default-IP-Routing-Table)
  Advertised to non peer-group peers:
```

```
 2.2.2.2 3.3.3.3 10.100.1.5 2000::2:2:2:2
Original VRF 0
20
  10.100.1.1 from 10.100.1.1 (5.5.5.5)
    Origin incomplete metric 2301, localpref 200, valid, external, best
    Last update: Wed Oct  5 16:48:28 2022
```

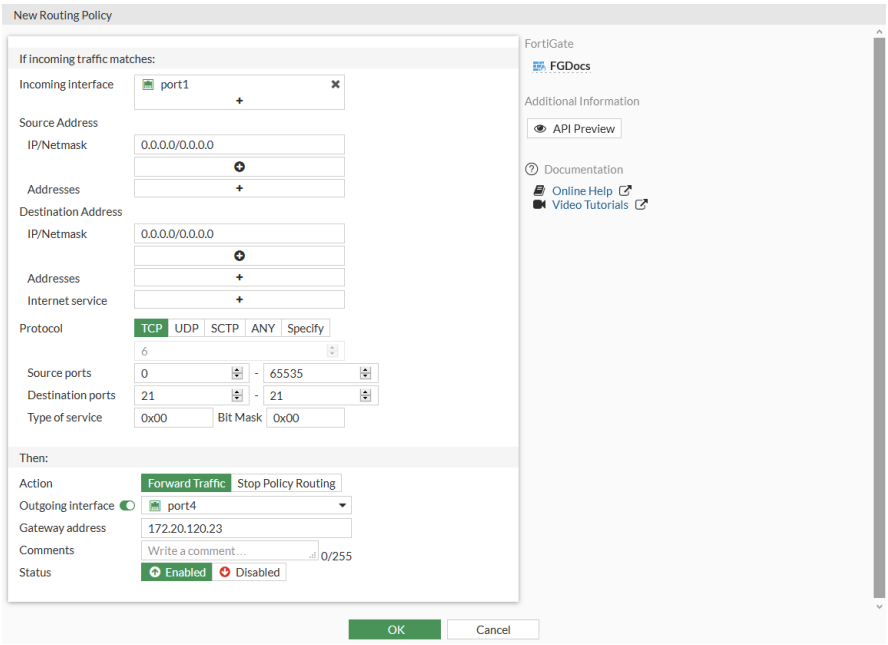
Policy routes

Policy routing allows you to specify an interface to route traffic. This is useful when you need to route certain types of network traffic differently than you would if you were using the routing table. You can use the incoming traffic's protocol, source or destination address, source interface, or port number to determine where to send the traffic.

When a packet arrives, the FortiGate starts at the top of the policy route list and attempts to match the packet with a policy. For a match to be found, the policy must contain enough information to route the packet. At a minimum, this requires the outgoing interface to forward the traffic, and the gateway to route the traffic to. If one or both of these are not specified in the policy route, then the FortiGate searches the routing table to find the best active route that corresponds to the policy route. If no routes are found in the routing table, then the policy route does not match the packet. The FortiGate continues down the policy route list until it reaches the end. If no matches are found, then the FortiGate does a route lookup using the routing table.

Policy routes are sometimes referred to as Policy-based routes (PBR).

Configuring a policy route



In this example, a policy route is configured to send all FTP traffic received at port1 out through port4 and to a next hop router at 172.20.120.23. To route FTP traffic, the protocol is set to TCP (6) and the destination ports are set to 21 (the FTP port).

To configure a policy route in the GUI:

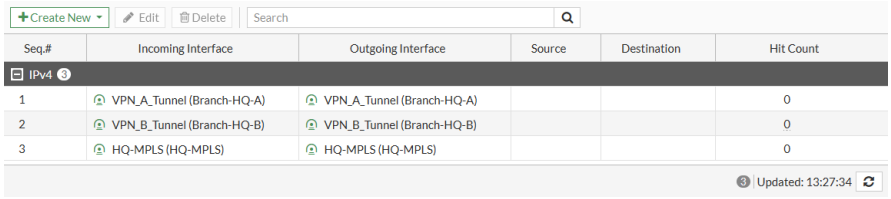
1. Go to *Network* > *Policy Routes*.
2. Click *Create New* > *Policy Route*.
3. Configure the following fields:

Incoming interface	port1
Source Address	0.0.0.0/0.0.0.0
Destination Address	0.0.0.0/0.0.0.0
Protocol	TCP
Destination ports	21 - 21
Type of service	0x00
Bit Mask	0x00

Outgoing interface	Enable and select port4
Gateway address	172.20.120.23

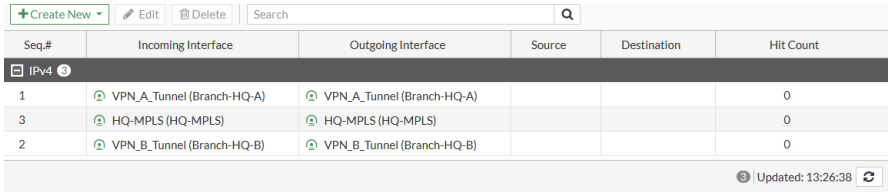
4. Click *OK*.

To configure a policy route in the CLI:



```
config router policy
    edit 1
        set input-device "port1"
        set src "0.0.0.0/0.0.0.0"
        set dst "0.0.0.0/0.0.0.0"
        set protocol 6
        set start-port 21
        set end-port 21
        set gateway 172.20.120.23
        set output-device "port4"
        set tos 0x00
        set tos-mask 0x00
    next
end
```

Moving a policy route



A routing policy is added to the bottom of the table when it is created. Routing policies can be moved to a different location in the table to change the order of preference. In this example, routing policy 3 will be moved before routing policy 2.

To move a policy route in the GUI:

1. Go to *Network* > *Policy Routes*.
2. In the table, select the policy route.

3. Drag the selected policy route to the desired position.

To move a policy route in the CLI:

```
config router policy
    move 3 after 1
end
```

Equal cost multi-path

Equal cost multi-path (ECMP) is a mechanism that allows a FortiGate to load-balance routed traffic over multiple gateways. Just like routes in a routing table, ECMP is considered after policy routing, so any matching policy routes will take precedence over ECMP.

ECMP pre-requisites are as follows:

- Routes must have the same destination and costs. In the case of static routes, costs include distance and priority
- Routes are sourced from the same routing protocol. Supported protocols include static routing, OSPF, and BGP

ECMP and SD-WAN implicit rule

ECMP and SD-WAN implicit rule are essentially similar in the sense that an SD-WAN implicit rule is processed after SD-WAN service rules are processed. See Implicit rule on page 696 to learn more.

The following table summarizes the different load-balancing algorithms supported by each:

ECMP	SD-WAN		Description
	GUI	CLI	
`source-ip-based`	Source IP	`source-ip-based`	Traffic is divided equally between the interfaces. Sessions that start at the same source IP address use the same path. This is the default selection.

ECMP	SD-WAN		Description
	GUI	CLI	
weight-based	Sessions	weight-based	The workload is distributed based on the number of sessions that are connected through the interface. The weight that you assign to each interface is used to calculate the percentage of the total sessions allowed to connect through an interface, and the sessions are distributed to the interfaces accordingly.
usage-based	Spillover	usage-based	The interface is used until the traffic bandwidth exceeds the ingress and egress thresholds that you set for that interface. Additional traffic is then sent through the next interface member.
source-dest-ip-based	Source-Destination IP	source-dest-ip-based	Traffic is divided equally between the interfaces. Sessions that start at the same source IP address and go to the same destination IP address use the same path.
Not supported	Volume	measured-volume-based	This mode is supported in SD-WAN only. The workload is distributed based on the number of packets that are going through the interface.

To configure the ECMP algorithm from the CLI:

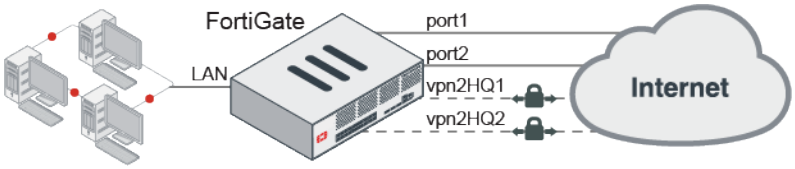
- At the VDOM level:

```
config system settings
    set v4-ecmp-mode {source-ip-based* | weight-based | usage-based | source-dest-ip-
based}
end
```

- If SD-WAN is enabled, the above option is not available and ECMP is configured under the SD-WAN settings:

```
config system sdwan
    set status enable
    set load-balance-mode {source-ip-based* | weight-based | usage-based | source-dest-
ip-based | measured-volume-based}
end
```

For ECMP in IPv6, the mode must also be configured under SD-WAN:



```
# diagnose sys vd list
system fib version=63
list virtual firewall info:
name=root/root index=0 enabled fib_ver=40 use=168 rt_num=46 asym_rt=0 sip_helper=0, sip_nat_
trace=1, mc_fwd=0, mc_ttl_nc=0, tpmc_sk_pl=0
ecmp=source-ip-based, ecmp6=source-ip-based asym_rt6=0 rt6_num=55 strict_src_check=0 dns_
log=1 ses_num=20 ses6_num=0 pkt_num=19154477
```

To change the number of paths allowed by ECMP:

```
config system settings
    set ecmp-max-paths <number of paths>
end
```

Setting `ecmp-max-paths` to the lowest value of `1` is equivalent to disabling ECMP.

ECMP configuration examples

The following examples demonstrate the behavior of ECMP in different scenarios:

- Example 1: Default ECMP on page 367
- Example 2: Same distance, different priority on page 368
- Example 3: Weight-based ECMP on page 368
- Example 4: Load-balancing BGP routes on page 369

Example 1: Default ECMP

```
config router static
    edit 1
        set gateway 172.16.151.1
        set device "port1"
    next
    edit 2
        set gateway 192.168.2.1
        set device "port2"
    next
end
```

```
# get router info routing-table all
Routing table for VRF=0
S*    0.0.0.0/0 [10/0] via 172.16.151.1, port1
                [10/0] via 192.168.2.1, port2
C    172.16.151.0/24 is directly connected, port1
C    192.168.2.0/24 is directly connected, port2
```

Result:

Both routes are added to the routing table and load-balanced based on the source IP.

Example 2: Same distance, different priority

```
config router static
    edit 1
        set gateway 172.16.151.1
        set priority 5
        set device "port1"
    next
    edit 2
        set gateway 192.168.2.1
        set device "port2"
    next
end
```

```
# get router info routing-table all
Routing table for VRF=0
S*    0.0.0.0/0 [10/0] via 192.168.2.1, port2
                [10/0] via 172.16.151.1, port1, [5/0]
C    172.16.151.0/24 is directly connected, port1
C    192.168.2.0/24 is directly connected, port2
```

Result:

Both routes are added to the routing table, but traffic is routed to `port2` which has a lower priority value with a default of `0`.

Example 3: Weight-based ECMP

```
config router static
    edit 3
        set dst 10.10.30.0 255.255.255.0
        set weight 80
        set device "vpn2HQ1"
    next
    edit 5
        set dst 10.10.30.0 255.255.255.0
        set weight 20
        set device "vpn2HQ2"
    next
end
```

```
# get router info routing-table all
Routing table for VRF=0
...
S    10.10.30.0/24 [10/0] is directly connected, vpn2HQ1, [0/80]
                   [10/0] is directly connected, vpn2HQ2, [0/20]
C    172.16.151.0/24 is directly connected, port1
C    192.168.0.0/24 is directly connected, port3
C    192.168.2.0/24 is directly connected, port2
```

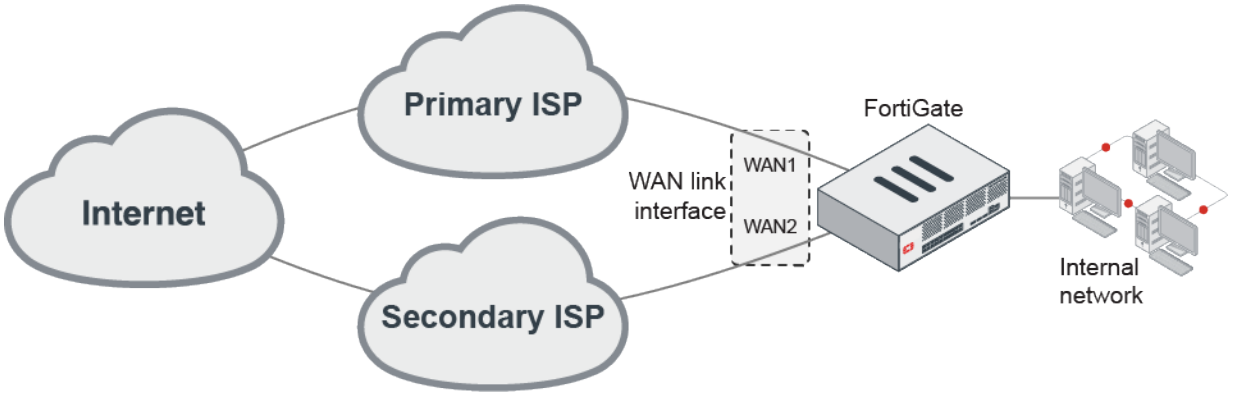
Result:

Both routes are added to the routing table, but 80% of the sessions to `10.10.30.0/24` are routed to `vpn2HQ1`, and 20% are routed to `vpn2HQ2`.

Example 4: Load-balancing BGP routes

```
config router bgp
    set as 64511
    set router-id 192.168.2.86
    set ebgp-multipath enable
    config neighbor
        edit "192.168.2.84"
            set remote-as 64512
        next
        edit "192.168.2.87"
            set remote-as 64512
        next
   end
end
# get router info routing-table all
Routing table for VRF=0
...
C    172.16.151.0/24 is directly connected, port1
C    192.168.0.0/24 is directly connected, port3
C    192.168.2.0/24 is directly connected, port2
B    192.168.80.0/24 [20/0] via 192.168.2.84, port2, 00:00:33
                     [20/0] via 192.168.2.87, port2, 00:00:33
```

Result:



The network `192.168.80.0/24` is advertised by two BGP neighbors. Both routes are added to the routing table, and traffic is load-balanced based on Source IP.

For multiple BGP paths to be added to the routing table, you must enable `ebgp-multipath` for eBGP or `ibgp-multipath` for iBGP. These settings are disabled by default.

Dual internet connections

Dual internet connections, also referred to as dual WAN or redundant internet connections, refers to using two FortiGate interfaces to connect to the Internet. This is generally accomplished with SD-WAN, but this legacy solution provides the means to configure dual WAN without using SD-WAN. You can use dual internet connections in several ways:

- Link redundancy: If one interface goes down, the second interface automatically becomes the main connection.
- Load sharing: This ensures better throughput.
- Use a combination of link redundancy and load sharing.

This section describes the following dual internet connection scenarios:

- Scenario 1: Link redundancy and no load-sharing on page 370
- Scenario 2: Load-sharing and no link redundancy on page 372
- Scenario 3: Link redundancy and load-sharing on page 373

Scenario 1: Link redundancy and no load-sharing

Link redundancy ensures that if your Internet access is no longer available through a certain port, the FortiGate uses an alternate port to connect to the Internet.

In this scenario, two interfaces, WAN1 and WAN2, are connected to the Internet using two different ISPs. WAN1 is the primary connection. In the event of a failure of WAN1, WAN2 automatically becomes the connection to the Internet. For this configuration to function correctly, you must configure the following settings:

- Link health monitor on page 370: To determine when the primary interface (WAN1) is down and when the connection returns.
- Routing on page 371: Configure a default route for each interface.
- Security policies on page 372: Configure security policies to allow traffic through each interface to the internal network.

Link health monitor

Adding a link health monitor is required for routing failover traffic. A link health monitor confirms the device interface connectivity by probing a gateway or server at regular intervals to ensure it is online and working. When the server is not accessible, that interface is marked as down.

Set the `interval` (how often to send a ping) and `failtime` (how many lost pings are considered a failure). A smaller interval value and smaller number of lost pings results in faster detection, but creates more traffic on your network.

The link health monitor supports both IPv4 and IPv6, and various other protocols including ping, tcp-echo, udp-echo, http, and twamp.

To add a link health monitor (IPv4) using the CLI:

```
config system link-monitor
    edit <link-monitor-name>
        set addr-mode ipv4
        set srcintf <interface-name>
        set server <server-IP-address>
        set protocol {ping tcp-echo udp-echo http twamp}
        set gateway-ip <gateway-IP-address>
        set interval <seconds>
        set failtime <retry-attempts>
        set recoverytime <number-of-successful-responses>
        set status enable
    next
end
```

Option	Description
`set update-cascade-interface {enable | disable}`	This option is used in conjunction with fail-detect and fail-alert options in interface settings to cascade the link failure down to another interface. See the Bring other interfaces down when link monitor fails KB article for details.
`set update-static-route {enable | disable}`	When the link fails, all static routes associated with the interface will be removed.

Routing

You must configure a default route for each interface and indicate your preferred route as follows:

- Specify different distances for the two routes. The lower of the two distance values is declared active and placed in the routing table.

  Or

- Specify the same distance for the two routes, but give a higher priority to the route you prefer by defining a lower value. Both routes will be added to the routing table, but the route with a higher priority will be chosen as the best route

In the following example, we will use the first method to configure different distances for the two routes. You might not be able to connect to the backup WAN interface because the FortiGate does not route traffic out of the backup interface. The FortiGate performs a reverse path look-up to prevent spoofed traffic. If an entry cannot be found in the routing table that sends the return traffic out through the same interface, the incoming traffic is dropped.

To configure the routing of the two interfaces using the GUI:

1. Go to *Network* > *Static Routes*, and click *Create New*.
2. Enter the following information:

Destination	For an IPv4 route, enter a subnet of `0.0.0.0/0.0.0.0`. For an IPv6 route, enter a subnet of `::/0`.
Interface	Select the primary connection. For example, `wan1`.
Gateway Address	Enter the gateway address.
Administrative Distance	Leave as the default of `10`.

3. Click *OK*.
4. Repeat the above steps to set *Interface* to `wan2` and *Administrative Distance* to `20`.

To configure the routing of the two interfaces using the CLI:

```
config router {static | static6}
    edit 1
        set dst 0.0.0.0 0.0.0.0
        set device wan1
        set gateway <gateway_address>
        set distance 10
```

```
    next
    edit 2
        set dst 0.0.0.0 0.0.0.0
        set device wan2
        set gateway <gateway_address>
        set distance 20
    next
end
```

Security policies

When you create security policies, you need to configure duplicate policies to ensure that after traffic fails over WAN1, regular traffic is allowed to pass through WAN2, as it did with WAN1. This ensures that failover occurs with minimal effect to users.

Scenario 2: Load-sharing and no link redundancy

Load sharing may be accomplished in a few of the following ways of the many possible ways:

- By defining a preferred route with a lower distance, and specifying policy routes to route certain traffic to the secondary interface.
- By defining routes with same distance values but different priorities, and specifying policy routes to route certain traffic to the secondary interface.
- By defining routes with same distance values and priorities, and use equal-cost multi-path (ECMP) routing to equally distribute traffic between the WAN interfaces.

In our example, we will use the first option for our configuration. In this scenario, because link redundancy is not required, you do not have to configure a link monitor.

Traffic behaviour without a link monitor is as follows:

- If the remote gateway is down but the primary WAN interface of a FortiGate is still up, the FortiGate will continue to route traffic to the primary WAN. This results in traffic interruptions.
- If the primary WAN interface of a FortiGate is down due to physical link issues, the FortiGate will remove routes to it and the secondary WAN routes will become active. Traffic will failover to the secondary WAN.

Routing

Configure routing as you did in Scenario 1: Link redundancy and no load-sharing on page 370 above.

Policy routes

By configuring policy routes, you can redirect specific traffic to the secondary WAN interface. This works in this case because policy routes are checked before static routes. Therefore, even though the static route for the secondary WAN is not in the routing table, traffic can still be routed using the policy route.

In this example, we will create a policy route to route traffic from one address group to the secondary WAN interface.

To configure a policy route from the GUI:

1. Go to *Network* > *Policy Routes*, and click *Create New*.
2. Enter the following information:

Incoming interface	Define the source of the traffic. For example, `internal`.
Source Address	If we prefer to route traffic only from a group of addresses, define an address or address group, and add here.
Destination Address	Because we want to route all traffic from the address group here, we do not specify a destination address.
Protocol	Specify any protocol.
Action	Forward traffic.
Outgoing interface	Select the secondary WAN as the outbound interface. For example, `wan2`.
Gateway address	Input the gateway address for your secondary WAN. Because its default route has a higher distance value and is not added to the routing table, the gateway address must be added here.

3. Click OK.

To configure a policy route from the CLI:

```
config router policy
    edit 1
        set input-device "internal"
        set srcaddr "Laptops"
        set gateway <gateway_address>
        set output-device "wan2"
    next
end
```

Security policies

Your security policies should allow all traffic from `internal` to WAN1. Because link redundancy is not needed, you do not need to duplicate all WAN1 policies to WAN2. You will only need to define policies used in your policy route.

Scenario 3: Link redundancy and load-sharing

In this scenario, both the links are available to distribute Internet traffic with the primary WAN being preferred more. Should one of the interfaces fail, the FortiGate will continue to send traffic over the other active interface. The configuration is a combination of both the link redundancy and the load-sharing scenarios. The main difference is that the configured routes have equal distance values, with the route with a higher priority being preferred more. This ensures both routes are active in the routing table, but the route with a higher priority will be the best route.

Link health monitor

Link monitor must be configured for both the primary and the secondary WAN interfaces. This ensures that if the primary or the secondary WAN fails, the corresponding route is removed from the routing table and traffic re-routed to the other

WAN interface.

For configuration details, see sample configurations in Scenario 1: Link redundancy and no load-sharing on page 370.

Routing

Both WAN interfaces must have default routes with the same distance. However, preference is given to the primary WAN by giving it a higher priority.

To configure the routing of the two interfaces using the CLI:

```
config router {static | static6}
    edit 1
        set dst 0.0.0.0 0.0.0.0
        set device wan1
        set gateway <gateway_address>
        set distance 10
        set priority 1
    next
    edit 2
        set dst 0.0.0.0 0.0.0.0
        set device wan2
        set gateway <gateway_address>
        set distance 10
        set priority 10
    next
end
```

Policy routes

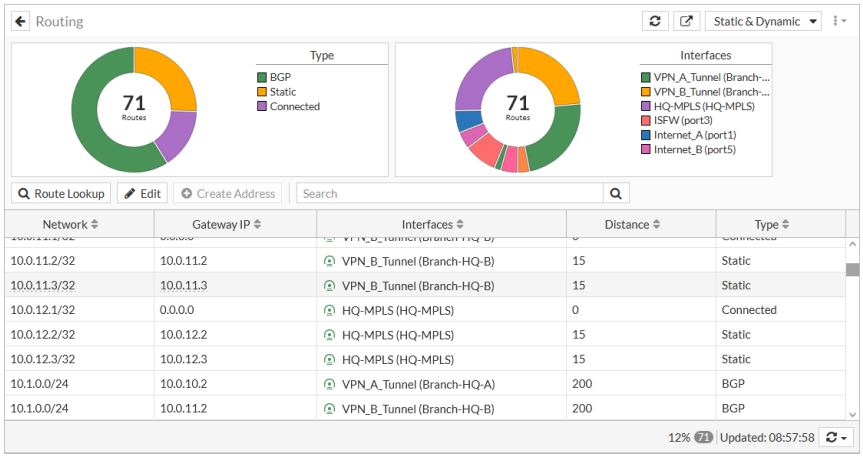
The policy routes configuration is very similar to that of the policy routes in Scenario 2: Load-sharing and no link redundancy on page 372, except that the gateway address should not be specified. When a policy route is matched and the gateway address is not specified, the FortiGate looks at the routing table to obtain the gateway. In case the secondary WAN fails, traffic may hit the policy route. Because there is no gateway specified and the route to the secondary WAN is removed by the link monitor, the policy route will by bypassed and traffic will continue through the primary WAN. This ensures that the policy route is not active when the link is down.

Security policies

When you create security policies, you need to configure duplicate policies to ensure that after traffic fails over WAN1, regular traffic is allowed to pass through WAN2, as it was with WAN1. This ensures that failover occurs with minimal effect to users.

Dynamic routing

Dynamic routing protocols attempt to build a map of the network topology to identify the best routes to reach different destinations. Instead of manually defining static routes, which is not scalable, dynamic routing typically involves defining neighbors and peer routers that share their network topology and routing updates with each other. Protocols like distance vector, link state, and path vector are used by popular routing protocols. FortiGate supports RIP, OSPF, BGP,



and IS-IS, which are interoperable with other vendors. When different dynamic routing protocols are used, the administrative distance of each protocol helps the FortiGate decide which route to pick.

Go to *System* > *Feature Visibility* and enable *Advanced Routing* to configure dynamic routing options in the GUI. See Feature visibility on page 2517 for more information.

This section includes:

- RIP on page 376
- OSPF on page 395
- BGP on page 412
- BFD on page 450
- Routing objects on page 459

To view the routing table and perform route look-ups in the GUI, go to *Dashboard* > *Network* and expand the *Routing* widget.

To view the routing table in the CLI:

```
# get router info routing-table all
Codes: K - kernel, C - connected, S - static, R - RIP, B - BGP
       O - OSPF, IA - OSPF inter area
       N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
       E1 - OSPF external type 1, E2 - OSPF external type 2
       i - IS-IS, L1 - IS-IS level-1, L2 - IS-IS level-2, ia - IS-IS inter area
       * - candidate default
Routing table for VRF=0
S*    0.0.0.0/0 [5/0] via 192.168.0.1, wan1
C     10.10.10.0/24 is directly connected, internal
C     169.254.2.1/32 is directly connected, Dialup-test
C     172.31.0.0/30 is directly connected, toKVM-MPLS
C     172.31.0.1/32 is directly connected, toKVM-MPLS
C     192.168.0.0/24 is directly connected, wan1
O     192.168.2.0/24 [110/101] via 10.10.10.11, internal, 00:00:26
S     192.168.20.0/24 [10/0] via 172.31.0.2, toKVM-MPLS
       [10/0] via 10.10.10.11, internal
```

RIP

Routing Information Protocol (RIP) is a distance-vector routing protocol that is intended for small and relatively homogeneous networks. It works well when there are minimal redundant paths and limited hop counts. FortiGate supports RIP version 1 (RFC 1058), RIP version 2 (RFC 2453), and RIPng (RFC 2080).

Basic configuration

To configure the FortiGate to participate in RIP using the most basic configurations in the GUI:

1. Go to *Network* > *RIP*.
2. Set the *Version*.
3. Add the networks that the FortiGate will advertise in and that will participate in RIP.
4. If the interface settings, such as passive interface, authentication, or enabling send/receive updates, must be edited, add the interfaces to the *Interface* table.
5. Click *Apply*.

To configure the FortiGate to participate in RIP using the most basic configurations in the CLI:

```
config router rip
    config network
        edit 1
            set prefix <subnet> <netmask>
        next
    end
    config interface
        edit <interface>
            set receive-version 2
            set send-version 2
        next
    end
end
```

Default route injection

Enabling *Inject default route* (`default-information-originate`) advertises a default route into the FortiGate's RIP network.

To enable/disable default route injection in the GUI:

1. Go to *Network* > *RIP*.
2. Expand the *Advanced Options*.
3. Enable/disable *Inject Default Route*.
4. Click *OK*.

To enable/disable default route injection in the CLI:

```
config router rip
    set default-information-originate {enable | disable}
```

```
end
```

Default metric

The default metric setting sets the default metric for all redistributed routes. If the default metric is set to five, and static routes are redistributed, then static routes have a metric of five. This value can be overridden by setting a specific metric value for a protocol. For example, the static route metric can be set to two, overriding the default metric.

```
config router rip
    set default-metric 5
    config redistribute "static"
        set status enable
        set metric 2
    end
end
```

The default metric is five, but redistributed static routes have a metric of two. So, the default metric is overridden and the metric for redistributed static routes is two.

Timers

RIP uses the update, timeout, and garbage timers to regulate its performance. The default timer settings are effective in most configurations. When customizing the settings, you must ensure that the new settings are compatible with your local routers and access servers.

Go to *Network* > *RIP* and expand the *Advanced Options* to configure the timers in the GUI, or use the CLI:

```
config router rip
    set timeout-timer <seconds>
    set update-timer <seconds>
    set garbage-timer <seconds>
end
```

Update timer

The update timer sets the interval between routing updates. The default value is 30 seconds. Randomness is added to help prevent network congestion due to multiple routers trying to update their neighbors simultaneously. The update timer must be at least three times shorter than the timeout timer.

If there is significant RIP traffic on the network, you can increase the update timer to send fewer updates. You must apply the same increase to all routers on the network to avoid timeouts that degrade your network speed.

Timeout timer

The timeout timer is the maximum amount of time that a reachable route is kept in the routing table since its last update. The default value is 180 seconds. If an update for the route is received before the timeout period elapses, then the timer is reset. The timeout timer should be at least three times longer than the update timer.

If routers are not responding to updates in time, increasing the timeout timer can help. A longer timeout timer results in longer update periods, and the FortiGate could wait a considerable amount of time for all of the timers to expire on an unresponsive route.

Garbage timer

The garbage timer is the amount of time that the FortiGate advertises a route as unreachable before deleting the route from the routing table. The default value is 120 seconds.

If the timer is short, older routes are removed from the routing table more quickly, resulting in a smaller routing table. This can be useful for large networks, or if the network changes frequently.

Authentication and key chain

RIP version 1 (RIPv1) has no authentication. RIP version 2 (RIPv2) uses text passwords or authentication keys to ensure that the routing information exchanged between routers is reliable. For authentication to work, both the sending and receiving routers must be set to use authentication and must be configured with the same password or keys. An authentication key that uses authentication key chains is more secure than a text password because the intervals when the key is valid can be configured.

A key chain is a list of one or more authentication keys that each have send and receive lifetimes. Keys are used to authenticate routing packets only during the keys specified lifetimes. The FortiGate migrates from one key to the next according to the scheduled lifetimes. The sending and receiving routers should have synchronized system dates and times to ensure that both ends are using the same keys at the same times. You can overlap the key lifetimes to make sure that a key is always available, even if there is some difference in the system times.

To configure a text password in the GUI:

1. Go to *Network* > *RIP*.
2. In the *Interfaces* table, click *Create New*, or edit an existing interface.
3. Enable *Authentication* and select *Text* or *MD5*.
4. Click *Change*, and enter the password.
5. Configure the remaining settings as needed.
6. Click *OK*.
7. Click *Apply*.

To configure a text password in the CLI:

```
config router rip
    config interface
        edit <interface>
            set auth-mode {text | md5}
            set auth-string **********
        next
    end
end
```

To configure a key chain with two sequentially valid keys and use it in a RIP interface:

```
config router key-chain
    edit rip_key
        config key
            edit 1
                set accept-lifetime 09:00:00 23 02 2020 09:00:00 17 03 2020
                set send-lifetime 09:00:00 23 02 2020 09:00:00 17 03 2020
```

```
                set key-string **********
            next
            edit 2
                set accept-lifetime 09:01:00 17 03 2020 09:00:00 1 04 2020
                set send-lifetime 09:01:00 17 03 2020 09:00:00 1 04 2020
                set key-string **********
            next
        end
    next
end

config router rip
    config interface
        edit port1
            set auth-keychain "rip_key"
        next
    end
end
```

Passive RIP interfaces

By default, an active RIP interface keeps the FortiGate routing table current by periodically asking neighbors for routes and sending out route updates. This can generate a significant amount of extra traffic in a large network.

A passive RIP interface listens to updates from other routers, but does not send out route updates. This can reduce network traffic when there are redundant routers in the network that would always send out essentially the same updates.

This example shows how to configure a passive RIPv2 interface on port1 using MD5 authentication.

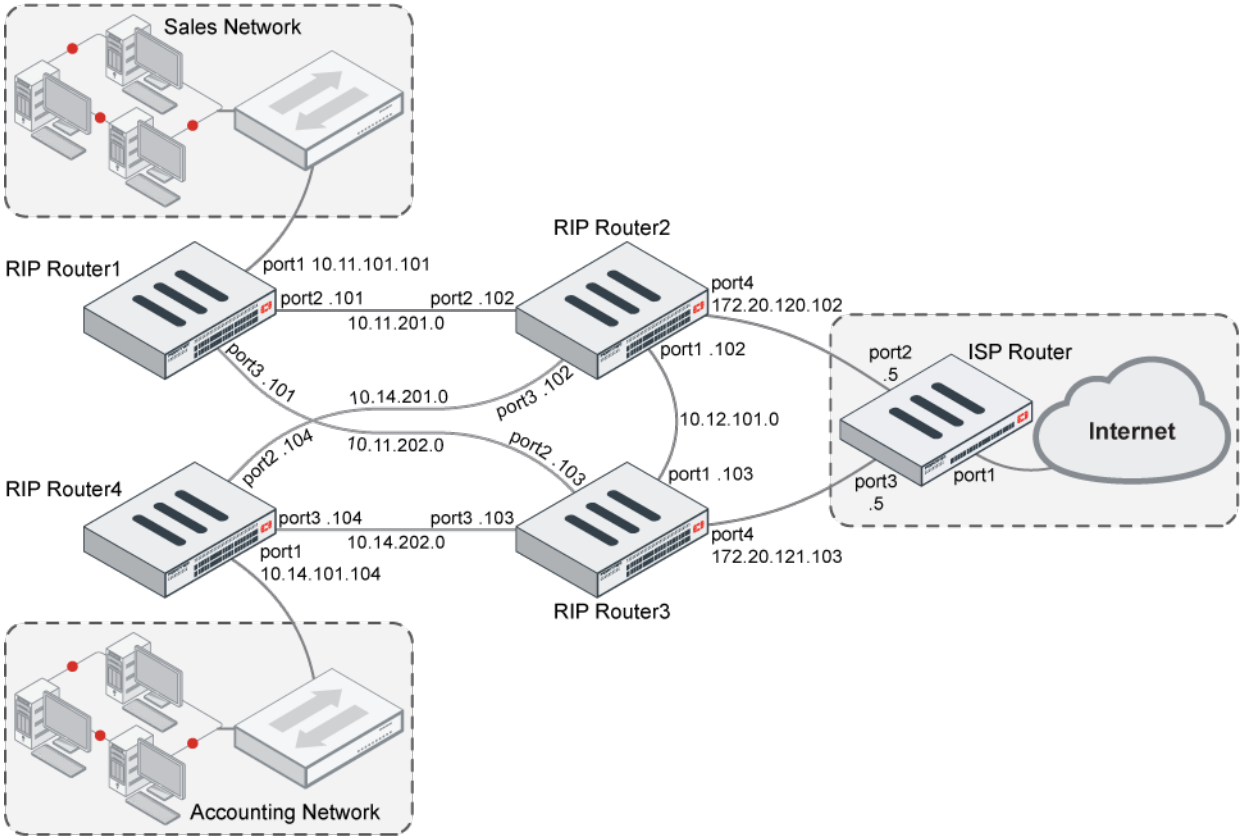
To configure a passive RIP interface in the GUI:

1. Go to *Network* > *RIP*.
2. In the *Interfaces* table, click *Create New*.
3. Set *Interface* to the required interface.
4. Enable *Passive*.
5. Enable *Authentication* and set it to *MD5*.
6. Click *Change* and enter a password.
7. Set *Receive Version* to *2*.
8. Click *OK*.

To configure a passive RIP interface in the CLI:

```
config router rip
    set passive-interface "port1"
    config interface
        edit "port1"
            set auth-mode md5
            set auth-string **********
            set receive-version 2
            set send-version 2
        next
```

```
    end
end
```



RIP and IPv6

RIP next generation (RIPng) is an extension of RIPv2 that includes support for IPv6. See Basic RIPng example on page 393 and IPv6 tunneling on page 570 for more information.

Basic RIP example

In this example, a medium-sized network is configured using RIPv2.

- Two core routers, RIP Router2 and RIP Router3, connect to the ISP router for two redundant paths to the internet.
- Two other routers, RIP Router1 and RIP Router4, connect to the two core routers and to different local networks.
- The ISP router is using RIP for its connections to the core routers, and redistributes its default route to the network - that is, default route injection is enabled.
- The ISP router uses NAT and has a static route to the internet. None of the other routers use NAT or static routes.

All of the FortiGate routers are configured as shown, using netmask 255.255.255.0. Firewall policies have been configured to allow the required traffic to flow across the interfaces.

Router	Interface	Interface name	IP address
Router1	port1	LoSales	10.11.101.101
	port2	vd12link0	10.11.201.101
	port3	vd13link0	10.11.202.101
Router2	port1	vd23link0	10.12.101.102
	port2	vd12link1	10.11.201.102
	port3	vd42link1	10.14.201.102
	port4	vdr2link1	172.20.120.102
Router3	port1	vd23link1	10.12.101.103
	port2	vd13link1	10.11.202.103
	port3	vd43link1	10.14.202.103
	port4	vdr3link1	172.20.121.103
Router4	port1	LoAccounting	10.14.101.104
	port2	vd42link0	10.14.201.104
	port3	vd43link0	10.14.202.104
ISP Router	port1	port1	To internet
	port2	vdr2link0	172.20.120.5
	port3	vdr3link0	172.20.121.5

After configuring each router, you can check the status of the connections by viewing the RIP database, RIP interfaces, and routing table. See Verifying the configuration on page 386.

After the network is configured, you can test it to ensure that when network events occur, such as a downed link, routing updates are triggered and converge as expected. See Testing the configuration and routing changes on page 390.

ISP router

To configure the ISP Router in the GUI:

1. Go to *Network* > *RIP*.
2. Set the *Version* to *2*.
3. Under *Networks*, add two networks:
   - *172.20.120.0/255.255.255.0*
   - *172.20.121.0/255.255.255.0*
4. Add the interfaces:
   a. In the *Interfaces* table, click *Create New*.
   b. Set *Interface* to *port2*.
   c. Leave the remaining settings as their default values.

d. Click *OK*.
e. Repeat these steps for *port3*.

5. Under *Advanced Options*, enable *Inject Default Route*.
   This setting allows the ISP router to share its default 0.0.0.0 routes with other routers in the RIP network.
6. Click *Apply*.

To configure the ISP Router in the CLI:

```
config router rip
    set default-information-originate enable
    config network
        edit 1
            set prefix 172.20.121.0 255.255.255.0
        next
        edit 2
            set prefix 172.20.120.0 255.255.255.0
        next
    end
    config interface
        edit "port2"
            set receive-version 2
            set send-version 2
        next
        edit "port3"
            set receive-version 2
            set send-version 2
        next
    end
end
```

Router2 and Router3

Router2 and Router3 RIP configurations have different IP addresses, but are otherwise the same.

To configure Router2 and Router3 in the GUI:

1. Go to *Network* > *RIP*.
2. Set the *Version* to *2*.
3. Under *Networks*, add the IP addresses for each port:

Router2	10.12.101.0/255.255.255.0
	10.11.201.0/255.255.255.0
	10.14.201.0/255.255.255.0
	172.20.120.0/255.255.255.0

Router3	10.12.101.0/255.255.255.0
	10.11.202.0/255.255.255.0
	10.14.202.0/255.255.255.0
	172.20.121.0/255.255.255.0

4. Add the interfaces:
   a. In the *Interfaces* table, click *Create New*.
   b. Set *Interface* to *port1*.
   c. Leave the remaining settings as their default values.
   d. Click *OK*.
   e. Repeat these steps for *port2*, *port3*, and *port4*.
5. Click *Apply*.

To configure Router2 in the CLI:

```
config router rip
    config network
        edit 1
            set prefix 10.12.101.0 255.255.255.0
        next
        edit 2
            set prefix 10.11.201.0 255.255.255.0
        next
        edit 3
            set prefix 10.14.201.0 255.255.255.0
        next
        edit 4
            set prefix 172.20.120.0 255.255.255.0
        next
    end
    config interface
        edit "port1"
            set receive-version 2
            set send-version 2
        next
        edit "port2"
            set receive-version 2
            set send-version 2
        next
        edit "port3"
            set receive-version 2
            set send-version 2
        next
        edit "port4"
            set receive-version 2
            set send-version 2
        next
    end
end
```

To configure Router3 in the CLI:

```
config router rip
    config network
        edit 1
            set prefix 10.12.101.0 255.255.255.0
        next
        edit 2
            set prefix 10.11.202.0 255.255.255.0
        next
        edit 3
            set prefix 10.14.202.0 255.255.255.0
        next
        edit 4
            set prefix 172.20.121.0 255.255.255.0
        next
    end
    config interface
        edit "port1"
            set receive-version 2
            set send-version 2
        next
        edit "port2"
            set receive-version 2
            set send-version 2
        next
        edit "port3"
            set receive-version 2
            set send-version 2
        next
        edit "port4"
            set receive-version 2
            set send-version 2
        next
    end
end
```

Router1 and Router4

Router1 and Router4 RIP configurations have different IP addresses, but are otherwise the same.

To configure Router1 and Router4 in the GUI:

1. Go to *Network* > *RIP*.
2. Set the *Version* to *2*.
3. Under *Networks*, add the IP addresses for each port:

Router1	10.11.101.0/255.255.255.0
	10.11.201.0/255.255.255.0
	10.11.202.0/255.255.255.0

Router4	10.14.101.0/255.255.255.0
	10.14.201.0/255.255.255.0
	10.14.202.0/255.255.255.0

4. Add the interfaces:
   a. In the *Interfaces* table, click *Create New*.
   b. Set *Interface* to *port1*.
   c. For port1 only, enable *Passive*.
   d. Leave the remaining settings as their default values.
   e. Click *OK*.
   f. Repeat these steps for *port2* and *port3*, making sure that *Passive* is disabled.
5. Click *Apply*.

To configure Router1 in the CLI:

```
config router rip
    config network
        edit 1
            set prefix 10.11.101.0 255.255.255.0
        next
        edit 2
            set prefix 10.11.201.0 255.255.255.0
        next
        edit 3
            set prefix 10.11.202.0 255.255.255.0
        next
    end
    set passive-interface "port1"
    config interface
        edit "port1"
            set receive-version 2
            set send-version 2
        next
        edit "port2"
            set receive-version 2
            set send-version 2
        next
        edit "port3"
            set receive-version 2
            set send-version 2
        next
    end
end
```

To configure Router4 in the CLI:

```
config router rip
    config network
        edit 1
            set prefix 10.14.101.0 255.255.255.0
        next
```

```
        edit 2
            set prefix 10.14.201.0 255.255.255.0
        next
        edit 3
            set prefix 10.14.202.0 255.255.255.0
        next
    end
    set passive-interface "port1"
    config interface
        edit "port1"
            set receive-version 2
            set send-version 2
        next
        edit "port2"
            set receive-version 2
            set send-version 2
        next
        edit "port3"
            set receive-version 2
            set send-version 2
        next
    end
end
```

Verifying the configuration

The interface's names are shown in the debugs. The same commands should also be run on the other routers.

To verify the configuration after the ISP router, Router2, and Route3 have been configured:

This verification can be done after the ISP router, Router2, and Router3 have been configured. Only Router2's debugs are shown.

1. Check the RIP interface information:

```
# get router info rip interface
Router2 is up, line protocol is up
  RIP is not enabled on this interface
ssl.Router2 is up, line protocol is up
  RIP is not enabled on this interface
vdr2link1 is up, line protocol is up
  Routing Protocol: RIP
    Receive RIPv2 packets only
    Send RIPv2 packets only
    Passive interface: Disabled
    Split horizon: Enabled with Poisoned Reversed
    IP interface address:
      172.20.120.102/24
vd12link1 is up, line protocol is up
  Routing Protocol: RIP
    Receive RIPv2 packets only
    Send RIPv2 packets only
    Passive interface: Disabled
    Split horizon: Enabled with Poisoned Reversed
    IP interface address:
      10.11.201.102/24
```

```
vd42link1 is up, line protocol is up
  Routing Protocol: RIP
    Receive RIPv2 packets only
    Send RIPv2 packets only
    Passive interface: Disabled
    Split horizon: Enabled with Poisoned Reversed
    IP interface address:
      10.14.201.102/24
vd23link0 is up, line protocol is up
  Routing Protocol: RIP
    Receive RIPv2 packets only
    Send RIPv2 packets only
    Passive interface: Disabled
    Split horizon: Enabled with Poisoned Reversed
    IP interface address:
      10.12.101.102/24
```

RIP starts exchanging routes as soon as the networks are added to the Router2 and Router3 configurations because the RIP interfaces are active by default, and start sending and receiving RIP updates when a matching interface on the subnet is found. The interface configuration allows the interface settings to be fine tuned, in this case to specify only RIPv2 support.

2. Check the RIP database:

```
# get router info rip database
Codes: R - RIP, Rc - RIP connected, Rs - RIP static, K - Kernel,
       C - Connected, S - Static, O - OSPF, I - IS-IS, B - BGP
   Network            Next Hop         Metric From            If     Time
R  0.0.0.0/0          172.20.120.5          2 172.20.120.5    vdr2link1 02:55
Rc 10.11.201.0/24                           1                 vd12link1
R  10.11.202.0/24     10.12.101.103         2 10.12.101.103   vd23link0 02:33
Rc 10.12.101.0/24                           1                 vd23link0
Rc 10.14.201.0/24                           1                 vd42link1
R  10.14.202.0/24     10.12.101.103         2 10.12.101.103   vd23link0 02:33
Rc 172.20.120.0/24                          1                 vdr2link1
R  172.20.121.0/24    10.12.101.103         2 10.12.101.103   vd23link0 02:33
```

3. Check the routing table:

```
# get router info routing-table all
Codes: K - kernel, C - connected, S - static, R - RIP, B - BGP
       O - OSPF, IA - OSPF inter area
       N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
       E1 - OSPF external type 1, E2 - OSPF external type 2
       i - IS-IS, L1 - IS-IS level-1, L2 - IS-IS level-2, ia - IS-IS inter area
       * - candidate default
Routing table for VRF=0
R*      0.0.0.0/0 [120/2] via 172.20.120.5, vdr2link1, 13:37:23
C       10.11.201.0/24 is directly connected, vd12link1
R       10.11.202.0/24 [120/2] via 10.12.101.103, vd23link0, 14:10:01
C       10.12.101.0/24 is directly connected, vd23link0
C       10.14.201.0/24 is directly connected, vd42link1
R       10.14.202.0/24 [120/2] via 10.12.101.103, vd23link0, 14:10:01
C       172.20.120.0/24 is directly connected, vdr2link1
R       172.20.121.0/24 [120/2] via 10.12.101.103, vd23link0, 13:20:36
```

Router2 has learned the default gateway from the ISP router, and has learned of other networks from Router3.

4. If firewall policies are correctly configured, the outside network can be reached:

```
# execute ping-options source 10.11.201.102
# execute ping 8.8.8.8
PING 8.8.8.8 (8.8.8.8): 56 data bytes
64 bytes from 8.8.8.8: icmp_seq=0 ttl=115 time=4.5 ms
64 bytes from 8.8.8.8: icmp_seq=1 ttl=115 time=4.2 ms
64 bytes from 8.8.8.8: icmp_seq=2 ttl=115 time=4.2 ms
64 bytes from 8.8.8.8: icmp_seq=3 ttl=115 time=4.2 ms
64 bytes from 8.8.8.8: icmp_seq=4 ttl=115 time=4.1 ms
--- 8.8.8.8 ping statistics ---
5 packets transmitted, 5 packets received, 0% packet loss
round-trip min/avg/max = 4.1/4.2/4.5 ms
```

```
# execute traceroute 8.8.8.8
traceroute to 8.8.8.8 (8.8.8.8), 32 hops max, 3 probe packets per hop, 84 byte packets
 1  172.20.120.5  0.101 ms  0.030 ms  0.014 ms
 2  172.16.151.1  0.169 ms  0.144 ms  0.131 ms
 3  * * *
```

To verify the configuration after Router1 and Router4 have also been configured:

This verification can be done after Router1 and Router4 have been configured. Only Router1's debugs are shown.

1. Check the RIP interface information:

```
# get router info rip interface
Router1 is up, line protocol is up
  RIP is not enabled on this interface
ssl.Router1 is up, line protocol is up
  RIP is not enabled on this interface
vd12link0 is up, line protocol is up
  Routing Protocol: RIP
    Receive RIPv2 packets only
    Send RIPv2 packets only
    Passive interface: Disabled
    Split horizon: Enabled with Poisoned Reversed
    IP interface address:
      10.11.201.101/24
vd13link0 is up, line protocol is up
  Routing Protocol: RIP
    Receive RIPv2 packets only
    Send RIPv2 packets only
    Passive interface: Disabled
    Split horizon: Enabled with Poisoned Reversed
    IP interface address:
      10.11.202.101/24
LoSales is up, line protocol is up
  Routing Protocol: RIP
    Receive RIPv2 packets only
    Send RIPv2 packets only
    Passive interface: Enabled
    Split horizon: Enabled with Poisoned Reversed
    IP interface address:
      10.11.101.101/24
      127.0.0.1/8
```

2. Check the RIP database:

```
# get router info rip database
Codes: R - RIP, Rc - RIP connected, Rs - RIP static, K - Kernel,
       C - Connected, S - Static, O - OSPF, I - IS-IS, B - BGP
   Network            Next Hop         Metric From            If     Time
R  0.0.0.0/0          10.11.202.103         3 10.11.202.103   vd13link0 02:35
Rc 10.11.101.0/24                           1                 LoSales
Rc 10.11.201.0/24                           1                 vd12link0
Rc 10.11.202.0/24                           1                 vd13link0
R  10.12.101.0/24     10.11.202.103         2 10.11.202.103   vd13link0 02:35
R  10.14.101.0/24     10.11.202.103         3 10.11.202.103   vd13link0 02:35
R  10.14.201.0/24     10.11.201.102         2 10.11.201.102   vd12link0 02:30
R  10.14.202.0/24     10.11.202.103         2 10.11.202.103   vd13link0 02:35
R  172.20.120.0/24    10.11.201.102         2 10.11.201.102   vd12link0 02:30
R  172.20.121.0/24    10.11.202.103         2 10.11.202.103   vd13link0 02:35
```

3. Check the routing table:

```
# get router info routing-table all
Codes: K - kernel, C - connected, S - static, R - RIP, B - BGP
       O - OSPF, IA - OSPF inter area
       N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
       E1 - OSPF external type 1, E2 - OSPF external type 2
       i - IS-IS, L1 - IS-IS level-1, L2 - IS-IS level-2, ia - IS-IS inter area
       * - candidate default
Routing table for VRF=0
R*      0.0.0.0/0 [120/3] via 10.11.202.103, vd13link0, 00:09:42
C       10.11.101.0/24 is directly connected, LoSales
C       10.11.201.0/24 is directly connected, vd12link0
C       10.11.202.0/24 is directly connected, vd13link0
R       10.12.101.0/24 [120/2] via 10.11.202.103, vd13link0, 00:09:42
R       10.14.101.0/24 [120/3] via 10.11.202.103, vd13link0, 00:09:42
R       10.14.201.0/24 [120/2] via 10.11.201.102, vd12link0, 00:09:42
R       10.14.202.0/24 [120/2] via 10.11.202.103, vd13link0, 00:09:42
R       172.20.120.0/24 [120/2] via 10.11.201.102, vd12link0, 00:09:42
R       172.20.121.0/24 [120/2] via 10.11.202.103, vd13link0, 00:09:42
```

4. If firewall policies are correctly configured, the accounting network and the internet are reachable from the sales network:

```
# execute ping-options source 10.11.101.101

Testing the configuration and routing changes

After the network is configured, test it to ensure that when network events occur, such as a downed link, routing updates are triggered and converge as expected.

In the following examples, we disable certain links to simulate network outages, then verify that routing and connectivity is restored after the updates have converged.

Example 1 - ISP router port3 interface goes down

In this example, a link outage occurs on port3 of the ISP router. Consequently, all routers must use Router2, and not Router3, to reach the internet. Note the RIP database before and after the link failure, and the time taken for the route updates to propagate and return to a functioning state.

Router4's debugs are shown.

Before:

```
# get router info rip database

```

After:

- You might see different routes, and the routes might change, while convergence is occurring. During convergence, the metric for your default route increases to 16.

```
# get router info rip database
Codes: R - RIP, Rc - RIP connected, Rs - RIP static, K - Kernel,
       C - Connected, S - Static, O - OSPF, I - IS-IS, B - BGP
   Network            Next Hop         Metric From            If     Time
R  0.0.0.0/0          10.14.202.103        16 10.14.202.103   vd43link0 01:50
```

- After convergence is complete, the RIP database will look similar to the following:

```
# get router info rip database
Codes: R - RIP, Rc - RIP connected, Rs - RIP static, K - Kernel,
       C - Connected, S - Static, O - OSPF, I - IS-IS, B - BGP
   Network            Next Hop         Metric From            If     Time
R  0.0.0.0/0          10.14.201.102         3 10.14.201.102   vd42link0 02:53
R  10.11.101.0/24     10.14.202.103         3 10.14.202.103   vd43link0 03:00

C       10.14.101.0/24 is directly connected, LoAccounting
C       10.14.201.0/24 is directly connected, vd42link0
```

```
C       10.14.202.0/24 is directly connected, vd43link0
R       172.20.120.0/24 [120/2] via 10.14.201.102, vd42link0, 02:58:39

# execute traceroute 8.8.8.8
traceroute to 8.8.8.8 (8.8.8.8), 32 hops max, 3 probe packets per hop, 84 byte packets
 1  10.14.201.102  0.167 ms  0.063 ms  0.029 ms
 2  172.20.120.5  0.117 ms  0.073 ms  0.041 ms
 3  172.16.151.1  0.303 ms  0.273 ms  0.253 ms
```

Example 2- Additional link failures on Router2

In addition to the link failure on the ISP router in example, port1 and port3 on Router2 have also failed. This means that Router4 must go through Router3, Router1, Router2, then the ISP router to reach the internet. Note that, for a period of time, some routes' metrics increase to 16. If no better routes are found for these networks, then they eventually disappear.

After the convergence completes, the RIP database and routing table on Router4 should resemble the following:

```
# get router info rip database
Codes: R - RIP, Rc - RIP connected, Rs - RIP static, K - Kernel,
       C - Connected, S - Static, O - OSPF, I - IS-IS, B - BGP
   Network            Next Hop         Metric From            If     Time
R  0.0.0.0/0          10.14.202.103         5 10.14.202.103   vd43link0 02:54
R  10.11.101.0/24     10.14.202.103         3 10.14.202.103   vd43link0 02:54
R  10.11.201.0/24     10.14.202.103         3 10.14.202.103   vd43link0 02:54
R  10.11.202.0/24     10.14.202.103         2 10.14.202.103   vd43link0 02:54
Rc 10.14.101.0/24                           1                 LoAccounting
Rc 10.14.202.0/24                           1                 vd43link0
R  172.20.120.0/24    10.14.202.103         4 10.14.202.103   vd43link0 02:54

# get router info routing-table all
Codes: K - kernel, C - connected, S - static, R - RIP, B - BGP
       O - OSPF, IA - OSPF inter area

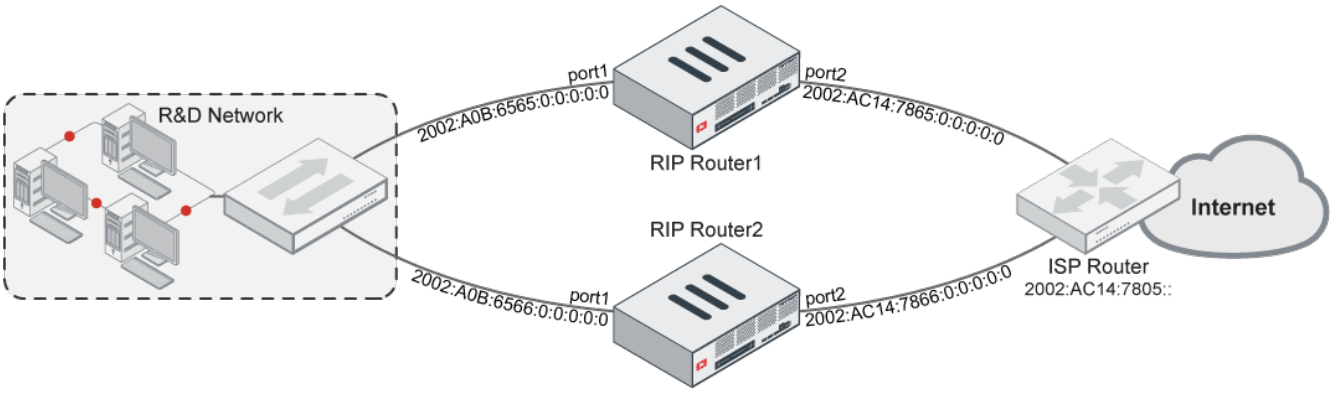
```

Reaching the internet on the default gateway now requires five hops from Router4:



```
# execute traceroute 8.8.8.8
traceroute to 8.8.8.8 (8.8.8.8), 32 hops max, 3 probe packets per hop, 84 byte packets
 1  10.14.202.103  0.087 ms  0.026 ms  0.012 ms
 2  10.11.202.101  0.045 ms  0.024 ms  0.025 ms
 3  10.11.201.102  0.048 ms  0.024 ms  0.015 ms
 4  172.20.120.5  0.050 ms  0.028 ms  0.019 ms
 5  * * *
```

Basic RIPng example

In this example, a small network is configured with RIP next generation (RIPng). Two FortiGates are connected to the internal network and the ISP, providing some redundancy to help ensure that the internal network can always reach the internet.

The FortiGates are running in NAT mode with VDOMs disabled, and firewall policies have already been configured to allow traffic to flow across the interfaces.

All of the internal computers and other network devices support IPv6 addressing and are running RIPng (where applicable), so no static routing is required. Internal network devices only need to know the FortiGate's internal interface network addresses.

Router	Interface (alias)	IPv6 address
Router1	port1 (internal)	2002:A0B:6565:0:0:0:0:0
	port2 (ISP)	2002:AC14:7865:0:0:0:0:0
Router2	port1 (internal)	2002:A0B:6566:0:0:0:0:0
	port2 (ISP)	2002:AC14:7866:0:0:0:0:0

On each FortiGate, the interfaces are configured first, and then RIPng. No redistribution or authentication is configured.

In the RIPng configuration, only the interface names are required. The ISP router and the other FortiGate are configured as neighbors. Declaring the neighbors reduces the discovery traffic when the routers start. There is no specific command to include a subnet in the RIP broadcast, and RIPng can only be configured using the CLI.

To configure Router1:

1. Configure the interfaces:

```
config system interface
    edit port1
        set allowaccess ping https ssh
        set type physical
        set description "Internal RnD network"
        set alias "internal"
        config ipv6
            set ip6-address 2002:a0b:6565::/0
        end
```

```
    next
    edit port2
        set allowaccess ping https ssh
        set type physical
        set description "ISP and Internet"
        set alias "ISP"
        config ipv6
            set ip6-address 2002:ac14:7865::/0
        end
    next
end
```

2. Configure RIPng:

```
config router ripng
    config neighbor
        edit 1
            set ip6 2002:a0b:6566::
            set interface port1
        next
        edit 2
            set ip6 2002:ac14:7805::
            set interface port2
        next
    end
    config interface
        edit port1
        next
        edit port2
        next
    end
end
```

To configure Router2:

1. Configure the interfaces:

```
config system interface
    edit port1
        set allowaccess ping https ssh
        set type physical
        set description "Internal RnD network"
        set alias "internal"
        config ipv6
            set ip6-address 2002:a0b:6566::/0
        end
    next
    edit port2
        set allowaccess ping https ssh
        set type physical
        set description "ISP and Internet"
        set alias "ISP"
        config ipv6
            set ip6-address 2002:ac14:7866::/0
        end
    next
end
```

2. Configure RIPng:

```
config router ripng
    config neighbor
        edit 1
            set ip6 2002:a0b:6565::
            set interface port1
        next
        edit 2
            set ip6 2002:ac14:7805::
            set interface port2
        next
    end
    config interface
        edit port1
        next
        edit port2
        next
    end
end
```

Testing the configuration

The following commands can be used to check the RIPng information on the FortiGates, and can help track down issues:

To view the local scope IPv6 addresses used as next-hops by RIPng on the FortiGate:

```
# diagnose ipv6 address list
```

To view IPv6 addresses that are installed in the routing table:

```
# diagnose ipv6 route list
```

To view the IPv6 routing table:

```
# get router info6 routing-table
```

This information is similar to the `diagnose ipv6 route list` command, but it is presented in an easier to read format.

To view the brief output on the RIP information for the interface listed:

```
# get router info6 rip interface external
```

This includes information such as, if the interface is up or down, what routing protocol is being used, and whether passive interface or split horizon is enabled.

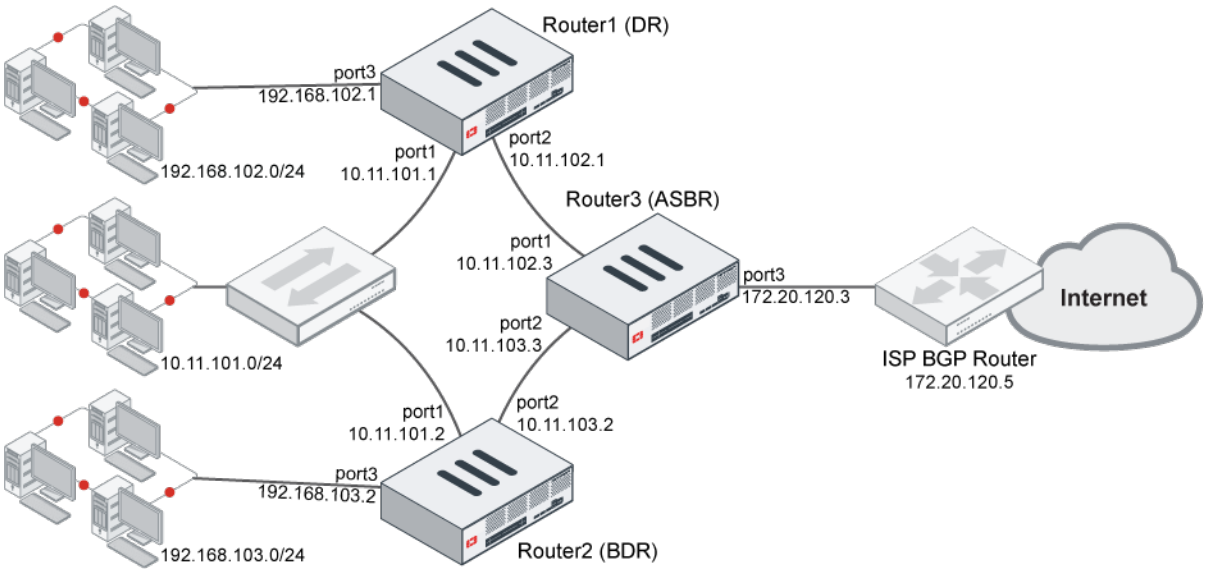
OSPF

Open Shortest Path First (OSPF) is a link state routing protocol that is commonly used in large enterprise networks with L3 switches, routers, and firewalls from multiple vendors. It can quickly detect link failures, and converges network traffic

without networking loops. It also has features to control which routes are propagated, allowing for smaller routing tables, and provides better load balancing on external links when compared to other routing protocols.

To configure OSPF in the GUI, go to *Network* > *OSPF*:

Option	Description
Router ID	A unique ID to identify your router in the network, typically in the format x.x.x.x.
Areas	The areas that the router is part of. For each are area, define the *Area ID*, *Type*, and *Authentication* method.
Networks	The networks that OSPF is enabled in, and the area that they belong to.
Interfaces	OSPF interfaces for transmitting and receiving packets. Configure interface properties, such as *Network Type*, *Cost*, *Hello interval*, and others.
Advanced Options	Settings for *Inject Default Route*, *Passive Interfaces*, and *Redistribute*. Redistribution can be enabled by protocol and the metric for each protocol can be configured.



This section includes the following topics:

- Basic OSPF example on page 396
- OSPFv3 neighbor authentication on page 407
- OSPF graceful restart upon a topology change on page 409

Basic OSPF example

In this example, three FortiGate devices are configured in an OSPF network.

- Router1 is the Designated Router (DR). It has the highest priority and the lowest IP address, to ensure that it becomes the DR.
- Router2 is the Backup Designated Router (BDR). It has a high priority to ensure that it becomes the BDR.
- Router3 is the Autonomous System Border Router (ASBR). It routes all traffic to the ISP BGP router for internet access. It redistributes routes from BGP and advertises a default route to its neighbors. It can allow different types of routes, learned outside of OSPF, to be used in OSPF. Different metrics can be assigned to these routes to make them more or less preferred than regular OSPF routes. Route maps could be used to further control what prefixes are advertised or received from the ISP.

FortiGate	Interface	IP address
Router1 (DR)	port1	10.11.101.1
	port2	10.11.102.1
	port3	192.168.102.1
Router2 (BDR)	port1	10.11.101.2
	port2	10.11.103.2
	port3	192.168.103.2
Router3 (ASBR)	port1	10.11.102.3
	port2	10.11.103.3
	port3	172.20.120.3

- Firewall policies are already configured to allow unfiltered traffic in both directions between all of the connected interfaces.
- The interfaces are already configured, and NAT is only used for connections to public networks. The costs for all of the interfaces is left at 0.
- The OSPF network belongs to Area 0, and is not connected to any other OSPF networks. All of the routers are part of the backbone 0.0.0.0 area, so no inter-area communications are needed.
- Router3 redistributes BGP routes into the OSPF AS and peers with the ISP BGP Router over eBGP. For information about configuring BGP, see BGP on page 412.
- The advertised networks - 10.11.101.0, 10.11.102.0, and 10.11.103.0 - are summarized by 10.11.0.0/16. Additional networks are advertised individually by the /24 subnet.

Router1

To configure Router1 in the GUI:

1. Go to *Network* > *OSPF*.
2. Set *Router ID* to *10.11.101.1*.
3. In the *Areas* table, click *Create New* and set the following:

Area ID	0.0.0.0
Type	Regular
Authentication	None

4. Click *OK*.
5. In the *Networks* table, click *Create New* and set the following:

Area	0.0.0.0
IP/Netmask	10.11.0.0 255.255.0.0

6. Click *OK*.
7. In the *Networks* table, click *Create New* again and set the following:

Area	0.0.0.0
IP/Netmask	192.168.102.0 255.255.255.0

8. Click *OK*.
9. In the *Interfaces* table, click *Create New* and set the following:

Name	Router1-Internal-DR
Interface	port1
Cost	0
Priority	255
Authentication	None
Timers	• Hello Interval: 10 • Dead Interval: 40

10. Click *OK*.
11. In the *Interfaces* table, click *Create New* again and set the following:

Name	Router1-External
Interface	port2
Cost	0
Authentication	None
Timers	• Hello Interval: 10 • Dead Interval: 40

12. Click *OK*.
13. Click *Apply*.

To configure Router1 in the CLI:

```
config router ospf
    set router-id 10.11.101.1
    config area
        edit 0.0.0.0
        next
    end
    config ospf-interface
        edit "Router1-Internal-DR"
            set interface "port1"
            set priority 255
            set dead-interval 40
            set hello-interval 10
        next
        edit "Router1-External"
            set interface "port2"
            set dead-interval 40
            set hello-interval 10
        next
    end
    config network
        edit 1
            set prefix 10.11.0.0 255.255.0.0
        next
        edit 2
            set prefix 192.168.102.0 255.255.255.0
        next
    end
end
```

Router2

To configure Router2 in the GUI:

1. Go to *Network* > *OSPF*.
2. Set *Router ID* to *10.11.101.2*.
3. In the *Areas* table, click *Create New* and set the following:

Area ID	0.0.0.0
Type	Regular
Authentication	None

4. Click *OK*.
5. In the *Networks* table, click *Create New* and set the following:

Area	0.0.0.0
IP/Netmask	10.11.0.0 255.255.0.0

6. Click *OK*.
7. In the *Networks* table, click *Create New* again and set the following:

Area	0.0.0.0
IP/Netmask	192.168.103.0 255.255.255.0

8. Click *OK*.
9. In the *Interfaces* table, click *Create New* and set the following:

Name	Router2-Internal
Interface	port1
Cost	0
Priority	250
Authentication	None
Timers	• Hello Interval: 10 • Dead Interval: 40

10. Click *OK*.
11. In the *Interfaces* table, click *Create New* again and set the following:

Name	Router2-External
Interface	port2
Cost	0
Authentication	None
Timers	• Hello Interval: 10 • Dead Interval: 40

12. Click *OK*.
13. Click *Apply*.

To configure Router2 in the CLI:

```
config router ospf
    set router-id 10.11.101.1
    config area
        edit 0.0.0.0
        next
    end
    config ospf-interface
        edit "Router2-Internal"
            set interface "port1"
            set priority 250
            set dead-interval 40
            set hello-interval 10
        next
        edit "Router2-External"
            set interface "port2"
```

```
            set dead-interval 40
            set hello-interval 10
        next
    end
    config network
        edit 1
            set prefix 10.11.0.0 255.255.0.0
        next
        edit 2
            set prefix 192.168.103.0 255.255.255.0
        next
    end
end
```

Router3

To configure Router3 in the GUI:

1. Go to *Network* > *OSPF*.
2. Set *Router ID* to *10.11.103.3*.
3. Under *Default Settings*, set *Inject default route* to *Regular Areas*.
   A default route must be present on Router3 to advertise it to other routers.
4. Enable *Redistribute BGP* and use the default settings.
5. In the *Areas* table, click *Create New* and set the following:

Area ID	0.0.0.0
Type	Regular
Authentication	None

6. Click *OK*.
7. In the *Networks* table, click *Create New* and set the following:

Area	0.0.0.0
IP/Netmask	10.11.0.0 255.255.0.0

8. Click *OK*.
9. In the *Interfaces* table, click *Create New* and set the following:

Name	Router3-Internal
Interface	port1
Cost	0
Authentication	None
Timers	• Hello Interval: 10 • Dead Interval: 40

10. Click *OK*.
11. In the *Interfaces* table, click *Create New* again and set the following:

Name	Router3-Internal2
Interface	port2
Cost	0
Authentication	None
Timers	• Hello Interval: 10 • Dead Interval: 40

12. Click *OK*.
13. Click *Apply*.

To configure Router3 in the CLI:

```
config router ospf
    set default-information-originate enable
    set router-id 10.11.103.3
    config area
        edit 0.0.0.0
        next
    end
    config ospf-interface
        edit "Router3-Internal"
            set interface "port1"
            set dead-interval 40
            set hello-interval 10
        next
        edit "Router3-Internal2"
            set interface "port2"
            set dead-interval 40
            set hello-interval 10
        next
    end
    config network
        edit 1
            set prefix 10.11.0.0 255.255.0.0
        next
    end
    config redistribute "bgp"
        set status enable
    end
end
```

To configure BGP on Router3 in the CLI:

```
config router bgp
    set as 64511
    set router-id 1.1.1.1
    config neighbor
        edit "172.20.120.5"
            set remote-as 64512
        next
    end
    config network
```

```
        edit 1
            set prefix 172.20.120.0 255.255.255.0
        next
    end
end
```

For more information on configuring BGP, see BGP on page 412.

Testing the configuration

Both the network connectivity and OSPF routing are tested. When a link goes down, routes should converge as expected.

Working state

- Router3:

```
Router3 # get router info ospf neighbor
OSPF process 0, VRF 0:
Neighbor ID     Pri   State           Dead Time   Address         Interface
10.11.101.1       1   Full/Backup     00:00:34    10.11.102.1     port1
10.11.101.2       1   Full/Backup     00:00:38    10.11.103.2     port2
```

```
Router3 # get router info ospf status
 Routing Process "ospf 0" with ID 10.11.103.3
 Process uptime is 18 hours 52 minutes
 Process bound to VRF default
 Conforms to RFC2328, and RFC1583Compatibility flag is disabled
 Supports only single TOS(TOS0) routes
 Supports opaque LSA
 Do not support Restarting
 This router is an ASBR (injecting external routing information)
 SPF schedule delay 5 secs, Hold time between two SPFs 10 secs
 Refresh timer 10 secs
 Number of incomming current DD exchange neighbors 0/5
 Number of outgoing current DD exchange neighbors 0/5
 Number of external LSA 3. Checksum 0x021B78
 Number of opaque AS LSA 0. Checksum 0x000000
 Number of non-default external LSA 2
 External LSA database is unlimited.
 Number of LSA originated 16
 Number of LSA received 100
 Number of areas attached to this router: 1
    Area 0.0.0.0 (BACKBONE)
        Number of interfaces in this area is 2(2)
        Number of fully adjacent neighbors in this area is 2
        Area has no authentication
        SPF algorithm last executed 00:37:36.690 ago
        SPF algorithm executed 13 times
        Number of LSA 6. Checksum 0x03eafa
```

```
Router3 # get router info routing-table all
Codes: K - kernel, C - connected, S - static, R - RIP, B - BGP
       O - OSPF, IA - OSPF inter area
       N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
       E1 - OSPF external type 1, E2 - OSPF external type 2
       i - IS-IS, L1 - IS-IS level-1, L2 - IS-IS level-2, ia - IS-IS inter area
```

```

OSPFv3 neighbor authentication

OSPFv3 neighbor authentication is available for enhanced IPv6 security.

To configure an OSPF6 interface:

```
config router ospf6
    config ospf6-interface
        edit <name>
            set authentication {none | ah | esp | area}
            set key-rollover-interval <integer>
            set ipsec-auth-alg {md5 | sha1 | sha256 | sha384 | sha512}
            set ipsec-enc-alg {null | des | 3des | aes128 | aes192 | aes256}
            config ipsec-keys
                edit <spi>
                    set auth-key <string>
                    set enc-key <string>
                next
            end
        next
    end
end
```

To configure an OSPF6 virtual link:

```
config router ospf6
    config area
        edit <id>
            config virtual-link
                edit <name>
                    set authentication {none | ah | esp | area}
                    set key-rollover-interval <integer>
                    set ipsec-auth-alg {md5 | sha1 | sha256 | sha384 | sha512}
                    set ipsec-enc-alg {null | des | 3des | aes128 | aes192 | aes256}
                    config ipsec-keys
                        edit <spi>
                            set auth-key <string>
                            set enc-key <string>
                        next
                    end
                next
            end
        next
    end
end
```

To configure an OSPF6 area:

```
config router ospf6
    config area
        edit <id>
            set authentication {none | ah | esp}
            set key-rollover-interval <integer>
            set ipsec-auth-alg {md5 | sha1 | sha256 | sha384 | sha512}
            set ipsec-enc-alg {null | des | 3des | aes128 | aes192 | aes256}
            config ipsec-keys
                edit <spi>
                    set auth-key <string>
                    set enc-key <string>
                next
            end
        next
    end
end
```

CLI command descriptions

Command	Description
<id>	Area entry IP address.
authentication {none | ah | esp | area}	Authentication mode: • `none`: Disable authentication • `ah`: Authentication Header • `esp`: Encapsulating Security Payload • `area`: Use the routing area authentication configuration
key-rollover-interval <integer>	Enter an integer value (300 - 216000, default = 300).
ipsec-auth-alg {md5 | sha1 | sha256 | sha384 | sha512}	Authentication algorithm.
ipsec-enc-alg {null | des | 3des | aes128 | aes192 | aes256}	Encryption algorithm.
<spi>	Security Parameters Index.
auth-key <string>	Authentication key should be hexadecimal numbers. Key length for each algorithm: • MD5: 16 bytes • SHA1: 20 bytes • SHA256: 32 bytes • SHA384:48 bytes • SHA512:84 bytes If the key is shorter than the required length, it will be padded with zeroes.
enc-key <string>	Encryption key should be hexadecimal numbers. Key length for each algorithm: • DES: 8 bytes • 3DES: 24 bytes

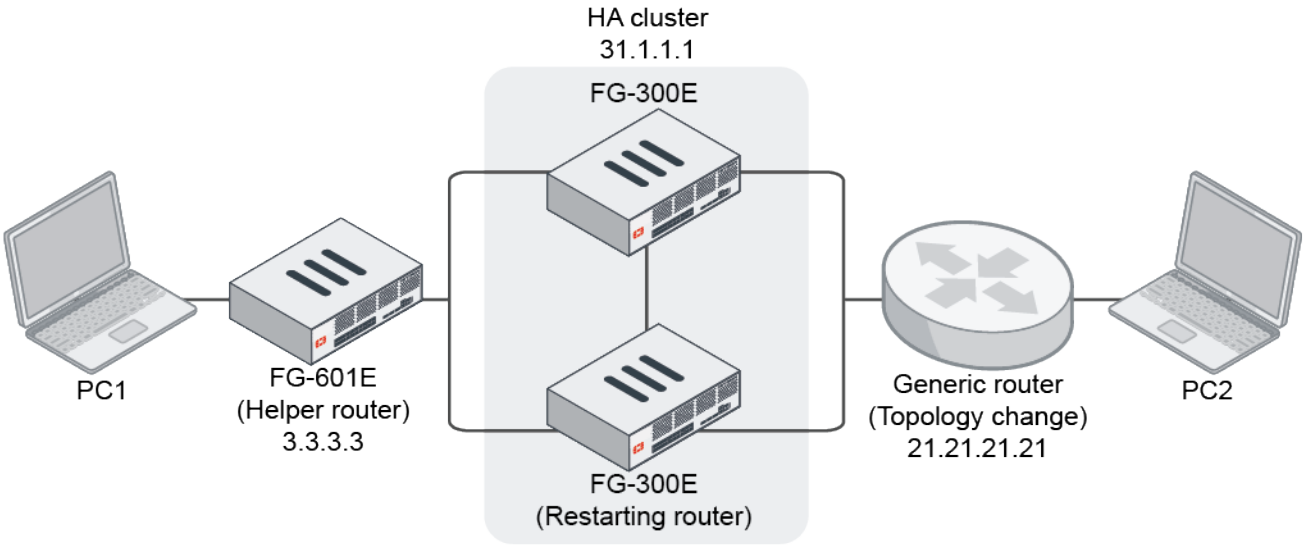
Command	Description
	• AES128: 16 bytes • AES192: 24 bytes • AES256: 32 bytes If the key is shorter than the required length, it will be padded with zeroes.

OSPF graceful restart upon a topology change

In OSPF graceful restart mode, the `restart-on-topology-change` option can be used to keep restarting the router in graceful restart mode when a topology change is detected during a restart.

```
config router ospf
    set restart-on-topology-change {enable | disable}
end
```

OSPFv3 graceful restart mode upon a topology change can be used in OSPF6:



```
config router ospf6
    set restart-on-topology-change {enable | disable}
end
```

Example

In this example, a restarting router (one of the FG-300Es in the HA cluster) informs its neighbors using grace LSAs before restarting its OSPF process. When the helper router (the FG-601E) receives the grace LSAs, it enters helper mode to help with the graceful restart until the graceful period expires. It will act as though there are no changes on the restarting router (FG-300E). A generic router simulates a topology change during the restart event.

If `restart-on-topology-change` is enabled on the restarting router, it will not exit the graceful restart mode even when a topology change is detected.

If `restart-on-topology-change` is disabled on the restarting router, it will exit graceful restart mode when a topology change is detected.

To configure the restarting router:

```
config router ospf
    set router-id 31.1.1.1
    set restart-mode graceful-restart
    set restart-period 180
    set restart-on-topology-change enable
    config area
        edit 0.0.0.0
        next
    end
    config network
        edit 1
            set prefix 172.16.200.0 255.255.255.0
        next
        edit 2
            set prefix 31.1.1.1 255.255.255.255
        next
    end
end
```

To configure the restarting helper router:

```
config router ospf
    set router-id 3.3.3.3
    set restart-mode graceful-restart
    config area
        edit 0.0.0.0
        next
    end
    config network
        edit 1
            set prefix 172.16.200.0 255.255.255.0
        next
        edit 2
            set prefix 3.3.3.3 255.255.255.255
        next
    end
end
```

Testing the configuration

Topology change with continuing graceful restart enabled:

When `restart-on-topology-change` is enabled and there is a topology change during the HA OSPF graceful restart, the graceful restart will continue. The routes on the helper router (FG-601E) are still there and no traffic will drop.

```
# get router info ospf neighbor
OSPF process 0, VRF 0:
Neighbor ID     Pri   State           Dead Time   Address         Interface
31.1.1.1          1   Full/DR         00:14:47*   172.16.200.31   port1
```

```
# get router info routing-table ospf
Routing table for VRF=0
O       21.21.21.21/32 [110/300] via 172.16.200.31, port1, 00:09:55
```

```
O       31.1.1.1/32 [110/200] via 172.16.200.31, port1, 00:55:31
O       100.21.1.0/24 [110/200] via 172.16.200.31, port1, 00:12:31

# get router info ospf neighbor
OSPF process 0, VRF 0:
Neighbor ID     Pri   State           Dead Time   Address         Interface
31.1.1.1          1   Full/DR         00:14:47*   172.16.200.31   port1

# get router info routing-table ospf
Routing table for VRF=0
O       21.21.21.21/32 [110/300] via 172.16.200.31, port1, 00:10:07
O       31.1.1.1/32 [110/200] via 172.16.200.31, port1, 00:55:43
O       100.21.1.0/24 [110/200] via 172.16.200.31, port1, 00:12:43

# get router info ospf neighbor
OSPF process 0, VRF 0:
Neighbor ID     Pri   State           Dead Time   Address         Interface
31.1.1.1          1   Full/DR         00:14:38*   172.16.200.31   port1

# get router info routing-table ospf
Routing table for VRF=0
O       21.21.21.21/32 [110/300] via 172.16.200.31, port1, 00:10:17
O       31.1.1.1/32 [110/200] via 172.16.200.31, port1, 00:55:53
O       100.21.1.0/24 [110/200] via 172.16.200.31, port1, 00:12:53

# get router info ospf neighbor
OSPF process 0, VRF 0:
Neighbor ID     Pri   State           Dead Time   Address         Interface
31.1.1.1          1   Full/DR         00:00:38    172.16.200.31   port1

# get router info routing-table ospf
Routing table for VRF=0
O       21.21.21.21/32 [110/300] via 172.16.200.31, port1, 00:10:37
O       31.1.1.1/32 [110/200] via 172.16.200.31, port1, 00:56:13
O       100.21.1.0/24 [110/200] via 172.16.200.31, port1, 00:13:13
```

Topology change with continuing graceful restart disabled:

When `restart-on-topology-change` is disabled and there is a topology change during the HA OSPF graceful restart, the graceful restart will exit. The routes on the helper router (FG-601E) are lost and traffic will drop.

```
# get router info ospf neighbor
OSPF process 0, VRF 0:
Neighbor ID     Pri   State           Dead Time   Address         Interface
31.1.1.1          1   Full/DR         00:14:57*   172.16.200.31   port1

# get router info routing-table ospf
Routing table for VRF=0
O       21.21.21.21/32 [110/300] via 172.16.200.31, port1, 00:11:16
O       31.1.1.1/32 [110/200] via 172.16.200.31, port1, 00:56:52
O       100.21.1.0/24 [110/200] via 172.16.200.31, port1, 00:13:52

# get router info ospf neighbor
OSPF process 0, VRF 0:
Neighbor ID     Pri   State           Dead Time   Address         Interface
31.1.1.1          1   Full/DR         00:14:42*   172.16.200.31   port1

# get router info routing-table ospf
Routing table for VRF=0
O       21.21.21.21/32 [110/300] via 172.16.200.31, port1, 00:11:31
```

```
O       31.1.1.1/32 [110/200] via 172.16.200.31, port1, 00:57:07
O       100.21.1.0/24 [110/200] via 172.16.200.31, port1, 00:14:07

# get router info ospf neighbor
OSPF process 0, VRF 0:
Neighbor ID     Pri   State           Dead Time   Address         Interface
31.1.1.1          1   Full/DR         00:14:40*   172.16.200.31   port1
```

No routes are lost:

```
# get router info routing-table ospf
Routing table for VRF=0
O       31.1.1.1/32 [110/200] via 172.16.200.31, port1, 00:57:09

# get router info ospf neighbor
OSPF process 0, VRF 0:
Neighbor ID     Pri   State           Dead Time   Address         Interface
31.1.1.1          1   Full/DR         00:14:38*   172.16.200.31   port1
```

No routes are lost:

```
# get router info routing-table ospf
Routing table for VRF=0
O       31.1.1.1/32 [110/200] via 172.16.200.31, port1, 00:57:11
```

No routes are lost:

```
# get router info routing-table ospf
Routing table for VRF=0
O       21.21.21.21/32 [110/300] via 172.16.200.31, port1, 00:04:42

O       100.21.1.0/24 [110/200] via 172.16.200.31, port1, 00:04:42
```

BGP

Border Gateway Protocol (BGP) is a standardized routing protocol that is used to route traffic across the internet. It exchanges routing information between Autonomous Systems (AS) on the internet and makes routing decisions based on path, network policies, and rule sets. BGP contains two distinct subsets: internal BGP (iBGP) and external BGP (eBGP). iBGP is intended for use within your own networks. eBGP is used to connect different networks together and is the main routing protocol for the internet backbone.

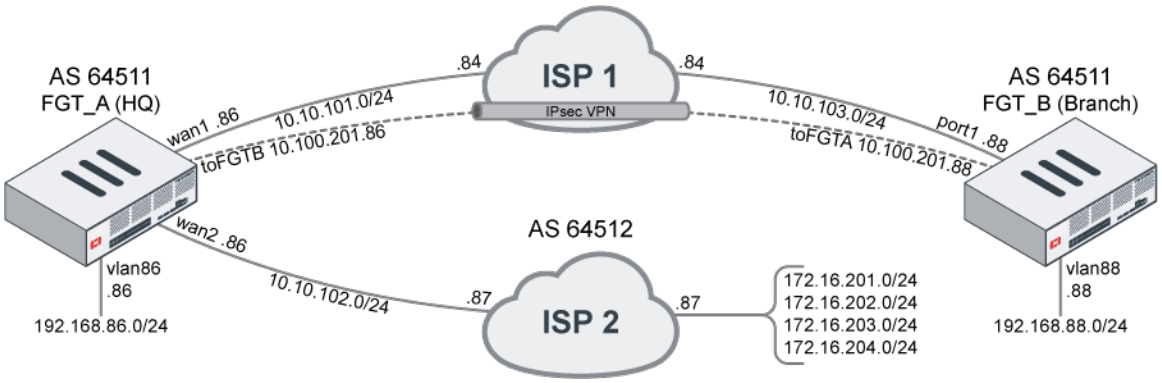
To configure BGP in the GUI, go to *Network* > *BGP*:

Option	Description
Local AS	The AS number for the local router.
Router ID	A unique ID to identify your router in the network, typically in the format x.x.x.x.
Neighbors	The neighbors that the FortiGate will be peering with. Configure the remote router's AS number, any other properties used for peering with the neighbor, and IPv4 and IPv6 filtering.
Neighbor Groups	The neighbor groups that share the same outbound policy configurations.
Neighbor Ranges	The source address range of BGP neighbors that will be automatically assigned to a neighbor group.

Option	Description
IPv4 & IPv6 Networks	The networks to be advertised to other BGP routers.
IPv4 & IPv6 Redistribute	Enable redistribution by protocol. Specify either *All* routes, or *Filter* by route map.
Dampening	Enable route flap dampening to reduce the propagation of flapping routes.
Graceful Restart	Enable BGP graceful restart, which causes the adjacent routers to keep routes active while the BGP peering is restarted on the FortiGate. This is useful in HA instances when failover occurs.
Advanced Options	Various advanced settings, such as *Local Preference*, *Distance internal*, *Keepalive*, *Holdtime*, and others
Best Path Selection	Configure path selection attributes on this router.

Currently, FortiGates do not support BGP graceful restart when peering with neighbor routers operating in graceful restart helper-only mode.

This section includes the following topics:



- Basic BGP example on page 413
- Route filtering with a distribution list on page 422
- Next hop recursive resolution using other BGP routes on page 426
- Next hop recursive resolution using ECMP routes on page 427
- BGP conditional advertisement on page 428
- BGP error handling per RFC 7606 on page 434
- BGP next hop tag-match mode on page 435
- BGP neighbor password on page 440
- BGP multi-exit discriminator on page 441
- Troubleshooting BGP on page 445

Basic BGP example

In this example, BGP is configured on two FortiGate devices. The FortiGates are geographically separated, and form iBGP peering over a VPN connection. FGT_A also forms eBGP peering with ISP2.

FGT_A learns routes from ISP2 and redistributes them to FGT_B while preventing any iBGP routes from being advertised.

The internal networks behind the FortiGates can communicate with each other, and the internal networks behind FGT_B can traverse FGT_A to reach networks that are advertised by ISP2.

- FGT_A and FGT_B have static routes to each other through ISP1. ISP1 does not participate in BGP.
- The IPsec VPN tunnel between FGT_A and FGT_B is configured with wildcard 0.0.0.0/0 networks for phase2 local and remote selectors. The VPN interfaces have IP addresses already configured and are used for peering between FGT_A and FGT_B.
- FGT_A is configure to peer with ISP2 on 10.10.108.86.
- The firewall policies between FGT_A and FGT_B are not NATed. The firewall policies egressing on wan2 are NATed.

Configuring iBGP peering

To configure FGT_A to establish iBGP peering with FGT_B in the GUI:

1. Go to *Network* > *BGP*.
2. Set *Local AS* to *64511*
3. Set *Router ID* to *1.1.1.1*.
4. In the *Neighbors* table, click *Create New* and set the following:

IP	10.100.201.88
Remote AS	64511

5. Click *OK*.
6. Under *Networks*, set *IP/Netmask* to *192.168.86.0/24*.
7. Click *Apply*.
8. In the CLI, set the interface used as the source IP address of the TCP connection (where the BGP session, TCP/179, is connecting from) for the neighbor (`update-source`) to `toFGTB`.

To configure FGT_A to establish iBGP peering with FGT_B in the CLI:

```
config router bgp
    set as 64511
    set router-id 1.1.1.1
    config neighbor
        edit "10.100.201.88"
            set remote-as 64511
            set update-source "toFGTB"
        next
    end
```

```
    config network
        edit 1
            set prefix 192.168.86.0 255.255.255.0
        next
    end
end
```

To configure FGT_B to establish iBGP peering with FGT_A in the GUI:

1. Go to *Network* > *BGP*.
2. Set *Local AS* to *64511*
3. Set *Router ID* to *2.2.2.2*.
4. In the *Neighbors* table, click *Create New* and set the following:

IP	10.100.201.86
Remote AS	64511

5. Click *OK*.
6. Under *Networks*, set *IP/Netmask* to *192.168.88.0/24*.
7. Click *Apply*.
8. In the CLI, set the interface used as the source IP address of the TCP connection (where the BGP session, TCP/179, is connecting from) for the neighbor (`update-source`) to `toFGTA`.

To configure FGT_B to establish iBGP peering with FGT_A in the CLI:

```
config router bgp
    set as 64511
    set router-id 2.2.2.2
    config neighbor
        edit "10.100.201.86"
            set remote-as 64511
            set update-source "toFGTA"
        next
    end
    config network
        edit 1
            set prefix 192.168.88.0 255.255.255.0
        next
    end
end
```

To check the FGT_A and FGT_B peering:

1. Check the BGP neighbors:

   ```
   # get router info bgp neighbors
   ```

2. Check the networks learned from neighbors:

   ```
   # get router info bgp network
   ```

3. Check that the routes are added to the routing table:

   ```
   # get router info routing-table all
   ```

To see the neighborship status, network, and routing table command outputs for the completed example, see Troubleshooting and debugging on page 418.

Configuring eBGP peering

By establishing eBGP peering with ISP2, learned routes will have a distance of 20 and will automatically be propagated to iBGP peers. iBGP peers do not change the next hop when they advertise a route. To make FGT_B receive a route with FGT_A as the next hop, and not ISP 2's network, *Next hop self* (`next-hop-self`) is enabled for routes advertised to FGT_B.

Additionally, to peer with another router that is multiple hops away, enable `ebg-enforce-multihop` in the neighbor configuration.

In this example, the iBGP routes are automatically advertised to the eBGP neighbor, so a route map is created to deny iBGP routes from being advertised to ISP 2. Prefixes from ISP 2 are advertised to FGT_A and FGT_B, but no prefixes are advertised from FGT_A to ISP 2.

To configure FGT_A to establish eBGP peering with ISP 2 in the GUI:

1. Configure a route map to prevent advertisement of iBGP routes to ISP 2:
   a. Go to *Network* > *Routing Objects* and click *Create New* > *Route Map*.
   b. Set *Name* to *exclude1*.
   c. In the *Rules* table, click *Create New*.
   d. Set *Action* to *Deny*.
   e. Under *Other Rule Variables*, enable *Match origin* and set it to *IGP*.
   f. Click *OK*.
   g. Click *OK*.
2. Update the BGP configuration:
   a. Go to *Network* > *BGP*.
   b. In the *Neighbors* table, click *Create New* and set the following:

IP	10.10.102.87
Remote AS	64512
Route map out	exclude1

   c. Click *OK*.
   d. In the *Neighbors* table, edit the previously created entry, *10.100.201.88*.
   e. Under *IPv4 Filtering*, select *Next hop self*.
   f. Click *OK*.
   g. Click *Apply*.

To configure FGT_A to establish eBGP peering with ISP 2 in the CLI:

1. Configure a route map to prevent advertisement of iBGP routes to ISP 2:

```
config router route-map
    edit "exclude1"
        config rule
            edit 1
```

```
                set action deny
                set match-origin igp
            next
        end
    next
end
```

2. Update the BGP configuration:

```
config router bgp
    config neighbor
        edit "10.10.102.87"
            set remote-as 64512
            set route-map-out "exclude1"
        next
        edit "10.100.201.88"
            set next-hop-self enable
        next
    end
end
```

To see the neighborship status, network, and routing table command outputs for the completed example, see Troubleshooting and debugging on page 418.

Firewall policies

On FGT_A configure the following policies:

- Allow the internal subnet to the VPN interface. Do not enable NAT. Enable security profiles as required.
- Allow the VPN interface to the internal subnet. Do not enable NAT. Enable security profiles as required.
- Allow the internal subnet to wan2. Enable NAT and security profiles as required.
- Allow VPN traffic from toFGTA to wan2. Enable NAT and security profiles as required.

On FGT_B configure the following policies:

- Allow the internal subnet to the VPN interface. Do not enable NAT. Enable security profiles as required.
- Allow the VPN interface to the internal subnet. Do not enable NAT. Enable security profiles as required.

To verify that pinging from FGT_B to FGT_A is successful:

```
FGT_B # execute ping-options source 192.168.88.88
FGT_B # execute ping 192.168.86.86
PING 192.168.86.86 (192.168.86.86): 56 data bytes
64 bytes from 192.168.86.86: icmp_seq=0 ttl=255 time=0.5 ms
...
--- 192.168.86.86 ping statistics ---
5 packets transmitted, 5 packets received, 0% packet loss
round-trip min/avg/max = 0.3/0.3/0.5 ms
```

To verify that pinging from FGT_B to a subnet in ISP 2 is successful:

```
FGT_B # execute ping-options source 192.168.88.88
FGT_B # execute ping 172.16.201.87
PING 172.16.201.87 (172.16.201.87): 56 data bytes
64 bytes from 172.16.201.87: icmp_seq=0 ttl=254 time=0.6 ms
...
```

```
--- 172.16.201.87 ping statistics ---
5 packets transmitted, 5 packets received, 0% packet loss
round-trip min/avg/max = 0.4/0.4/0.6 ms

FGT_B # execute traceroute-options source 192.168.88.88
FGT_B # execute traceroute 172.16.201.87
traceroute to 172.16.201.87 (172.16.201.87), 32 hops max, 3 probe packets per hop, 84 byte
packets
 1  10.100.201.86  0.315 ms  0.143 ms  0.110 ms
 2  172.16.201.87  0.258 ms  0.144 ms  0.222 ms
```

Troubleshooting and debugging

When troubleshooting issues, logically step through the debugs. For example, if peering cannot be established between FGT_A and FGT_B:

1. Verify the basic connectivity between the FGT_A wan1 interface and the FGT_B port1 interface.
2. Verify that the VPN between FGT_A and FGT_B is established.
3. Verify the connectivity between the VPN interfaces.
4. Check the neighborship status on each peer. Use the BGP state to help determine the possible issue, for example:

Idle state	The local FortiGate has not started the BGP process with the neighbor. This could be because the eBGP peer is multiple hops away, but multihop is not enabled.
Connect	The local FortiGate has started the BGP process, but has not initiated a TCP connection, possibly due to improper routing.
Active	The local FortiGate has initiated a TCP connection, but there is no response. This might indicate issues with the delivery or the response from the remote peer.

5. If there are issues establishing the TCP connection, use the command `diagnose sniffer packet any 'tcp and port 179'` to identify the problem at the packet level.

The following outputs show instances where all of the configurations are completed, peering has formed, and routes have been exchanged. The debug output during each configuration step might differ from these outputs. These debug outputs can be used to help identify what might be missing or misconfigured on your device.

To verify the status of the neighbors:

```
FGT_A # get router info bgp neighbors
VRF 0 neighbor table:
BGP neighbor is 10.10.102.87, remote AS 64512, local AS 64511, external link
  BGP version 4, remote router ID 192.168.2.87
  BGP state = Established, up for 01:54:37

C       192.168.88.0/24 is directly connected, vlan88
```

Route filtering with a distribution list

During BGP operations, routes can be propagated between BGP peers and redistributed from other routing protocols. In some situations, advertising routes from one peer to another might need to be prevented.

The Basic BGP example on page 413 explains using a route map to filter routes that are learned from iBGP to prevent them from propagating to an eBGP peer. In this example, a distribution list is used to prevent certain routes from one peer from being advertised to another peer.

- A company has its own web and email servers in an OSPF area, and needs to advertise routes to these resources to external peers. Users, routers, and other server all reside in the OSPF area.

- The FortiGate acts as the BGP border router, redistributing routes from the company's network to its BGP peers. It is connected to the OSPF area using its DMZ interface.
- Two ISP managed BGP peers in an AS (Peer 1 and Peer 2) are used to access the internet, and routes must not to be advertised from Peer 1 to Peer 2. The manufacturers of these routers, and information about other devices on the external BGP AS, are not known.
- Routes to the BGP peers are redistributed so that external locations can access the web and email servers in the OSPF area. The FortiGate device's external interfaces and the BGP peers are in different ASs, and form eBGP peers.
- Other networking devices must be configured for BGP. The peer routers must be updated with the FortiGate device's BGP information, including IP addresses, AS number, and any specific capabilities that are used, such as IPv6, graceful restart, BFD, and so on.
- It is assumed that security policies have been configured to allow traffic between the networks and NAT is not used. To tighten security, only the required services should be allowed inbound to the various servers.
- In a real life scenario, public IP addresses would be used in place of private IP addresses.

Configuring BGP

In this example, Peer 1 routes are blocked from being advertised to Peer 2 using an access list. All incoming routes from Peer 1 are blocked when updates are sent to Peer 2.

Routes learned from OSPF are redistributed into BGP. EBGP multi path is enabled to load-balance traffic between the peers using ECMP. See Equal cost multi-path on page 365 for more information.

To configure BGP in the GUI:

1. Configure an access list to block Peer 1 routes:
   a. Go to *Network* > *Routing Objects* and click *Create New* > *Access List*.
   b. Set *Name* to *block_peer1*.
   c. In the *Rules* table, click *Create New*.
   d. Set *Action* to *Deny*.
   e. Enable *Exact Match* and specify the prefix *172.21.111.0 255.255.255.0*.
   f. Click *OK*.
   g. Click *OK*.
2. Configure BGP:
   a. Go to *Network* > *BGP*.
   b. Set *Local AS* to *65001*
   c. Set *Router ID* to *10.11.201.110*.
   d. In the *Neighbors* table, click *Create New* and set the following:

IP	172.21.111.5
Remote AS	65001

   e. Click *OK*.
   f. In the *Neighbors* table, click *Create New* again and set the following:

IP	172.22.222.5

Remote AS	65001
Distribute list out	Enable, and select the *block_peer1* access list.

g. Click *OK*.
h. Under *IPv4 Redistribute*, enable *OSPF* and select *ALL*.
i. Expand *Best Path Selection* and enable *EBGP multi path*.
j. Click *Apply*.

To configure BGP in the CLI:

1. Configure an access list to block Peer 1 routes:

```
config router access-list
    edit "block_peer1"
        config rule
            edit 1
                set action deny
                set prefix 172.21.111.0 255.255.255.0
                set exact-match enable
            next
        end
    next
end
```

2. Configure BGP:

```
config router bgp
    set as 65001
    set router-id 10.11.201.110
    set ebgp-multipath enable
    config neighbor
        edit "172.21.111.5"
            set remote-as 65001
        next
        edit "172.22.222.5"
            set distribute-list-out "block_peer1"
            set remote-as 65001
        next
    end
    config redistribute "ospf"
        set status enable
    end
end
```

Configuring OSPF

In this example, all of the traffic is within the one OSPF area, and there are other OSPF routers in the network. When adjacencies are formed, other routers receive the routes advertised from the FortiGate that are redistributed from BGP.

To configure OSPF in the GUI:

1. Go to *Network* > *OSPF*.
2. Set *Router ID* to *10.11.201.110*.

3. In the *Areas* table, click *Create New* and set the following:

Area ID	0.0.0.0
Type	Regular
Authentication	None

4. Click *OK*.
5. In the *Networks* table, click *Create New* and set the following:

Area	0.0.0.0
IP/Netmask	10.11.201.0 255.255.255.0

6. Click *OK*.
7. In the *Interfaces* table, click *Create New* and set the following:

Name	OSPF_dmz_network
Interface	dmz

8. Click *OK*.
9. Enable *Redistribute BGP* and set *Metric value* to *1*.
10. Click *Apply*.

To configure OSPF in the CLI:

```
config router ospf
    set router-id 10.11.201.110
    config area
        edit 0.0.0.0
        next
    end
    config ospf-interface
        edit "OSPF_dmz_network"
            set interface "dmz"
        next
    end
    config network
        edit 1
            set prefix 10.11.201.0 255.255.255.0
        next
    end
    config redistribute "bgp"
        set status enable
        set metric 1
    end
end
```

Testing the configuration

To test this configuration, run the standard connectivity checks, and also make sure that routes are being passed between protocols as expected. Use the following checklist to help verify that the FortiGate is configured successfully:

1. Check that the FortiGate has established peering with BGP Peer 1 and Peer 2:

```
# get router info bgp summary
# get router info bgp neighbors
```

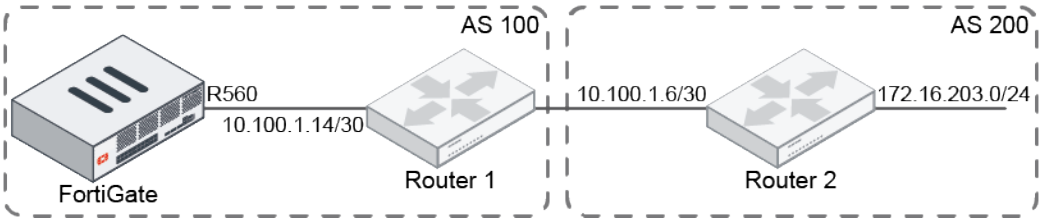
2. Check that the FortiGate has formed adjacency with OSPF neighbors:

```
# get router info ospf status
# get router info ospf neighbors
```

3. Check the routing table on the FortiGate to make sure that routes from both OSPF and BGP are included:

```
# get router info routing-table all
```

4. Check devices in the OSPF network for internet connectivity and to confirm that routes redistributed from BGP are in their routing tables.
5. Check the routing table on Peer 2 to confirm that no routes from Peer 1 are included.
6. Check that the routes from the internal OSPF network are redistributed to Peer 1 and Peer 2.
7. Verify connectivity to the HTTP and email servers.



Next hop recursive resolution using other BGP routes

By default, BGP routes are not considered when a BGP next hop requires recursive resolution. They are considered when `recursive-next-hop` is enabled. Recursive resolution will resolve to one level.

To consider BGP routes for recursive resolution of next hops:

```
config router bgp
    set recursive-next-hop enable
end
```

Example

To see the change in the routing table when the option is enabled:

1. Check the BGP routing table:

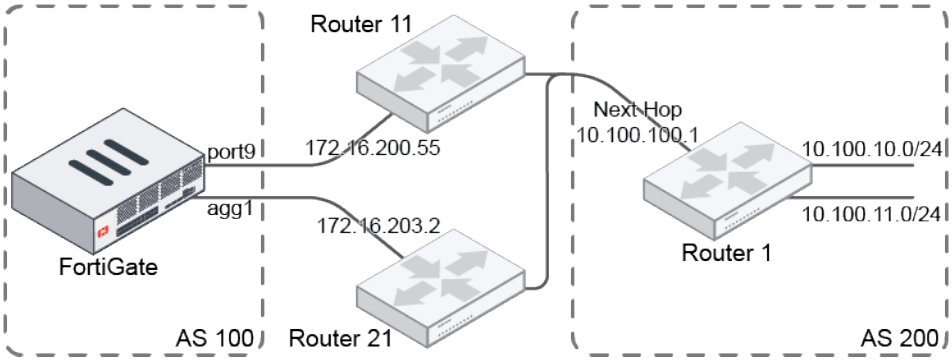
```
# get router info routing-table bgp
Routing table for VRF=0
B       10.100.1.4/30 [200/0] via 10.100.1.14 (recursive is directly connected, R560),
00:02:06
```

2. Enable BGP routes for recursive resolution of next hops:

```
config router bgp
    set recursive-next-hop enable
end
```

3. Check the BGP routing table again:

```
# get router info routing-table bgp
Routing table for VRF=0
B       10.100.1.4/30 [200/0] via 10.100.1.14 (recursive is directly connected, R560),
00:02:15
B       172.16.203.0/24 [200/0] via 10.100.1.6 (recursive via 10.100.1.14, R560),
00:00:06
```



The second BGP route's next hop is now recursively resolved by another BGP route.

Next hop recursive resolution using ECMP routes

When there are multiple ECMP routes to a BGP next hop, all of them are considered for the next hop recursive resolution. This ensures that the outgoing traffic can be load balanced.

To support multipath, either EGBP or IGBP multipath must be enabled:

```
config router bgp
    set ebgp-multipath enable
    set ibgp-multipath enable
end
```

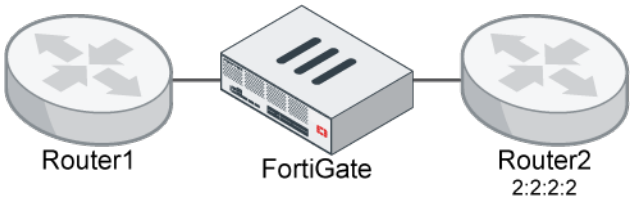
In this example, there are two static routes. The FortiGate has learned two BGP routes from Router 1 that have the same next hop at 10.100.100.1. The next hop is resolved by the two static routes.

To verify that the routes are added to the BGP routing table:

1. Check the two static routes:

```
# get router info routing-table static
Routing table for VRF=0
S       10.100.100.0/24 [10/0] via 172.16.200.55, port9
                        [10/0] via 172.16.203.2, agg1
```

2. Confirm that both routes are in the BGP routing table:



```
# get router info routing-table bgp
Routing table for VRF=0
B       10.100.10.0/24 [20/200] via 10.100.100.1 (recursive via 172.16.200.55, port9),
00:00:07
                                                 (recursive via 172.16.203.2, agg1),
00:00:07
B       10.100.11.0/24 [20/200] via 10.100.100.1 (recursive via 172.16.200.55, port9),
00:00:07
                                                 (recursive via 172.16.203.2, agg1),
00:00:07
```

BGP conditional advertisement

BGP conditional advertisement allows the router to advertise a route only when certain conditions are met. Multiple conditions can be used together, with conditional route map entries treated as an AND operator, and IPv6 is supported.

Multiple conditions example

In this example, the FortiGate only advertises routes to its neighbor 2.2.2.2 if it learns multiple BGP routes defined in its conditional route map entry. All conditionals must be met.

To configure multiple conditions in BGP conditional advertisements:

1. Configure the IPv4 prefix list:

```
config router prefix-list
    edit "281"
        config rule
            edit 1
                set prefix 172.28.1.0 255.255.255.0
                unset ge
                unset le
            next
        end
    next
    edit "222"
        config rule
            edit 1
                set prefix 172.22.2.0 255.255.255.0
                unset ge
                unset le
            next
        end
    next
end
```

2. Configure the community list:

```
config router community-list
    edit "30:5"
        config rule
            edit 1
                set action permit
                set match "30:5"
            next
        end
    next
end
```

3. Configure the IPv4 route maps:

```
config router route-map
    edit "comm1"
        config rule
            edit 1
                set match-community "30:5"
                set set-route-tag 15
            next
        end
    next
    edit "2224"
        config rule
            edit 1
                set match-ip-address "222"
            next
        end
    next
    edit "2814"
        config rule
            edit 1
                set match-ip-address "281"
            next
        end
    next
end
```

4. Configure the IPv6 prefix list:

```
config router prefix-list6
    edit "adv-222"
        config rule
            edit 1
                set prefix6 2003:172:22:1::/64
                unset ge
                unset le
            next
        end
    next
    edit "list6-2"
        config rule
            edit 1
                set prefix6 2003:172:28:2::/64
                unset ge
                unset le
```

```
            next
        end
    next
end
```

5. Configure the IPv6 route maps:

```
config router route-map
    edit "map-222"
        config rule
            edit 1
                set match-ip6-address "adv-222"
            next
        end
    next
    edit "map-282"
        config rule
            edit 1
                set action deny
                set match-ip6-address "list6-2"
            next
        end
    next
end
```

6. Configure the BGP settings:

```
config router bgp
    config neighbor
        edit "2.2.2.2"
            config conditional-advertise
                edit "2224"
                    set condition-routemap "2814" "2224" "comm1"
                    set condition-type non-exist
                next
            end
        next
        edit "2003::2:2:2:2"
            config conditional-advertise6
                edit "map-222"
                    set condition-routemap "map-222" "map-282"
                next
                end
            set route-reflector-client6 enable
        next
    end
end
```

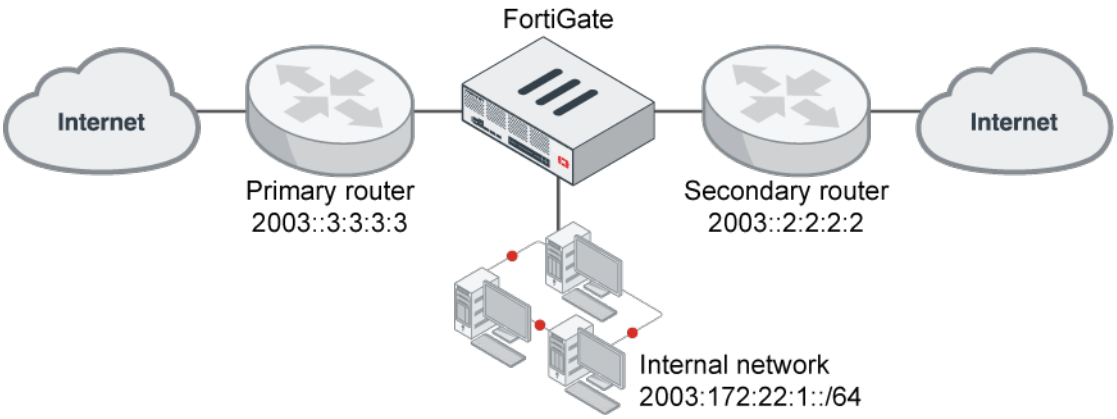
To verify the IPv4 conditional advertisements:

```
# get router info bgp neighbors 2.2.2.2
...
  Conditional advertise-map:
       Adv-map 2224root 2814root, cond-state 0-1
                         2224root, cond-state 0-1
                        comm1root, cond-state 0-0
...
```

In this output, the condition is that the routes in route maps 2814, 2224 and comm1 do not exist. However, routes for 2814 and 2224 exist, so the conditions are not met.

To verify the IPv6 conditional advertisements:

```
# get router info6 bgp neighbors 2003::2:2:2:2
...
  Conditional advertise-map:
        Adv-map map-222root map-222root, cond-state 1-1
                            map-282root, cond-state 1-0
...
```



In this output, the condition is that the routes in route maps map-222 and map-282 exist. However, routes for map-222 exist, but map-282 does not, so the conditions are not met.

To view the conditional route maps:

```
# diagnose ip router command show-vrf root show running router bgp
...
 neighbor 2.2.2.2 advertise-map 2224root exist-map 2814root
 neighbor 2.2.2.2 advertise-map 2224root exist-map 2224root
 neighbor 2.2.2.2 advertise-map 2224root exist-map comm1root
... ...
 !
 address-family ipv6
 neighbor 2003::2:2:2:2 advertise-map map-222root non-exist-map map-222root
 neighbor 2003::2:2:2:2 advertise-map map-222root non-exist-map map-282root
!
```

IPv6 example 1

In this example, the FortiGate advertises its local network to the secondary router when the primary router is down. The FortiGate detects the primary router is down in the absence of a learned route.

- When the FortiGate learns route 2003:172:28:1::/64 from the primary router, it does not advertise its local route (2003:172:22:1::/64) to the secondary router.
- When the FortiGate does not learn route 2003:17:28:1::/64 from the primary router, advertises its local route (2003:172:22:1::/64) to the secondary router.
- The BGP conditional advertisement condition is set to be true if the condition route map (2003:172:28:1::/64) is not matched (`non-exist`).

To configure BGP conditional advertisement with IPv6:

1. Configure the IPv6 prefix lists:

```
config router prefix-list6
    edit "adv-222"
        config rule
            edit 1
                set prefix6 2003:172:22:1::/64
                unset ge
                unset le
            next
        end
    next
    edit "lrn-281"
        config rule
            edit 1
                set prefix6 2003:172:28:1::/64
                unset ge
                unset le
            next
        end
    next
end
```

2. Configure the route maps:

```
config router route-map
    edit "map-221"
        config rule
            edit 1
                set match-ip6-address "adv-222"
            next
        end
    next
    edit "map-281"
        config rule
            edit 1
                set match-ip6-address "lrn-281"
            next
        end
    next
end
```

3. Configure BGP:

```
config router bgp
    set as 65412
    set router-id 1.1.1.1
    set ibgp-multipath enable
    set network-import-check disable
    set graceful-restart enable
    config neighbor
        edit "2003::2:2:2:2"
            set soft-reconfiguration6 enable
            set remote-as 65412
            set update-source "loopback1"
            config conditional-advertise6
```

```
                edit "map-221"
                    set condition-routemap "map-281"
                    set condition-type non-exist
                next
            end
        next
        edit "2003::3:3:3:3"
            set soft-reconfiguration6 enable
            set remote-as 65412
            set update-source "loopback1"
        next
    end
end
```

In this configuration, if route map `map-281` does not exist, then the FortiGate advertises route map `map-221` to neighbor 2003::2:2:2:2.

4. Verify the routing table:

```
# get router info6 routing-table bgp
B       2003:172:28:1::/64 [200/0] via 2003::3:3:3:3 (recursive via
****::***:***:****:****, port9), 01:23:45
B       2003:172:28:2::/64 [200/0] via 2003::3:3:3:3 (recursive via
****::***:***:****:****, port9), 23:09:22
```

When the FortiGate learns 2003:172:28:1::/64, it will not advertise its local route 2003:172:22:1::/64 to neighbor 2003::2:2:2:2. If the FortiGate has not learned 2003:172:28:1::/64, it will advertise its local route 2003:172:22:1::/64 to neighbor 2003::2:2:2:2.

IPv6 example 2

With the same IPv6 prefix lists and route maps, when the FortiGate does learn 2003:172:28:1::/64, it advertises local route 2003:172:22:1::/64 to the secondary router. The BGP conditional advertisement condition is set to be true if the condition route map is matched (`exist`).

To configure BGP conditional advertisement with IPv6:

1. Configure BGP:

```
config router bgp
    config neighbor
        edit "2003::2:2:2:2"
            config conditional-advertise6
                edit "map-221"
                    set condition-routemap "map-281"
                    set condition-type exist
                next
            end
        next
    end
end
```

2. Verify the routing table:

```
# get router info6 routing-table bgp
B       2003:172:28:1::/64 [200/0] via 2003::3:3:3:3 (recursive via
****::***:***:****:****, port9), 01:23:45
```

```
B       2003:172:28:2::/64 [200/0] via 2003::3:3:3:3 (recursive via
****::***:***:****:****, port9), 23:09:22
```

When the FortiGate learns 2003:172:28:1::/64, it will advertise its local route 2003:172:22:1::/64 to neighbor 2003::2:2:2:2. If the FortiGate has not learned route 2003:172:28:1::/64, it will not advertise its local route 2003:172:22:1::/64 to neighbor 2003::2:2:2:2.

BGP error handling per RFC 7606

The FortiGate uses one of the three approaches to handle malformed attributes in BGP UPDATE messages, in order of decreasing severity:

1. Notification and Session reset
2. Treat-as-withdraw
3. Attribute discard

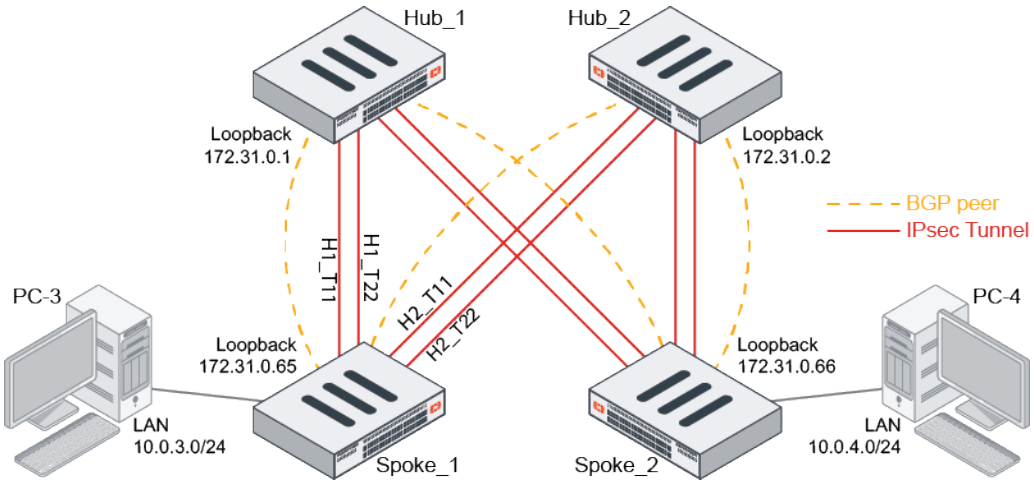
When a BGP UPDATE message contains multiple malformed attributes, the most severe approach that is triggered by one of the attributes is followed. See RFC 7606 for more information.

The following table lists the BGP attributes, and how FortiGate handles a malformed attribute in the UPDATE message:

BGP attribute	Handling
origin	Handled by the treat-as-withdraw approach.
AS path	Handled by the treat-as-withdraw approach.
AS 4 path	Handled by the attribute discard approach.
aggregator	Handled by the attribute discard approach.
aggregator 4	Handled by the attribute discard approach.
next-hop	Handled by the treat-as-withdraw approach.
multiple exit discriminator	Handled by the treat-as-withdraw approach.
local preference	Handled by the treat-as-withdraw approach.
atomic aggregate	Handled by the attribute discard approach.
community	Handled by the treat-as-withdraw approach.
extended community	Handled by the treat-as-withdraw approach.
originator	Handled by the treat-as-withdraw approach.
cluster	Handled by the treat-as-withdraw approach.
PMSI	Handled by the treat-as-withdraw approach.
MP reach	Handled by the notification message approach.
MP unreach	Handled by the notification message approach.
attribute set	Handled by the treat-as-withdraw approach.
AIGP	Handled by the treat-as-withdraw approach.

BGP attribute	Handling
Unknown	If the BGP flag does not indicate that this is an optional attribute, this malformed attribute is handled by the notification message approach.

BGP next hop tag-match mode



Tag-match mode can be configured to increase flexibility when controlling how BGP routes' next hops are resolved:

```
config router bgp
    set tag-resolve-mode {disable | preferred | merge}
end
```

Best-match (`disable`)	Resolve the BGP route's next hops with best-matched routes. This is the default setting.
Tag-match (`preferred`)	Resolve the BGP route's next hops with routes that have the same tag. If there are no results, resolve the next hops with best-matched routes.
Tag-and-best-match (`merge`)	Merge tag-match with best-match if they are using different routes, then let shortcuts hide their parents. The results exclude the next hops of tag-match whose interfaces have appeared in best-match.

In these examples:

- Each spoke has two IPsec tunnels to each hub, and one BGP peer on loopback interface to each hub (route-reflector).
- The loopbacks are exchanged with IKE between the spokes and hubs. They are installed as static routes that are used to provide reachability for establishing BGP neighbors.
- The summary BGP routes from the loopback IP address ranges that originated on the hubs are advertised to the spokes for resolving the BGP next hop s on the spokes.
- The spokes' PC LAN subnets are reflected by the hubs.
- Spoke_1 receives BGP routes (the LAN subnet and loopback IP summary) from Hub_1 with tag 1 and from Hub_2 with tag 2.
- SD-WAN is enabled on Spoke_1, and all of the tunnels are SD-WAN members.

Example 1: Connection between Hub and Spoke down

If the connections between Hub_1 and Spoke_2 are down, traffic from PC_3 to PC_4 can still go through Hub_1 because of the best-match resolving on Spoke_1, but packets will be dropped on Hub_1. When tag-match is enabled on Spoke_1, the spoke will resolve the PC_4 LAN route to Hub2, and traffic will be forwarded to Hub_2 and reach its destination.

To test the tag-match mode:

1. View the key routes on Spoke_1:

```
Spoke_1(root) # get router info routing-table all
C       10.0.3.0/24 is directly connected, port4
B       10.0.4.0/24 [200/0] via 172.31.0.66 [2] (recursive via H1_T11 tunnel
172.31.1.1), 20:09:52
              (recursive via H1_T22 tunnel 10.0.0.2), 20:09:52
              (recursive via H2_T11 tunnel 172.31.1.101), 20:09:52
              (recursive via H2_T22 tunnel 10.0.0.4), 20:09:52
B       172.31.0.0/25 [200/0] via 172.31.0.1 (recursive via H1_T11 tunnel 172.31.1.1),
23:25:37
              (recursive via H1_T22 tunnel 10.0.0.2), 23:25:37
            [200/0] via 172.31.0.2 (recursive via H2_T11 tunnel 172.31.1.101), 23:25:37
              (recursive via H2_T22 tunnel 10.0.0.4), 23:25:37
S       172.31.0.1/32 [15/0] via H1_T11 tunnel 172.31.1.1, [1/0]
            [15/0] via H1_T22 tunnel 10.0.0.2, [1/0]
S       172.31.0.2/32 [15/0] via H2_T11 tunnel 172.31.1.101, [1/0]
            [15/0] via H2_T22 tunnel 10.0.0.4, [1/0]
C       172.31.0.65/32 is directly connected, Loopback0
...
```

   172.31.0.0/25 is the loopback IP summary originated by both Hub_1 and Hub_2. The next hop of the PC_4 LAN route is resolved to Hub_1 (H1_T11, H1_T22) and Hub_2 (H2_T11, H2_T22) based on the loopback IP summary route.

2. When connections between Spoke_2 and Hub_1 fails due to the BGP neighbor, tunnels, or physical ports going down, the PC_4 LAN route can be still resolved to Hub_1 and Hub_2 because the loopback IP summary can still be received from both Hub_1 and Hub_2:

```
Spoke_1(root) # get router info routing-table all
C       10.0.3.0/24 is directly connected, port4
B       10.0.4.0/24 [200/0] via 172.31.0.66 (recursive via H1_T11 tunnel 172.31.1.1),
00:03:06
              (recursive via H1_T22 tunnel 10.0.0.2), 00:03:06
              (recursive via H2_T11 tunnel 172.31.1.101), 00:03:06
              (recursive via H2_T22 tunnel 10.0.0.4), 00:03:06
B       172.31.0.0/25 [200/0] via 172.31.0.1 (recursive via H1_T11 tunnel 172.31.1.1),
23:55:34
              (recursive via H1_T22 tunnel 10.0.0.2), 23:55:34
            [200/0] via 172.31.0.2 (recursive via H2_T11 tunnel 172.31.1.101), 23:55:34
              (recursive via H2_T22 tunnel 10.0.0.4), 23:55:34
...
```

3. If traffic sent from PC_3 to PC_4 goes through Hub_1, packets are dropped because there is no PC_4 LAN route on Hub_1:

```
Spoke_1 (root) # diagnose sniffer packet any 'host 10.0.4.2' 4
interfaces=[any]
```

```
filters=[host 10.0.4.2]
11.261264 port4 in 10.0.3.2 -> 10.0.4.2: icmp: echo request
11.261349 H1_T11 out 10.0.3.2 -> 10.0.4.2: icmp: echo request
12.260268 port4 in 10.0.3.2 -> 10.0.4.2: icmp: echo request
12.260291 H1_T11 out 10.0.3.2 -> 10.0.4.2: icmp: echo request

Hub_1 (root) #  diagnose sniffer packet any 'host 10.0.4.2' 4
interfaces=[any]
filters=[host 10.0.4.2]
6.966064 EDGE_T1 in 10.0.3.2 -> 10.0.4.2: icmp: echo request
7.965012 EDGE_T1 in 10.0.3.2 -> 10.0.4.2: icmp: echo request
```

4. If the tag-match mode is set to tag-match (`preferred`) on Spoke_1, then the PC_4 LAN route can only be resolved to Hub_2 because of tag-match checking:

```
Spoke_1(root) # get router info routing-table all
C       10.0.3.0/24 is directly connected, port4
B       10.0.4.0/24 [200/0] via 172.31.0.66 tag 2 (recursive via H2_T11 tunnel
172.31.1.101), 00:02:35
              (recursive via H2_T22 tunnel 10.0.0.4), 00:02:35
B       172.31.0.0/25 [200/0] via 172.31.0.1 tag 1 (recursive via H1_T11 tunnel
172.31.1.1), 03:18:41
              (recursive via H1_T22 tunnel 10.0.0.2), 03:18:41
            [200/0] via 172.31.0.2 tag 2 (recursive via H2_T11 tunnel 172.31.1.101),
03:18:41
              (recursive via H2_T22 tunnel 10.0.0.4), 03:18:41
...
```

```
Spoke_1 (root) # get router info routing-table details 10.0.4.0/24

Routing table for VRF=0
Routing entry for 10.0.4.0/24
  Known via "bgp", distance 200, metric 0, best
  Last update 00:01:11 ago
  * 172.31.0.66, tag 2 (recursive via H2_T11 tunnel 172.31.1.101), tag-match
              (recursive via H2_T22 tunnel 10.0.0.4), tag-match
```

5. If traffic is again sent from PC_3 to PC_4, it will go through Hub_2 and reach the destination:

```
Spoke_1 (root) # diagnose sniffer packet any 'host 10.0.4.2' 4
interfaces=[any]
filters=[host 10.0.4.2]
7.216948 port4 in 10.0.3.2 -> 10.0.4.2: icmp: echo request
7.217035 H2_T11 out 10.0.3.2 -> 10.0.4.2: icmp: echo request
7.217682 H2_T11 in 10.0.4.2 -> 10.0.3.2: icmp: echo reply
7.217729 port4 out 10.0.4.2 -> 10.0.3.2: icmp: echo reply
```

Example 2: SD-WAN failover when shortcut down

After the shortcut from Spoke_1 to Spoke_2 is established, Spoke_1 will only resolve the PC_4 LAN route to the shortcut, because of best-match resolving, prohibiting SD-WAN failover. When tag-and-best-match is enabled on Spoke_1, the spoke can resolve the PC_4 LAN route to the shortcut and to other alternative tunnels, allowing SD-WAN failover.

To test the tag-and-best-match mode:

1. Unset `tag-resolve-mode` and resume the connections between Spoke_2 and Hub_1. The routing table on Spoke_1 changes to the initial state:

```
Spoke_1(root) # get router info routing-table all
C       10.0.3.0/24 is directly connected, port4
B       10.0.4.0/24 [200/0] via 172.31.0.66 [2] (recursive via H1_T11 tunnel
172.31.1.1), 00:01:54
              (recursive via H1_T22 tunnel 10.0.0.2), 00:01:54
              (recursive via H2_T11 tunnel 172.31.1.101), 00:01:54
              (recursive via H2_T22 tunnel 10.0.0.4), 00:01:54
B       172.31.0.0/25 [200/0] via 172.31.0.1 (recursive via H1_T11 tunnel 172.31.1.1),
03:30:35
              (recursive via H1_T22 tunnel 10.0.0.2), 03:30:35
            [200/0] via 172.31.0.2 (recursive via H2_T11 tunnel 172.31.1.101), 03:30:35
              (recursive via H2_T22 tunnel 10.0.0.4), 03:30:35
S       172.31.0.1/32 [15/0] via H1_T11 tunnel 172.31.1.1, [1/0]
            [15/0] via H1_T22 tunnel 10.0.0.2, [1/0]
S       172.31.0.2/32 [15/0] via H2_T11 tunnel 172.31.1.101, [1/0]
            [15/0] via H2_T22 tunnel 10.0.0.4, [1/0]
C       172.31.0.65/32 is directly connected, Loopback0

...
```

2. Send traffic from PC_3 to PC_4.

   The shortcut from Spoke_1 o Spoke_2 is established.

   The PC_4 LAN route is only resolved to the shortcut because of best-match resolving. If the shortcut is out of SLA, then the traffic cannot switch over to another, alternative tunnel.

```
Spoke_1 (root) # get router info routing-table all
C       10.0.3.0/24 is directly connected, port4
B       10.0.4.0/24 [200/0] via 172.31.0.66 [2] (recursive via H1_T11_0 tunnel
10.0.0.40), 00:09:22
B       172.31.0.0/25 [200/0] via 172.31.0.1 (recursive via H1_T11 tunnel 172.31.1.1),
03:40:12
              (recursive via H1_T22 tunnel 10.0.0.2), 03:40:12
            [200/0] via 172.31.0.2 (recursive via H2_T11 tunnel 172.31.1.101), 03:40:12
              (recursive via H2_T22 tunnel 10.0.0.4), 03:40:12
S       172.31.0.1/32 [15/0] via H1_T11 tunnel 172.31.1.1, [1/0]
            [15/0] via H1_T22 tunnel 10.0.0.2, [1/0]
S       172.31.0.2/32 [15/0] via H2_T11 tunnel 172.31.1.101, [1/0]
            [15/0] via H2_T22 tunnel 10.0.0.4, [1/0]
C       172.31.0.65/32 is directly connected, Loopback0
S       172.31.0.66/32 [15/0] via H1_T11_0 tunnel 10.0.0.40, [1/0]
...
```

3. If the tag-match mode is set to tag-and-best-match (`merge`) on Spoke_1, then the PC_4 LAN route is resolved to the `H1_T11_0` shortcut based on best-match resolving, and to `H1_T11, H1_T22, H2_T11, H2_T22` based on tag-match resolving. It is then resolved to `H1_T11, H1_T22, H2_T11, H2_T22` after letting the shortcut hide its parent tunnel.

```
Spoke_1 (root) # get router info routing-table all
C       10.0.3.0/24 is directly connected, port4
B       10.0.4.0/24 [200/0] via 172.31.0.66 tag 1 (recursive via H1_T11_0 tunnel
10.0.0.40), 00:07:36
```

```
              (recursive via H1_T22 tunnel 10.0.0.2), 00:07:36
             [200/0] via 172.31.0.66 tag 2 (recursive via H1_T11_0 tunnel 10.0.0.40),
00:07:36
              (recursive via H2_T11 tunnel 172.31.1.101), 00:07:36
              (recursive via H2_T22 tunnel 10.0.0.4), 00:07:36
B       172.31.0.0/25 [200/0] via 172.31.0.1 tag 1 (recursive via H1_T11 tunnel
172.31.1.1), 03:48:26
              (recursive via H1_T22 tunnel 10.0.0.2), 03:48:26
             [200/0] via 172.31.0.2 tag 2 (recursive via H2_T11 tunnel 172.31.1.101),
03:48:26
              (recursive via H2_T22 tunnel 10.0.0.4), 03:48:26
S       172.31.0.1/32 [15/0] via H1_T11 tunnel 172.31.1.1, [1/0]
            [15/0] via H1_T22 tunnel 10.0.0.2, [1/0]
S       172.31.0.2/32 [15/0] via H2_T11 tunnel 172.31.1.101, [1/0]
            [15/0] via H2_T22 tunnel 10.0.0.4, [1/0]
C       172.31.0.65/32 is directly connected, Loopback0

```

BGP neighbor password

A BGP neighbor password is used for the neighbor range. Once a BGP group is configured, it uses a password to establish the neighborhood.

```
config router bgp
    config neighbor-group
        edit <name>
            set password <password>
        next
```

```
    end
end
```

To configure the BGP group:

1. Configure the R3 FortiGate settings:

```
config router bgp
    config neighbor-group
        edit "FGT"
            set soft-reconfiguration enable
            set remote-as 65050
            set local-as 65518
            set local-as-no-prepend enable
            set local-as-replace-as enable
            set route-map-in "del-comm"
            set keep-alive-timer 30
            set holdtime-timer 90
            set update-source "npu0_vlink0"
            set weight 1000
            set password ENC ********
        next
    end
    config neighbor-range
        edit 1
            set prefix 172.16.201.0 255.255.255.0
            set max-neighbor-num 10
            set neighbor-group "FGT"
        next
    end
end
```

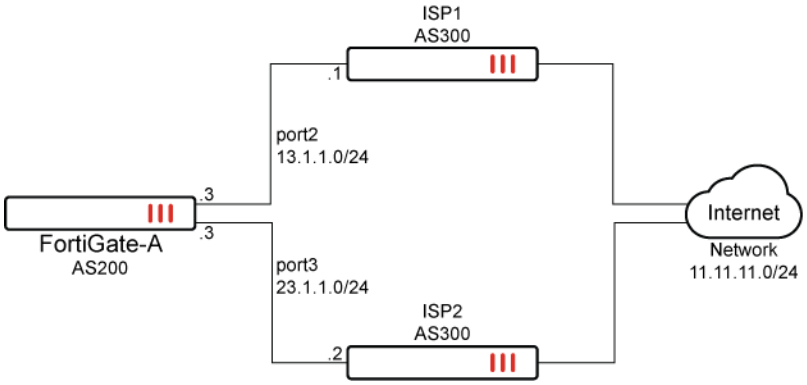
2. Configure the R4 router settings:

```
config router bgp
    config neighbor
        edit "172.16.201.1"
            set soft-reconfiguration enable
            set remote-as 65518
            set password ********
        next
    end
end
```

BGP multi-exit discriminator

Border Gateway Protocol (BGP) is the routing protocol that governs how internet traffic is efficiently routed between autonomous systems (AS). BGP uses path attributes for its best path calculation to a network.

Multi-Exit Discriminator (MED) is a BGP path attribute that discriminates among multiple exit or entry points to the same neighboring AS. MED is also known as Optional Non-Transitive path attribute. The lower the MED value, the more preferred the path is to the receiving router.



MED is typically utilized when an AS has multiple exit points to another AS. In such cases, the AS may want to influence incoming traffic by advertising different MED values for the same route.

Common use case

A common use case for MED is in the context of a dual-homed AS. In a dual-homed AS scenario, the FortiGate connects to two different ISPs belonging to the same AS for redundancy and load balancing. By manipulating the MED value, the AS can direct traffic to one ISP over the other. For instance, if one link is congested, the AS can advertise a higher MED value for that link, making the other link more suitable to incoming traffic.

MED is a BGP path attribute that discriminates among multiple exit or entry points to the same neighboring AS. If an administrator has two or more eBGP peering to different AS then the local preference can be used to influence the routing decision.

The following example discusses the use of MED in dual-homed AS network and the configuration of MED Path Attribute on FortiOS.

Characteristics of the topology include the following:

- FortiGate-A has two internet service providers: ISP1 and ISP2.
- FortiGate-A belongs to AS 200.
- ISP1 and ISP2 both belong to AS 300.
- FortiGate-A will establish eBGP peering relationships with ISP1 and ISP2.
- Network 11.11.11.0/24 resides on the Internet and is reachable by both ISP1 and ISP2.
- eBGP multipath is enabled on FortiGate-A if FortiGate-A needs to perform equal cost load-balancing of traffic between both ISP1 and ISP2 to reach to 11.11.11.0/24.
- The network 11.11.11.0/24 on the Internet is being advertised by both ISP1 and ISP2 to FortiGate-A through eBGP.

For this example, the traffic originating from behind the FortiGate-A should prefer ISP1 rather than ISP2 to reach 11.11.11.0/24, and needs to use the BGP MED Path Attribute. This is done by configuring `set set-metric` in a route map configuration and ensuring the MED value of ISP1 is less than that of ISP2.

To configure MED in a dual-homed AS network using the CLI:

1. Configure eBGP peering on FortiGate-A by specifying the BGP neighbors:

```
config router bgp
    set as 200
    set router-id 2.2.2.2
    config neighbor
        edit "13.1.1.1"
            set remote-as 300
        next
        edit "23.1.1.2"
            set remote-as 300
        next
    end
end
```

2. Configure eBGP on ISP1 and ISP2, and advertise the 11.11.11.0/24 network:

```
config router bgp
    set as 300
    set router-id 3.3.3.3
    config neighbor
        edit "13.1.1.3"
            set remote-as 200
        next
    end
    config network
        edit 1
            set prefix 11.11.11.0 255.255.255.0
        next
    end
end
```

3. Verify the eBGP neighbors on Fortigate-A with ISP1 and ISP2:

```
# get router info bgp summary
VRF 0 BGP router identifier 2.2.2.2, local AS number 200
BGP table version is 6
1 BGP AS-PATH entries
0 BGP community entries

Neighbor V         AS MsgRcvd MsgSent   TblVer  InQ OutQ Up/Down  State/PfxRcd
13.1.1.1 4        300      48      50        0    0    0 00:25:45        1
23.1.1.2 4        300      56      60        6    0    0 00:26:30        1
```

4. Configure the prefix list to filter and select the 11.11.11.0/24 subnet inside the prefix list:
   a. Configure ISP1:

```
config router prefix-list
    edit "ISP1_Prefix_List"
        config rule
            edit 1
                set prefix 11.11.11.0 255.255.255.0
            next
        end
    next
end
```

b. Configure ISP2:

```
config router prefix-list
    edit "ISP2_Prefix_List"
        config rule
            edit 1
                set prefix 11.11.11.0 255.255.255.0
            next
        end
    next
end
```

5. Configure route maps and configure the MED value:

a. Configure ISP1:

```
config router route-map
    edit "MED_Route_MAP"
        config rule
            edit 1
                set match-ip-address "ISP1_Prefix_List"
                set set-metric 300
            next
        end
    next
end
```

b. Configure ISP2:

```
config router route-map
    edit "MED_Route_MAP_2"
        config rule
            edit 1
                set match-ip-address "ISP2_Prefix_List"
                set set-metric 400
            next
        end
    next
end
```

6. Apply the route map in the outbound direction:

Applying the configuration in the outbound direction ensures that the MED is changed to the respective value for the route 11.11.11.0/24 specified in the prefix list.

a. Configure the ISP1 BGP:

```
config router bgp
    set as 300
    set router-id 3.3.3.3
    config neighbor
        edit "13.1.1.3"
            set remote-as 200
            set route-map-out "MED_Route_MAP"
        next
    end
end
```

b. Configure the ISP2 BGP:

```
config router bgp
    set as 300
    set router-id 4.4.4.4
    config neighbor
        edit "23.1.1.3"
            set remote-as 200
            set route-map-out "MED_Route_MAP_2"
        next
    end
end
```

7. Verify that ISP1 is selected as the best path to reach the 11.11.11.0/24 network:

The neighbor that is considered the best, valid route is marked with a `*>`.

```
# get router info bgp network
VRF 0 BGP table version is 6, local router ID is 2.2.2.2
Status codes: s suppressed, d damped, h history, * valid, > best, i - internal,
              S Stale
Origin codes: i - IGP, e - EGP, ? - incomplete

   Network          Next Hop            Metric LocPrf Weight RouteTag Path
*> 11.11.11.0/24    13.1.1.1               300             0        0 300 i <-/1>
*                   23.1.1.2               400             0        0 300 i <-/->

Total number of prefixes 1
```

8. Verify the routing table of FortiGate-A:

The routing table only contains the best and valid paths.

```
# get router info routing-table details
Codes: K - kernel, C - connected, S - static, R - RIP, B - BGP
       O - OSPF, IA - OSPF inter area
       N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
       E1 - OSPF external type 1, E2 - OSPF external type 2
       i - IS-IS, L1 - IS-IS level-1, L2 - IS-IS level-2, ia - IS-IS inter area
       * - candidate default

Routing table for VRF=0
B       11.11.11.0/24 [20/300] via 13.1.1.1, port2, 00:37:47
C       13.1.1.0/24 is directly connected, port2
C       23.1.1.0/24 is directly connected, port3
```

Troubleshooting BGP

There are some features in BGP that are used to deal with problems that may arise. Typically, the problems with a BGP network that has been configured involve routes going offline frequently. This is called route flap and causes problems

for the routers using that route.

Clearing routing table entries

To see if a new route is being properly added to the routing table, you can clear all or some BGP neighbor connections (sessions) using the `execute router clear bgp` command.

For example, if you have 10 routes in the BGP routing table and you want to clear the specific route to IP address 10.10.10.1, enter the following CLI command:

```
# execute router clear bgp ip 10.10.10.1
```

To remove all routes for AS number 650001, enter the following CLI command:

```
# execute router clear bgp as 650001
```

Route flap

When routers or hardware along a route go offline and back online that is called a route flap. Flapping is the term that is used if these outages continue, especially if they occur frequently.

Route flap is a problem in BGP because each time a peer or a route goes down, all the peer routers that are connected to that out-of-service router advertise the change in their routing tables. This creates a lot of administration traffic on the network and the same traffic re-occurs when that router comes back online. If the problem is something like a faulty network cable that alternates online and offline every 10 seconds, there could easily be an overwhelming amount of routing updates sent out unnecessarily.

Another possible reason for route flap occurs with multiple FortiGate devices in HA mode. When an HA cluster fails over to the secondary unit, other routers on the network may see the HA cluster as being offline, resulting in route flap. While this doesn't occur often, or more than once at a time, it can still result in an interruption in traffic which is disruptive for network users. The easy solution for this problem is to increase the timers on the HA cluster, such as TTL timers, so they don't expire during the failover process. Also, configuring graceful restart on the HA cluster helps with a smooth failover.

The first method of dealing with route flap is to check your hardware. If a cable is loose or bad, it can easily be replaced and eliminate the problem. If an interface on the router is bad, either avoid using that interface or swap in a functioning router. If the power source is bad on a router, either replace the power supply or use a power conditioning backup power supply. These quick and easy fixes can save you from configuring more complex BGP options. However, if the route flap is from another source, configuring BGP to deal with the outages will ensure your network users uninterrupted service.

Some methods of dealing with route flap in BGP include:

- Holdtime timer on page 446
- Dampening on page 447
- Graceful restart on page 448
- BFD on page 449

Holdtime timer

The first step to troubleshooting a flapping route is the holdtime timer. This timer reduces how frequently a route going down will cause a routing update to be broadcast.

Once activated, the holdtime timer won't allow the FortiGate to accept any changes to that route for the duration of the timer. If the route flaps five times during the timer period, only the first outage will be recognized by the FortiGate. For the duration of the other outages, there won't be changes because the Fortigate is essentially treating this router as down. If the route is still flapping after the timer expires, it will start again.

If the route isn't flapping (for example, if it goes down, comes up, and stays back up) the timer will still count down and the route is ignored for the duration of the timer. In this situation, the route is seen as down longer than it really is but there will be only the one set of route updates. This isn't a problem in normal operation because updates are not frequent.

The potential for a route to be treated as down when it's really up can be viewed as a robustness feature. Typically, you don't want most of your traffic being routed over an unreliable route. So if there's route flap going on, it's best to avoid that route if you can. This is enforced by the holdtime timer.

How to configure the holdtime timer

There are three different route flapping situations that can occur: the route goes up and down frequently, the route goes down and back up once over a long period of time, or the route goes down and stays down for a long period of time. These can all be handled using the holdtime timer.

For example, your network has two routes that you want to set the timer for. One is your main route (to 10.12.101.4) that all of your Internet traffic goes through, and it can't be down for long if it's down. The second is a low speed connection to a custom network that's used infrequently (to 10.13.101.4). The timer for the main route should be fairly short (for example, 60 seconds). The second route timer can be left at the default, since it's rarely used.

To configure the BGP holdtime timer:

```
config router bgp
    config neighbor
        edit 10.12.101.4
            set holdtime-timer 60
            set keepalive-timer 60
        next
        edit 10.13.101.4
            set holdtime-timer 180
            set keepalive-timer 60
        next
    end
end
```

Dampening

Dampening is a method that's used to limit the amount of network problems due to flapping routes. With dampening, the flapping still occurs but the peer routers pay less and less attention to that route as it flaps more often. One flap doesn't start dampening, but the second flap starts a timer where the router won't use that route because it is considered unstable. If the route flaps again before the timer expires, the timer continues to increase. There's a period of time called the reachability half-life, after which a route flap will be suppressed for only half the time. This half-life comes into effect when a route has been stable for a while but not long enough to clear all the dampening completely. For the flapping route to be included in the routing table again, the suppression time must expire.

If the route flapping was temporary, you can clear the flapping or dampening from the FortiGate device's cache by using one of the `execute router clear bgp` CLI commands:

```
# execute router clear bgp dampening {<ip_address> | <ip_address/netmask>}
```

or

```
# execute router clear bgp flap-statistics {<ip_address> | <ip_address/netmask>}
```

For example, to remove route flap dampening information for the 10.10.0.0/16 subnet, enter the following CLI command:

```
# execute router clear bgp dampening 10.10.0.0/16
```

To configure BGP route dampening:

```
config router bgp
    set dampening {enable | disable}
    set dampening-max-suppress-time <minutes_integer>
    set dampening-reachability-half-life <minutes_integer>
    set dampening-reuse <reuse_integer>
    set dampening-route-map <routemap-name_str>
    set dampening-suppress <limit_integer>
    set dampening-unreachability-half-life <minutes_integer>
end
```

Graceful restart

BGP4 has the capability to gracefully restart.

In some situations, route flap is caused by routers that appear to be offline but the hardware portion of the router (control plane) can continue to function normally. One example of this is when some software is restarting or being upgraded but the hardware can still function normally.

Graceful restart is best used for these situations where routing won't be interrupted, but the router is unresponsive to routing update advertisements. Graceful restart doesn't have to be supported by all routers in a network, but the network will benefit when more routers support it.

FortiGate HA clusters can benefit from graceful restart. When a failover takes place, the HA cluster advertises that it is going offline, and will not appear as a route flap. It will also enable the new HA main unit to come online with an updated and usable routing table. If there is a flap, the HA cluster routing table will be out-of-date.

For example, the FortiGate is one of four BGP routers that send updates to each other. Any of those routers may support graceful starting. When a router plans to go offline, it sends a message to its neighbors stating how long it expects to be offline. This way, its neighboring routers don't remove it from their routing tables. However, if that router isn't back online when expected, the routers will mark it offline. This prevents routing flap and its associated problems.

FortiGate devices support both graceful restart of their own BGP routing software and neighboring BGP routers.

Currently, FortiGates do not support BGP graceful restart when peering with neighbor routers operating in graceful restart helper-only mode.

To configure BGP graceful restart:

```
config router bgp
    set graceful-restart {disable | enable}
    set graceful-restart-time <seconds_integer>
    set graceful-stalepath-time <seconds_integer>
    set graceful-update-delay <seconds_integer>
    config neighbor
        edit 10.12.101.4
            set capability-graceful-restart {enable | disable}
        next
    end
end
```

Before the restart, the router sends its peers a message to say it's restarting. The peers mark all the restarting router's routes as stale, but they continue to use the routes. The peers assume the router will restart, check its routes, and take

care of them, if needed, after the restart is complete. The peers also know what services the restarting router can maintain during its restart. After the router completes the restart, the router sends its peers a message to say it's done restarting.

To restart the router:

```
# execute router restart
```

Scheduled time offline

Graceful restart is a means for a router to advertise that it is going to have a scheduled shutdown for a very short period of time. When neighboring routers receive this notice, they will not remove that router from their routing table until after a set time elapses. During that time, if the router comes back online, everything continues to function as normal. If that router remains offline longer than expected, then the neighboring routers will update their routing tables as they assume that the router will be offline for a long time.

The following example demonstrates if you want to configure graceful restart on the FortiGate where you expect the FortiGate to be offline for no more than two minutes, and after three minutes the BGP network should consider the FortiGate to be offline.

To configure graceful restart time settings:

```
config router bgp
    set graceful-restart enable
    set graceful-restart-time 120
    set graceful-stalepath-time 180
end
```

BFD

Bidirectional Forwarding Detection (BFD) is a protocol that you can use to quickly locate hardware failures in the network. Routers running BFD communicate with each other and if a timer runs out on a connection then that router is declared down. BFD then communicates this information to the routing protocol and the routing information is updated.

For more information about BFD, see BFD on page 450.

BGP path selection process

Sometimes the FortiGate may receive multiple BGP paths from neighbors and must decide which is the best path to take. The following criteria are used to determine the best path.

Consider only routes with no AS loops and a valid next hop, and then:

1. Prefer the highest weight (this attribute is local to the FortiGate).
2. Prefer the highest local preference (applicable within AS).
3. Prefer the route originated by the local router (next hop = 0.0.0.0).
4. Prefer the shortest AS path.
5. Prefer the lowest origin code (IGP > EGP > incomplete).
6. Prefer the lowest MED (exchanged between autonomous systems).
7. Prefer the EBGP path over IBGP path.
8. Prefer the path through the closest IGP neighbor.
9. Prefer the oldest route for EBGP paths.

10. Prefer the path with the lowest neighbor BGP router ID.
11. Prefer the path with the lowest neighbor IP address.

BFD

Bidirectional Forwarding Detection (BFD) is a protocol that you can use to quickly locate hardware failures in the network. Routers running BFD send packets to each other at a negotiated rate. If packets from a BFD-enabled router fail to arrive, that router is declared to be down. BFD communicates this information to the associated routing protocols and the routing information is updated. It helps detect one way device failure and is used for fast convergence of routing protocols.

BFD can run on an entire FortiGate, selected interfaces, or on a protocol, such as BGP, for all configured interfaces. The configuration hierarchy allows each lower level to override the BFD setting of the upper level. For example, if you enable BFD for an entire FortiGate, you can disable BFD for an interface or for BGP.

Echo mode and authentication are not supported for BFD on the FortiGate.

BFD can be enabled per device, VDOM, or interface. Once enabled, a BFD neighbor should be defined. Finally, enable BFD on a route or routing protocol.

To configure BFD for an entire FortiGate:

```
config system settings
    set bfd {enable | disable}
    set bfd-desired-min-tx <ms>
    set bfd-required-min-rx <ms>
    set bfd-detect-mult <multiplier>
    set bfd-dont-enforce-src-port {enable | disable}
end
```

To configure BFD for an interface:

```
config system interface
    edit <interface-name>
        set bfd {global | enable | disable}
        set bfd-desired-min-tx <ms>
        set bfd-required-min-rx <ms>
        set bfd-detect-mult <multiplier>
    next
end
```

To configure BFD neighbors:

```
config router {bfd | bfd6}
    config neighbor
        edit <IP-address>
            set interface <interface-name>
        next
```

```
    end
end
```

To show BFD neighbors:

```
# get router {info | info6} bfd neighbor
```

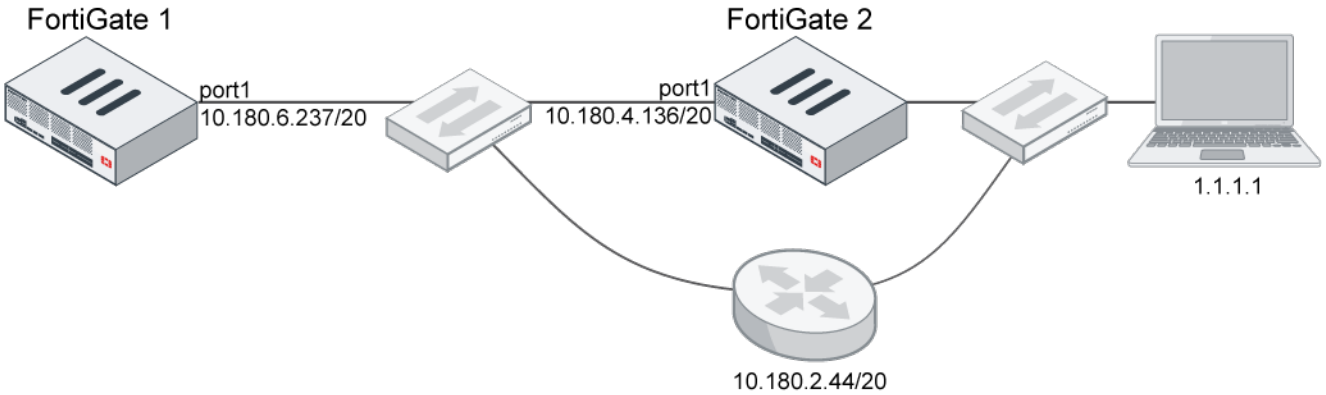
To show BFD requests:

```
# get router {info | info6} bfd requests
```

BFD and static routes

BFD for static routes allows you to configure routing failover based on remote path failure detection. BFD removes a static route from the routing table if the FortiGate can't reach the route's destination and returns the route to the routing table if the route's destination is restored.

For example, you can add two static routes with BFD enabled. If one of the routes has a higher priority, all matching traffic uses that route. If BFD determines that the link to the gateway of the route with the higher priority is down, the higher priority route is removed from the routing table and all matching traffic uses the lower priority route. If the link to the gateway for the higher priority route comes back up, BFD adds the route back into the routing table and all matching traffic switches to use the higher priority route.



You can configure BFD for IPv4 and IPv6 static routes.

To configure BFD for static routes:

```
config router {static | static6}
    edit <sequence-number>
        set bfd {enable | disable}
        set device <gateway-out-interface>
    next
end
```

Example

The following example demonstrates the configuration of static routes between two FortiGates. There is a host behind FortiGate 2 with an IP address of 1.1.1.1. FortiGate 1 has multiple paths to reach the host.

To configure static routes:

1. Configure FortiGate 1:

```
config system interface
    edit "port1"
        set vdom "root"
        set ip 10.180.6.237 255.255.240.0
        set allowaccess ping
        set bfd enable
    next
end
config router bfd
    config neighbor
        edit 10.180.4.136
            set interface "port1"
        next
    end
end
```

2. Configure FortiGate 2:

```
config system interface
    edit "port1"
        set vdom "root"
        set ip 10.180.4.136 255.255.240.0
        set allowaccess ping
        set bfd enable
    next
end
config router bfd
    config neighbor
        edit 10.180.6.237
            set interface "port1"
        next
    end
end
```

3. Configure two static routes:

```
config router static
    edit 2
        set dst 1.1.1.1 255.255.255.255
        set gateway 10.180.4.136
        set device "port1"
        set bfd enable
    next
    edit 3
        set dst 1.1.1.1 255.255.255.255
        set gateway 10.180.2.44
        set distance 20
        set device "port1"
    next
end
```

4. Confirm that BFD neighborship is established:

```
# get router info bfd neighbor
OurAddress      NeighAddress    State       Interface       LDesc/RDesc
10.180.6.237    10.180.4.136    UP          port1           1/1
```

5. Review the active route in the routing table:

```
# get router info routing-table all
S       1.1.1.1/32 [10/0] via 10.180.4.136, port1
C       10.180.0.0/20 is directly connected, port1
```

The route with the lower distance is preferred in the routing table.

If port1 on FortiGate 2 goes down or FortiGate 1 is unable to reach 10.180.4.126, the BFD neighborship will go down.

```
# get router info bfd neighbor
OurAddress      NeighAddress    State       Interface       LDesc/RDesc
10.180.6.237    10.180.4.136    DOWN        port1           1/1
```

With BFD neighborship down, the FortiGate is unable to reach 1.1.1.1/32 through gateway 10.180.4.136. The routing table will be updated so that the route through gateway 10.180.2.44 is active in the routing table.

```
# get router info routing-table all
S       1.1.1.1/32 [20/0] via 10.180.2.44, port1
C       10.180.0.0/20 is directly connected, port1
```

BFD removes a static route from the routing table if the FortiGate cannot reach the route's destination. The static route will be returned to the routing table is the route's destination is restored.

BFD and OSPF

You can configure BFD for Open Shortest Path First (OSPF) on a FortiGate. FortiGate supports BFD for OSPF for both IPv4 and IPv6. BFD must be configured globally and per interface.

To configure BFD for OSPF:

```
config router {ospf | ospf6}
    set bfd {enable | disable}
end
```

To enable BFD on a specific OSPF interface:

```
config router {ospf | ospf6}
    set bfd enable
    config {ospf-interface | ospf6-interface}
        edit <ID>
            set bfd {global | enable | disable}
            set area-id <IP address>
        next
    end
end
```

If BFD is configured when OSPF is not, no BFD packets will be sent. When both BFD and OSFP are configured, the neighbors for both will be the same. Use the following commands to confirm that the neighbor IP addresses match:

```
# get router info ospf neighbor
# get router info bfd neighbor
```

BFD and BGP

While BGP can detect route failures, BFD can be configured to detect these failures more quickly, which allows for faster responses and improved convergence. This can be balanced with the bandwidth BFD uses in its frequent route checking.

The `config router bgp` commands allow you to set the addresses of the neighbor units that are also running BFD. Both units must be configured with BFD in order to use it.

To configure BFD for BGP:

```
config router bgp
    config neighbor
        edit <neighbor-IP-address>
            set bfd {enable | disable}
        next
    end
end
```

BFD for Multihop paths

FortiGate BFD can support neighbors connected over multiple hops. When BFD is down, BGP sessions will be reset and will try to re-establish neighbor connection immediately. See BFD for multihop path for BGP on page 455 for more information.

To configure BFD for multihop paths:

```
config router {bfd | bfd6}
    config multihop-template
        edit <ID>
            set src <IP address/netmask>
            set dst <IP address/netmask>
            set bfd-desired-min-tx <integer>
            set bfd-required-min-rx <integer>
            set bfd-detect-mult <integer>
            set auth-mode {none | md5}
            set md5-key <password>
        next
    end
end
```

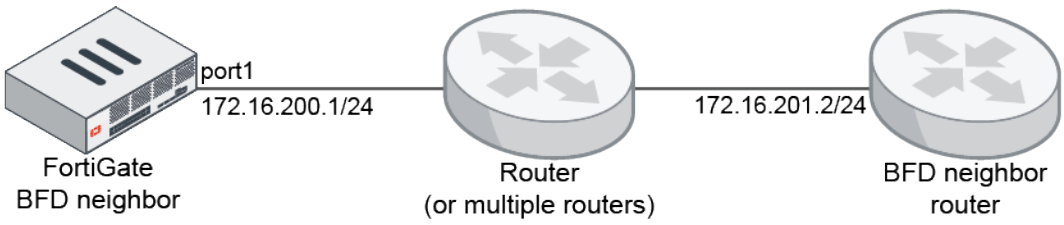
Troubleshooting BFD

You can troubleshoot BFD using the following commands:

```
# get router {info | info6} bfd neighbor
# get router {info | info6} bfd requests
# diagnose sniffer packet any <filter> <sniffer count>
```

```
# diagnose debug application bfdd <debug level>
# diagnose debug enable
```

BFD for multihop path for BGP



In BFD, a FortiGate can support neighbors connected over multiple hops. When BFD is down, BGP sessions are reset and will try to immediately re-establish neighbor connections. Previously, BFD was only supported when two routers or FortiGates were directly connected on the same network.

```
config router {bfd | bfd6}
    config multihop-template
        edit <ID>
            set src <class_IP/netmask>
            set dst <class_IP/netmask>
            set bfd-desired-min-tx <integer>
            set bfd-required-min-rx <integer>
            set bfd-detect-mult <integer>
            set auth-mode {none | md5}
            set md5-key <password>
        next
    end
end
```

`src <class_IP/netmask>`	Enter the source prefix.
`dst <class_IP/netmask>`	Enter the destination prefix.
`bfd-desired-min-tx <integer>`	Set the BFD desired minimal transmit interval, in milliseconds (100 - 30000, default = 250).
`bfd-required-min-rx <integer>`	Set the BFD required minimal transmit interval, in milliseconds (100 - 30000, default = 250).
`bfd-detect-mult <integer>`	Set the BFD detection multiplier (3 - 50, default = 3).
`auth-mode {none | md5}`	Set the authentication mode (none or meticulous MD5).
`md5-key <password>`	Enter the password.

Example

This example includes IPv4 and IPv6 BFD neighbor configurations. The BFD neighbor is also a BGP neighbor that is in a different AS.

To configure BFD with multihop BGP paths:

1. Enable BFD on all interfaces:

```
config system settings
    set bfd enable
end
```

2. Enable BFD on port1 and ignore the global configuration:

```
config system interface
    edit "port1"
        set bfd enable
    next
end
```

3. Configure the BGP neighbors:

```
config router bgp
    set as 65412
    set router-id 1.1.1.1
    config neighbor
        edit "172.16.201.2"
            set bfd enable
            set ebgp-enforce-multihop enable
            set soft-reconfiguration enable
            set remote-as 65050
        next
        edit "2000:172:16:201::2"
            set bfd enable
            set ebgp-enforce-multihop enable
            set soft-reconfiguration enable
            set remote-as 65050
        next
    end
end
```

4. Configure the IPv4 BFD:

```
config router bfd
    config multihop-template
        edit 1
            set src 172.16.200.0 255.255.255.0
            set dst 172.16.201.0 255.255.255.0
            set auth-mode md5
            set md5-key **********
        next
    end
end
```

5. Configure the IPv6 BFD:

```
config router bfd6
    config multihop-template
        edit 1
            set src 2000:172:16:200::/64
            set dst 2000:172:16:201::/64
        next
```

```
    end
end
```

Testing the connection

1. Verify the BFD status for IPv4 and IPv6:

```
# get router info bfd requests
BFD Peer Requests:
    client types(ct in 0x): 01=external 02=static
        04=ospf 08=bgp 10=pim-sm
src=172.16.200.1     dst=172.16.201.2     ct=08 ifi=9 type=SM
```

```
# get router info bfd neighbor
OurAddress      NeighAddress    State       Interface       LDesc/RDesc
172.16.200.1    172.16.201.2    UP          port1           5/3/M
```

```
# get router info6 bfd requests
BFD Peer Requests:
    client types(ct in 0x): 01=external 02=static
        04=ospf 08=bgp 10=pim-sm
src=2000:172:16:200::1
dst=2000:172:16:201::2
ct=08 ifi=9 type=SM
```

```
# get router info6 bfd neighbor
OurAddress: 2000:172:16:200::1
NeighAddress: 2000:172:16:201::2
State: UP Interface: port1 Desc: 6/4 Multi-hop
```

2. Verify the BGP status and the BGP routing table:

```
# get router info bgp summary
VRF 0 BGP router identifier 1.1.1.1, local AS number 65412
BGP table version is 11
3 BGP AS-PATH entries
0 BGP community entries

Neighbor           V         AS MsgRcvd MsgSent   TblVer  InQ OutQ Up/Down  State/PfxRcd
172.16.201.2       4      65050     185     187       10    0    0 00:54:20        4
2000:172:16:201::2 4      65050     159     160       10    0    0 00:54:24        4

Total number of neighbors 2
```

```
# get router info routing-table bgp
Routing table for VRF=0
B       172.28.1.0/24 [20/0] via 172.16.201.2 (recursive via 172.16.200.4, port1),
00:54:32
B       172.28.2.0/24 [20/0] via 172.16.201.2 (recursive via 172.16.200.4, port1),
00:54:32
B       172.28.5.0/24 [20/0] via 172.16.201.2 (recursive via 172.16.200.4, port1),
00:54:32
B       172.28.6.0/24 [20/0] via 172.16.201.2 (recursive via 172.16.200.4, port1),
00:54:32
```

```
# get router info6 bgp summary
VRF 0 BGP router identifier 1.1.1.1, local AS number 65412
BGP table version is 8
3 BGP AS-PATH entries
```

```
0 BGP community entries

Neighbor           V         AS MsgRcvd MsgSent   TblVer  InQ OutQ Up/Down  State/PfxRcd
172.16.201.2       4      65050     185     187        7    0    0 00:54:24        3
2000:172:16:201::2 4      65050     159     160        7    0    0 00:54:28        3

Total number of neighbors 2

# get router info6 routing-table bgp
Routing table for VRF=0
B       2000:172:28:1::/64 [20/0] via 2000:172:16:201::2 (recursive via
2000:172:16:200::4, port1), 00:54:40
B       2000:172:28:2::/64 [20/0] via 2000:172:16:201::2 (recursive via
2000:172:16:200::4, port1), 00:54:40
B       2000:172:28:3::/64 [20/0] via 2000:172:16:201::2 (recursive via
2000:172:16:200::4, port1), 00:54:40
```

3. Simulate a disruption to the BFD connection. The BFD neighbor is lost:

```
# get router info bfd neighbor
OurAddress      NeighAddress    State       Interface       LDesc/RDesc

# get router info6 bfd neighbor
```

4. The BGP neighbor is reset, and the FortiGate attempts to re-establish a connection with the neighbor. The timers are reset once the neighbor connection is re-established:

```
# get router info bgp summary
VRF 0 BGP router identifier 1.1.1.1, local AS number 65412
BGP table version is 12
4 BGP AS-PATH entries
0 BGP community entries

Neighbor           V         AS MsgRcvd MsgSent   TblVer  InQ OutQ Up/Down  State/PfxRcd

172.16.201.2       4      65050     189     192       11    0    0 00:00:11        4
2000:172:16:201::2 4      65050     165     167       12    0    0 00:00:08        4

Total number of neighbors 2

# get router info6 bgp summary
VRF 0 BGP router identifier 1.1.1.1, local AS number 65412
BGP table version is 10
4 BGP AS-PATH entries
0 BGP community entries

Neighbor           V         AS MsgRcvd MsgSent   TblVer  InQ OutQ Up/Down  State/PfxRcd
172.16.201.2       4      65050     189     192        8    0    0 00:00:15        3
2000:172:16:201::2 4      65050     165     167        9    0    0 00:00:12        3

Total number of neighbors 2
```

5. The BGP routes are learned again, and there are new timers in the route tables:

```
# get router info routing-table bgp
Routing table for VRF=0
B       172.28.1.0/24 [20/0] via 172.16.201.2 (recursive via 172.16.200.4, port1),
00:00:15
B       172.28.2.0/24 [20/0] via 172.16.201.2 (recursive via 172.16.200.4, port1),
```

```
00:00:15
B       172.28.5.0/24 [20/0] via 172.16.201.2 (recursive via 172.16.200.4, port1),
00:00:15
B       172.28.6.0/24 [20/0] via 172.16.201.2 (recursive via 172.16.200.4, port1),
00:00:15
```

```
# get router info6 routing-table bgp
Routing table for VRF=0
B       2000:172:28:1::/64 [20/0] via 2000:172:16:201::2 (recursive via
2000:172:16:200::4, port1), 00:00:13
B       2000:172:28:2::/64 [20/0] via 2000:172:16:201::2 (recursive via
2000:172:16:200::4, port1), 00:00:13
B       2000:172:28:3::/64 [20/0] via 2000:172:16:201::2 (recursive via
2000:172:16:200::4, port1), 00:00:13
```

Routing objects

The following objects can be configured from the *Network* > *Routing Objects* page:

- Route maps on page 459
- Access lists on page 462
- Prefix lists on page 464
- AS path lists on page 466
- Community lists on page 467

Route maps

Route maps are a powerful tool to apply custom actions to dynamic routing protocols based on specific conditions. They are used primarily in BGP to manipulate routes advertised by the FortiGate (`route-map-out`) or received routes from other BGP routers (`route-map-in`).

Route maps can be used in OSPF for conditional `default-information-originate`, filtering external routes, or matching specific routes for redistribution. Similarly, route maps can be used by RIP to match routes for redistribution.

A route map may have multiple rules that are processed from the top down. Each rule has an action to permit or deny. The rules have criteria for matching a route based on various attributes, or setting attributes based on a matched route.

For example, a route map can be used to match BGP routes with a certain community string, and then set an AS path to the matching route. This can be applied to a BGP neighbor by configuring the route map in setting for that neighbor.

To configure a route map that matches criteria based on other routing objects:

```
config router route-map
    edit <name>
        config rule
            edit <id>
                set action {permit | deny}
                set match-as-path <string>
                set match-community <string>
                set match-ip-address <string>
                set match-ip6-address <string>
                set match-ip-nexthop <string>
                set match-ip6-nexthop <string>
```

```
            next
        end
    next
end
```

`match-as-path <string>`	Match a BGP AS path list.
`match-community <string>`	Match a BGP community list.
`match-ip-address <string>`	Match an IPv4 address permitted by `access-list` or `prefix-list`.
`match-ip6-address <string>`	Match an IPv6 address permitted by `access-list6` or `prefix-list6`.
`match-ip-nexthop <string>`	Match a next hop IPv4 address passed by `access-list` or `prefix-list`.
`match-ip6-nexthop <string>`	Match a next hop IPv6 address passed by `access-list6` or `prefix-list6`.

Route maps can be used by various routing protocols, such as RIP, OSPF, and BGP.

To use a route map with RIP:

```
config router rip
    config redistribute
        edit <name>
            set routemap <string>
        next
    end
end
```

To use a route map with OSPF:

```
config router ospf
    set default-information-route-map <string>
    set distribute-route-map-in <string>
    config redistribute <string>
        set routemap <string>
    end
end
```

`default-information-route-map <string>`	Enter the default information route map.
`distribute-route-map-in <string>`	Enter the route map to filter incoming external routes.
`redistribute <string>`	Configure the redistribute protocol.

To use a route map with BGP:

```
config router bgp
    config neighbor
        edit <ip>
            set route-map-in <string>
            set route-map-in6 <string>
            set route-map-in-vpnv4 <string>
            set route-map-out <string>
```

```
            set route-map-out-preferable <string>
            set route-map-out6 <string>
            set route-map-out6-preferable <string>
            set route-map-out-vpnv4 <string>
            set route-map-out-vpnv4-preferable <string>
        next
    end
    config network
        edit <id>
            set prefix <IP/netmask>
            set route-map <string>
        next
    end
    config redistribute <string>
        set route-map <string>
    end
end
```

route-map-in <string>	Enter the IPv4 inbound route map filter.
route-map-in6 <string>	Enter the IPv6 inbound route map filter.
route-map-in-vpnv4 <string>	Enter the VPNv4 inbound route map filter.
route-map-out <string>	Enter the IPv4 outbound route map filter.
route-map-out-preferable <string>	Enter the IPv4 outbound route map filter if the peer is preferred.
route-map-out6 <string>	Enter the IPv6 outbound route map filter.
route-map-out6-preferable <string>	Enter the IPv6 outbound route map filter if the peer is preferred.
route-map-out-vpnv4 <string>	Enter the VPNv4 outbound route map filter.
route-map-out-vpnv4-preferable <string>	Enter the VPNv4 outbound route map filter if the peer is preferred.
route-map <string>	Enter the route map to modify the generated route.
redistribute <string>	Configure the redistribute protocol.

To use a route map with BGP conditional advertisement:

```
config router bgp
    set as <AS_number>
    config neighbor
        edit <ip>
            set remote-as <AS_number>
            config conditional-advertise
                edit <advertise-routemap>
                    set condition-routemap <name1>, <name2>, ...
                    set condition-type {exist | non-exist}
                next
            end
        next
```

```
    end
end
```

`<advertise-routemap>`	Edit the advertising route map.
`condition-routemap <name1>, <name2>, ...`	Enter the list of conditional route maps.

Access lists

Access lists are simple lists used for filtering routes based on a prefix consisting of an IPv4 or IPv6 address and netmask.

To configure an IPv4 access list:

```
config router access-list
    edit <name>
        config rule
            edit <id>
                set action {permit | deny}
                set prefix <IPv4_address>
                set wildcard <wildcard_filter>
                set exact-match {enable | disable}
            next
        end
    next
end
```

To configure an IPv6 access list:

```
config router access-list6
    edit <name>
        config rule
            edit <id>
                set action {permit | deny}
                set prefix <IPv6_address>
                set exact-match {enable | disable}
            next
        end
    next
end
```

In RIP, an access list can be used in the `distribute-list` setting to filter received or advertised routes, or in an `offset-list` to offset the hop count metric for a specific prefix.

To use an access list in RIP:

```
config router rip
    config distribute-list
        edit <id>
            set direction {in | out}
            set listname <string>
        next
    end
```

```
    config offset-list
        edit <id>
            set direction {in | out}
            set access-list <string>
            set offset <integer>
        next
    end
end
```

`listname <string>`	Enter the distribute access or prefix list name.
`access-list <string>`	Enter the access list name.

In OSPF, an access list can be used in the `distribute-list-in` setting to act as a filter to prevent a certain route from being inserted into the routing table. An access list can also be used in the `distribute-list` to filter the routes that can be distributed from other protocols.

To use an access list in OSPF:

```
config router ospf
    set distribute-list-in <string>
    config distribute-list
        edit <id>
            set access-list <string>
            set protocol {connected | static | rip}
        next
    end
end
```

`distribute-list-in <string>`	Enter the filter for incoming routes.
`access-list <string>`	Enter the access list name.

In BGP, an access list can be used to filter updates from a neighbor or to a neighbor.

To use an access list in BGP:

```
config router bgp
    config neighbor
        edit <ip>
            set distribute-list-in <string>
            set distribute-list-in6 <string>
            set distribute-list-in-vpnv4 <string>
            set distribute-list-out <string>
            set distribute-list-out6 <string>
            set distribute-list-out-vpnv4 <string>
        next
    end
end
```

`distribute-list-in <string>`	Enter the filter for IPv4 updates from this neighbor.

`distribute-list-in6 <string>`	Enter the filter for IPv6 updates from this neighbor.
`distribute-list-in-vpnv4 <string>`	Enter the filter for VPNv4 updates from this neighbor.
`distribute-list-out <string>`	Enter the filter for IPv4 updates to this neighbor.
`distribute-list-out6 <string>`	Enter the filter for IPv6 updates to this neighbor.
`distribute-list-out-vpnv4 <string>`	Enter the filter for VPNv4 updates to this neighbor.

In a route map, an access list can be used to match IP addresses and next hops.

To use an access list in a route map:

```
config router route-map
    edit <name>
        config rule
            edit <id>
                set match-ip-address <string>
                set match-ip6-address <string>
                set match-ip-nexthop <string>
                set match-ip6-nexthop <string>
            next
        end
    next
end
```

`match-ip-address <string>`	Match an IPv4 address permitted by `access-list` or `prefix-list`.
`match-ip6-address <string>`	Match an IPv6 address permitted by `access-list6` or `prefix-list6`.
`match-ip-nexthop <string>`	Match a next hop IPv4 address passed by `access-list` or `prefix-list`.
`match-ip6-nexthop <string>`	Match a next hop IPv6 address passed by `access-list6` or `prefix-list6`.

Prefix lists

Similar to access lists, prefix lists are simple lists used for filtering routes based on a prefix consisting of an IPv4 or IPv6 address and netmask, but they use settings to specify the minimum (`ge`, greater than or equal) and maximum (`le`, less than or equal) prefix length to be matched. For example, a prefix of 10.0.0.0/8 with a `ge` of 16 will match anything in the 10.0.0.0/8 network with /16 or above; 10.10.0.0/16 will match, and 10.10.0.0/12 will not match.

To configure an IPv4 prefix list:

```
config router prefix-list
    edit "prefix-list1"
        config rule
            edit 1
                set action {permit | deny}
                set prefix <IPv4_address>
```

```
                set ge <integer>
                set le <integer>
            next
        end
    next
end
```

To configure an IPv6 prefix list:

```
config router prefix-list6
    edit "prefix-list-IPv6"
        config rule
            edit 1
                set action {permit | deny}
                set prefix6 <IPv6_address>
                set ge <integer>
                set le <integer>
            next
        end
    next
end
```

In RIP, an prefix list can be used in the `distribute-list` setting to filter received or advertised routes.

To use a prefix list in RIP:

```
config router rip
    config distribute-list
        edit <id>
            set listname <string>
        next
    end
end
```

`listname <string>`	Enter the distribute access or prefix list name.

In OSPF, a prefix list can be used in the `distribute-list-in` setting to act as a filter to prevent a certain route from being inserted into the routing table.

To use a prefix list in OSPF:

```
config router ospf
    set distribute-list-in <string>
end
```

`distribute-list-in <string>`	Enter the filter for incoming routes.

In BGP, a prefix list can be used to filter updates from a neighbor or to a neighbor.

To use a prefix list in BGP:

```
config router bgp
    config neighbor
        edit <ip>
```

```
            set prefix-list-in <string>
            set prefix-list-in6 <string>
            set prefix-list-in-vpnv4 <string>
            set prefix-list-out <string>
            set prefix-list-out6 <string>
            set prefix-list-out-vpnv4 <string>
        next
    end
end
```

`prefix-list-in <string>`	Enter the IPv4 inbound filter for updates from this neighbor.
`prefix-list-in6 <string>`	Enter the IPv6 inbound filter for updates from this neighbor.
`prefix-list-in-vpnv4 <string>`	Enter the inbound filter for VPNv4 updates from this neighbor.
`prefix-list-out <string>`	Enter the IPv4 outbound filter for updates to this neighbor.
`prefix-list-out6 <string>`	Enter the IPv6 outbound filter for updates to this neighbor.
`prefix-list-out-vpnv4 <string>`	Enter the outbound filter for VPNv4 updates to this neighbor.

In a route map, a prefix list can be used to match IP addresses and next hops.

To use a prefix list in a route map:

```
config router route-map
    edit <name>
        config rule
            edit <id>
                set match-ip-address <string>
                set match-ip6-address <string>
                set match-ip-nexthop <string>
                set match-ip6-nexthop <string>
            next
        end
    next
end
```

`match-ip-address <string>`	Match an IPv4 address permitted by `access-list` or `prefix-list`.
`match-ip6-address <string>`	Match an IPv6 address permitted by `access-list6` or `prefix-list6`.
`match-ip-nexthop <string>`	Match a next hop IPv4 address passed by `access-list` or `prefix-list`.
`match-ip6-nexthop <string>`	Match a next hop IPv6 address passed by `access-list6` or `prefix-list6`.

AS path lists

AS path lists use regular expressions to compare and match the AS_PATH attribute for a BGP route. They can be used to filter inbound or outbound routes from a BGP neighbor, or as matching criteria in a route map to match an AS_PATH in a BGP route.

To configure an AS path list:

```
config router aspath-list
    edit <name>
        config rule
            edit <id>
                set action {deny | permit}
                set regexp <string>
            next
        end
    next
end
```

To use an AS path list in BGP:

```
config router bgp
    config neighbor
        edit <ip>
            set filter-list-in <string>
            set filter-list-in6 <string>
            set filter-list-out <string>
            set filter-list-out6 <string>
        next
    end
end
```

`filter-list-in <string>`	Enter the BGP filter for IPv4 inbound routes.
`filter-list-in6 <string>`	Enter the BGP filter for IPv6 inbound routes.
`filter-list-out <string>`	Enter the BGP filter for IPv4 outbound routes.
`filter-list-out6 <string>`	Enter the BGP filter for IPv6 outbound routes.

To use an AS path list in a route map:

```
config router route-map
    edit <name>
        config rule
            edit <id>
                set match-as-path <string>
            next
        end
    next
end
```

`match-as-path <string>`	Match a BGP AS path list.

Community lists

Community lists provide a means to filter BGP routes using a community string. They can be applied in a route map to match routes that have the community string defined in the community list.

To configure a community list:

```
config router community-list
    edit <name>
        set type {standard | expanded}
        config rule
            edit <id>
                set action {deny | permit}
                set regexp <string>
                set match <string>
            next
        end
    next
end
```

To use a community list in a route map to match a BGP community:

```
config router route-map
    edit <name>
        config rule
            edit <id>
                set match-community <string>
            next
        end
    next
end
```

`match-community <string>`	Match a BGP community list.

In an SD-WAN deployment, a remote BGP router or spoke may communicate a preferred interface or path to route traffic using a community string. See Using BGP tags with SD-WAN rules on page 758 and Controlling traffic with BGP route mapping and service rules on page 764 for examples.

Multicast

The following topics include information about multicast:

- Multicast routing and PIM support on page 468
- Configuring multicast forwarding on page 469

Multicast routing and PIM support

Multicasting (also called IP multicasting) consists of using a single multicast source to send data to many receivers. Multicasting can be used to send data to many receivers simultaneously while conserving bandwidth and reducing network traffic. Multicasting can be used for one-way delivery of media streams to multiple receivers and for one-way data transmission for news feeds, financial information, and so on. Many dynamic routing protocols such as RIPv2, OSPF, and EIGRP use multicasting to share hello packets and routing information.

A FortiGate can operate as a Protocol Independent Multicast (PIM) version 2 router. FortiGates support PIM sparse mode (RFC 4601) and PIM dense mode (RFC 3973), and can service multicast servers or receivers on the network segment to which a FortiGate interface is connected. Multicast routing is not supported in transparent mode.

To support PIM communications, the sending and receiving applications, and all connecting PIM routers in between, must be enabled with PIM version 2. PIM can use static routes, RIP, OSPF, or BGP to forward multicast packets to their destinations. To enable source-to-destination packet delivery, sparse mode or dense mode must be enabled on the PIM router interfaces. Sparse mode routers cannot send multicast messages to dense mode routers. If the FortiGate is located between a source and a PIM router, between two PIM routers, or is connected directly to a receiver, you must manually create a multicast policy to pass encapsulated (multicast) packets or decapsulated data (IP traffic) between the source and destination.

PIM domains

A PIM domain is a logical area comprising a number of contiguous networks. The domain contains at least one bootstrap router (BSR), and if sparse mode is enabled, a number of rendezvous points (RPs) and designated routers (DRs). When PIM is enabled, the FortiGate can perform any of these functions at any time as configured.

A PIM domain can be configured in the GUI by going to *Network* > *Multicast*, or in the CLI using `config router multicast`. Note that PIM version 2 must be enabled on all participating routers between the source and receivers. Use `config router multicast` to set the global operating parameters.

When PIM is enabled, the FortiGate allocates memory to manage mapping information. The FortiGate communicates with neighboring PIM routers to acquire mapping information and, if required, processes the multicast traffic associated with specific multicast groups.

Instead of sending multiple copies of generated IP traffic to more than one specific IP destination address, PIM-enabled routers encapsulate the data and use a Class D multicast group address (224.0.0.0 to 239.255.255.255) to forward multicast packets to multiple destinations. A single stream of data can be sent because one destination address is used. Client applications receive multicast data by requesting that the traffic destined for a certain multicast group address be delivered to them.

Configuring multicast forwarding

There is sometimes confusion between the terms forwarding and routing. These two functions should not take place at the same time. Multicast forwarding should be enabled when the FortiGate is in NAT mode and you want to forward multicast packets between multicast routers and receivers. However, this function should not be enabled when the FortiGate itself is operating as a multicast router, or has an applicable routing protocol that uses multicast.

Multicast forwarding is not supported on enhanced MAC VLAN interfaces. To use multicast with enhanced MAC VLAN interfaces, use PIM (Multicast routing and PIM support on page 468).

There are two steps to configure multicast forwarding:

1. Enabling multicast forwarding on page 469
2. Configuring multicast policies on page 470

Enabling multicast forwarding

Multicast forwarding is enabled by default. If a FortiGate is operating in transparent mode, adding a multicast policy enables multicast forwarding. In NAT mode you must use the `multicast-forward` setting to enable or disable

multicast forwarding.

Multicast forwarding in NAT mode

When `multicast-forward` is enabled, the FortiGate forwards any multicast IP packets in which the TTL is 2 or higher to all interfaces and VLAN interfaces, except the receiving interface. The TTL in the IP header will be reduced by 1. Even though the multicast packets are forwarded to all interfaces, you must add multicast policies to allow multicast packets through the FortiGate.

To enable multicast forwarding in NAT mode:

```
config system settings
    set multicast-forward enable
end
```

Prevent the TTL for forwarded packets from being changed

You can use the `multicast-ttl-notchange` option so that the FortiGate does not increase the TTL value for forwarded multicast packets. Use this option only if packets are expiring before reaching the multicast router.

To prevent the TTL for forwarded packets from being changed:

```
config system settings
    set multicast-ttl-notchange enable
end
```

Disable multicast traffic from passing through the FortiGate without a policy check in transparent mode

In transparent mode, the FortiGate does not forward frames with multicast destination addresses. The FortiGate should not interfere with the multicast traffic used by routing protocols, streaming media, or other multicast communication. To avoid any issues during transmission, you can disable `multicast-skip-policy` and configure multicast security policies.

To disable multicast traffic from passing through the FortiGate without a policy check in transparent mode:

```
config system settings
    set multicast-skip-policy disable
end
```

Configuring multicast policies

Multicast packets require multicast policies to allow packets to pass from one interface to another. Similar to firewall policies, in a multicast policy you specify the source and destination interfaces, and the allowed address ranges for the source and destination addresses of the packets. You can also use multicast policies to configure source NAT and destination NAT for multicast packets.

Keep the following in mind when configuring multicast policies:

- The matched forwarded (outgoing) IP multicast source IP address is changed to the configured IP address.
- The `snat` setting is optional. Use it when SNAT is needed.

IPv4 and IPv6 multicast policies can be configured in the GUI. Go to *System* > *Feature Visibility*, and enable *Multicast Policy* and *IPv6*.

Sample basic policy

In this basic policy, multicast packets received on an interface are flooded unconditionally to all interfaces on the forwarding domain, except the incoming interface.

```
config firewall multicast-policy
    edit 1
        set srcintf "any"
        set dstintf "any"
        set srcaddr "all"
        set dstaddr "all"
    next
end
```

The destination address (`dstaddr`) is a multicast address object. The `all` option corresponds to all multicast addresses in the range 224.0.0.0-239.255.255.255.

Sample policy with specific source and destination interfaces

This multicast policy only applies to the source port `wan1` and the destination port `internal`.

```
config firewall multicast-policy
    edit 1
        set srcintf "wan1"
        set dstintf "internal"
        set srcaddr "all"
        set dstaddr "all"
    next
end
```

Sample policy with specific source address object

In this policy, packets are allowed to flow from `wan1` to `internal`, and sourced by the address 172.20.120.129, which is represented by the `example_addr-1` address object.

```
config firewall multicast-policy
    edit 1
        set srcintf "wan1"
        set dstintf "internal"
        set srcaddr "example_addr-1"
        set dstaddr "all"
    next
end
```

Sample detailed policy

This policy accepts multicast packets that are sent from a PC with IP address 192.168.5.18 to destination address range 239.168.4.0-255. The policy allows the multicast packets to enter the `internal` interface and then exit the `external` interface. When the packets leave the external interface, their source address is translated to 192.168.18.10.

```
config firewall address
    edit "192.168.5.18"
        set subnet 192.168.5.18 255.255.255.255
    next
end

config firewall multicast-address
    edit "239.168.4.0"
        set start-ip 239.168.4.0
        set end-ip 239.168.4.255
    next
end

config firewall multicast-policy
    edit 1
        set srcintf "internal"
        set dstintf "external"
        set srcaddr "192.168.5.18"
        set dstaddr "239.168.4.0"
        set snat enable
        set snat-ip 192.168.18.10
    next
end
```

To configure multicast policies in the GUI, enable *Multicast Policy* in *System* > *Feature Visibility*.

Using multi VDOM mode

When using multi VDOM mode, it is important to avoid causing a multicast network loop by creating an all-to-all multicast policy. By default, on models that support NPU virtual links, changing the `vdom-mode` to `multi-vdom` will create a pair of npu0_vlink0 and npu0_vlink1 interfaces in the same root VDOM. By virtue of the all-to-all multicast policy and the fact the npu0_vlink interfaces are virtually connected, it forms a multicast network loop.

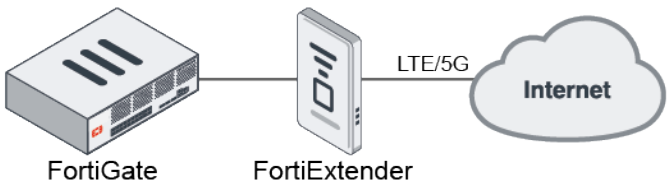
Therefore, when using multi VDOM mode:

1. Ensure there is no existing all-to-all multicast policy before changing to multi VDOM mode.
2. If an all-to-all multicast policy must be defined, ensure that no two connected interfaces (such as npu0_vlink0 and npu0_vlink1) belong in the same VDOM.

This configuration will result in a multicast loop:

```
config system global
    set vdom-mode multi-vdom
end
config firewall multicast-policy
    edit 1
        set logtraffic enable
        set srcintf "any"
        set dstintf "any"
        set srcaddr "all"
        set dstaddr "all"
    next
```

```
end
show system interface
config system interface
    edit "npu0_vlink0"
        set vdom "root"
        set type physical
    next
    edit "npu0_vlink1"
        set vdom "root"
        set type physical
    next
end
```



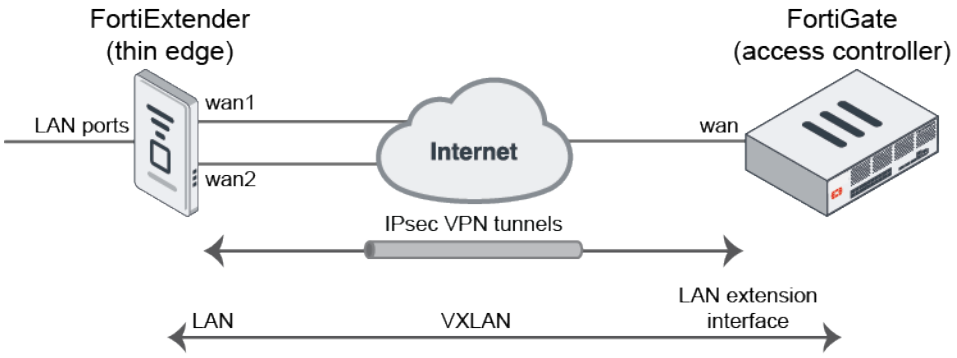
FortiExtender

There are two configuration modes available on the FortiGate for FortiExtender integration: WAN extension mode and LAN extension mode.

For information about configuring FortiExtender, see the FortiExtender Admin Guide (FGT-Managed) and Admin Guide (Standalone).

WAN extension mode

In WAN extension mode, the FortiExtender works as an extended WAN interface in IP pass-through mode. The FortiGate manages FortiExtender over the CAPWAP protocol in IP pass-through mode, and is integrated into FortiOS as a manageable interface.

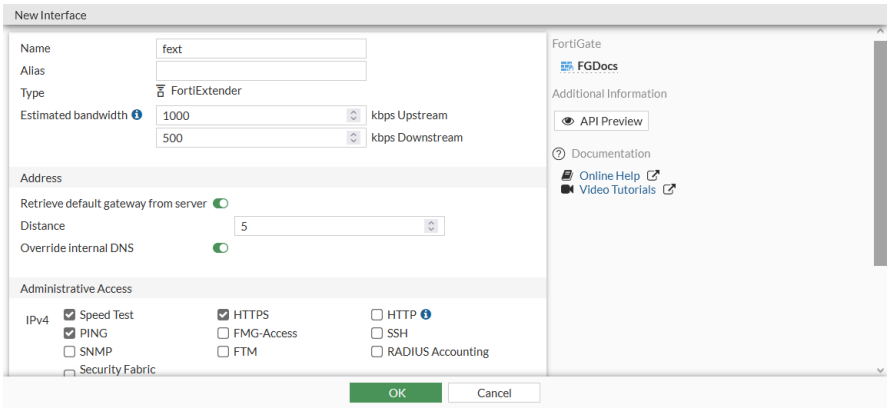


Sample configurations in WAN extension mode could include connecting a FortiExtender to two FortiGates in HA active-passive mode, or connecting two FortiExtenders to two FortiGates in HA active-active mode to provide dual active redundancy for wireless WAN access.

For more information, see FortiExtender and FortiGate integration in the FortiExtender (Managed) Administration Guide.

LAN extension mode

The LAN extension configuration mode allows FortiExtender to provide remote thin edge connectivity back to the FortiGate over a backhaul connection. A FortiExtender deployed at a remote location will discover the FortiGate access controller (AC) and form an IPsec tunnel (or multiple tunnels when multiple links exist on the FortiExtender) back to the FortiGate. A VXLAN is established over the IPsec tunnels to create an L2 network between the FortiGate and the network behind the remote FortiExtender.



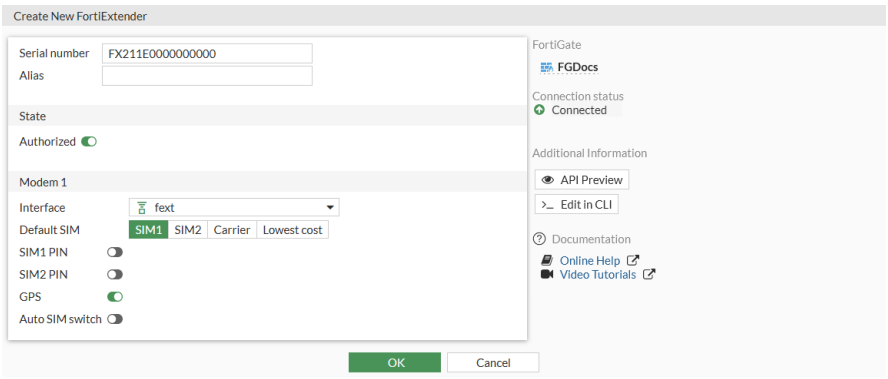
For more information, see FortiExtender as FortiGate LAN extension in the FortiExtender (Managed) Administration Guide.

Adding a FortiExtender

To add a FortiExtender to the FortiGate, create a virtual FortiExtender interface, then add a FortiExtender and assign the interface to the modem. Like other interface types, the FortiExtender interface can be used in static routes, SD-WAN (see Manage dual FortiExtender devices), policies, and other functions.

To create a virtual FortiExtender interface in the GUI:

1. Go to *Network* > *Interfaces* and click *Create New* > *FortiExtender*.
2. Enter a name for the interface.
3. Configure the remaining settings as needed. See Interface settings on page 150 for more details.



4. Click *OK*.

To add a FortiExtender in the GUI:

1. Go to *Network* > *FortiExtender* and click *Create New* > *Extenders*.
2. Enter your FortiExtender's serial number in the *Serial number* field.
3. Optionally, set an *Alias* for the FortiExtender.
4. In the *State* section, enable *Authorized*.
5. Set *Interface* to the FortiExtender interface.

6. Configure the remaining setting as required. See the FortiExtender Administration Guide (FGT-Managed) for more information.

7. Click *OK*.
8. In the extenders list, right-click on the FortiExtender and select *Diagnostics and Tools* to review the modem and SIM status, and other details about the FortiExtender.

To create a virtual FortiExtender interface in the CLI:

```
config system interface
    edit "fext"
        set vdom "root"
        set mode dhcp
        set allowaccess ping https speed-test
        set type fext-wan
        set estimated-upstream-bandwidth 1000
        set estimated-downstream-bandwidth 500
    next
end
```

To configure the FortiExtender in the CLI:

```
config extender-controller extender
    edit "FX211E0000000000"
        set id "FX211E0000000000"
        set authorized enable
        config modem1
            set ifname "fext"
        end
    next
end
```

To verify the modem settings in the CLI:

```
get extender modem-status FX211E0000000000 1
Modem 0:
    physical_port:       2-1.2
    manufacture:         Sierra Wireless, Incorporated
    product:             Sierra Wireless, Incorporated
    ....
```

Direct IP support for LTE/4G

Direct IP is a public IP address that is assigned to a computing device, which allows the device to directly access the internet.

When an LTE modem is enabled in FortiOS, a DHCP interface is created. As a result, the FortiGate can acquire direct IP (which includes IP, DNS, and gateway) from the LTE network carrier.

Since some LTE modems require users to input the access point name (APN) for the LTE network, the LTE modem configuration allows you to set the APN.

LTE modems can only be enabled by using the CLI.

To enable direct IP support using the CLI:

1. Enable the LTE modem:

```
config system lte-modem
  set status enable
end
```

2. Check that the LTE interface was created:

```
config system interface
  edit "wwan"
    set vdom "root"
    set mode dhcp
    set status down
    set distance 1
    set type physical
    set snmp-index 23
  next
end
```

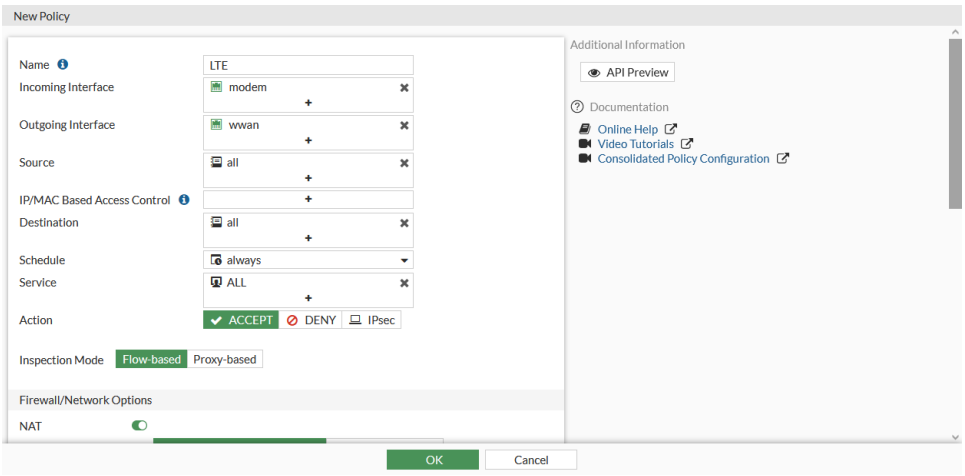
Shortly after the LTE modem joins its carrier network, `wwan` is enabled and granted direct IP:

```
config system interface
    edit wwan
        get
name                : wwan
....
ip                  : 100.112.75.43 255.255.255.248
....
status              : up
....
defaultgw           : enable
DHCP Gateway        : 100.112.75.41
Lease Expires       : Thu Feb 21 19:33:27 2019
dns-server-override : enable
Acquired DNS1       : 184.151.118.254
Acquired DNS2       : 70.28.245.227
....
```

PCs can reach the internet via the following firewall policy:

```
config firewall policy
  edit 5
    set name "LTE"
    set srcintf "port9"
    set dstintf "wwan"
    set srcaddr "all"
    set dstaddr "all"
    set action accept
    set schedule "always"
    set service "ALL"
    set utm-status enable
    set fsso disable
    set nat enable
  next
end
```

Sample LTE interface



When an LTE modem is enabled, you can view the LTE interface in the GUI and check the acquired IP, DNS, and gateway.

To view the LTE interface in the GUI:

1. Go to *Network* > *Interfaces*.
2. Double-click the LTE interface (*wwan*) to view the properties.
3. Look in the *Address* section to see the *Obtained IP/Netmask*, *Acquired DNS*, and *Default Gateway*.
4. Click *Return*.

To configure the firewall policy that uses the LTE interface:

1. Go to *Policy & Objects* > *Firewall Policy*.
2. Edit the LTE policy.
3. In the *Outgoing Interface* field, select the interface (`wwan` in this example).
4. Configure the rest of the policy as needed.

5. Click *OK*.

Limitations

- Most LTE modems have a preset APN in their SIM card. Therefore, the APN does not need to be set in the FortiOS configuration. In cases where the internet cannot be accessed, consult with your carrier and set the APN in the LTE modem configuration (for example, inet.bell.ca):

```
config system lte-modem
  set status enable
  set apn "inet.bell.ca"
end
```

- Some models, such as the FortiGate 30E-3G4G, have built-in LTE modems. In this scenario, the LTE modem is enabled by default. The firewall policy via the LTE interface is also created by default. Once you plug in a SIM card, your network devices can connect to the internet.

  Sample FortiGate 30E-3G4G default configuration:

```
config system lte-modem
  set status enable
  set extra-init ''
  set manual-handover disable
  set force-wireless-profile 0
  set authtype none
  set apn ''
  set modem-port 255
  set network-type auto
  set auto-connect disable
  set gpsd-enabled disable
  set data-usage-tracking disable
  set gps-port 255
end
```

```
config firewall policy
....
  edit 3
    set srcintf "internal"
```

```
        set dstintf "wwan"
        set srcaddr "all"
        set dstaddr "all"
        set action accept
        set schedule "always"
        set service "ALL"
        set nat enable
      next
    end
```

LLDP reception

Device detection can scan LLDP as a source for device identification, but the FortiGate does not read or store the full information. Enabling LLDP reception allows the FortiGate to receive and store LLDP messages, learn about active neighbors, and makes the LLDP information available via the CLI, REST API, and SNMP.

You need to enable `device-identification` at the interface level, and then `lldp-reception` can be enabled on three levels: globally, per VDOM, or per interface.

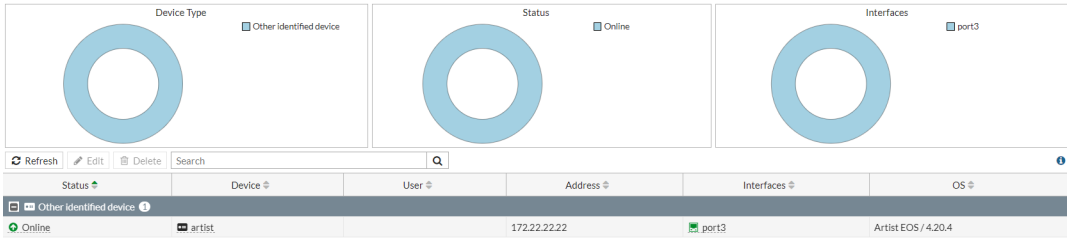
To configure device identification on an interface:

```
config system interface
    edit <port>
        set device-identification enable
    next
end
```

To configure LLDP reception globally:

```
config system global
    set lldp-reception enable
end
```

To configure LLDP reception per VDOM:



```
config system setting
    set lldp-reception enable
end
```

To configure LLDP reception per interface:

```
config system interface
    edit <port>
        set lldp-reception enable
    next
end
```

To view the LLDP information in the GUI:

1. Go to *Dashboard* > *Users & Devices*.
2. Expand the *Device Inventory* widget to full screen.

To view the received LLDP information in the CLI:

```
# diagnose user device list
    hosts
      vd root/0 44:0a:a0:0a:0a:0a gen 3 req S/2
        created 10290s gen 1 seen 0s port3 gen 1
        ip 172.22.22.22 src lldp
        type 20 'Other Network Device' src lldp id 155 gen 2
        os 'Artist EOS ' version '4.20.4' src lldp id 155
        host 'artist' src lldp
```

To view additional information about LLDP neighbors and ports:

```
# diagnose lldprx neighbor {summary | details | clear}
# diagnose lldprx port {details | summary | neighbor | filter}
# diagnose lldprx port neighbor {summary | details}
```

Note that the port index in the output corresponds to the port index from the following command:

```
# diagnose netlink interface list port2 port3 | grep index
      if=port2 family=00 type=1 index=4 mtu=1500 link=0 master=0
      if=port3 family=00 type=1 index=5 mtu=1500 link=0 master=0
```

To view the received LLDP information in the REST API:

```
{
  "http_method":"GET",
  "results":[
    {
      "mac":"90:9c:9c:c9:c9:90",
      "chassis_id":"90:9C:9C:C9:C9:90",

```

Virtual routing and forwarding

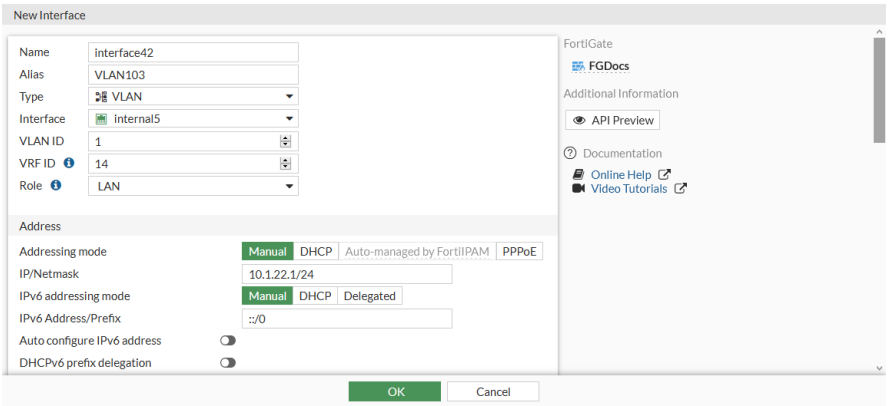
Virtual Routing and Forwarding (VRF) is used to divide the FortiGate's routing functionality (layer 3), including interfaces, routes, and forwarding tables, into separate units. Packets are only forwarded between interfaces that have the same VRF.

VDOMs divide the FortiGate into two or more complete and independent virtual units that include all FortiGate functions. VDOMs can be used for routing segmentation, but that should not be the only reason to implement them when a less complex solution (VRFs) can be used. VDOMs also support administration boundaries, but VRFs do not.

Up to 252 VRFs can be configured per VDOM for any device, but only ten VDOMs can be configured by default on a FortiGate (more VDOMs can be configured on larger devices with additional licenses).

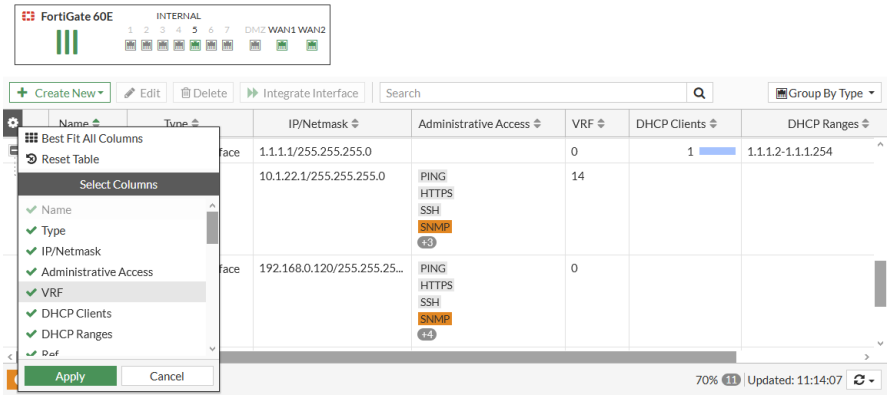
- Implementing VRF on page 482
- VRF routing support on page 483
- Route leaking between VRFs with BGP on page 488
- Route leaking between multiple VRFs on page 491
- VRF with IPv6 on page 501
- IBGP and EBGP support in VRF on page 505
- Support cross-VRF local-in and local-out traffic for local services on page 507

Implementing VRF



VRFs are always enabled and, by default, all routing is done in VRF 0. To use additional VRFs, assign a VRF ID to an interface. All routes relating to that interface are isolated to that VRF specific routing table. Interfaces in one VRF cannot reach interfaces in a different VRF.

If some traffic does have to pass between VRFs, route leaking can be used. See Route leaking between VRFs with BGP on page 488.

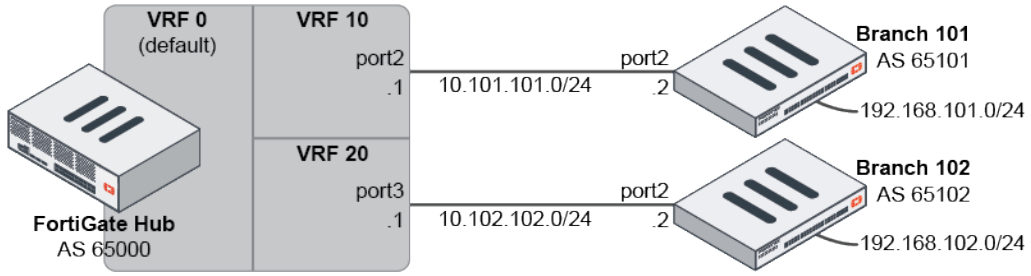


Enable *Advanced Routing* in *System* > *Feature Visibility* to configure VRFs.

To configure a VRF ID on an interface in the GUI:

1. Go to *Network* > *Interfaces* and click *Create New* > *Interface*.
2. Enter a value in the VRF ID field.
3. Configure the other settings as needed.

4. Click *OK*.
5. To add the VRF column in the interface table, click the gear icon, select *VRF*, and click *Apply*.



To configure a VRF ID on an interface in the CLI:

```
config system interface
    edit interface42
        ...
        set vrf 14
    next
end
```

VRF routing support

VRF supports static routing, OSPF, and BGP. Other routing protocols require using VDOMs.

BGP

In this example, BGP is used to update the VRF that it is neighbors with.

The hub is configured with two neighbors connected to two interfaces. The branches are configured to match the hub, with branch networks configured to redistribute into BGP.

Policies must be created on the hub and branches to allow traffic between them.

To configure the hub:

```
config router bgp
    set as 65000
    config neighbor
        edit "10.101.101.2"
            set soft-reconfiguration enable
            set interface "port2"
            set remote-as 65101
            set update-source "port2"
        next
        edit "10.102.102.2"
            set soft-reconfiguration enable
            set interface "port3"
            set remote-as 65102
            set update-source "port3"
        next
    end
end
```

To configure branch 101:

```
config router bgp
    set as 65101
    config neighbor
        edit "10.101.101.1"
            set soft-reconfiguration enable
            set interface "port2"
            set remote-as 65000
            set update-source "port2"
        next
    end
    config redistribute connected
        set status enable
    end
end
```

To configure branch 102:

```
config router bgp
    set as 65102
    config neighbor
        edit "10.102.102.1"
            set soft-reconfiguration enable
            set interface "port2"
            set remote-as 65000
            set update-source "port2"
        next
    end
    config redistribute connected
        set status enable
    end
end
```

To verify the BGP neighbors and check the routing table on the hub:

```
# get router info bgp summary
BGP router identifier 192.168.0.1, local AS number 65000
BGP table version is 2
2 BGP AS-PATH entries
0 BGP community entries

Neighbor               V       AS              MsgRcvd MsgSent TblVer  InQ     OutQ Up/Down    State/Pf
10.101.101.2   4       65101           4               4               2               0       0
10.102.102.2   4       65102           3               3               1               0       0

Total number of neighbors 2
```

```
# get router info routing-table all
Routing table for VRF=0
Codes (…)
S*      0.0.0.0/0 [10/0] via 192.168.0.254, port1
C       10.101.101.0/24 is directly connected, port2
C       10.102.102.0/24 is directly connected, port3
C       192.168.0.0/24 is directly connected, port1
```

```
B      192.168.101.0/24 [20/0] via 10.101.101.2, port2, 00:01:25
B      192.168.102.0/24 [20/0] via 10.102.102.2, port3, 00:00:50
```

To configure VRF on the hub:

1. Put the interfaces into VRF:

```
config system interface
    edit port2
        set vrf 10
    next
    edit port3
        set vrf 20
    next
end
```

2. Restart the router to reconstruct the routing tables:

```
# execute router restart
```

3. Check the routing tables:

```
# get router info routing-table all
Routing table for VRF=0
Codes (…)
S*     0.0.0.0/0 [10/0] via 192.168.0.254, port1
C      192.168.0.0/24 is directly connected, port1

Routing table for VRF=10
C      10.101.101.0/24 is directly connected, port2
B      192.168.101.0/24 [20/0] via 10.101.101.2, port2, 00:02:25

Routing table for VRF=20
C      10.102.102.0/24 is directly connected, port3
B      192.168.102.0/24 [20/0] via 10.102.102.2, port2, 00:01:50
```

4. Check the BGP summary:

```
# get router info bgp summary

VRF 10 BGP router identifier 10.101.101.1, local AS number 65000
BGP table version is 1
2 BGP AS-PATH entries
0 BGP community entries

Neighbor               V       AS              MsgRcvd MsgSent TblVer  InQ     OutQ Up/Down    State
10.101.101.2   4       65101           4               4               2               0       0

Total number of neighbors 1

VRF 10 BGP router identifier 10.101.101.1, local AS number 65000
BGP table version is 1
2 BGP AS-PATH entries
0 BGP community entries

Neighbor               V       AS              MsgRcvd MsgSent TblVer  InQ     OutQ Up/Down    State
10.102.102.2   4       65102           3               3               1               0       0
```

```
Total number of neighbors 1
```

OSPF

OSPF routes in VRFs work the same as BGP: the interface that OSPF is using is added to the VRF.

To configure the hub:

1. Configure OSPF:

```
config router ospf
    set router-id 1.1.1.1
    config area
        edit 0.0.0.0
        next
    end
    config ospf-interface
        edit Branch101
            set interface "port2"
            set dead-interval 40
            set hello-interval 10
        next
        edit Branch102
            set dead-interval 40
            set hello-interval 10
        next
    end
    config network
        edit 0
            set prefix 10.101.101.0 255.255.255.0
        next
        edit 0
            set prefix 10.102.102.0 255.255.255.0
        next
        edit 0
            set prefix 192.168.1.0 255.255.255.0
        next
    end
end
```

2. Put the interfaces into VRF:

```
config system interface
    edit port2
        set vrf 10
    next
    edit port3
        set vrf 20
    next
end
```

To configure branch 101:

```
config router ospf
    set router-id 101.101.101.101
    config area
        edit 0.0.0.0
        next
    end
    config ospf-interface
        edit HUB
            set interface port2
            set dead-interval 40
            set hello-interval 10
        next
    end
    config network
        edit 0
            set prefix 10.101.101.0 255.255.255.0
        next
        edit 0
            set prefix 192.168.101.0 255.255.255.0
        next
    end
end
```

To check the routing table and OSPF summary:

```
# get router info routing-table ospf
# get router info ospf interface
```

Static route

Static routes in VRFs work the same as BGP and OSPF because the interface that the static route is using is added to the VRF.

To add a VRF ID in a static route in the GUI:

1. Configure the interface:
   a. Go to *Network* > *Interfaces*.
   b. Click *Create New* > *Interface* or *Edit* an existing interface.
   c. Enter a value in the *VRF ID* field.
   d. Configure the other settings as needed.
   e. Click *OK*.
2. Add a static route to VRF. For example, using blackhole:
   a. Go to *Network* > *Static Routes*.
   b. Click *Create New* and select the type of static route.
   c. Enter a *Subnet*.
   d. In the *Interface* field, select *Blackhole*.
   e. In the *VRF ID* field, enter the ID created in step one.
   f. Click *OK*.

To add a VRF ID in a static route in the CLI:

1. Configure the interface:

```
config system interface
    edit port2
        set vrf 10
    next
end
```

2. Add a static route to the VRF. For example, using blackhole:

```
config router static
    edit 3
        set dst 0.0.0.0/0
        set blackhole enable
        set vrf 10
    next
end
```

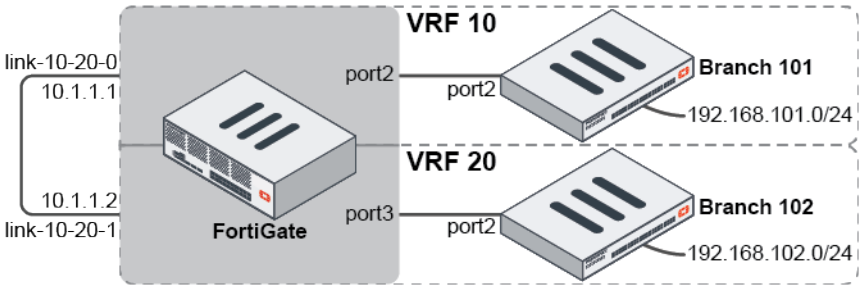
A static route can also be added to the VRF when using an IPsec interface by enabling VPN ID with IPIP encapsulation. See SD-WAN segmentation over a single overlay on page 853 for more information.

To add a static route to the VRF when using IPsec:

```
config vpn ipsec phase1-interface
    edit "vpn1"
        set interface "port2"
        set auto-discovery-receiver enable
        set encapsulation vpn-id-ipip
        set remote-gw 1.1.101.1
        set psksecret ******
    next
end
config router static
    edit 1
        set dst 10.32.0.0 255.224.0.0
        set device "vpn1"
        set vrf 10
    next
end
```

To check the routing table:

```
# get router info routing-table static
```



Route leaking between VRFs with BGP

Route leaking allows you to configure communication between VRFs. If route leaking is not configured, then the VRFs are isolated. This example shows route leaking with BGP using virtual inter-VDOM links.

In this example, a hub FortiGate forms BGP neighbors with two branches. It learns the networks 192.168.101.0/24 and 192.168.102.0/24 from the neighbors and separates them into VRF 10 and VRF 20.

To leak the learned routes to each other, an inter-VDOM link (IVL) is formed. An IVL normally bridges two VDOMs, but in this case the links reside on the same VDOM and are used to bridge the two VRFs. NPU links could also be used on models that support it to deliver better performance.

VRF 10 has a leaked route to 192.168.102.0/24 on IVL *link-10-20-0*, and VRF 20 has a leaked route to 192.168.101.0/24 on IVL *link-10-20-1*,

To configure route leaking:

1. Allow interface subnets to use overlapping IP addresses:

```
config system settings
    set allow-subnet-overlap enable
end
```

2. Configure the inter-VDOM links:

```
config system vdom-link
    edit link-10-20-
    next
end
```

3. Configure the interface settings:

```
config system interface
    edit link-10-20-0
        set vdom "root"
        set vrf 10
        set ip 10.1.1.1/30
    next
    edit link-10-20-1
        set vdom "root"
        set vrf 20
        set ip 10.1.1.2/30
    next
end
```

4. Create the prefix lists:

   These objects define the subnet and mask that are leaked.

```
config router prefix-list
    edit VRF10_Route
        config rule
            edit 1
                set prefix 192.168.101.0 255.255.255.0
            next
        end
```

```
    next
    edit VRF20_Route
        config rule
            edit 1
                set prefix 192.168.102.0 255.255.255.0
            next
        end
    next
end
```

5. Create the route map:

   The route map can be used to group one or more prefix lists.

```
config router route-map
    edit "Leak_from_VRF10_to_VRF20"
        config rule
            edit 1
                set match-ip-address "VRF10_Route"
            next
        end
    next
    edit "Leak_from_VRF20_to_VRF10"
        config rule
            edit 1
                set match-ip-address "VRF20_Route"
            next
        end
    next
end
```

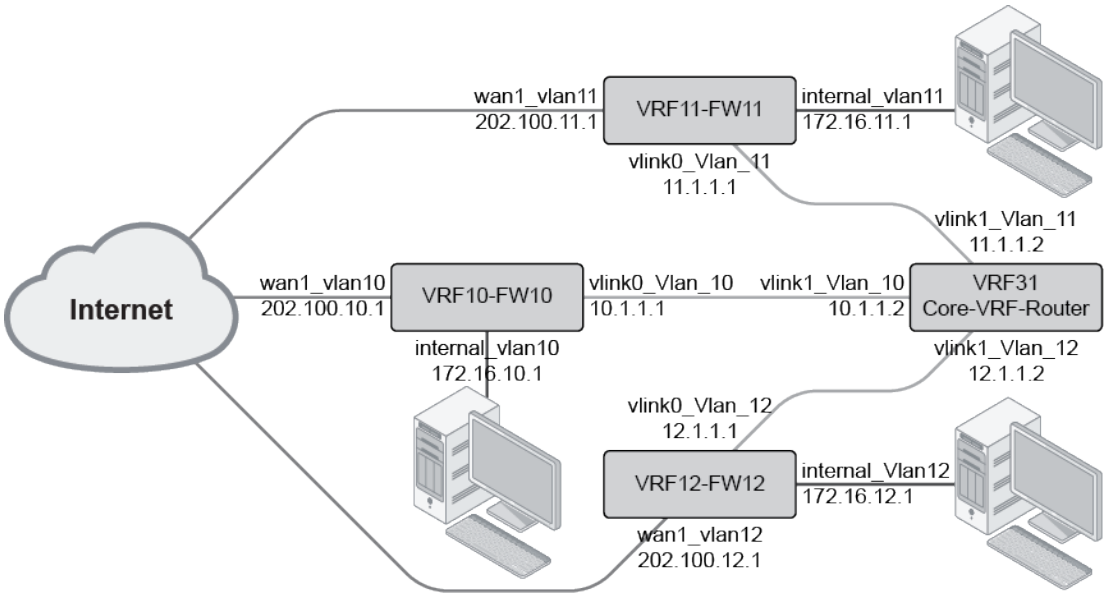
6. Configure the VRF leak in BGP, specifying a source VRF, destination VRF, an the route map to use:

```
config router bgp
    config vrf
        edit "10"
            config leak-target
                edit "20"
                    set route-map "Leak_from_VRF10_to_VRF20"
                    set interface "link-10-20-0"
                next
            end
        next
        edit "20"
            config leak-target
                edit "10"
                    set route-map "Leak_from_VRF20_to_VRF10"
                    set interface "link-10-20-1"
                next
            end
        next
    end
end
```

7. Create policies to allow traffic between the VRFs.

   Without a policy permitting traffic on the route between the VRFs, the VRFs are still isolated.

Route leaking between multiple VRFs



In this example, routing leaking between three VRFs in a star topology is configured. This allows the solution to be scaled to more VRFs without building full mesh, one-to-one connections between each pair of VRFs. VLAN subinterfaces are created on VDOM links to connect each VRF to the central VRF, allowing routes to be leaked from a VRF to the central VRF, and then to the other VRFs. Static routes are used for route leaking in this example.

For instructions on creating route leaking between two VRFs, see Route leaking between VRFs with BGP on page 488.

Physical topology:

Logical topology:

In this example, a specific route is leaked from each of the VRFs to each of the other VRFs. VLAN subinterfaces are created based on VDOM links to connect each VRF to the core VRF router.

Multi VDOM mode is enabled so that NP VDOM links can be used. The setup could be configured without enabling multi VDOM mode by manually creating non-NP VDOM links, but this is not recommended as the links are not offloaded to the NPU.

After VDOMs are enabled, all of the configuration is done in the *root* VDOM.

To configure the FortiGate:

1. Enable multi VDOM mode:

```
config system global
    set vdom-mode multi-vdom
end
```

   If the FortiGate has an NP, the VDOM links will be created:

```
# show system interface
config system interface
    ...
    edit "npu0_vlink0"
        set vdom "root"
        set type physical
    next
    edit "npu0_vlink1"
        set vdom "root"
        set type physical
    next
    ...
end
```

   If multi VDOM mode is not used, the VDOM links can be manually created:

```
config system vdom-link
    edit <name of vdlink>
    next
end
```

2. Allow interface subnets to use overlapping IP addresses:

```
config vdom
    edit root
        config system settings
            set allow-subnet-overlap enable
        end
```

3. Configure the inter-connecting VLAN subinterfaces between VRF based on VDOM-LINK:

```
config system interface
    edit "vlink0_Vlan_10"
        set vdom "root"
        set vrf 10
        set ip 10.1.1.1 255.255.255.252
        set allowaccess ping https ssh http
        set alias "vlink0_Vlan_10"
        set role lan
        set interface "npu0_vlink0"
```

```
            set vlanid 10
        next
        edit "vlink1_Vlan_10"
            set vdom "root"
            set vrf 31
            set ip 10.1.1.2 255.255.255.252
            set allowaccess ping https ssh http
            set alias "vlink1_Vlan_10"
            set role lan
            set interface "npu0_vlink1"
            set vlanid 10
        next
        edit "vlink0_Vlan_11"
            set vdom "root"
            set vrf 11
            set ip 11.1.1.1 255.255.255.252
            set allowaccess ping https ssh http
            set alias "vlink0_Vlan_11"
            set role lan
            set interface "npu0_vlink0"
            set vlanid 11
        next
        edit "vlink1_Vlan_11"
            set vdom "root"
            set vrf 31
            set ip 11.1.1.2 255.255.255.252
            set allowaccess ping https ssh http
            set alias "vlink1_Vlan_11"
            set role lan
            set interface "npu0_vlink1"
            set vlanid 11
        next
        edit "vlink0_Vlan_12"
            set vdom "root"
            set vrf 12
            set ip 12.1.1.1 255.255.255.252
            set allowaccess ping https ssh http
            set alias "vlink0_Vlan_12"
            set role lan
            set interface "npu0_vlink0"
            set vlanid 12
        next
        edit "vlink1_Vlan_12"
            set vdom "root"
            set vrf 31
            set ip 12.1.1.2 255.255.255.252
            set allowaccess ping https ssh http
            set alias "vlink1_Vlan_12"
            set role lan
            set interface "npu0_vlink1"
            set vlanid 12
        next
    end
```

4. Configure a zone to allow intrazone traffic between VLANs in the central VRF:

```
config system zone
    edit "Core-VRF-Router"
        set intrazone allow
        set interface "vlink1_Vlan_10" "vlink1_Vlan_11" "vlink1_Vlan_12"
    next
end
```

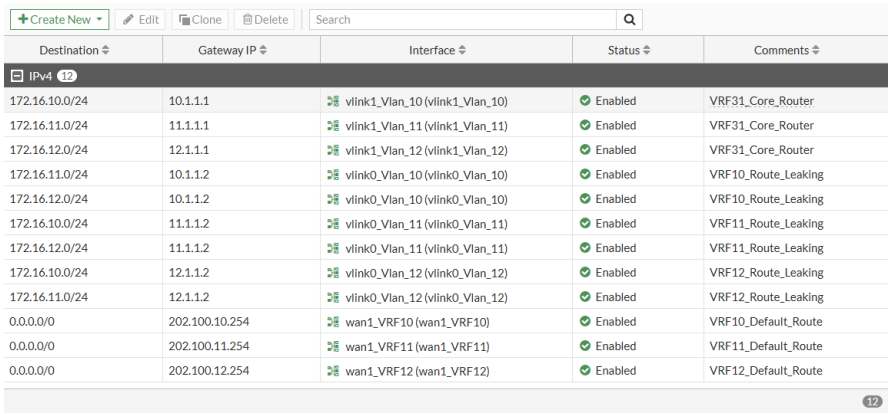
5. Add allow policies for the VRF31 core router:

```
config firewall policy
    edit 0
        set name "any_to_core_vrf31"
        set srcintf "any"
        set dstintf "Core-VRF-Router"
        set srcaddr "all"
        set dstaddr "all"
        set action accept
        set schedule "always"
        set service "ALL"
        set logtraffic all
    next
    edit 0
        set name "core_vrf31_to_any"
        set srcintf "Core-VRF-Router"
        set dstintf "any"
        set srcaddr "all"
        set dstaddr "all"
        set action accept
        set schedule "always"
        set service "ALL"
        set logtraffic all
    next
end
```

6. Configure VRF10, VRF11, and VRF12 on the Internal and WAN VLAN sub-interfaces:

```
config system interface
    edit "Internal_VRF10"
        set vdom "root"
        set vrf 10
        set ip 172.16.10.1 255.255.255.0
        set allowaccess ping https ssh http
        set alias "Internal_VRF10"
        set role lan
        set interface "internal"
        set vlanid 10
    next
    edit "Internal_VRF11"
        set vdom "root"
        set vrf 11
        set ip 172.16.11.1 255.255.255.0
        set allowaccess ping https ssh http
        set alias "Internal_VRF11"
        set role lan
        set interface "internal"
        set vlanid 11
    next
```

```
    edit "Internal_VRF12"
        set vdom "root"
        set vrf 12
        set ip 172.16.12.1 255.255.255.0
        set allowaccess ping https ssh http
        set alias "Internal_VRF12"
        set role lan
        set interface "internal"
        set vlanid 12
    next
    edit "wan1_VRF10"
        set vdom "root"
        set vrf 10
        set ip 202.100.10.1 255.255.255.0
        set allowaccess ping
        set alias "wan1_VRF10"
        set role wan
        set interface "wan1"
        set vlanid 10
    next
    edit "wan1_VRF11"
        set vdom "root"
        set vrf 11
        set ip 202.100.11.1 255.255.255.0
        set allowaccess ping
        set alias "wan1_VRF11"
        set role wan
        set interface "wan1"
        set vlanid 11
    next
    edit "wan1_VRF12"
        set vdom "root"
        set vrf 12
        set ip 202.100.12.1 255.255.255.0
        set allowaccess ping
        set alias "wan1_VRF12"
        set role wan
        set interface "wan1"
        set vlanid 12
    next
end
```



7. Configure static routing and route leaking between each VRF and Core-VRF-Router:

```
config router static
    edit 1
        set dst 172.16.10.0 255.255.255.0
        set gateway 10.1.1.1
        set device "vlink1_Vlan_10"
        set comment "VRF31_Core_Router"
    next
    edit 2
        set dst 172.16.11.0 255.255.255.0
        set gateway 11.1.1.1
        set device "vlink1_Vlan_11"
        set comment "VRF31_Core_Router"
```

```
next
edit 3
    set dst 172.16.12.0 255.255.255.0
    set gateway 12.1.1.1
    set device "vlink1_Vlan_12"
    set comment "VRF31_Core_Router"
next
edit 4
    set dst 172.16.11.0 255.255.255.0
    set gateway 10.1.1.2
    set device "vlink0_Vlan_10"
    set comment "VRF10_Route_Leaking"
next
edit 5
    set dst 172.16.12.0 255.255.255.0
    set gateway 10.1.1.2
    set device "vlink0_Vlan_10"
    set comment "VRF10_Route_Leaking"
next
edit 6
    set dst 172.16.10.0 255.255.255.0
    set gateway 11.1.1.2
    set device "vlink0_Vlan_11"
    set comment "VRF11_Route_Leaking"
next
edit 7
    set dst 172.16.12.0 255.255.255.0
    set gateway 11.1.1.2
    set device "vlink0_Vlan_11"
    set comment "VRF11_Route_Leaking"
next
edit 8
    set dst 172.16.10.0 255.255.255.0
    set gateway 12.1.1.2
    set device "vlink0_Vlan_12"
    set comment "VRF12_Route_Leaking"
next
edit 9
    set dst 172.16.11.0 255.255.255.0
    set gateway 12.1.1.2
    set device "vlink0_Vlan_12"
    set comment "VRF12_Route_Leaking"
next
edit 10
    set gateway 202.100.10.254
    set device "wan1_VRF10"
    set comment "VRF10_Default_Route"
next
edit 11
    set gateway 202.100.11.254
    set device "wan1_VRF11"
    set comment "VRF11_Default_Route"
next
edit 12
    set gateway 202.100.12.254
```

```
        set device "wan1_VRF12"
        set comment "VRF12_Default_Route"
    next
end
```

In the GUI, go to *Network* > *Static Routes* to view the static routes:

+Create New | Edit | Clone | Delete | Search

Destination	Gateway IP	Interface	Status	Comments
IPv4 12				
172.16.10.0/24	10.1.1.1	vlink1_Vlan_10 (vlink1_Vlan_10)	Enabled	VRF31_Core_Router
172.16.11.0/24	11.1.1.1	vlink1_Vlan_11 (vlink1_Vlan_11)	Enabled	VRF31_Core_Router
172.16.12.0/24	12.1.1.1	vlink1_Vlan_12 (vlink1_Vlan_12)	Enabled	VRF31_Core_Router
172.16.11.0/24	10.1.1.2	vlink0_Vlan_10 (vlink0_Vlan_10)	Enabled	VRF10_Route_Leaking
172.16.12.0/24	10.1.1.2	vlink0_Vlan_10 (vlink0_Vlan_10)	Enabled	VRF10_Route_Leaking
172.16.10.0/24	11.1.1.2	vlink0_Vlan_11 (vlink0_Vlan_11)	Enabled	VRF11_Route_Leaking
172.16.12.0/24	11.1.1.2	vlink0_Vlan_11 (vlink0_Vlan_11)	Enabled	VRF11_Route_Leaking

8. Configure firewall policies for VRF10, VRF11, and VRF12

```
config firewall policy
    edit 6
        set name "VRF10_to_Internet_Policy"
        set srcintf "Internal_VRF10"
        set dstintf "wan1_VRF10"
        set srcaddr "all"
        set dstaddr "all"
        set action accept
        set schedule "always"
        set service "ALL"
        set logtraffic all
        set nat enable
    next
    edit 7
        set name "VRF10_to_VRF_Leaking_Route"
        set srcintf "Internal_VRF10"
        set dstintf "vlink0_Vlan_10"
        set srcaddr "all"
        set dstaddr "all"
        set action accept
        set schedule "always"
        set service "ALL"
        set logtraffic all
    next
    edit 8
        set name "VRF_Leaking_Route_to_VRF10"
        set srcintf "vlink0_Vlan_10"
        set dstintf "Internal_VRF10"
        set srcaddr "all"
        set dstaddr "all"
        set action accept
        set schedule "always"
        set service "ALL"
        set logtraffic all
```

```
next
edit 9
    set name "VRF11_to_Internet_Policy"
    set srcintf "Internal_VRF11"
    set dstintf "wan1_VRF11"
    set srcaddr "all"
    set dstaddr "all"
    set action accept
    set schedule "always"
    set service "ALL"
    set logtraffic all
    set nat enable
next
edit 10
    set name "VRF11_to_VRF_Leaking_Route"
    set srcintf "Internal_VRF11"
    set dstintf "vlink0_Vlan_11"
    set srcaddr "all"
    set dstaddr "all"
    set action accept
    set schedule "always"
    set service "ALL"
    set logtraffic all
next
edit 11
    set name "VRF_Leaking_Route_to_VRF11"
    set srcintf "vlink0_Vlan_11"
    set dstintf "Internal_VRF11"
    set srcaddr "all"
    set dstaddr "all"
    set action accept
    set schedule "always"
    set service "ALL"
    set logtraffic all
next
edit 12
    set name "VRF12_to_Internet_Policy"
    set srcintf "Internal_VRF12"
    set dstintf "wan1_VRF12"
    set srcaddr "all"
    set dstaddr "all"
    set action accept
    set schedule "always"
    set service "ALL"
    set logtraffic all
    set nat enable
next
edit 13
    set name "VRF12_to_VRF_Leaking_Route"
    set uuid 92bccf8e-b27b-51eb-3c56-6d5259af6299
    set srcintf "Internal_VRF12"
    set dstintf "vlink0_Vlan_12"
    set srcaddr "all"
    set dstaddr "all"
    set action accept
```

```
        set schedule "always"
        set service "ALL"
        set logtraffic all
    next
    edit 14
        set name "VRF_Leaking_Route_to_VRF12"
        set srcintf "vlink0_Vlan_12"
        set dstintf "Internal_VRF12"
        set srcaddr "all"
        set dstaddr "all"
        set action accept
        set schedule "always"
        set service "ALL"
        set logtraffic all
    next
end
```

In the GUI, go to *Policy & Objects* > *Firewall Policy* to view the policies.

To check the results:

1. On the FortiGate, check the routing table to see each VRF:

```
# get router info routing-table all
Codes: K - kernel, C - connected, S - static, R - RIP, B - BGP
       O - OSPF, IA - OSPF inter area
       N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
       E1 - OSPF external type 1, E2 - OSPF external type 2
       i - IS-IS, L1 - IS-IS level-1, L2 - IS-IS level-2, ia - IS-IS inter area
       * - candidate default

Routing table for VRF=0
C       10.6.30.0/24 is directly connected, mgmt

Routing table for VRF=10

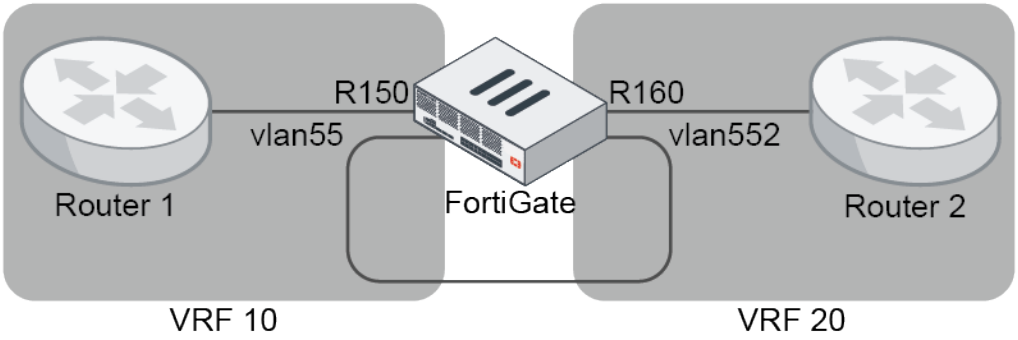
VRF with IPv6

IPv6 routes support VRF. Static, connected, OSPF, and BGP routes can be isolated in different VRFs. BGP IPv6 routes can be leaked from one VRF to another.

```
config router bgp
    config vrf6
        edit <origin vrf-id>
            config leak-target
                edit <target vrf-id>
                    set route-map <route-map>
                    set interface <interface>
                next
            end
        next
```



```
    end
end
```

The origin or target VRF ID is an integer value from 0 - 31.

```
config router static6
    edit <id>
        set vrf <vrf-id>
    next
end
```

Using a VRF leak on BGP

In this example, the route 2000:5:5:5::/64 learned from Router 1 is leaked to VRF 20 through the interface vlan552. Conversely, the route 2009:3:3:3::/64 learned from Router 2 is leaked to VRF 10 through interface vlan55.

To configure VRF leaking in BGP:

1. Configure the BGP neighbors:

```
config router bgp
    set as 65412
    config neighbor
        edit "2000:10:100:1::1"
            set activate disable
            set remote-as 20
            set update-source "R150"
        next
        edit "2000:10:100:1::5"
            set activate disable
            set soft-reconfiguration enable
            set interface "R160"
            set remote-as 20
        next
    end
end
```

2. Configure the VLAN interfaces:

```
config system interface
    edit "vlan55"
        set vdom "root"
        set vrf 10
        set ip 55.1.1.1 255.255.255.0
```

```
            set device-identification enable
            set role lan
            set snmp-index 51
            config ipv6
                set ip6-address 2000:55::1/64
            end
            set interface "npu0_vlink0"
            set vlanid 55
        next
        edit "vlan552"
            set vdom "root"
            set vrf 20
            set ip 55.1.1.2 255.255.255.0
            set device-identification enable
            set role lan
            set snmp-index 53
            config ipv6
                set ip6-address 2000:55::2/64
            end
            set interface "npu0_vlink1"
            set vlanid 55
        next
    end
```

3. Configure the IPv6 prefixes:

```
config router prefix-list6
    edit "1"
        config rule
            edit 1
                set prefix6 2000:5:5:5::/64
                unset ge
                unset le
            next
        end
    next
    edit "2"
        config rule
            edit 1
                set prefix6 2009:3:3:3::/64
                unset ge
                unset le
            next
        end
    next
end
```

4. Configure the route maps:

```
config router route-map
    edit "from106"
        config rule
            edit 1
                set match-ip6-address "1"
            next
        end
    next
```

```
    edit "from206"
        config rule
            edit 1
                set match-ip6-address "2"
            next
        end
    next
end
```

5. Configure the IPv6 route leaking (leak route 2000:5:5:5::/64 learned from Router 1 to VRF 20, then leak route 2009:3:3:3::/64 learned from Router 2 to VRF 10):

```
config router bgp
    config vrf6
        edit "10"
            config leak-target
                edit "20"
                    set route-map "from106"
                    set interface "vlan55"
                next
            end
        next
        edit "20"
            config leak-target
                edit "10"
                    set route-map "from206"
                    set interface "vlan552"
                next
            end
        next
    end
end
```

To verify the VRF leaking:

1. Check the routing table before the leak:

```
# get router info6 routing-table bgp
Routing table for VRF=10
B       2000:5:5:5::/64 [20/0] via fe00::2000:0000:0000:00, R150, 00:19:45

Routing table for VRF=20
B       2008:3:3:3::/64 [20/0] via fe00::3000:0000:0000:00, R160, 00:18:49
B       2009:3:3:3::/64 [20/0] via fe00::3000:0000:0000:00, R160, 00:18:49
```

2. Check the routing table after the leak:

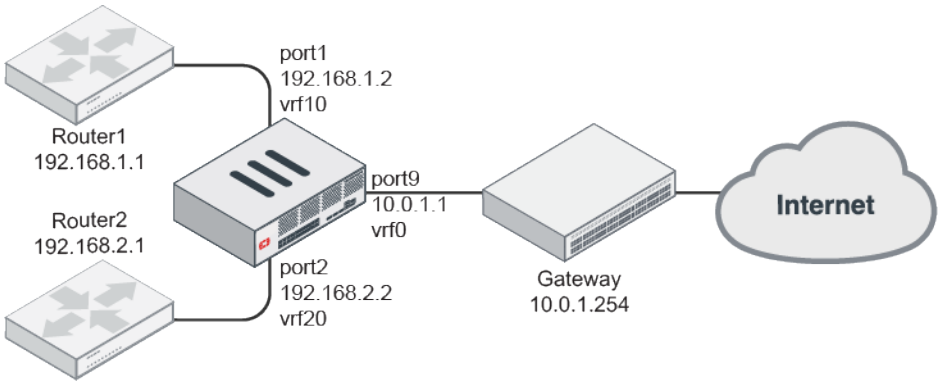
```
# get router info6 routing-table bgp
Routing table for VRF=10
B       2000:5:5:5::/64 [20/0] via fe00::2000:0000:0000:0, R150, 00:25:45
B       2009:3:3:3::/64 [20/0] via fe80::10:0000:0000:4245, vlan55, 00:00:17

Routing table for VRF=20
B       2000:5:5:5::/64 [20/0] via fe80::10:0000:0000:4244, vlan552, 00:00:16
B       2008:3:3:3::/64 [20/0] via fe00::3000:0000:0000:00, R160, 00:24:49
B       2009:3:3:3::/64 [20/0] via fe00::3000:0000:0000:00, R160, 00:24:49
```

Using VRF on a static route

In this example, a VRF is defined on static route 22 so that it will only appear in the VRF 20 routing table.

To configure the VRF on the static route:



```
config router static6
    edit 22
        set dst 2010:2:2:2::/64
        set blackhole enable
        set vrf 20
    next
end
```

IBGP and EBGP support in VRF

Support is included for internal and external border gateway protocols (IBGP and EBGP) in virtual routing and forwarding (VRF).

FortiGate can establish neighbor connections with other FortiGates or routers, and the learned routes are put into different VRF tables according to the neighbor's settings.

This example uses the following topology:

- BGP routes learned from the Router1 neighbor are put into vrf10.
- BGP routes learned from the Router2 neighbor are put into vrf20.

To configure this example:

```
config system interface
    edit port1
        set vrf 10
    next
    edit port2
        set vrf 20
    next
end
```

```
config router bgp
    config neighbor
        edit "192.168.1.1"
```

```
            set update-source port1
        next
        edit "192.168.2.1"
            set interface port2
        next
    end
end
```

Results

Using the above topology:

- Both Router1 and Router2 establish OSPF and BGP neighbor with the FortiGate.
- Router1 advertises 10.10.1.0/24 into OSPF and 10.10.2.0/24 into BGP.
- Router2 advertises 20.20.1.0/24 into OSPF and 20.20.2.0/24 into BGP.

When port1 and port2 have not set VRF, all of the routing is in VRF=0:

```
# get router info routing-table all
Codes: K - kernel, C - connected, S - static, R - RIP, B - BGP
       O - OSPF, IA - OSPF inter area
       N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
       E1 - OSPF external type 1, E2 - OSPF external type 2
       i - IS-IS, L1 - IS-IS level-1, L2 - IS-IS level-2, ia - IS-IS inter area
       * - candidate default

Routing table for VRF=0
S*      0.0.0.0/0 [5/0] via 10.0.1.254, port9
C       10.0.1.0/24 is directly connected, port9
O       10.10.1.0/24 [110/10] via 192.168.1.1, port1, 00:18:31
B       10.10.2.0/24 [20/200] via 192.168.1.1, port1, 00:01:31
O       20.20.1.0/22 [110/10] via 192.168.2.1, port2, 00:19:05
B       20.20.2.0/24 [20/200] via 192.168.2.1, port2, 00:01:31
C       192.168.1.0/24 is directly connected, port1
C       192.168.2.0/24 is directly connected, port2
```

After VRF is set for BGP, BGP routes are added to the VRF tables along with OSPF and connected routes:

```
# get router info routing-table all
Codes: K - kernel, C - connected, S - static, R - RIP, B - BGP
       O - OSPF, IA - OSPF inter area
       N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
       E1 - OSPF external type 1, E2 - OSPF external type 2
       i - IS-IS, L1 - IS-IS level-1, L2 - IS-IS level-2, ia - IS-IS inter area
       * - candidate default

Routing table for VRF=0
S*      0.0.0.0/0 [5/0] via 10.0.1.254, port9
C       10.0.1.0/24 is directly connected, port9

Routing table for VRF=10
O       10.10.1.0/24 [110/10] via 192.168.1.1, port1, 00:18:31
B       10.10.2.0/24 [20/200] via 192.168.1.1, port1, 00:01:31
C       192.168.1.0/24 is directly connected, port1

Routing table for VRF=20
O       20.20.1.0/22 [110/10] via 192.168.2.1, port2, 00:19:05
```

```
B       20.20.2.0/24 [20/200] via 192.168.2.1, port2, 00:01:31
C       192.168.2.0/24 is directly connected, port2
```

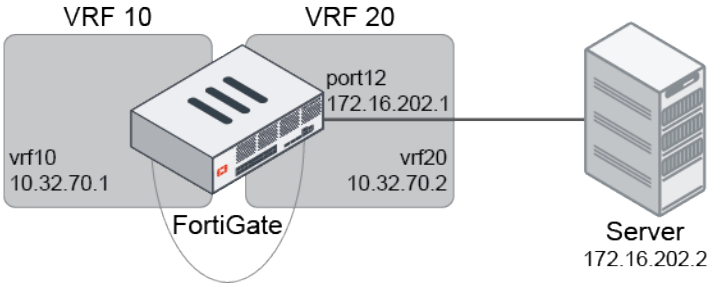
BGP neighbor groups

This feature is also supported in the BGP neighbor groups. For example:

```
config router bgp
    config neighbor-group
        edit "FGT"
            set update-source "port1"
        next
    end
    config neighbor-range
        edit 1
            set prefix 172.16.201.0 255.255.255.0
            set neighbor-group "FGT"
        next
    end
end
```

Note that the `set interface` command is not supported.

Support cross-VRF local-in and local-out traffic for local services



When local-out traffic such as SD-WAN health checks, SNMP, syslog, and so on are initiated from an interface on one VRF and then pass through interfaces on another VRF, the reply traffic will be successfully forwarded back to the original VRF.

VRF 0 is a special VRF. By default, all routing is done in VRF 0. So all routes in different VRFs, such as VRF 10 or VRF 20, will all be included in VRF 0. VRF 0 cannot be used in the cross-VRF case.

For local-in and local-out traffic, all routes relating to one VRF are isolated from other VRFs so interfaces in one VRF cannot reach interfaces in a different VRF, except for VRF 0.

Example

In this example, there is an NPU VDOM link that is configured on the root VDOM. Two VLANs, vrf10 and vrf20, are created on either ends of the NPU VDOM link, each belonging to a different VRF.

When pinging from the vrf10 interface in VRF 10 to the destination server 172.16.202.2, since there is a single static route for VRF 10 with a gateway of vrf20/10.32.70.2, traffic is sent to the next hop and subsequently routed through port12 to the server.

As seen in the sniffer trace, the ICMP replies are received on port12 in VRF 20, then pass through vrf20, and are ultimately forwarded back to vrf10 in VRF 10. The traffic flow demonstrates that local-out traffic sourced from one VRF passing through another VRF can return back to the original VRF.

To configure cross-VRF local-out traffic for local services:

1. Configure the interfaces:

```
config system interface
    edit "vrf10"
        set vdom "root"
        set vrf 10
        set ip 10.32.70.1 255.255.255.0
        set allowaccess ping
        set device-identification enable
        set role lan
        set snmp-index 35
        set interface "npu0_vlink0"
        set vlanid 22
    next
    edit "vrf20"
        set vdom "root"
        set vrf 20
        set ip 10.32.70.2 255.255.255.0
        set allowaccess ping
        set device-identification enable
        set role lan
        set snmp-index 36
        set interface "npu0_vlink1"
        set vlanid 22
    next
    edit "port12"
        set vdom "root"
        set vrf 20
        set ip 172.16.202.1 255.255.255.0
        set allowaccess ping https ssh snmp http telnet fgfm radius-acct probe-response
fabric ftm speed-test
        set type physical
        set alias "TO_FGT_D_port22"
        set snmp-index 14
        config ipv6
            set ip6-address 2003:172:16:202::1/64
            set ip6-allowaccess ping
        end
    next
end
```

2. Configure the firewall policy:

```
config firewall policy
    edit 1
        set srcintf "vrf20"
        set dstintf "port12"
```

```
        set action accept
        set srcaddr "all"
        set dstaddr "all"
        set srcaddr6 "all"
        set dstaddr6 "all"
        set schedule "always"
        set service "ALL"
    next
end
```

3. Configure the static route:

```
config router static
    edit 2
        set gateway 10.32.70.2
        set distance 3
        set device "vrf10"
    next
end
```

To test the configuration:

1. Execute a ping from the vrf10 interface in VRF 10 to the destination server (172.16.202.2):

```
# execute ping-options interface vrf10
# execute ping 172.16.202.2
PING 172.16.202.2 (172.16.202.2): 56 data bytes
64 bytes from 172.16.202.2: icmp_seq=0 ttl=254 time=0.1 ms
64 bytes from 172.16.202.2: icmp_seq=1 ttl=254 time=0.0 ms

--- 172.16.202.2 ping statistics ---
2 packets transmitted, 2 packets received, 0% packet loss
round-trip min/avg/max = 0.0/0.0/0.1 ms
```

2. Run a sniffer trace on 172.16.202.2 for ICMP:

```
# diagnose sniffer packet any "host 172.16.202.2 and icmp" 4

```

NetFlow

NetFlow allows you to collect IP network traffic statistics for an interface, and then export those statistics for analysis. NetFlow samplers, that sample every packet, are configured per interface. Full NetFlow is supported through the information maintained in the firewall session.

To configure NetFlow:

```
config system netflow
    set collector-ip <ip>
    set collector-port <port>
    set source-ip <ip>
    set active-flow-timeout <integer>
    set inactive-flow-timeout <integer>
    set template-tx-timeout <integer>
    set template-tx-counter <integer>
end
```

`collector-ip <ip>`	Collector IPv4 or IPv6 address.
`collector-port <port>`	NetFlow collector port number (0 - 65535).
`source-ip <ip>`	Source IPv4 or IPv6 address, for communication with the NetFlow agent.
`active-flow-timeout <integer>`	Timeout to report active flows, in seconds (60 - 3600, default = 1800).
`inactive-flow-timeout <integer>`	Timeout for periodic report of finished flows, in seconds (10 - 600, default = 15).
`template-tx-timeout <integer>`	Timeout for periodic template flowset transmission, in seconds (60 - 86400, default = 1800).
`template-tx-counter <integer>`	Counter of flowset records, before resending a template flowset record (10 - 6000, default = 20).

To configure NetFlow in a specific VDOM:

```
config vdom
    edit <vdom>
        config system vdom-netflow
            set vdom-netflow enable
            set collector-ip <ip>
            set collector-port <port>
            set source-ip <ip>
        end
    next
end
```

To configure a NetFlow sampler on an interface:

```
config system interface
    edit <interface>
        set netflow-sampler {disable | tx | rx | both}
```

```
    next
end
```

disable	Disable the NetFlow protocol on this interface (default).
tx	Monitor transmitted traffic on this interface.
rx	Monitor received traffic on this interface.
both	Monitor transmitted/received traffic on this interface.

Verification and troubleshooting

If data are not seen on the NetFlow collector after it has been configured, use the following sniffer commands to verify if the FortiGate and the collector are communicating:

- By collector port:

  ```
  # diagnose sniffer packet 'port <collector-port>'  6 0 a
  ```

- By collector IP address:

  ```
  # diagnose sniffer packet 'host <collector-ip>' 6 0 a
  ```

NetFlow uses the sflow daemon. The current NetFlow configuration can be viewed using test level 3 or 4:

```
# diagnose test application sflowd 3
```

```
# diagnose test application sflowd 4
Netflow Cache Stats:
vdoms=1 Collectors=1 Cached_intf=2 Netflow_enabled_intf=1 Live_sessions=0 Session cache max
count:71950
```

NetFlow templates

NetFlow uses templates to capture and categorize the data that it collects. FortiOS supports the following NetFlow templates:

Name	Template ID	Description
STAT_OPTIONS	256	Statistics information about exporter
APP_ID_OPTIONS	257	Application information
IPV4	258	No NAT IPv4 traffic
IPV6	259	No NAT IPv6 traffic
ICMP4	260	No NAT ICMPv4 traffic
ICMP6	261	No NAT ICMPv6 traffic
IPV4_NAT	262	Source/Destination NAT IPv4 traffic
IPV4_AF_NAT	263	AF NAT IPv4 traffic (4->6)

Name	Template ID	Description
IPV6_NAT	264	Source/Destination NAT IPv6 traffic
IPV6_AF_NAT	265	AF NAT IPv6 traffic (6->4)
ICMP4_NAT	266	Source/Destination NAT ICMPv4 traffic
ICMP4_AF_NAT	267	AF NAT ICMPv4 traffic (4->6)
ICMP6_NAT	268	Source/Destination NAT ICMPv6 traffic
ICMPv6_AF_NAT	269	AF NAT ICMPv6 traffic (6->4)

NetFlow on FortiExtender and tunnel interfaces

NetFlow sampling is supported on FortiExtender and VPN tunnel interfaces.

VPN tunnel interfaces can be IPsec, IP in IP, or GRE tunnels. NetFlow sampling is supported on both NPU and non-NPU offloaded tunnels.

Examples

In the following examples, a FortiExtender and a VPN tunnel interface are configured with NetFlow sampling.

To configure a FortiExtender interface with NetFlow sampling:

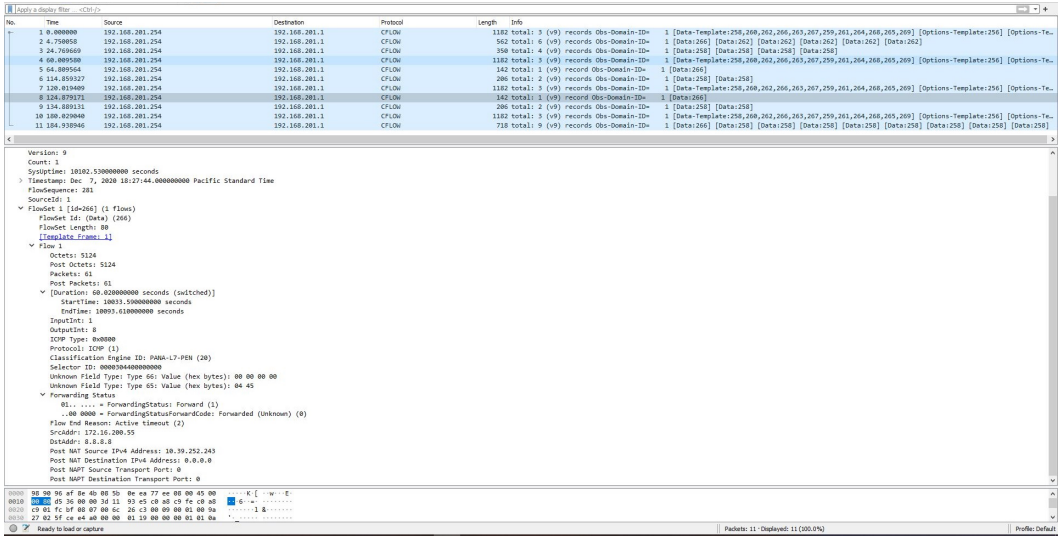
1. Configure a FortiExtender interface with NetFlow sampling enabled for both transmitted and received traffic:

```
config system interface
    edit "fext-211"
        set vdom "root"
        set mode dhcp
        set type fext-wan
        set netflow-sampler both
        set role wan
        set snmp-index 8
        set macaddr 2a:4e:68:a3:f4:6a
    next
end
```

2. Check the NetFlow status and configuration:

Device index 26 is the FortiExtender interface `fext-211`.

```
# diagnose test application sflowd 3
===== Netflow Vdom Configuration =====
Global collector:172.18.60.80:[2055] source ip: 0.0.0.0 active-timeout(seconds):60
inactive-timeout(seconds):600
____ vdom: root, index=0, is master, collector: disabled (use global config) (mgmt vdom)
   |_ coll_ip:172.18.60.80[2055],src_ip:10.6.30.105,seq_num:300,pkts/time to next
template: 18/29
   |_ exported: Bytes:3026268, Packets:11192, Sessions:290 Flows:482
   |____ interface:fext-211 sample_direction:both device_index:26 snmp_index:8
```



3. Check the network interface list:

```
# diagnose netlink interface list
...
if=fext-211 family=00 type=1 index=26 mtu=1500 link=0 master=0
ref=27 state=start present fw_flags=60000 flags=up broadcast run multicast
...
```

4. Check the session list for the FortiExtender interface and NetFlow flowset packet:

```
# diagnose sys session list
session info: proto=1 proto_state=00 duration=1732 expire=59 timeout=0 flags=00000000
socktype=0 sockport=0 av_idx=0 use=3
origin-shaper=
reply-shaper=
per_ip_shaper=
class_id=0 ha_id=0 policy_dir=0 tunnel=/ vlan_cos=0/255
state=may_dirty netflow-origin netflow-reply
statistic(bytes/packets/allow_err): org=145572/1733/1 reply=145572/1733/1 tuples=2
tx speed(Bps/kbps): 83/0 rx speed(Bps/kbps): 83/0
orgin->sink: org pre->post, reply pre->post dev=5->26/26->5
gwy=10.39.252.244/172.16.200.55

no_ofld_reason:  non-npu-intf
total session 1
```

5. The flowset packet can be captured on UDP port 2055 by a packet analyzer, such as Wireshark:

To configure a VPN tunnel interface with NetFlow sampling:

1. Configure a VPN interface with NetFlow sampling enabled for both transmitted and received traffic:

```
config system interface
    edit "A-to-B_vpn"
        set vdom "vdom1"
        set type tunnel
        set netflow-sampler both
        set snmp-index 42
        set interface "port3"
    next
end
```

2. Configure the VPN tunnel:

```
config vpn ipsec phase1-interface
    edit "A-to-B_vpn"
        set interface "port3"
        set peertype any
        set net-device disable
        set proposal aes128-sha256 aes256-sha256 aes128-sha1 aes256-sha1
        set comments "VPN: A-to-B_vpn [Created by VPN wizard]"
        set wizard-type static-fortigate
        set remote-gw 10.2.2.2
        set psksecret ENC
    next
end
```

```
config vpn ipsec phase2-interface
    edit "A-to-B_vpn"
        set phase1name "A-to-B_vpn"
        set proposal aes128-sha1 aes256-sha1 aes128-sha256 aes256-sha256 aes128gcm
aes256gcm chacha20poly1305
        set comments "VPN: A-to-B_vpn [Created by VPN wizard]"
        set src-addr-type name
        set dst-addr-type name
        set src-name "A-to-B_vpn_local"
```

```
        set dst-name "A-to-B_vpn_remote"
    next
end
```

3. Check the NetFlow status and configuration:

   Device index 52 is the VPN interface `A-to-B_vpn`.

```
# diagnose test application sflowd 3
===== Netflow Vdom Configuration =====
Global collector:172.18.60.80:[2055] source ip: 0.0.0.0 active-timeout(seconds):60
inactive-timeout(seconds):15
____ vdom: vdom1, index=1, is master, collector: disabled (use global config) (mgmt
vdom)
   |_ coll_ip:172.18.60.80[2055],src_ip:10.1.100.1,seq_num:60,pkts/time to next

```

5. The flowset packet can be captured on UDP port 2055 by a packet analyzer, such as Wireshark:

sFlow

sFlow is a method of monitoring the traffic on your network to identify areas on the network that may impact performance and throughput. FortiGate supports sFlow v5. sFlow collector software is available from a number of third-party software vendors. For more information about sFlow, see www.sflow.org.

The packet information that the FortiGate's sFlow agent collects depends on the interface type:

- On an internal interface, when the interface receives packets from devices with private IP addresses, the collected information includes the private IP addresses.
- On an external, or WAN, interface, when the interface receives to route to or from the internet, the collected information includes the IP address of the WAN interface as the source or destination interface, depending on the direction of the traffic. It does not include IP addresses that are NATed on another interface.

sFlow datagrams contain the following information:

- Packet headers, such as MAC, IPv4, and TCP
- Sample process parameters, such as rate and pool
- Input and output ports
- Priority (802.1p and ToS)
- VLAN (802.1Q)
- Source prefixes, destination prefixes, and next hop addresses
- BGP source AS, source peer AS, destination peer AS, communities, and local preference
- User IDs (TACACS, RADIUS) for source and destination
- Interface statistics (RFC 1573, RFC 2233, and RFC 2358)

Configuring sFlow

sFlow can be configured globally, then on traffic VDOMs and individual interfaces.

When configuring sFlow on a VDOM, the collector can be specified, or the collector that is configured globally can be used.

sFlow is supported on some interface types, such as physical, VLAN, and aggregate. It is not supported on virtual interfaces, such as VDOM link, IPsec, GRE, or SSL. When configuring sFlow on an interface, the rate that the agent samples traffic, the direction of that traffic, and the frequency that the agent sends sFlow datagrams to the sFlow collector can be specified. If sFlow is configured on the VDOM that the interface belongs to, the agent sends datagrams to the collector configured for the VDOM. Otherwise, the datagrams are sent to the collector that is configured globally.

Configuring sFlow for an interface disables NP offloading for all traffic on that interface.

To configure sFlow globally:

```
config system sflow
    set collector-ip <ipv4_address>
    set collector-port <port>
    set source-ip <ipv4_address>
    set interface-select-method {auto | sdwan | specify}
    set interface <interface>
end
```

`collector-ip <ipv4_address>`	The IPv4 address of the sFlow collector that sFlow agents added to interface (default = 0.0.0.0).
`collector-port <port>`	The UDP port number used for sending sFlow datagrams (0 - 65535, default = 6343). Only configured this option if required by the sFlow collector or your network configuration.
`source-ip <ipv4_address>`	The source IPv4 address that the sFlow agent used to send datagrams to the collector (default = 0.0.0.0). If this option is not configured, the FortiGate uses the IP address of the interface that it sends the datagram through.
`interface-select-method {auto | sdwan | specify}`	How the outgoing interface to reach the server is selected (default = auto).
`interface <interface>`	The outgoing interface used to reach the server. This option is only available when `interface-select-method` is `specify`.

To configure sFlow for a VDOM:

```
config vdom
    edit <vdom>
        config system vdom-sflow
            set vdom-sflow {enable | disable}
            set collector-ip <ipv4_address>
            set collector-port <port>
            set source-ip <ipv4_address>
            set interface-select-method {auto | sdwan | specify}
            set interface <interface>
        end
    next
end
```

`vdom-sflow {enable | disable}`	Enable/disable the sFlow configuration for the current VDOM (default = disable).
`collector-ip <ipv4_address>`	The IPv4 address of the sFlow collector that sFlow agents added to interface (default = 0.0.0.0). If this option is not configured, the global setting will be used.
`collector-port <port>`	The UDP port number used for sending sFlow datagrams (0 - 65535, default = 6343). Only configured this option if required by the sFlow collector or your network configuration. If this option is not configured, the global setting will be used.
`source-ip <ipv4_address>`	The source IPv4 address that the sFlow agent used to send datagrams to the collector (default = 0.0.0.0). If this option is not configured, the FortiGate uses the IP address of the interface that it sends the datagram through.
`interface-select-method {auto | sdwan | specify}`	How the outgoing interface to reach the server is selected (default = auto).
`interface <interfae>`	The outgoing interface used to reach the server. This option is only available when `interface-select-method` is `specify`.

To configure sFlow on an interface:

```
config system interface
    edit <interface>
        set sflow-sampler {enable | disable}
        set sample-rate <integer>
        set polling-interval <integer>
        set sample-direction {tx | rx | both}
    next
end
```

`sflow-sampler {enable | disable}`	Enable/disable sFlow on this interface (default = disable).
`sample-rate <integer>`	The average number of packets that the agent lets pass before taking a sample (10 - 99999, default = 2000). Setting a lower rate will sample a higher number of packets, increasing the accuracy or the sampling data, but also increasing the CPU and network bandwidth usage. The default value is recommended.
`polling-interval <integer>`	The amount of time that the agent waits between sending datagrams to the collector, in seconds (1 - 255, default = 20). Setting a higher value lowers the amount of data that the agent sends across the network, but makes the collector's view of the network less current.
`sample-direction {tx | rx | both}`	The direction of the traffic that the agent collects (default = both).

Link monitor

The link monitor is a mechanism that allows the FortiGate to probe the status of a detect server in order to determine the health of the link, next hop, or the path to the server. Ping, TCP echo, UDP echo, HTTP, and TWAMP protocols can be used for the probes. Typically, the detect server is set to a stable server several hops away. Multiple servers can also be configured with options to define the protocol and weights for each server.

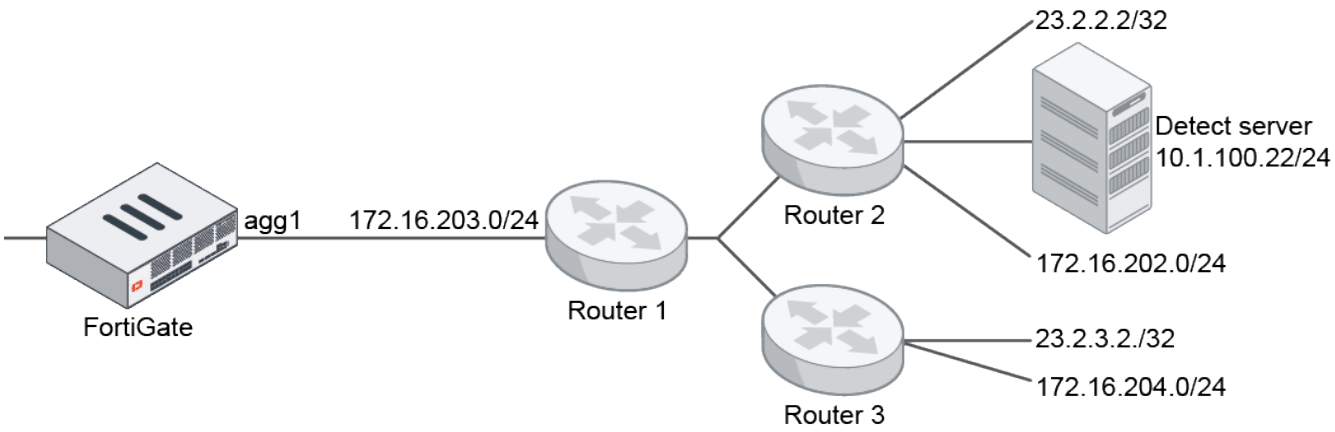
The link monitor serves several purposes. In the most basic configuration, it can be used to detect failures and remove routes associated with the interface and gateway to prevent traffic from routing out the failed link. More granularity is added in 7.0 that allows only the routes specified in the link monitor to be removed from the routing table. With this benefit, only traffic to specific routing destinations are removed, rather than all routing destinations.

Another enhancement starting in 7.0.1 is an option to toggle between enabling or disabling policy route updates when a link health monitor fails.

The link monitor can also monitor remote servers for HA failover. Using the HA built-in link monitor, it is only able to detect physical link failovers to trigger HA link failover. With the link monitor, remote servers can be used to monitor the health of the path to the server in order to trigger HA failover.

Finally, the link monitor can cascade the failure to other interfaces. When the `update-cascade-interface` option is enabled, the interface can be configured in conjunction with `fail-detect` enabled to trigger a link down event on other interfaces.

The following topics provide more information about the link monitor:



- Link monitor with route updates on page 531
- Enable or disable updating policy routes when link health monitor fails on page 533
- Add weight setting on each link health monitor server on page 535
- Dual internet connections on page 369
- SLA link monitoring for dynamic IPsec and SSL VPN tunnels on page 538

Link monitor with route updates

When a link monitor fails, only the routes that are specified in the link monitor are removed from the routing table, instead of all the routes with the same interface and gateway. If no routes are specified, then all of the routes are removed. Only IPv4 routes are supported.

Example

In this example, the FortiGate has several routes to 23.2.2.2/32 and 172.16.202.2/24, and is monitoring the link *agg1* by pinging the server at 10.1.100.22. The link monitor uses the gateway 172.16.203.2.

When the link monitor fails, only the routes to the specified subnet using interface *agg1* and gateway 172.16.203.2 are removed.

To configure the link monitor:

```
config system link-monitor
    edit "22"
        set srcintf "agg1"
        set server "10.1.100.22"
        set gateway-ip 172.16.203.2
        set route "23.2.2.2/32" "172.16.202.0/24"
    next
end
```

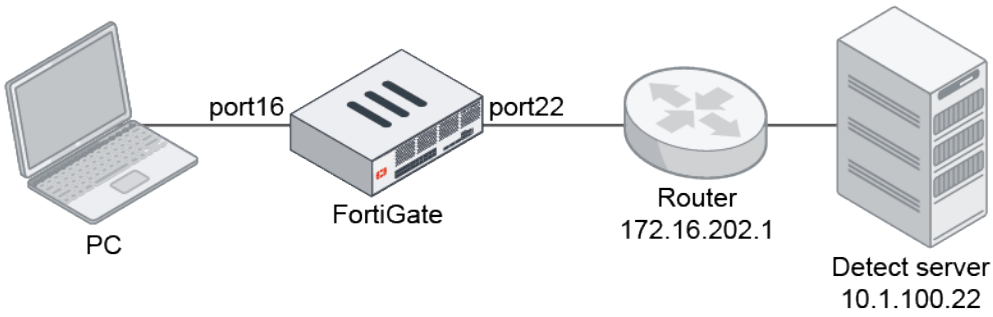
To check the results:

1. When the link monitor is alive:

```
# get router info routing-table static
Routing table for VRF=0
S*      0.0.0.0/0 [5/0] via 10.100.1.249, port12
S       10.1.100.0/24 [10/0] via 172.16.203.2, agg1
S       23.2.2.2/32 [10/0] via 172.16.203.2, agg1
S       23.2.3.2/32 [10/0] via 172.16.203.2, agg1
S       172.16.201.0/24 [10/0] via 172.16.200.4, port9
S       172.16.202.0/24 [10/0] via 172.16.203.2, agg1
S       172.16.204.0/24 [10/0] via 172.16.200.4, port9
                        [10/0] via 172.16.203.2, agg1
                        [10/0] via 172.16.206.2, vlan100, [100/0]
```

2. When the link monitor is dead:

```
# get router info routing-table static
Routing table for VRF=0
S*      0.0.0.0/0 [5/0] via 10.100.1.249, port12
S       10.1.100.0/24 [10/0] via 172.16.203.2, agg1
S       23.2.3.2/32 [10/0] via 172.16.203.2, agg1
S       172.16.201.0/24 [10/0] via 172.16.200.4, port9
S       172.16.204.0/24 [10/0] via 172.16.200.4, port9
                        [10/0] via 172.16.203.2, agg1
                        [10/0] via 172.16.206.2, vlan100, [100/0]
```



Enable or disable updating policy routes when link health monitor fails

An option has been added to toggle between enabling or disabling policy route updates when a link health monitor fails. By disabling policy route updates, a link health monitor failure will not cause corresponding policy-based routes to be removed.

```
config system link-monitor
    edit <name>
        set update-policy-route {enable | disable}
    next
end
```

Example

In the following topology, the FortiGate is monitoring the detect server, 10.1.100.22. The FortiGate has a policy-based route to destination 172.16.205.10 using the same gateway (172.16.202.1) and interface (port22). By configuring `update-policy-route disable`, the policy-based route is not removed when the link health monitor detects a failure.

To disable updating policy routes when the link health monitor fails:

1. Configure the link health monitor:

```
config system link-monitor
    edit "test-1"
        set srcintf "port22"
        set server "10.1.100.22"
        set gateway-ip 172.16.202.1
        set failtime 3
        set update-policy-route disable
    next
end
```

2. Configure the policy route:

```
config router policy
    edit 1
        set input-device "port16"
        set dst "172.16.205.10/255.255.255.255"
        set gateway 172.16.202.1
        set output-device "port22"
        set tos 0x14
        set tos-mask 0xff
```

```
    next
end
```

3. When the health link monitor status is up, verify that the policy route is active.
   a. Verify the link health monitor status:

```
# diagnose sys link-monitor status
Link Monitor: test-1, Status: alive, Server num(1), HA state: local(alive), shared
(alive)
Flags=0x1 init, Create time: Fri May 28 15:20:15 2021
Source interface: port22 (14)
Gateway: 172.16.202.1
Interval: 500 ms
Service-detect: disable
Diffservcode: 000000
Class-ID: 0
  Peer: 10.1.100.22(10.1.100.22)
        Source IP(172.16.202.2)
        Route: 172.16.202.2->10.1.100.22/32, gwy(172.16.202.1)
        protocol: ping, state: alive
                Latency(Min/Max/Avg): 0.374/0.625/0.510 ms
                Jitter(Min/Max/Avg): 0.008/0.182/0.074
                Packet lost: 0.000%
                Number of out-of-sequence packets: 0
                Fail Times(0/3)
                Packet sent: 7209, received: 3400, Sequence(sent/rcvd/exp):
7210/7210/7211
```

   b. Verify the policy route list:

```
# diagnose firewall proute  list
list route policy info(vf=root):
id=1 dscp_tag=0xff 0xff flags=0x0 tos=0x14 tos_mask=0xff protocol=0 sport=0-0 iif=41
dport=0-65535 oif=14(port22) gwy=172.16.202.1
source wildcard(1): 0.0.0.0/0.0.0.0
destination wildcard(1): 172.16.205.10/255.255.255.255
hit_count=1 last_used=2021-05-27 23:04:33
```

4. When the health link monitor status is down, verify that the policy route is active:
   a. Verify the link health monitor status:

```
# diagnose sys link-monitor status
Link Monitor: test-1, Status: die, Server num(1), HA state: local(die), shared(die)
Flags=0x9 init log_downgateway, Create time: Fri May 28 15:20:15 2021
Source interface: port22 (14)
Gateway: 172.16.202.1
Interval: 500 ms
Service-detect: disable
Diffservcode: 000000
Class-ID: 0
  Peer: 10.1.100.22(10.1.100.22)
        Source IP(172.16.202.2)
        Route: 172.16.202.2->10.1.100.22/32, gwy(172.16.202.1)
        protocol: ping, state: die
                Packet lost: 11.000%
                Number of out-of-sequence packets: 0
                Recovery times(0/5) Fail Times(0/3)
```

```
                    Packet sent: 7293, received: 3471, Sequence(sent/rcvd/exp):
  7294/7281/7282
```

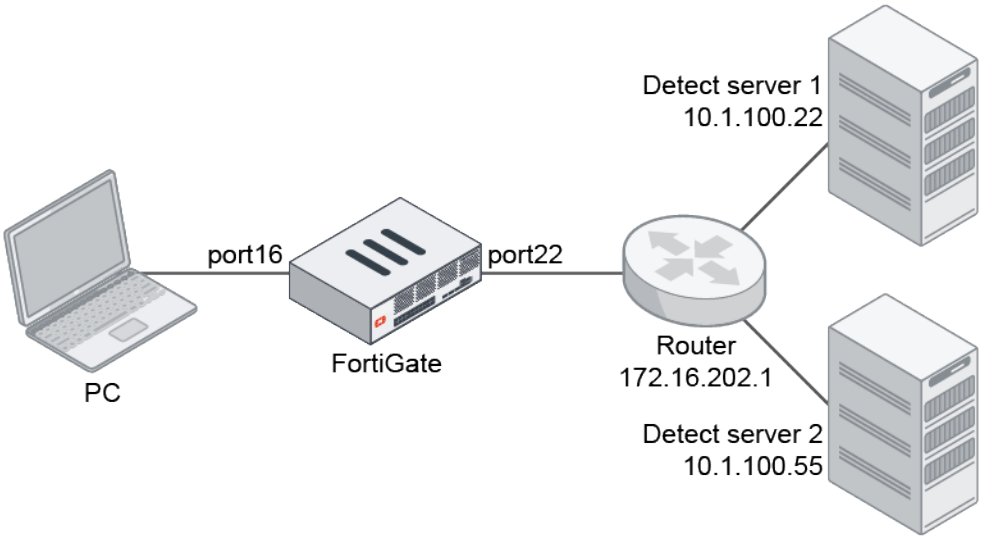
b. Verify the policy route list:

```
# diagnose firewall proute list
list route policy info(vf=root):
id=1 dscp_tag=0xff 0xff flags=0x0 tos=0x14 tos_mask=0xff protocol=0 sport=0-0 iif=41
dport=0-65535 oif=14(port22) gwy=172.16.202.1
source wildcard(1): 0.0.0.0/0.0.0.0
destination wildcard(1): 172.16.205.10/255.255.255.255
hit_count=1 last_used=2021-05-27 23:04:33
```

If the `update-policy-route` setting is enabled, the link health monitor would be down and the policy-based route would be disabled:

```
# diagnose firewall proute list
list route policy info(vf=root):
id=1 dscp_tag=0xff 0xff flags=0x8 disable tos=0x14 tos_mask=0xff protocol=0 sport=0-0
iif=41 dport=0-65535 oif=14(port22) gwy=172.16.202.1
source wildcard(1): 0.0.0.0/0.0.0.0
destination wildcard(1): 172.16.205.10/255.255.255.255
hit_count=1 last_used=2021-05-27 23:04:33
```

Add weight setting on each link health monitor server



Prior to FortiOS 7.0.1, the link health monitor is determined to be dead when all servers are unreachable. Starting in 7.0.1, the link health monitor can configure multiple servers and allow each server to have its own weight setting. When the link health monitor is down, it will trigger static route updates and cascade interface updates if the weight of all dead servers exceeds the monitor's fail weight threshold.

```
config system link-monitor
    edit <name>
        set srcintf <interface>
        set server-config {default | individual}
        set fail-weight <integer>
        config server-list
            edit <id>
                set dst <address>
                set weight <integer>
            next
        end
    next
end
```

`server-config`	Set the server configuration mode: • default: all servers share the same attributes. • individual: some attributes can be specified for individual servers.
`fail-weight <integer>`	Threshold weight to trigger link failure alert (0 - 255, default = 0).
`server-list`	Configure the servers to be monitored by the link monitor.
`dst <address>`	Enter the IP address of the server to be monitored.
`weight <integer>`	Weight of the monitor to this destination (0 - 255, default = 0).

Examples

In the following topology, there are two detect servers that connect to the FortiGate through a router: server 1 (10.1.100.22) and server 2 (10.1.100.55).

Alive link health monitor

In this configuration, one server is dead and one server alive. The failed server weight is not over the threshold, so the link health monitor status is alive.

To configure the weight settings on the link health monitor:

1. Configure the link health monitor:

```
config system link-monitor
    edit "test-1"
        set srcintf "port22"
        set server-config individual
        set gateway-ip 172.16.202.1
        set failtime 3
        set fail-weight 40
        config server-list
            edit 1
                set dst "10.1.100.22"
                set weight 60
            next
            edit 2
                set dst "10.1.100.55"
                set weight 30
            next
        end
    next
end
```

2. Trigger server 2 to go down. The link monitor is still alive because the fail weight threshold has not been reached.

3. Verify the link health monitor status:

```
# diagnose sys link-monitor status test-1
Link Monitor: test-1, Status: alive, Server num(2), HA state: local(alive), shared
(alive)
Flags=0x1 init, Create time: Fri Jun  4 17:23:29 2021
Source interface: port22 (14)
Gateway: 172.16.202.1
Interval: 500 ms
Service-detect: disable
Diffservcode: 000000
Class-ID: 0
Fail-weight (40): not activated
  Peer: 10.1.100.22(10.1.100.22)
        Source IP(172.16.202.2)
        Route: 172.16.202.2->10.1.100.22/32, gwy(172.16.202.1)
        protocol: ping, state: alive
                Latency(Min/Max/Avg): 0.417/0.585/0.530 ms
                Jitter(Min/Max/Avg): 0.007/0.159/0.057
                Packet lost: 0.000%
                Number of out-of-sequence packets: 0
                Fail Times(0/3)
                Packet sent: 239, received: 236, Sequence(sent/rcvd/exp): 240/240/241
  Peer: 10.1.100.55(10.1.100.55)
        Source IP(172.16.202.2)
        Route: 172.16.202.2->10.1.100.55/32, gwy(172.16.202.1)
        Fail weight 30 applied
        protocol: ping, state: dead
                Packet lost: 100.000%
                Number of out-of-sequence packets: 0
                Recovery times(0/5) Fail Times(1/3)
                Packet sent: 239, received: 3, Sequence(sent/rcvd/exp): 240/4/5
```

Dead link health monitor

In this configuration, one server is dead and one server alive. The failed server weight is over the threshold, so the link health monitor status is dead.

To configure the weight settings on the link health monitor:

1. Configure the link health monitor:

```
config system link-monitor
    edit "test-1"
        set srcintf "port22"
        set server-config individual
        set gateway-ip 172.16.202.1
        set failtime 3
        set fail-weight 40
        config server-list
            edit 1
                set dst "10.1.100.22"
                set weight 30
            next
            edit 2
                set dst "10.1.100.55"
```

```
                set weight 50
            next
        end
    next
end
```

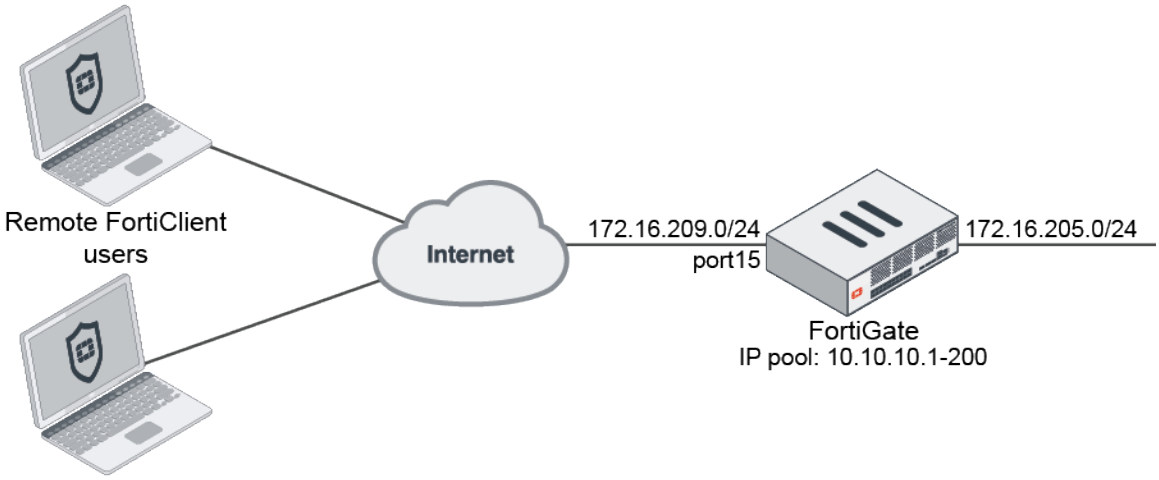
2. Trigger server 2 to go down. The link monitor is dead because the fail weight threshold has been reached.
3. Verify the link health monitor status:

```
# diagnose sys link-monitor status  test-1
Link Monitor: test-1, Status: dead, Server num(2), HA state: local(dead), shared(dead)
Flags=0x9 init log_downgateway, Create time: Fri Jun  4 17:23:29 2021
Source interface: port22 (14)
Gateway: 172.16.202.1
Interval: 500 ms
Service-detect: disable
Diffservcode: 000000
Class-ID: 0
Fail-weight (40): activated
  Peer: 10.1.100.22(10.1.100.22)
        Source IP(172.16.202.2)
        Route: 172.16.202.2->10.1.100.22/32, gwy(172.16.202.1)
        protocol: ping, state: alive
                Latency(Min/Max/Avg): 0.393/0.610/0.520 ms
                Jitter(Min/Max/Avg): 0.009/0.200/0.095
                Packet lost: 0.000%
                Number of out-of-sequence packets: 0
                Fail Times(0/3)
                Packet sent: 680, received: 677, Sequence(sent/rcvd/exp): 681/681/682
  Peer: 10.1.100.55(10.1.100.55)
        Source IP(172.16.202.2)
        Route: 172.16.202.2->10.1.100.55/32, gwy(172.16.202.1)
        Fail weight 50 applied
        protocol: ping, state: dead
                Packet lost: 100.000%
                Number of out-of-sequence packets: 0
                Recovery times(0/5) Fail Times(1/3)
                Packet sent: 680, received: 3, Sequence(sent/rcvd/exp): 681/4/5
```

SLA link monitoring for dynamic IPsec and SSL VPN tunnels

The link health monitor settings can measure SLA information of dynamic VPN interfaces, which assign IP addresses to their clients during tunnel establishment. This includes SSL VPN tunnels, IPsec remote access, and IPsec site-to-site tunnels.

This feature currently only supports IPv4 and the ICMP monitoring protocol. In the IPsec tunnel settings, `net-device` must be disabled.



```
config system link-monitor
    edit <name>
        set server-type {static | dynamic}
    next
end
```

To view the dial-up tunnel statistics:

```
# diagnose sys link-monitor tunnel {name | all} [<tunnel_name>]
```

Example

In this example, endpoint users dial up using FortiClient to create IPSec tunnels with the FortiGate and obtain IP addresses. The link monitor on the FortiGate's dynamic VPN interface detects the path quality to the endpoints.

To configure SLA link health monitoring in dynamic IPsec tunnels:

1. Configure the IPsec phase 1 interface:

```
config vpn ipsec phase1-interface
    edit "for_Branch"
        set type dynamic
        set interface "port15"
        set mode aggressive
        set peertype any
        set net-device disable
        set mode-cfg enable
        set proposal aes128-sha256 aes256-sha256 aes128-sha1 aes256-sha1
        set dpd on-idle
        set dhgrp 5
        set xauthtype auto
        set authusrgrp "vpngroup"
        set assign-ip-from name
        set ipv4-netmask 255.255.255.0
        set dns-mode auto
        set ipv4-split-include "172.16.205.0"
        set ipv4-name "client_range"
        set save-password enable
        set psksecret **********
        set dpd-retryinterval 60
    next
end
```

2. Configure the IPsec phase 2 interface:

```
config vpn ipsec phase2-interface
    edit "for_Branch_p2"
        set phase1name "for_Branch"
        set proposal aes128-sha1 aes256-sha1 aes128-sha256 aes256-sha256 aes128gcm
aes256gcm chacha20poly1305
        set dhgrp 5
    next
end
```

3. Configure the dynamic interface:

```
config system interface
    edit "for_Branch"
        set vdom "root"
        set ip 10.10.10.254 255.255.255.255
        set type tunnel
        set remote-ip 10.10.10.253 255.255.255.0
        set snmp-index 100
        set interface "port15"
    next
end
```

4. Add the IPsec dial-up tunnel to the link health monitor:

```
config system link-monitor
    edit "1"
        set srcintf "for_Branch"
        set server-type dynamic
    next
end
```

5. Once endpoint users have connected using FortiClient, verify the tunnel information:

```
# get vpn ipsec tunnel summary
'for_Branch_0' 10.1.100.23:0  selectors(total,up): 1/1  rx(pkt,err): 21091/0  tx
(pkt,err): 20741/0
'for_Branch_1' 10.1.100.13:0  selectors(total,up): 1/1  rx(pkt,err): 19991/0  tx
(pkt,err): 20381/0
```

6. Verify the link health monitor status:

```
# diagnose sys link-monitor tunnel all
for_Branch_0 (1): state=alive, peer=10.10.10.1, create_time=2022-02-08 10:43:11,
srcintf=for_Branch, latency=0.162, jitter=0.018, pktloss=0.000%
for_Branch_1 (1): state=alive, peer=10.10.10.2, create_time=2022-02-08 10:49:24,
srcintf=for_Branch, latency=0.266, jitter=0.015, pktloss=0.000%
```

7. Manually add 200 ms latency on the path between the FortiGate and FortiClients.
8. Verify the link health monitor status again:

```
# diagnose sys link-monitor tunnel all
for_Branch_0 (1): state=alive, peer=10.10.10.1, create_time=2022-02-08 10:43:11,
srcintf=for_Branch, latency=200.177, jitter=0.021, pktloss=0.000%
for_Branch_1 (1): state=alive, peer=10.10.10.2, create_time=2022-02-08 10:49:24,
srcintf=for_Branch, latency=200.257, jitter=0.017, pktloss=0.000%
```

IPv6

From an administrative point of view IPv6 works almost the same as IPv4 in FortiOS. The primary difference is the use of IPv6 format for addresses. See IPv6 overview on page 541 for more information.

By default, the IPv6 settings are not displayed in the GUI.

To enable IPv6 in the GUI:

1. Go to *System* > *Feature Visibility*.
2. Under *Core Features*, enable *IPv6*.
3. Click *Apply*.

Once enabled, you will be able to use IPv6 addresses as well as the IPv4 addressing for the following FortiGate firewall features which are not limited to:

- Interfaces
- DHCP Server
- DHCP Relay
- DNS
- Static Routes
- Firewall Policy
- NAT
- Addresses
- Virtual IPs
- IP Pools
- IPsec VPN
- GRE over IPsec

This section also contains the following topics:

- IPv6 overview on page 541
- IPv6 quick start on page 542
- Neighbor discovery proxy on page 546
- IPv6 address assignment on page 547
- NAT66, NAT46, NAT64, and DNS 64 on page 559
- DHCPv6 relay on page 569
- IPv6 tunneling on page 570
- IPv6 configuration examples on page 581

IPv6 overview

Internet Protocol version 6 (IPv6) is the latest version of the Internet Protocol (IP) and was developed to address the limitations of its predecessor, IPv4. The primary issue with IPv4 is its limited number of addresses, which are based on a 32-bit scheme and have a theoretical limit of 2 to the power of 32. In contrast, IPv6 uses a 128-bit address scheme, allowing for a much larger theoretical limit of 2 to the power of 128 addresses.

In simpler terms:

- IPv4 can support 4 294 967 296 addresses.
- IPv6 can support 340 282 366 920 938 463 463 374 607 431 768 211 456 addresses.

In addition to the expanded number of addresses, some of the other benefits of IPv6 include:

- More efficient routing due to reduction in the size of routing tables. This is achieved through hierarchical address allocation, which allows for more efficient routing of data packets.
- Reduced management requirements by supporting stateless auto-reconfiguration of hosts. This means that devices can automatically configure their network settings without the need for manual intervention.
- Improved methods to change Internet Service Providers. With IPv6, it is easier for users to switch between different ISPs without experiencing any service disruption.
- Better mobility support by providing seamless connection. This means that devices can move between different networks without losing their connection.
- Multi-homing. This allows a device to have multiple network connections, providing increased reliability and redundancy.
- Improved security with built-in support for IPsec. IPsec is a security protocol that provides authentication and encryption for data transmitted over a network.
- IPv6 offers scoped addresses with link-local, unique local, and global address spaces. This allows for more flexible addressing and improved network organization.

Address Type	Notation	Description	Example
Link-local Unicast	FE80::/10	Designed for use on a local link and are automatically configured on all interfaces. These addresses are not routable.	FE80::1
Unique Local Unicast	FC00::/7	Similar to IPv4 private addresses and can be used on your own network. They are not routable globally.	FC00::1 FD00::1
Global Unicast	2001::/3	Similar to IPv4 public addresses and can be used on the Internet. They are routable globally.	2001::1 3000::1

See Internet Protocol Version 6 Address Space for more information.

IPv6 quick start

This section provides an introduction to setting up a few basic IPv6 settings on the FortiGate. See Basic administration on page 55 for more information about basic FortiGate administration.

This chapter provides instructions for basic IPv6 configuration that should work in most cases, regardless of whether the device has an existing IPv4 configuration or is a new FortiGate device.

The topics covered in this section include:

- Configuring an interface on page 543
- Configuring the default route on page 543
- Configuring the DNS on page 544
- Configuring the address object on page 544

- Configuring the address group on page 545
- Configuring the firewall policy on page 545

Before starting, make sure to enable the IPv6 feature.

To enable IPv6 in the GUI:

1. Go to *System* > *Feature Visibility*.
2. Under *Core Features*, enable *IPv6*.
3. Click *Apply*.

Configuring an interface

To configure an interface in the GUI:

1. Go to *Network* > *Interfaces*.
2. Select an interface and click *Edit*.
3. In the *Address* section, enter the *IPv6 Address/Prefix*.
4. In the *Administrative Access* section, select the IPv6 access options as needed (such as *PING*, *HTTPS*, and *SSH*).
5. Click *OK*.

To configure an interface in the CLI:

```
config system interface
    edit <interface name>
        config ipv6
            set ip6-address <IPv6 prefix>
            set ip6-allowaccess{ping | https | ssh | snmp | http | telnet | fgfm | fabric}
        end
    next
end
```

Configuring the default route

Setting the default route enables basic routing to allow the FortiGate to return traffic to sources that are not directly connected. The gateway address should be your existing router or L3 switch that the FortiGate is connected to. Set the interface to be the interface the gateway is connected to.

To configure the default route in the GUI:

1. Go to *Network* > *Static Routes*.
2. Click *Create New* > *IPv6 Static Route*.
3. Leave the *Destination* prefix as ::/0. This is known as a default route, since it would match any IPv6 address.
4. Enter the *Gateway Address*.
5. Select an *Interface*.
6. Click *OK*.

To configure the default route in the CLI:

```
config router static6
    edit 0
        set gateway <IPv6 address>
        set device <interface name>
    next
end
```

Configuring the DNS

To configure a DNS domain list in the GUI:

1. Go to *Network* > *DNS*.
2. Under *IPv6 DNS Settings*, configure the primary and secondary DNS servers as needed.
3. Click *Apply*.

To configure a DNS domain list in the CLI:

```
config system dns
    set ip6-primary <IPv6 address>
    set ip6-secondary <IPv6 address>
end
```

Configuring the address object

Addresses define sources and destinations of network traffic and can be used in many functions such as firewall policies, ZTNA, and so on. When creating an IPv6 address object, several different types of addresses can be specified similar to IPv4 addresses. See Address Types on page 1152 for more information.

To configure an IPv6 address in the GUI:

1. Go to *Policy & Objects* > *Addresses*.
2. Select *Create New* > *Address*.
3. In the *Category* field, select *IPv6 Address*.
4. Enter a *Name* for the address object.
5. In the *Type* field, select one of the types from the dropdown menu.
6. Configure the rest of the settings as required.
7. Click *OK*.

To configure an IPv6 address in the CLI:

```
config firewall address6
    edit <name>
        set type {ipprefix | iprange | fqdn | geography | dynamic | template | mac}
    next
end
```

Configuring the address group

Address groups are designed for ease of use in the administration of the device. See Address group on page 1168 for more information.

To create an address group:

1. Go to *Policy & Objects* > *Addresses*.
2. Go to *Create New* > *Address Group*.
3. In the *Category* field, select *IPv6 Group*.
4. Enter a *Group name* for the address object.
5. Select the + in the *Members* field. The *Select Entries* pane opens.
6. Select members of the group. It is possible to select more than one entry. Select the *x* icon in the field to remove an entry.
7. Enter any additional information in the *Comments* field.
8. Click *OK*.

To configure an address group in the CLI:

```
config firewall addrgrp6
    edit <name>
        set member <name>
    next
end
```

Configuring the firewall policy

A firewall policy must be in place for any traffic that passes through a FortiGate. See Firewall policy on page 1033 for more information.

To create a firewall policy in the GUI:

1. Go to *Policy & Objects* > *Firewall Policy*.
2. Enter a *Name* and configure the following necessary settings:

Incoming Interface	Incoming (ingress) interface
Outgoing Interface	Outgoing (egress) interface
Source	Source IPv6 address name and address group names
Destination	Destination IPv6 address name and address group names
Schedule	Schedule name
Service	Service and service group names
Action	Policy action

To configure a firewall policy in the CLI:

```
config firewall policy
    edit <policyid>
        set srcintf <name>
        set dstintf <name>
        set action {accept | deny}
        set srcaddr6 <name>
        set dstaddr6 <name>
        set schedule <name>
        set service <name>
    next
end
```

See IPv6 quick start example on page 581 for a sample configuration.

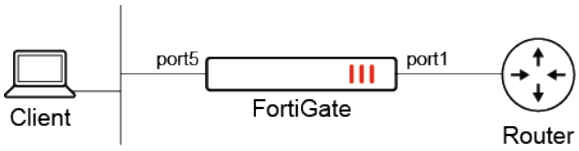
Neighbor discovery proxy

This feature provides support for proxying the IPv6 Neighbor Discovery Protocol (NDP) to allow the following ICMP messages to be forwarded between upstream and downstream interfaces:

- Router Advertisement (RA)
- Neighbor Solicitation (NS)
- Neighbor Advertisement (NA)
- Router Solicitation (RS)
- Redirect

Typically only one interface receives RA traffic, and the interface is automatically considered the upstream interface.

The Neighbor Discovery Protocol (NDP) is a layer 2 protocol that performs several tasks to improve the efficiency and consistency of data transmission across multiple networks and processes. NDP uses ICMPv6 messages to perform the following tasks:



- Stateless auto-configuration: This enables the auto-configuration of IPv6 addresses without the need for a DHCP server. This means that each host on the network can automatically configure its unique IPv6 link-local address and global unicast address.
- Address Resolution: NDP performs a function similar to IPv4's Address Resolution Protocol (ARP), but instead of using ARP, it uses NDP to dynamically resolve IPv6 addresses to their corresponding MAC addresses.
- Neighbor Unreachability Detection (NUD): This function detects when a host is no longer reachable, allowing for more efficient routing and data transmission.
- Duplicate Address Detection (DAD): This function verifies that there is no duplication of unicast IPv6 addresses in the network, ensuring that each host has a unique address.

Configure ND proxy in the CLI using the following syntax:

```
config system nd-proxy
    set status {enable|disable}
    set member <interface> <interface> [<interface>...]
end
```

Option	Description
status	Enable/disable the use of neighbor discovery proxy.
member	List of interfaces using the neighbor discovery proxy.

In this example, the client is connected to a FortiGate device that is configured as an ND (Neighbor Discovery) proxy. Port1 is the upstream interface that receives Router Advertisement (RA) traffic, and port5 is the downstream interface that connects to the client. This setup allows the FortiGate device to facilitate communication between the client and the IPv6 router.

To configure ND Proxy on FortiGate:

1. Enable address auto-configuration on the upstream interface:

```
config system interface
    edit "port1"
        config ipv6
            set autoconf enable
        end
    next
end
```

2. Enable ND proxy on the interfaces:

```
config system nd-proxy
   set status enable
   set member "port1" "port5"
end
```

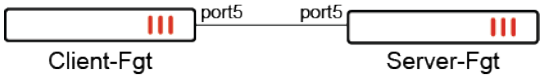
See RFC 4389 for more information on Neighbor Discovery Proxies (ND Proxy).

IPv6 address assignment

On the FortiGate, an interface can use the following methods to obtain an IPv6 address:

- IPv6 stateless address auto-configuration (SLAAC) on page 548
- DHCPv6 stateful server on page 549
- SLAAC with DHCPv6 stateless server on page 551
- IPv6 prefix delegation on page 553

You can configure IPv6 using the CLI. To configure IPv6 using the GUI, ensure IPv6 is enabled by going to *System* > *Feature Visibility* and enabling *IPv6*.



IPv6 stateless address auto-configuration (SLAAC)

FortiGate can easily obtain an IPv6 address on any given interface using SLAAC (stateless address auto-configuration). SLAAC is designed only for IP assignments and does not provide DNS server addresses to hosts. See RFC 4862 for more information.

Use one of the following options to obtain a DNS server address:

- DHCPv6 stateful server on page 549
- SLAAC with DHCPv6 stateless server on page 551

In this example, Server-Fgt is connected to Client-Fgt. Server-Fgt has SLAAC enabled, which allows Client-Fgt to automatically obtain an IPv6 address using the auto-configuration IPv6 address option.

To enable IPv6 auto-configuration in the GUI:

1. Configure SLAAC on Server-Fgt:
   a. Go to *Network* > *Interfaces* and edit port5.
   b. Configure the following settings:

IPv6 addressing mode	Manual
IPv6 Address/Prefix	2001:db8:d0c:1::1/64
Stateless Address Auto-configuration (SLAAC)	Enable
IPv6 prefix list	Enable
IPv6 prefix	2001:db8:d0c:1::/64

   c. Click *OK*.
2. Configure Client-Fgt to automatically obtain an IPv6 address:
   a. Go to *Network* > *Interfaces* and edit port5.
   b. Enable *Auto configure IPv6 address*. Client-Fgt uses the prefix that it obtains from the Server-Fgt interface, and automatically generates an IPv6 address.
3. Verify that Client-Fgt automatically generated an IPv6 address:
   a. Go to *Network* > *Interfaces* and edit port5. The *IPv6 Address/Prefix* field is populated with an IPv6 address.

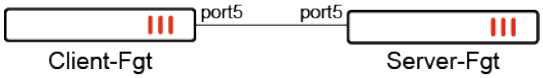
To enable IPv6 auto-configuration in the CLI:

1. Configure SLAAC on Server-Fgt:

```
config system interface
    edit "port5"
        config ipv6
            set ip6-address 2001:db8:d0c:1::1/64
            set ip6-send-adv enable
            config ip6-prefix-list
                edit 2001:db8:d0c:1::/64
                next
            end
        end
    next
end
```

2. Configure Client-Fgt to automatically obtain an IPv6 address:

```
config system interface
    edit "port5"
        config ipv6
            set autoconf enable
        end
    next
end
```



3. Verify that Client-Fgt automatically generated an IPv6 address:

```
# diagnose ipv6 address list | grep port5
dev=4 devname=port5 flag= scope=0 prefix=64 addr=2001:db8:d0c:1:20c:29ff:fe4d:f83d
preferred=604419 valid=2591619 cstamp=976270 tstamp=979470
```

DHCPv6 stateful server

Similar to a DHCPv4 server, a DHCPv6 server is stateful. It can track client/server states, assign IP addresses to clients, and maintain full control over the process. In addition to assigning IP addresses, a DHCP server can also provide DNS server addresses. However, this IP address assignment method does not support failover protection. If the DHCPv6 server fails, hosts are unable to obtain an IPv6 address, and the network ceases to function. Furthermore, DHCPv6 does not provide gateway information. See RFC 3315 for more information.

In this example, Server-Fgt is connected to Client-Fgt. Server-Fgt has a stateful DHCPv6 server configured that allows Client-Fgt to automatically obtain an IPv6 address and DNS server address using the DHCP option.

To configure a DHCPv6 stateful server in the GUI:

1. Configure the Server-Fgt with DHCPv6 stateful server:
   a. Go to *Network* > *Interfaces* and edit port5.
   b. Configure the following settings:

DHCPv6 Server	Enable
IPv6 subnet	2001:db8:d0c:1::/64
DNS service	Same as System DNS
Stateful server.	Enable
IP mode	IP range
Address range	2001:db8:d0c:1::a to 2001:db8:d0c:1::f

   c. Click *OK*.
2. Configure Client-Fgt to obtain an IPv6 address using DHCP:
   a. Go to *Network* > *Interfaces* and edit port5.
   b. Set *IPv6 addressing mode* to *DHCP*.
   c. Click *OK*.
3. Verify that Client-Fgt obtained an IPv6 address and DNS server address from the DHCPv6 server:
   a. Go to *Network* > *Interfaces* and edit port5. The *Obtained IP/Netmask* and *Acquired DNS* fields are populated with an IPv6 address.

To configure a DHCPv6 stateful server in the CLI:

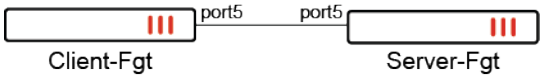
1. Configure Server-Fgt with DHCPv6 stateful server:

```
config system dhcp6 server
    edit 1
        set dns-service default
        set subnet 2001:db8:d0c:1::/64
        set interface "port5"
        config ip-range
            edit 1
                set start-ip 2001:db8:d0c:1::a
                set end-ip 2001:db8:d0c:1::f
            next
        end
    next
end
```

2. Configure Client-Fgt to obtain an IPv6 address using DHCP:

```
config system interface
    edit "port5"
        config ipv6
            set ip6-mode dhcp
        end
    next
end
```

3. Verify that Client-Fgt obtained an IPv6 address and DNS server address from the DHCPv6 server:



```
# diagnose ipv6 address list | grep port5
dev=4 devname=port5 flag=P scope=0 prefix=128 addr=2001:db8:d0c:1::a
preferred=4294967295 valid=4294967295 cstamp=1298969 tstamp=1298969ip6-address
# dia test application dnsproxy 3
worker idx: 0
```

```
VDOM: root, index=0, is primary, vdom dns is enabled, pip-0.0.0.0 dns_log=1
dns64 is disabled
DNS servers:
2001:db8:d0c:1::ff:53 vrf=0 tz=0 encrypt=none req=1 to=1 res=0 rt=0 ready=1 timer=0
probe=0 failure=1 last_failed=19812
```

SLAAC with DHCPv6 stateless server

Using Stateless Address Auto Configuration (SLAAC) with a stateless DHCPv6 server provides a solution for obtaining other host configurations, such as DNS server addresses, while retaining the auto-configuration aspect of SLAAC. This approach also provides failover protection in the event that the DHCPv6 server fails. In addition to obtaining host configurations through the stateless DHCPv6 server, interfaces can also obtain gateway information through Router Advertisements (RAs). This allows for a robust and flexible IPv6 network configuration.

In this example, Server-Fgt is connected to Client-Fgt. Server-Fgt has both SLAAC and stateless DHCPv6 server enabled. This allows Client-Fgt to automatically obtain an IPv6 address using the *Auto configure IPv6 address* option and to acquire a DNS server address using the `dhcp6-information-request` option.

To enable IPv6 auto-configuration with DHCPv6 stateless server in the GUI:

1. Configure SLAAC on Server-Fgt:
   a. Go to *Network* > *Interfaces* and edit port5.
   b. Configure the following settings:

IPv6 addressing mode	Manual
IPv6 Address/Prefix	2001:db8:d0c:1::1/64
Stateless Address Auto-configuration (SLAAC)	Enable
IPv6 prefix list	Enable
IPv6 prefix	2001:db8:d0c:1::/64

   c. Click *OK*.
   d. Input the following commands from the CLI:

```
config system interface
    edit "port5"
        config ipv6
            set ip6-other-flag enable
        end
    next
end
```

2. Configure DHCPv6 stateless server on the Server-Fgt:
   a. Go to *Network* > *Interfaces* and edit port5.
   b. Configure the following settings:

DHCPv6 Server	Enable
DNS service	Same as System DNS
Stateful server	Disable

c. Click *OK*.

3. Configure Client-Fgt to automatically obtain an IPv6 address and DNS server address from the DHCPv6 server:
   a. Go to *Network* > *Interfaces* and edit port5.
   b. Enable *Auto configure IPv6 address*. Client-Fgt uses the prefix obtained from the Server-Fgt interface to automatically generate an IPv6 address.
   c. Input the following commands from the CLI:

```
config system interface
    edit "port5"
        config ipv6
            set dhcp6-information-request enable
        end
    next
end
```

   d. Click *OK*.
4. Verify that Client-Fgt automatically generated an IPv6 address and obtained the DNS server address from the DHCPv6 server:
   a. Go to *Network* > *Interfaces* and edit port5. The IPv6 Address/Prefix field is populated with an IPv6 address
   b. Use the below CLI command to verify the DNS server address:

```
#dia test application dnsproxy 3
worker idx: 0
VDOM: root, index=0, is primary, vdom dns is enabled, pip-0.0.0.0 dns_log=1
dns64 is disabled
DNS servers:
2001:db8:d0c:1::1:53 vrf=0 tz=0 encrypt=none req=1 to=1 res=0 rt=0 ready=1 timer=0
probe=0 failure=1 last_failed=46738
...
```

To enable IPv6 autoconfiguration with DHCPv6 stateless server in the CLI:

1. Configure SLAAC on Server-Fgt:

```
config system interface
    edit "port5"
        config ipv6
            set ip6-address 2001:db8:d0c:1::1/64
            set ip6-send-adv enable
            set ip6-other-flag enable
            config ip6-prefix-list
                edit 2001:db8:d0c:1::/64
            next
        end
    next
end
```

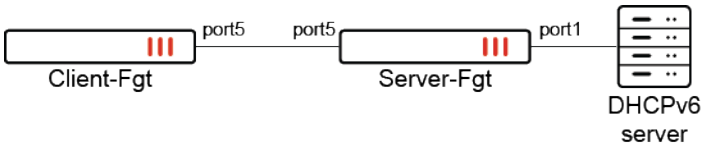
2. Configure DHCPv6 stateless server on the Server-Fgt:

```
config system dhcp6 server
    edit 1
        set dns-service default
        set interface "port5"
    next
end
```

3. Configure the Client-Fgt to obtain an IPv6 address automatically:

```
config system interface
    edit "port5"
        config ipv6
            set autoconf enable
            set dhcp6-information-request enable
        end
    next
end
```

4. Verify that Client-Fgt automatically generated an IPv6 address and obtained the DNS server address from the DHCPv6 server:



```
# diagnose ipv6 address list | grep port5
dev=4 devname=port5 flag= scope=0 prefix=64 addr=2001:db8:d0c:1:20c:29ff:fe4d:f83d
preferred=604681 valid=2591881 cstamp=1675487 tstamp=1772919
# dia test application dnsproxy 3
worker idx: 0
VDOM: root, index=0, is primary, vdom dns is enabled, pip-0.0.0.0 dns_log=1
dns64 is disabled
DNS servers:
2001:db8:d0c:1::1:53 vrf=0 tz=0 encrypt=none req=1 to=1 res=0 rt=0 ready=1 timer=0
probe=0 failure=1 last_failed=46738
…
```

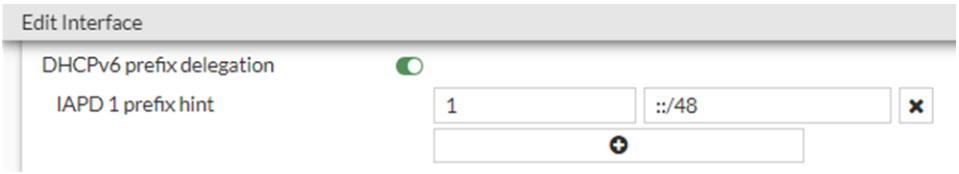
IPv6 prefix delegation

IPv6 prefix delegation allows the dynamic assignment of an address prefix and DNS server address to an upstream interface. An upstream interface is typically the interface that is connected to an Internet Service Provider (ISP). This process also automates the assignment of prefixes to downstream interfaces. A downstream interface is any interface that is not an upstream interface and uses delegated addressing mode. Downstream interfaces can be configured to request specific IPv6 subnets from the upstream interface. Once a downstream interface receives the IPv6 address, other devices connected to the downstream interface can obtain an IPv6 address by using DHCPv6 or by configuring their own IP address using auto-configuration.

In this example, Server-Fgt is connected to a DHCPv6 server provided by the ISP through an upstream interface (port1). Server-Fgt is configured with a delegate interface (port5) to receive the IPv6 prefix and DNS server address from the upstream interface.

A downstream interface (port5) connects Client-Fgt to Server-Fgt. The Client-Fgt interface (port5) is configured to receive the IPv6 address and DNS server address from the Server-FortiGate using DHCP addressing mode or auto-configuration.

Using the GUI or CLI to configure a downstream FortiGate to obtain the IPv6 and DNS server address from delegated interface using DHCP mode requires the following steps:



1. Configure the following items on Server_FGT:
   - Upstream interface
   - Downstream interface
   - DHCPv6 server on the downstream interface.
2. Configure Client_FGT to receive IPv6 prefix and DNS from the delegated interface.

Instead of configuring a DHCPv6 server on the downstream interface of Server_FGT, you can configure SLAAC. See IPv6 prefix delegation with SLAAC on page 557.

GUI configuration

To configure Server_FGT:

1. Configure the upstream interface on Server-Fgt:
   a. Go to *Network* > *Interfaces* and edit the port1.
   b. Enable *DHCPv6 prefix delegation*.
   c. Select the + in the IAPD prefix hint to open the ID and prefix field.
   d. Enter *1* for *ID* and *::/48* for *prefix* field. You can add two or more entries. Select the *x* icon in the field to remove an entry.

   e. Click *OK*.
2. Verify upstream interface obtained the prefix delegation, see Verify upstream interface obtained prefix delegation and DNS server address.
3. Configure the downstream interface on Server-Fgt:
   a. Go to *Network* > *Interfaces* and edit port5.
   b. Set *IPv6 addressing mode* to *Delegated*.
   c. Enter *1* for *Identity association identifier* field.
   d. Set *IPv6 upstream* interface to *port1*.
   e. Click *OK*.
4. Verify downstream interface obtained an IPv6 Address/Prefix:
   a. Go to *Network* > *Interfaces* and edit port5. The IPv6 Address/Prefix field is populated with an IPv6 Address/Prefix.
5. Configure DHCPv6 Server on the downstream interface:
   a. Go to *Network* > *Interfaces* and edit the port5
   b. Enable *DHCPv6 Server*.
   c. Set *DNS service* to *Delegated*.
   d. From the *Upstream interface* dropdown list, select *port1*.
   e. Input the following commands from the CLI:

```
config system dhcp6 server
    edit 1
        set delegated-prefix-iaid 1
    next
end
```

f. Enable *Stateful server*.
g. Set *IP mode* to *Delegated*.
h. Click *OK*.

To configure Client_FGT:

1. Configure the Client-Fgt interface using DHCP mode:
   a. Go to *Network* > *Interfaces* and edit the port5.
   b. Set *IPv6 addressing mode* to *DHCP*. This allows Client_Fgt to obtain the IPv6 prefix and DNS from the delegated interface.
   c. Click *OK*.
2. Verify that Client-Fgt obtained an IPv6 address and the DNS server address from the delegated interface:
   a. Go to *Network* > *Interfaces* and edit port5. The *Obtained IP/Netmask* and *Acquired DNS* fields are populated with an IPv6 address.

CLI configuration

Using the CLI to configure a downstream FortiGate to obtain the IPv6 and DNS server address from delegated interface using DHCP mode requires the following steps:

To configure Server_FGT:

1. Configure the upstream interface on Server-Fgt:

```
config system interface
    edit "port1"
        config ipv6
            set dhcp6-prefix-delegation enable
            config dhcp6-iapd-list
                edit 1
                    set prefix-hint ::/48
                next
            end
        end
    next
end
```

2. Verify upstream interface obtained prefix delegation and DNS server address:

```
config system interface
     edit port1
        config ipv6
Server-Fgt # get
ip6-mode            : static
```

```
…
dhcp6-prefix-delegation: enable
delegated-prefix iaid 1     : 2001:db8:d0c::/48
preferred-life-time         : 4294967295
valid-life-time     : 4294967295
delegated-DNS1      : 2001:db8::35
delegated-DNS2      : ::
…
dhcp6-iapd-list:
    == [ 1 ]
    iaid:     1       prefix-hint: ::/48           prefix-hint-plt: 604800
 prefix-hint-vlt: 2592001
```

3. Configure the downstream interface on Server-Fgt:

```
config system interface
    edit "port5"
        config ipv6
            set ip6-mode delegated
            set ip6-delegated-prefix-iaid 1
            set ip6-upstream-interface "port1"
        end
    next
end
```

4. Verify downstream interface obtained an IPv6 Address/Prefix:

```
config system interface
    edit "port5"
        config ipv6
Server-Fgt # get
ip6-mode            : delegated
nd-mode             : basic
ip6-address         : 2001:db8:d0c::/48
…
ip6-delegated-prefix-iaid: 1
ip6-upstream-interface: port1
ip6-subnet          : ::/0
```

5. Configure DHCPv6 server on the downstream interface:

```
config system dhcp6 server
    edit 1
        set dns-service delegated
        set interface "port5"
        set upstream-interface "port1"
        set delegated-prefix-iaid 1
        set ip-mode delegated
    next
end
```

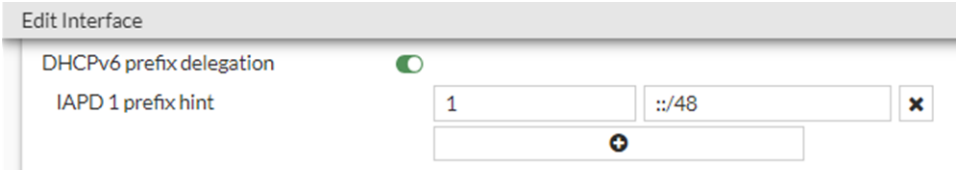
To configure Client_FGT:

1. Configure Client-Fgt interface to use DHCP mode:

```
config system interface
    edit "port5"
        config ipv6
            set ip6-mode dhcp
        end
    next
end
```

2. Verify Client-Fgt obtained an IPv6 address and the DNS server address from the delegated interface:

```
# diagnose ipv6 address list | grep port5
dev=7 devname=port5 flag=P scope=0 prefix=128 addr=2001:db8:d0c::1
preferred=4294967295 valid=4294967295 cstamp=43208325 tstamp=43208325
# dia test application dnsproxy 3
worker idx: 0
VDOM: root, index=0, is primary, vdom dns is enabled, pip-0.0.0.0 dns_log=1
dns64 is disabled
DNS servers:
2001:db8::35:53 vrf=0 tz=0 encrypt=none req=3 to=2 res=0 rt=1046 ready=1 timer=0
probe=0 failure=2 last_failed=65131
```



IPv6 prefix delegation with SLAAC

A downstream FortiGate can be configured to obtain the IPv6 address and DNS server address from a delegated interface using SLAAC instead of DHCPv6. Following is a summary of the configuration steps:

1. Configure the following items on Server_FGT:
   - Upstream interface
   - Downstream interface
   - SLAAC on the downstream interface
2. Configure Client_FGT to receive IPv6 prefix and DNS from the delegated interface.

To configure Server_FGT:

1. Configure the upstream interface on Server-Fgt:
   a. Go to *Network* > *Interfaces* and edit the port1.
   b. Enable *DHCPv6 prefix delegation*.
   c. Select the + in the IAPD prefix hint to open the ID and prefix field.
   d. Enter *1* for *ID* and *::/48* for *prefix* field. You can add two or more entries. Select the *x* icon in the field to remove an entry.

   e. Click *OK*.

2. Verify upstream interface obtained the prefix delegation, see Verify upstream interface obtained prefix delegation and DNS server address.
3. Configure the downstream interface on Server-Fgt:
   a. Go to *Network* > *Interfaces* and edit port5.
   b. Set *IPv6 addressing mode* to *Delegated*.
   c. Enter *1* for *Identity association identifier* field.
   d. Set *IPv6 upstream* interface to *port1*.
   e. Click *OK*.
4. Verify downstream interface obtained an IPv6 Address/Prefix:
   a. Go to *Network* > *Interfaces* and edit port5. The IPv6 Address/Prefix field is populated with an IPv6 Address/Prefix.
5. Configure SLAAC on downstream interface:

```
config system interface
    edit "port5"
        config ipv6
            set ip6-mode delegated
            set ip6-send-adv enable
            set ip6-delegated-prefix-iaid 1
            set ip6-upstream-interface "port1"
            config ip6-delegated-prefix-list
                edit 1
                    set upstream-interface "port1"
                    set delegated-prefix-iaid 1
                    set subnet 0:0:0:1::/64
                    set rdnss-service delegated
                next
            end
        end
    next
end
```

To configure Client_FGT:

1. Configure Client-Fgt interface using auto-configure:

```
config system interface
    edit "port5"
        config ipv6
            set autoconf enable
        end
    next
end
```

2. Verify Client-Fgt automatically generated an IPv6 address and obtained the DNS server address from the delegated interface:

```
# diagnose ipv6 address list | grep port5
```

```
dev=4 devname=port5 flag= scope=0 prefix=64 addr=2000:db8:d0c:1:20c:29ff:fe4d:f847
preferred=4294967295 valid=4294967295 cstamp=17203697 tstamp=17225377
```

FortiGate can send DNS server addresses using Router Advertisement (RA), which allows any device that is capable of receiving DNS server addresses by using RA to obtain DNS server addresses.

Additionally, FortiGate can receive DNS server addresses through the use of SLAAC with a DHCPv6 stateless server, even though it is currently unable to receive DNS server addresses using RA due to RFC 4862 implementation. See SLAAC with DHCPv6 stateless server on page 551 for more information.

NAT66, NAT46, NAT64, and DNS 64

Multiple NAT46 and NAT64 related objects are consolidated into regular objects. A per-VDOM virtual interface, naf.<vdom>, is automatically added to process NAT46 and NAT64 traffic. The features include:

- `vip46` and `vip64` settings are consolidated in `vip` and `vip6` configurations.
- `policy46` and `policy64` settings are consolidated in `firewall policy` settings.
- `nat46` and `nat64` are included in `firewall policy` settings.
- `ippool` and `ippool6` support NAT46 and NAT64 (when enabled, the IP pool should match a subnet).
- Central SNAT supports NAT46 and NAT64.
- `add-nat46-route` in `ippool6` and `add-nat64-route` in `ippool` are enabled by default. The FortiGate generates a static route that matches the IP range in `ippool6` or `ippool` for the naf tunnel interface.

Automatic processing of the naf tunnel interface is not supported in security policies.

To configure NAT46 or NAT64 translation, use the standard `vip` or `vip6` setting, apply it in a firewall policy, enable NAT46 or NAT64, and enter the IP pool to complete the configuration.

The external IP address cannot be the same as the external interface IP address.

This section includes:

- NAT66 policy on page 559
- NAT46 policy on page 561
- NAT64 policy and DNS64 (DNS proxy) on page 564

NAT66 policy

NAT66 is used for translating an IPv6 source or destination address to a different IPv6 source or destination address. NAT66 is not as common or as important as IPv4 NAT, as many IPv6 addresses do not need NAT66 as much as IPv4 NAT. However, NAT66 can be useful for a number of reasons. For example, you may have changed the IP addresses of

some devices on your network but want traffic to still appear to be coming from their old addresses. You can use NAT66 to translate the source addresses of packets from the devices to their old source addresses.

In FortiOS, NAT66 options can be added to an IPv6 security policy. Configuring NAT66 is very similar to configuring NAT in an IPv4 security policy.

To configure NAT66:

1. Go to *Policy & Objects* > *Firewall Policy*.
2. Click *Create New*.
3. Configure the required policy parameters.
4. Enable *NAT* and select *Use Outgoing Interface Address*. For packets that match this policy, its source IP address is translated to the IP address of the outgoing interface.
5. Click *OK*.

Nat66 can also translate one IPv6 source address to another address that is not the same as the address of the existing interface. You can do this using IP pools.

To configure the IPv6 pool:

1. Go to *Policy & Objects* > *IP Pools*.
2. Click *Create New*.
3. Enter the following:

IP Pool Type	IPv6 Pool
Name	test-ippool6-1
External IP Range	2000:172:16:101::1-2000:172:16:101::1

4. Click *OK*.

To use the IPv6 pool in the firewall policy:

1. Go to *Policy & Objects* > *Firewall Policy*.
2. Click *Create New* or edit an existing policy.
3. Configure the required policy parameters.
4. Enable *NAT* and select *Use Dynamic IP Pool*.
5. Click *OK*.

NAT66 destination address translation

NAT66 can also be used to translate destination addresses. This is done in an IPv6 policy by using IPv6 virtual IPs. For example, the destination address 2001:db8::dd can be mapped to 2001:db8::ee.

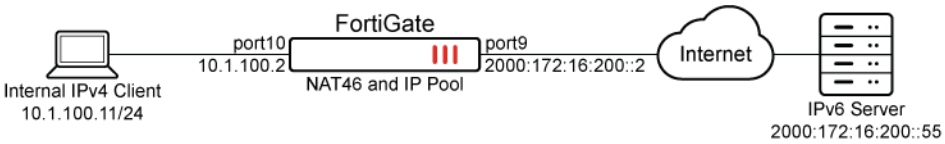
To configure the IPv6 VIP:

1. Go to *Policy & Objects* > *Virtual IPs*.
2. Click *Create New*.

3. Enter the following:

VIP type	IPv6
Name	example-vip6
External IP address/range	2001:db8::dd
Map to IPv6 address/range	2001:db8::ee

4. Click *OK*.



To use the IPv6 VIP in the firewall policy:

1. Go to *Policy & Objects* > *Firewall Policy*.
2. Click *Create New* or edit an existing policy.
3. Configure the required policy parameters.
4. In the *Destination* field, select *example-vip6* from the dropdown menu.
5. Click *OK*.

NAT46 policy

NAT46 refers to the mechanism that allows IPv4 addressed hosts to communicate with IPv6 hosts. Without such a mechanism, IPv4 environments cannot connect to IPv6 networks.

Sample topology

In this example, an IPv4 client tries to connect to an IPv6 server. A VIP is configured on FortiGate to map the server IPv6 IP address `2000:172:16:200:55` to an IPv4 address `10.1.100.55`. On the other side, an IPv6 IP pool is configured and the source address of packets from client are changed to the defined IPv6 address. In this setup, the client PC can access the server by using IP address `10.1.100.55`.

Sample configuration

To configure NAT46 in the GUI:

1. Enable IPv6:
   a. Go to *System* > *Feature Visibility*.
   b. In the *Core Features* section, enable *IPv6*.
   c. Click *Apply*.
2. Configure the VIP:

a. Go to *Policy & Objects* > *Virtual IPs* and click *Create New* > *Virtual IP*.
b. Enter the following:

VIP type	IPv4
Name	vip46_server
Interface	port2
Type	Static NAT
External IP address/range	10.1.100.55
Map to IPv6 address/range	2000:172:16:200::55

c. Click *OK*.

3. Configure the IPv6 IP pool:
a. Go to *Policy & Objects* > *IP Pools* and click *Create New*.
b. Enter the following:

IP Pool Type	IPv6 Pool
Name	client_external
External IP address/range	2000:172:16:201::-2000:172:16:201::7
NAT46	Enable

c. Click *OK*.

4. Configure the firewall policy:
a. Go to *Policy & Objects* > *Firewall Policy* and click *Create New*.
b. Enter the following:

Name	policy46-1
Incoming Interface	port10
Outgoing Interface	port9
Source	all
Destination	vip46_server
Schedule	always
Service	ALL
Action	ACCEPT
NAT	NAT46
IP Pool Configuration	client_external

c. Configure the other settings as needed.
d. Click *OK*.

To configure NAT46 in the CLI:

1. Enable IPv6:

```
config system global
    set gui-ipv6 enable
end
```

2. Configure the VIP:

```
config firewall vip
    edit "vip46_server"
        set extip 10.1.100.55
        set nat44 disable
        set nat46 enable
        set extintf "port2"
        set ipv6-mappedip 2000:172:16:200::55
    next
end
```

3. Configure the IPv6 IP pool:

```
config firewall ippool6
    edit "client_external"
        set startip 2000:172:16:201::
        set endip 2000:172:16:201::7
        set nat46 enable
    next
end
```

4. Configure the firewall policy:

```
config firewall policy
    edit 2
        set name "policy46-1"
        set srcintf "port10"
        set dstintf "port9"
        set action accept
        set nat46 enable
        set srcaddr "all"
        set dstaddr "vip46_server"
        set srcaddr6 "all"
        set dstaddr6 "all"
        set schedule "always"
        set service "ALL"
        set logtraffic all
        set auto-asic-offload disable
        set ippool enable
        set poolname6 "client_external"
    next
end
```

Sample troubleshooting

To trace the flow and troubleshoot:

```
# diagnose debug flow filter saddr 10.1.100.11
# diagnose debug flow show function-name enable
show function name
# diagnose debug flow show iprope enable
show trace messages about iprope
# diagnose debug flow trace start 5

NAT64 policy and DNS64 (DNS proxy)

NAT64 policy translates IPv6 addresses to IPv4 addresses so that a client on an IPv6 network can communicate transparently with a server on an IPv4 network.

NAT64 policy is usually implemented in combination with the DNS proxy called DNS64. DNS64 synthesizes AAAA records from A records and is used to synthesize IPv6 addresses for hosts that only have IPv4 addresses. DNS proxy and DNS64 are interchangeable terms.

Sample topology

In this example, a host on the internal IPv6 network communicates with `ControlPC.qa.fortinet.com` that only has IPv4 address on the Internet. Central NAT is disabled.

1. The host on the internal network does a DNS lookup for `ControlPC.qa.fortinet.com` by sending a DNS query for an AAAA record for `ControlPC.qa.fortinet.com`.
2. The DNS query is intercepted by the FortiGate DNS proxy. The DNS proxy performs an A-record query for `ControlPC.qa.fortinet.com` and gets back an RRSet containing a single A record with the IPv4 address `172.16.200.55`.
3. The DNS proxy then synthesizes an AAAA record. The IPv6 address in the AAAA record begins with the configured NAT64 prefix in the upper 96 bits and the received IPv4 address in the lower 32 bits. By default, the resulting IPv6 address is `64:ff9b::172.16.200.55`.
4. The host on the internal network receives the synthetic AAAA record and sends a packet to the destination address `64:ff9b::172.16.200.55`.
5. The packet is routed to the FortiGate internal interface (port10) where it is accepted by the NAT64 security policy.
6. The FortiGate translates the destination address of the packets from IPv6 address `64:ff9b::172.16.200.55` to IPv4 address `172.16.200.55` and translates the source address of the packets to `172.16.200.200` (or another address in the IP pool range) and forwards the packets out the port9 interface to the Internet.

Sample configuration

To configure a NAT64 policy with DNS64 in the GUI:

1. Enable IPv6 and DNS database:
   a. Go to *System* > *Feature Visibility*.
   b. In the *Core Features* section, enable *IPv6*.
   c. In the *Additional Features* section, enable *DNS Database*.
   d. Click *Apply*.
2. Enable DNS proxy on the IPv6 interface:
   a. Go to *Network* > *DNS Servers*.
   b. In the *DNS Service on Interface* table, click *Create New*.
   c. For *Interface*, select *port10*.
   d. For *Mode*, select *Forward to System DNS*.
   e. Click *OK*.
3. Configure the IPv6 DHCP server:

a. Go to *Network* > *Interfaces* and edit port10.
b. Enable *DHCPv6 Server* and enter the following:

IPv6 subnet	2001:db8:1::/64
DNS service	Specify
DNS server 1	2001:db8:1::10

c. Click *OK*.

4. Configure the IPv6 VIP for the destination IPv6 addresses:

   These are all of the IPv6 addresses that the FortiGate DNS proxy synthesizes when an IPv6 device performs a DNS query that resolves to an IPv4 Address. In this example, the synthesized IPv6 address in the AAAA record begins with the configured NAT64 prefix in the upper 96 bits, so the VIP is for all the IPv6 addresses that begin with 64:ff9b.

   a. Go to *Policy & Objects* > *Virtual IPs* and click *Create New* > *Virtual IP*.
   b. Enter the following:

VIP type	IPv6
Name	vip6
Eternal IP address/range	64:ff9b::-64:ff9b::ffff:ffff
Map to IPv4 address/range	Use Embedded

   c. Click *OK*.

5. Configure the IPv6 firewall address for the internal network:

   a. Click *Create New* > *Address*.
   b. Enter the following:

Category	IPv6 Address
Name	internal-net6
Type	IPv6 Subnet
IP/Netmask	2001:db8:1::/48

   c. Click *OK*.

6. Configure the IP pool containing the IPv4 address that is used as the source address of the packets exiting port9:

   a. Go to *Policy & Objects* > *IP Pools* and click *Create New*.
   b. Enter the following:

IP Pool Type	IPv4 Pool
Name	exit-pool4
Type	Overload
External IP address/range	172.16.200.200-172.16.200.207
NAT64	Enable

External IP address/range must start and end on the boundaries of a valid subnet. For example, 172.16.200.0-172.16.200.7 and 172.16.200.16-172.16.200.31 are a valid subnets (/29 and /28 respectively).

c. Click *OK*.

7. Configure the NAT64 policy:
   a. Go to *Policy & Objects* > *Firewall Policy* and click *Create New*.
   b. Enter the following:

Name	policy64-1
Incoming Interface	port10
Outgoing Interface	port9
Source	internal-net6
Destination	vip6
Schedule	always
Service	ALL
Action	ACCEPT
NAT	NAT64
IP Pool Configuration	exit-pool4

   c. Click *OK*.

To configure a NAT64 policy with DNS64 in the CLI:

1. Enable IPv6 and DNS database:

```
config system global
   set gui-ipv6 enable
end

config system settings
   set gui-dns-database enable
end
```

2. Enable DNS proxy on the IPv6 interface:

```
config system dns-server
   edit "port10"
       set mode forward-only
   next
end
```

3. Configure the IPv6 DHCP server:

```
config system dhcp6 server
   edit 1
       set subnet 2001:db8:1::/64
       set interface "port10"
       set dns-server1 2001:db8:1::10
```

```
   next
end
```

4. Configure the IPv6 VIP for the destination IPv6 addresses:

```
config firewall vip6
    edit "vip6"
        set extip 64:ff9b::-64:ff9b::ffff:ffff
        set embedded-ipv4-address enable
    next
end
```

5. Configure the IPv6 firewall address for the internal network:

```
config firewall address6
    edit "internal-net6"
        set ip6 2001:db8:1::/48
    next
end
```

6. Configure the IP pool containing the IPv4 address that is used as the source address of the packets exiting port9:

```
config firewall ippool
    edit "exit-pool4"
        set startip 172.16.200.200
        set endip 172.16.200.207
        set nat64 enable
    next
end
```

External IP address/range must start and end on the boundaries of a valid subnet. For example, 172.16.200.0-172.16.200.7 and 172.16.200.16-172.16.200.31 are a valid subnets (/29 and /28 respectively).

7. Configure the NAT64 policy:

```
config firewall policy
    edit 1
        set name "policy64-1"
        set srcintf "port10"
        set dstintf "port9"
        set action accept
        set nat64 enable
        set srcaddr "all"
        set dstaddr "all"
        set srcaddr6 internal-net6
        set dstaddr6 vip6
        set schedule "always"
        set service "ALL"
        set ippool enable
        set poolname "exit-pool4"
    next
end
```

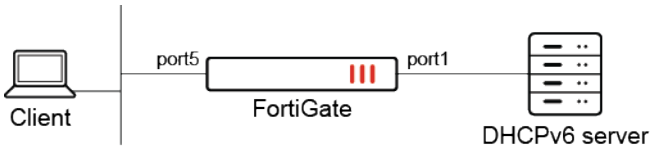
To enable DNS64 and related settings using the CLI:

Enabling DNS64 means that all IPv6 traffic received by the current VDOM can be subject to NAT64 if the source and destination address matches an NAT64 security policy.

By default, the setting `always-synthesize-aaaa-record` is enabled. If you disable this setting, the DNS proxy (DNS64) will attempt to find an AAAA records for queries to domain names and therefore resolve the host names to IPv6 addresses. If the DNS proxy cannot find an AAAA record, it synthesizes one by adding the NAT64 prefix to the A record.

```
config system dns64
    set status {enable | disable}
    set dns64-prefix <ipv6-prefix>
    set always-synthesize-aaaa-record {enable | disable}
end
```

By default, the `dns64-prefix` is `64:ff9b::/96`.



DHCPv6 relay

Similar to DHCPv4, DHCPv6 facilities communication between networks by relaying queries and responses between a client and a DHCP server on separate networks. The FortiGate device serves as a DHCPv6 relay agent and forwards DHCPv6 messages between clients and servers. The relay agent receives DHCPv6 messages from clients and forwards them to the appropriate DHCPv6 server. In response, the server sends a message containing configuration information for the client, which the relay agent forwards to the client. This enables seamless information exchange between the two networks.

Configure DHCPv6 relay in the CLI using the following syntax:

```
config system interface
    edit <interface>
        config ipv6
            set dhcp6-relay-service {enable|disable}
            set dhcp6-relay-type regular
            set dhcp6-relay-ip <ip6-address>
        end
    next
end
```

In this example, a client connects to a FortiGate device that is configured to function as a DHCPv6 relay. Port1 on the FortiGate device connects to a DHCPv6 server, and port5 is configured as a DHCPv6 relay. The DHCPv6 server has an IP address of 2000:db8:d0c::a. This configuration enables the FortiGate device to facilitate communication between the client and the DHCPv6 server on separate networks.

To configure DHCPv6 relay on the FortiGate:

```
config system interface
    edit port5
        config ipv6
            set dhcp6-relay-service enable
```

```
            set dhcp6-relay-type regular
            set dhcp6-relay-ip 2000:db8:d0c::a
        end
    next
end
```

IPv6 tunneling

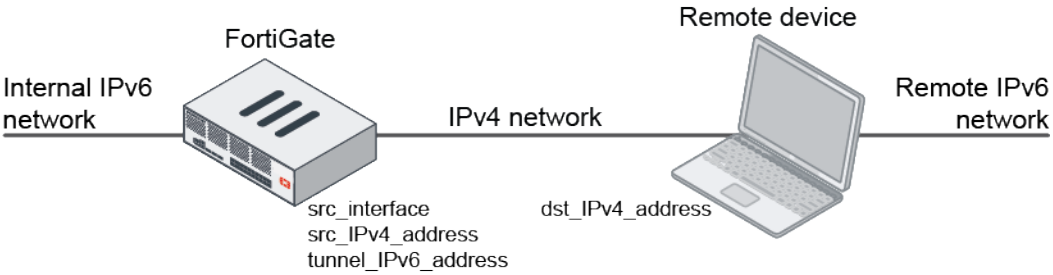
IPv6 tunneling involves tunneling IPv6 packets from an IPv6 network through an IPv4 network to another IPv6 network. This is different than NAT because once the packet reaches its final destination, the true originating address of the sender is still readable. The IPv6 packets are encapsulated within packets with IPv4 headers that carry their IPv6 payload through the IPv4 network. IPv6 tunneling is suitable in networks that have completely transitioned over to IPv6 but need an internet connection, which is still mostly IPv4 addresses.

Both IPv6 tunneling devices, whether they are a host or a network device, must be dual stack compatible. The tunneling process is as follows:

1. The tunnel entry node creates an encapsulating IPv4 header and transmits the encapsulated packet.
2. The tunnel exit node receives the encapsulated packet.
3. The IPv4 header is removed.
4. The IPv6 header is updated and the IPv6 packet is processed.

There are two types of tunnels in IPv6 tunneling, automatic and configured. Automatic tunnels are configured by using IPv4 address information embedded in an IPv6 address. The IPv6 address of the destination host includes information about which IPv4 address the packet should be tunneled to. Configured tunnels are manually configured, and they are used for IPv6 addresses that do not have any embedded IPv4 information. The IPv6 and IPv4 addresses of the tunnel endpoints must be specified.

Tunnel configurations



There are four tunneling configurations available depending on which segment of the path between the endpoints of the session the encapsulation takes place.

Type	Description
Network device-to-network device	Dual stack capable devices connected by an IPv4 infrastructure can tunnel IPv6 packets between themselves. The tunnel spans one segment of the path taken by the IPv6 packets.
Host-to-network device	Dual stack capable hosts can tunnel IPv6 packets to an intermediary IPv6 or IPv4 network device that is reachable through an IPv4 infrastructure. The tunnel spans the first segment of the path taken by the IPv6 packets.
Host-to-host	Dual stack capable hosts that are interconnected by an IPv4 infrastructure can tunnel IPv6 packets between themselves. The tunnel spans the entire path taken by the IPv6 packets.
Network device-to-host	Dual stack capable network devices can tunnel IPv6 packets to their final destination IPv6 or IPv4 host. The tunnel spans only the last segment of the path taken by the IPv6 packets.

Regardless of whether the tunnel starts at a host or a network device, the node that does the encapsulation needs to maintain soft state information, such as the maximum transmission unit (MTU), about each tunnel in order to process the IPv6 packets.

6in4 tunnel

The following tunnel configuration tunnels IPv6 traffic over an IPv4 network. An internal IPv6 interface can be configured under `config system interface`.

To configure an IPv6 tunnel over IPv4:

```
config system sit-tunnel
    edit <name>
        set source <src_IPv4_address>
        set destination <dst_IPv4_address>
        set interface <src_interface>
        set ip6 <tunnel_IPv6_address>
    next
end
```

4in6 tunnel

Conversely, the following tunnel configuration tunnels IPv4 traffic over an IPv6 network.

To configure an IPv4 tunnel over IPv6:

```
config system ipv6-tunnel
    edit <name>
        set source <src_IPv6_address>
        set destination <dst_IPv6_address>
        set interface <src_interface>
    next
end
```

The preceding configurations are not available in transparent mode.

This section includes:

- Configuring IPv4 over IPv6 DS-Lite service on page 576

IPv6 IPsec VPN

This topic describes how to configure the IPv6 IPsec VPN feature on your FortiGate device.

You can configure IPv6 using the CLI. To configure IPv6 using GUI, ensure IPv6 is enabled by going to *System* > *Feature Visibility* and enabling IPv6.

Overview

FortiOS supports route-based IPv6 IPsec, but not policy-based. This section describes different ways IPv6 IPsec can be used:

IPv4 over IPv6	The VPN gateways have IPv6 addresses. The protected networks have IPv4 addresses. The phase 2 configurations at either end use IPv4 selectors. See Site-to-site IPv4 over IPv6 VPN example on page 596 for sample configuration.
IPv6 over IPv4	The VPN gateways have IPv4 addresses. The protected networks use IPv6 addresses. The phase 2 configurations at either end use IPv6 selectors. See Site-to-site IPv6 over IPv4 VPN example on page 605 for sample configuration.
IPv6 over IPv6	Both the VPN gateways and the protected networks use IPv6 addresses. The phase 2 configurations at either end use IPv6 selectors. See Site-to-site IPv6 over IPv6 VPN example on page 588 for sample configuration.

Configuring IPv6 IPsec VPNs

Configuration of an IPv6 IPsec VPN follows the same sequence as for an IPv4 route-based VPN:

Phase 1 and Phase 2 settings	The configuration is the same as for an IPv4 route-based VPN, except that `ip-version` is set to `6` and the `remote-gw6` keyword is used to specify an IPv6 remote gateway address. See Phase 1 configuration on page 1576 and Phase 2 configuration on page 1590 for more information.
Security policies	To complete the VPN configuration, you need a security policy in each direction to permit traffic between the protected network's port and the IPsec interface. You need IPv6 policies unless the VPN is IPv4 over IPv6. See VPN security policies on page 1594 for more information.
Routing	Appropriate routing is needed for both the IPsec packets and the encapsulated traffic within them: • You need a route, which could be the default route, to the remote VPN gateway via the appropriate interface. • You need a route to the remote protected network via the IPsec interface.

- You need a blackhole route to the remote protected network to ensure that IPsec traffic doesn't match the default route when the IPsec tunnel is down.

Routing is dependent on the method:

- **IPv4 over IPv6**: The route to the remote VPN gateway is an IPv6 route. The route to the remote protected network is an IPv4 route.
- **IPv6 over IPv4**: The route to the remote VPN gateways is an IPv4 route. The route to the remote protected network is an IPv6 route.
- **IPv6 over IPv6**: Routes to both the remote VPN gateway and the remote protected network are IPv6 routes.

You can create a new IPv6 static route from *Network* > *Static Routes*.

You can configure Phase 1 and Phase 2 settings from *VPN* > *IPsec Wizard*.

To configure Phase 1 and phase 2 settings:

1. Go to *VPN* > *IPsec Wizard*.
2. Enter a name and set *Template type* to *Custom*.
3. Click *Next*.
4. Under *Network*, set *IP Version* to *IPv6* .
5. Configure the rest of phase 1 and phase 2 settings as required and click *OK*.

IPv6 GRE tunnels

IPv6 addresses can be used at both ends of a GRE tunnel in the same way as with IPv4. See GRE over IPsec on page 1621 for more information.

The configuration is similar to a tunnel for IPv4. However, when you configure the specific tunnel, you need to set the `ip-version` option to `6`. This will enable IPv6-specific options for the tunnel.

To configure a GRE tunnel:

```
config system gre-tunnel
    edit <name of tunnel>
        set ip-version 6
        set remote-gw6 <IPv6 address of the remote gateway>
        set local-gw6 <IPv6 address of the local gateway>
    next
end
```

IPv6 tunnel inherits MTU based on physical interface

The MTU of an IPv6 tunnel interface is calculated from the MTU of its parent interface minus headers.

Example

In this topology, FortiGate B and FortiGate D are connected over an IPv6 network. An IPv6 tunnel is formed, and IPv4 can be used over the IPv6 tunnel. The tunnel interface MTU is based on the physical interface MTU minus the IP and TCP headers (40 bytes). On FortiGate B's physical interface port5, the MTU is set to 1320. The IPv6 tunnel is based on port5, and its MTU value of 1280 is automatically calculated from the MTU value of its physical interface minus the header. The same is true for port3 on FortiGate D.

To verify the MTU for the IPv6 tunnel on FortiGate B:

1. Configure port5:

```
config system interface
    edit "port5"
        set vdom "root"
        set type physical
        set snmp-index 7
        config ipv6
            set ip6-address 2000:172:16:202::1/64
            set ip6-allowaccess ping
        end
        set mtu-override enable
        set mtu 1320
    next
end
```

2. Configure the IPv6 tunnel:

```
config system ipv6-tunnel
    edit "B_2_D"
        set source 2000:172:16:202::1
        set destination 2000:172:16:202::2
        set interface "port5"
    next
end
```

3. Configure the tunnel interface:

```
config system interface
    edit "B_2_D"
        set vdom "root"
        set ip 172.16.210.1 255.255.255.255
        set allowaccess ping https http
        set type tunnel
        set remote-ip 172.16.210.2 255.255.255.255
        set snmp-index 33
        config ipv6
            set ip6-address 2000:172:16:210::1/64
            set ip6-allowaccess ping
            config ip6-extra-addr
```

```
                edit fe80::2222/10
                next
            end
        end
        set interface "port5"
    next
end
```

4. Verify the interface lists:

```
# diagnose netlink interface list port5

To verify the MTU for the IPv6 tunnel on FortiGate D:

1. Configure port3:

```
config system interface
    edit "port3"
        set vdom "root"
        set type physical
        set snmp-index 5
        config ipv6
            set ip6-address 2000:172:16:202::2/64
            set ip6-allowaccess ping
        end
        set mtu-override enable
        set mtu 1320
    next
end
```

2. Configure the IPv6 tunnel:

```
config system ipv6-tunnel
    edit "D_2_B"
        set source 2000:172:16:202::2
        set destination 2000:172:16:202::1
        set interface "port3"
```

```
        next
    end
```

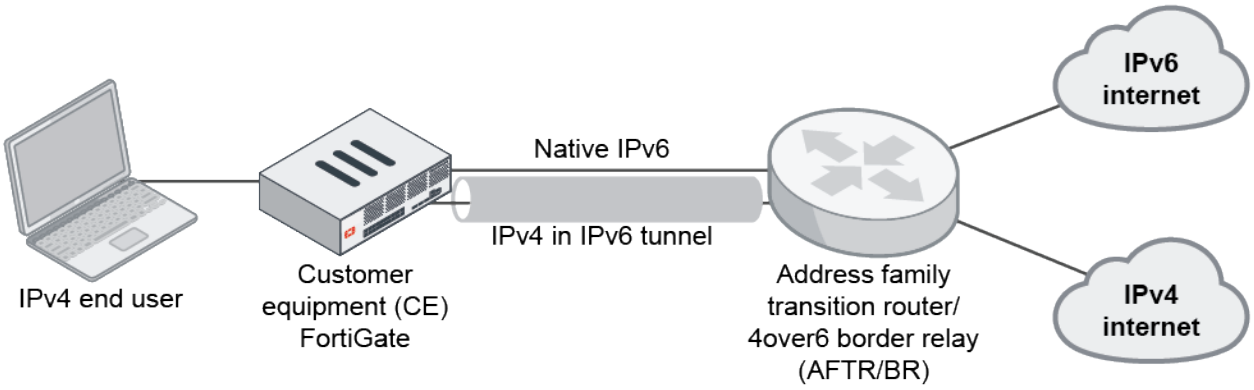
3. Configure the tunnel interface:

```
config system interface
    edit "D_2_B"
        set vdom "root"
        set ip 172.16.210.2 255.255.255.255
        set allowaccess ping https http
        set type tunnel
        set remote-ip 172.16.210.1 255.255.255.255
        set snmp-index 36
        config ipv6
            set ip6-address 2000:172:16:210::2/64
            set ip6-allowaccess ping
            config ip6-extra-addr
                edit fe80::4424/10
                next
            end
        end
        set interface "port3"
    next
end
```

4. Verify the interface lists:

```
# diagnose netlink interface list port3
```

```
# diagnose netlink interface list D_2_B
```



Configuring IPv4 over IPv6 DS-Lite service

IPv4 over IPv6 DS-Lite service can be configured on a virtual network enabler (VNE) tunnel. In addition, VNE tunnel fixed IP mode supports username and password authentication.

```
config system vne-tunnel
    set status enable
    set mode {map-e | fixed-ip | ds-lite}
    set ipv4-address <IPv4_address>
    set br <IPv6_address or FQDN>
    set http-username <string>
    set http-password <password>
end
```

`mode {map-e | fixed-ip | ds-lite}`	Set the VNE tunnel mode: • map-e: MAP-E • fixed-ip: fixed IP • ds-lite: DS-Lite
`ipv4-address <IPv4_address>`	Enter the tunnel IPv4 address and netmask. This setting is optional.
`br <IPv6_address or FQDN>`	Enter the IPv6 or FQDN of the border relay.
`http-username <string>`	Enter the HTTP authentication user name.
`http-password <password>`	Enter the HTTP authentication password.

DS-Lite allows applications using IPv4 to access the internet with IPv6. DS-Lite is supported by internet providers that do not have enough public IPv4 addresses for their customers, so DS-Lite is used for IPv6 internet connections. When a DS-Lite internet connections is used, the FortiGate encapsulates all data from IPv4 applications into IPv6 packets. The packets are then transmitted to the internet service provider using the IPv6 connection. Next, a dedicated server unpacks the IPv6 packets and forwards the IPv4 data to the actual destination on the internet.

DS-Lite example

In this example, DS-Lite VNE tunnel mode is used between the FortiGate and the BR.

To configure a DS-Lite tunnel between the FortiGate and the BR:

1. Configure the IPv6 interface:

```
config system interface
    edit "wan1"
        set vdom "root"
        set mode dhcp
        set allowaccess ping fgfm
        set type physical
        set role wan
        set snmp-index 1
        config ipv6
            set ip6-allowaccess ping
            set dhcp6-information-request enable
            set autoconf enable
            set unique-autoconf-addr enable
        end
    next
end
```

2. Configure the VNE tunnel:

```
config system vne-tunnel
    set status enable
    set interface "wan1"
    set ssl-certificate "Fortinet_Factory"
    set auto-asic-offload enable
    set ipv4-address 192.168.1.99 255.255.255.255
    set br "dgw.xxxxx.jp"
    set mode ds-lite
end
```

3. View the wan1 IPv6 configuration details:

```
config system interface
    edit "wan1"
        config ipv6
            get
                ip6-mode            : static
                nd-mode             : basic
                ip6-address         : 2001:f70:2880:xxxx:xxxx:xxxx:fe39:ccd2/64
                ip6-allowaccess     : ping
                icmp6-send-redirect : enable
                ra-send-mtu         : enable
                ip6-reachable-time  : 0
                ip6-retrans-time    : 0
                ip6-hop-limit       : 0
                dhcp6-information-request: enable
                cli-conn6-status    : 1
                vrrp-virtual-mac6   : disable
                vrip6_link_local    : ::
                ip6-dns-server-override: enable
                Acquired DNS1       : 2001:f70:2880:xxxx:xxxx:xxxx:fe40:9082
                Acquired DNS2       : ::
                ip6-extra-addr:
                ip6-send-adv        : disable
                autoconf            : enable
                prefix      : 2001:f70:2880:xxxx::/64
                preferred-life-time         : 942735360
                valid-life-time     : 1077411840
                unique-autoconf-addr: enable
                interface-identifier: ::
                dhcp6-relay-service : disable
        end
    next
end
```

4. Verify the IPv6 address list:

```
# diagnose ipv6 address list
dev=5 devname=wan1 flag= scope=0 prefix=64 addr=2001:f70:2880:xxxx:xxxx:xxxx:fe39:ccd2
preferred=11525 valid=13325 cstamp=6520 tstamp=6892
dev=5 devname=wan1 flag=P scope=253 prefix=64 addr=fe80::xxxx:xxxx:fe39:ccd2
preferred=4294967295 valid=4294967295 cstamp=6373 tstamp=6373
dev=18 devname=root flag=P scope=254 prefix=128 addr=::1 preferred=4294967295
valid=4294967295 cstamp=3531 tstamp=3531
dev=25 devname=vsys_ha flag=P scope=254 prefix=128 addr=::1 preferred=4294967295
valid=4294967295 cstamp=5604 tstamp=5604
dev=27 devname=vsys_fgfm flag=P scope=254 prefix=128 addr=::1 preferred=4294967295
valid=4294967295 cstamp=6377 tstamp=6377
```

5. Test the tunnel connection by pinging the Google public DNS IPv6 address:

```
# execute ping6 2001:4860:4860::8888
PING 2001:4860:4860::8888(2001:4860:4860::8888) 56 data bytes
64 bytes from 2001:4860:4860::8888: icmp_seq=1 ttl=114 time=6.89 ms
64 bytes from 2001:4860:4860::8888: icmp_seq=2 ttl=114 time=3.39 ms
64 bytes from 2001:4860:4860::8888: icmp_seq=3 ttl=114 time=3.46 ms
64 bytes from 2001:4860:4860::8888: icmp_seq=4 ttl=114 time=3.34 ms
64 bytes from 2001:4860:4860::8888: icmp_seq=5 ttl=114 time=3.39 ms
--- 2001:4860:4860::8888 ping statistics ---
5 packets transmitted, 5 packets received, 0% packet loss, time 4079ms
rtt min/avg/max/mdev = 3.340/4.097/6.895/1.400 ms
```

Fixed IP mode example

In this example, fixed IP VNE tunnel mode with HTTP authentication is used between the FortiGate and the BR.

To configure a fixed IP mode with HTTP authentication between the FortiGate and the BR:

1. Configure the IPv6 interface:

```
config system interface
    edit "wan1"
        set vdom "root"
        set mode dhcp
        set allowaccess ping fgfm
        set type physical
        set role wan
        set snmp-index 1
        config ipv6
            set ip6-allowaccess ping
            set dhcp6-information-request enable
            set autoconf enable
        end
    next
end
```

2. Configure the VNE tunnel:

```
config system vne-tunnel
    set status enable
    set interface "wan1"
    set ipv4-address 120.51.xxx.xxx1 255.255.255.255
    set br "2001:f60:xxxx:xxxx::1"
    set update-url "https://ddnsweb1.ddns.xxxxxx.jp/cgi-bin/ddns_
api.cgi?d=xxxxxx.v4v6.xxxxx.jp&p=**********&a=[IP6]&u=xxxxxx.v4v6.xxxxx.jp"
    set mode fixed-ip
    set http-username "laptop-1"
    set http-password **********
end
```

3. Verify the wan1 IPv6 configuration details:

```
config system interface
    edit "wan1"
        config ipv6
```

```
            get
                ....
```

4. Verify the VNE daemon:

```
# diagnose test application vned 1
------------------------------------------------------------------------------
vdom: root/0, is master, devname=wan1 link=0 tun=vne.root mode=fixed-ip ssl_
cert=Fortinet_Factory
end user ipv6 perfix: 2001:f70:2880:xxxx::/64
interface ipv6 addr: 2001:f70:2880:xxxx:xxxx:xxxx:fe39:ccd2
config ipv4 perfix: 120.51.xxx.xxx1/255.255.255.255
config br: 2001:f60:xxxx:xxxx::1
HTTP username: laptop-1
update url: https://ddnsweb1.ddns.xxxxxx.jp/cgi-bin/ddns_
api.cgi?d=xxxxxx.v4v6.xxxxx.jp&p=**********&a=[IP6]&u=xxxxxx.v4v6.xxxxx.jp

5 packets transmitted, 5 packets received, 0% packet loss, time 4039ms
rtt min/avg/max/mdev = 3.276/4.195/6.992/1.409 ms
```

IPv6 configuration examples

The following topics provide instructions on different IPv6 configuration examples:

- IPv6 quick start example on page 581
- Site-to-site IPv6 over IPv6 VPN example on page 588
- Site-to-site IPv4 over IPv6 VPN example on page 596
- Site-to-site IPv6 over IPv4 VPN example on page 605

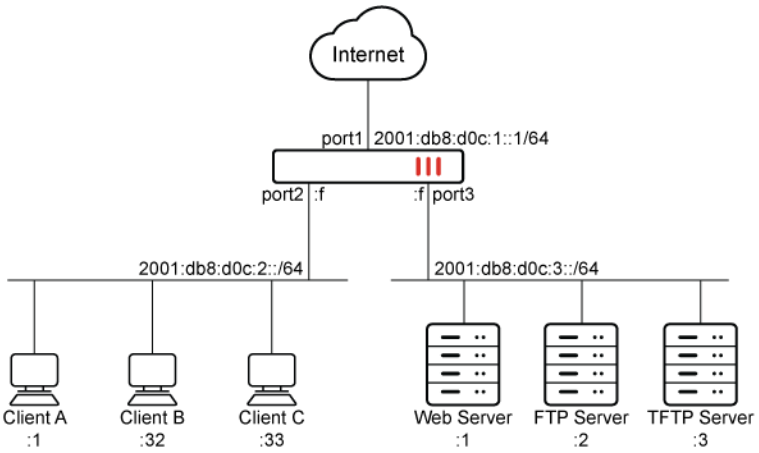
IPv6 quick start example

In this example, a host belonging to a specific range on the internal IPv6 network can communicate exclusively with the web server and FTP server.

Additionally, all internal clients can access the Internet.

Prerequisites

Before you begin to configure IPv6, go through the following steps:



1. Obtain an IPv6 /48 global routing prefix, commonly known as a site prefix. To procure a 48-bit IPv6 site prefix for your organization simply liaise with your ISP.
2. Design a subnetting plan for your organization's IPv6 network using a 16-bit subnet ID, allowing for up to 65 535 subnets. The specific scheme will depend on the network's size, structure, and the organization's needs.

At this stage, the following installation and configuration conditions are assumed:

- You have administrative access to the GUI or CLI.
- The FortiGate unit is incorporated into your WAN or other networks, but for simplicity, only the standalone ForiGate configuration is displayed.

Topology

The following topology is used for this example:

- The company is assigned the site prefix of 2001:db8:d0c::/48 by their ISP.
- The IPv6 address for the Web Server is 2001:db8:d0c:3::1/64.
- The IPv6 address for the FTP Server is 2001:db8:d0c:3::2/64.
- The IPv6 address for the TFTP Server is 2001:db8:d0c:3::3/64.
- The range on the internal IPv6 network that can access both servers is from 2001:db8:d0c:2::1 to 2001:db8:d0c:2::32.
- The IPv6 address of port1 is 2001:db8:d0c:1::1/64.
- The IPv6 address of port2 is 2001:db8:d0c:2::f/64.
- The IPv6 address of port3 is 2001:db8:d0c:3::f/64.
- The IPv6 address of the default gateway is 2001:db8:d0c:1::f/64.

Please note that the IPv6 addresses used in this example are for illustrative purposes only and should not be used in your environment.

The 2001:db8::/32 prefix is a special IPv6 prefix designated for use in documentation examples. See RFC 3849 for more information.

To configure the example in the GUI:

1. Configure the IPv6 address on port1, port2 and port3:
   a. Go to *Network* > *Interfaces* and edit port1.
   b. For *IPv6 addressing Mode*, select manual and enter the *IPv6 Address/Prefix*.

IPv6 Address/Prefix	2001:db8:d0c:1::1/64

   c. Click *OK*.
   d. Repeat steps a and b for port2.

IPv6 Address/Prefix	2001:db8:d0c:2::f/64

   e. Repeat steps a and b for port3.

IPv6 Address/Prefix	2001:db8:d0c:3::f/64

2. Configure the default route:

a. Go to *Network* > *Static Routes*.
b. Click *Create New* > *IPv6 Static Route*.
c. Configure the following settings:

Destination	::/0
Gateway Address	2001:db8:d0c:1::f
Interface	port1

d. Select *OK*.

3. Configure the IPv6 firewall address for the Web Server:
   a. Go to *Policy & Objects* > *Addresses*.
   b. Select *Create New* > *Address*.
   c. Select *IPv6 Address* and fill out the fields with the following information:

Name	Web_Server
Type	IPv6 Subnet
IPv6 Address	2001:db8:d0c:3::1/128

   d. Select *OK*.
4. Configure the IPv6 firewall address for the FTP Server:
   a. Go to *Policy & Objects* > *Addresses*.
   b. Select *Create New* > *Address*.
   c. Select *IPv6 Address* and fill out the fields with the following information:

Name	FTP_Server
Type	IPv6 Subnet
IPv6 Address	2001:db8:d0c:3::2/128

   d. Select *OK*.
5. Configure the IPv6 address group, which includes both the Web and FTP servers:
   a. Go to *Policy & Objects* > *Addresses*.
   b. Select *Create New* > *Address Group*.
   c. Select *IPv6 Group* and fill out the fields with the following information:

Group name	Custom_Server
Members	Web_Server, FTP_Server

   d. Select *OK*.
6. Configure the IPv6 firewall address for the Internal IPv6 network range which can access both the Web and FTP server:
   a. Go to *Policy & Objects* > *Addresses*.
   b. Select *Create New* > *Address*.

c. Select *IPv6 Address* and fill out the fields with the following information:

Name	Internal_Custom_Range
Type	IPv6 Range
IP Range	2001:db8:d0c:2::1 - 2001:db8:d0c:2::32

d. Select *OK*.

7. Configure the IPv6 firewall policy to allow IPv6 traffic from *Internal_Custom_Range* to *Custom_Server*:
   a. Go to *Policy & Objects* > *Firewall Policy*.
   b. Click *Create New*.
   c. Name the policy and configure the following parameters:

Incoming Interface	port2
Outgoing Interface	port3
Source	Internal_Custom_Range
Destination	Custom_Server
Schedule	always
Service	FTP, HTTPS
Action	ACCEPT

   d. Click *OK*.
8. Configure the IPv6 firewall policy to allow IPv6 traffic from internal clients to the Internet:
   a. Go to *Policy & Objects* > *Firewall Policy*.
   b. Click *Create New*.
   c. Name the policy and configure the following parameters:

Incoming Interface	port2
Outgoing Interface	port1
Source	all
Destination	all
Schedule	always
Service	ALL
Action	ACCEPT

   d. Click *OK*.

To configure the example in the CLI:

1. Configure the IPv6 address on port1, port2, and port3:

```
config system interface
    edit "port1"
        config ipv6
```

```
            set ip6-address 2001:db8:d0c:1::1/64
        end
    next
    edit "port2"
        config ipv6
            set ip6-address 2001:db8:d0c:2::f/64
        end
    next
    edit "port3"
        config ipv6
            set ip6-address 2001:db8:d0c:3::f/64
        end
    next
end
```

2. Configure the default route:

```
config router static6
    edit 0
        set gateway 2001:db8:d0c:1::f
        set device "port1"
    next
end
```

3. Configure the IPv6 firewall address for the Web Server:

```
config firewall address6
    edit "Web_Server"
        set ip6 2001:db8:d0c:3::1/128
    next
end
```

4. Configure the IPv6 firewall address for the FTP Server:

```
config firewall address6
    edit "FTP_Server"
        set ip6 2001:db8:d0c:3::2/128
    next
end
```

5. Configure the IPv6 address group, which includes for the Web and FTP Servers:

```
config firewall addrgrp6
    edit "Custom_Server"
        set member "FTP_Server" "Web_Server"
    next
end
```

6. Configure the IPv6 firewall address for the Internal IPv6 network range which can access both the Web and FTP Server:

```
config firewall address6
    edit "Internal_Custom_Range"
        set type iprange
        set start-ip 2001:db8:d0c:2::1
        set end-ip 2001:db8:d0c:2::32
    next
end
```

7. Configure the IPv6 firewall policy to allow IPv6 traffic from *Internal_Custom_Range* to *Custom_Server*:

```
config firewall policy
    edit 1
        set name "IPv6_internal_to_server"
        set srcintf "port2"
        set dstintf "port3"
        set action accept
        set srcaddr6 "Internal_Custom_Range"
        set dstaddr6 "Custom_Server"
        set schedule "always"
        set service "FTP" "HTTPS"
        set utm-status enable
        set logtraffic all
    next
end
```

8. Configure the IPv6 firewall policy to allow IPv6 traffic from Internal clients to the Internet:

```
config firewall policy
    edit 1
        set name "IPv6_internal_to_internet"
        set srcintf "port2"
        set dstintf "port1"
        set action accept
        set srcaddr6 "all"
        set dstaddr6 "all"
        set schedule "always"
        set service "ALL"
        set utm-status enable
        set logtraffic all
    next
end
```

Verification

The following commands can be used to verify that IPv6 traffic is entering and leaving the FortiGate as expected. See Debugging the packet flow on page 3133 for more information.

```
diagnose debug enable
diagnose debug flow trace start6 200
```

The output below indicates that hosts belonging to the *Internal_Custom_Range* can successfully reach both the *Web_Server* and *FTP_Server* defined in the *Custom_Server* address group.

However, they are unable to reach the TFTP server, as it is not included in the *Custom_Server* group. Furthermore, hosts with IPv6 addresses that do not belong to the *Internal_Custom_Range* are not able to access *Custom_Server*.

Host belonging to *Internal_Custom_Range* accessing *Web_Server*:

```
id=65308 trace_id=21 func=resolve_ip6_tuple_fast line=4962 msg="vd-root:0 received a packet

Site-to-site IPv6 over IPv6 VPN example

In this example, clients on IPv6-addressed networks communicate securely over public IPv6 infrastructure.

The following topology is used for this example:

- Port2 connects to the public network and port3 connects to the local network.
- The IPv6 address for HQ1 port2 and port3 is 2001:db8:d0c:1::e and 2001:db8:d0c:4::e, respectively.
- The IPv6 address for HQ2 port2 and port3 is 2001:db8:d0c:2::e and 2001:db8:d0c:3::e, respectively.

Please note that the IPv6 addresses used in this example are for illustrative purposes only and should not be used in your environment.

The 2001:db8::/32 prefix is a special IPv6 prefix designated for use in documentation examples. See RFC 3849 for more information.

To configure the example in the GUI:

1. Configure the HQ1 FortiGate.
   a. Configure the IPv6 address on port2 and port3:
      i. Go to *Network* > *Interfaces* and edit port2.
      ii. Set *IPv6 addressing mode* to *Manual* and enter the *IPv6 Address/Prefix*.

IPv6 Address/Prefix	2001:db8:d0c:1::e/64

      iii. Click *OK*.
      iv. Repeat these steps for port3.

IPv6 Address/Prefix	2001:db8:d0c:4::e/64

   b. Configure IPsec settings:
      i. Go to *VPN* > *IPsec Wizard* and enter a VPN name.
      ii. Set *Template type* to *Custom*.
      iii. Click *Next*.
      iv. Configure the following *Network* settings:

IP Version	IPv6

Remote Gateway	Static IP Address
IP Address	2001:db8:d0c:2::e
Interface	port2

v. Configure the following *Authentication* settings:

Method	Pre-shared Key
Pre-shared Key	sample

vi. Configure the following *New Phase 2* settings:

Local Address	IPv6 Subnet
Remote Address	IPv6 Subnet

c. Configure the IPv6 firewall policy to allow IPv6 traffic from port3 to the IPsec interface:
   i. Go to *Policy & Objects* > *Firewall Policy*.
   ii. Click *Create New*.
   iii. Name the policy and configure the following parameters:

Incoming Interface	port3
Outgoing Interface	to_HQ2
Source	all
Destination	all
Schedule	always
Service	ALL
Action	ACCEPT

   iv. Click *OK*.
d. Configure the IPv6 firewall policy to allow IPv6 traffic from the IPsec interface to port3:
   i. Go to *Policy & Objects* > *Firewall Policy*.
   ii. Click *Create New*.
   iii. Name the policy and configure the following parameters:

Incoming Interface	to_HQ2
Outgoing Interface	port3
Source	all
Destination	all
Schedule	always
Service	ALL
Action	ACCEPT

   iv. Click *OK*.

e. Configure the static routes:

i. Go to *Network* > *Static Routes*.

ii. Click *Create New* > *IPv6 Static Route*.

iii. Configure the following settings for the default route to the remote VPN gateway:

Destination	::/0
Gateway Address	2001:db8:d0c:1::f
Interface	port2

iv. Select *OK*.

v. Repeat the first two steps and configure the following settings for the route to the remote protected network:

Destination	2001:db8:d0c:3::/64
Interface	to_HQ2

vi. Select *OK*.

vii. Repeat the first two steps and configure the following settings for the blackhole route:

Destination	2001:db8:d0c:3::/64
Interface	Blackhole
Administrative Distance	254

viii. Select *OK*.

2. Configure the HQ2 FortiGate:

a. Configure the IPv6 address on port2 and port3:

i. Go to *Network* > *Interfaces* and edit port2.

ii. Set *IPv6 addressing mode* to *Manual* and enter the *IPv6 Address/Prefix*.

IPv6 Address/Prefix	2001:db8:d0c:2::e/64

iii. Click *OK*.

iv. Repeat these steps for port3.

IPv6 Address/Prefix	2001:db8:d0c:3::e/64

b. Configure IPsec settings:

i. Go to *VPN* > *IPsec Wizard* and enter a VPN name.

ii. Set *Template type* to *Custom*.

iii. Click *Next*.

iv. Configure the following *Network* settings:

IP Version	IPv6
Remote Gateway	Static IP Address
IP Address	2001:db8:d0c:1::e

Interface	port2

v. Configure the following *Authentication* settings:

Method	Pre-shared Key
Pre-shared Key	sample

vi. Configure the following *New Phase 2* settings:

Local Address	IPv6 Subnet
Remote Address	IPv6 Subnet

c. Configure the IPv6 firewall policy to allow IPv6 traffic from port3 to the IPsec interface:
   i. Go to *Policy & Objects* > *Firewall Policy*.
   ii. Click *Create New*.
   iii. Name the policy and configure the following parameters:

Incoming Interface	port3
Outgoing Interface	to_HQ1
Source	all
Destination	all
Schedule	always
Service	ALL
Action	ACCEPT

   iv. Click *OK*.
d. Configure the IPv6 firewall policy to allow IPv6 traffic from the IPsec interface to port3:
   i. Go to *Policy & Objects* > *Firewall Policy*.
   ii. Click *Create New*.
   iii. Name the policy and configure the following parameters:

Incoming Interface	to_HQ1
Outgoing Interface	port3
Source	all
Destination	all
Schedule	always
Service	ALL
Action	ACCEPT

   iv. Click *OK*.
e. Configure the static routes:

i. Go to *Network* > *Static Routes*.
ii. Click *Create New* > *IPv6 Static Route*.
iii. Configure the following settings for the default route to the remote VPN gateway:

Destination	::/0
Gateway Address	2001:db8:d0c:2::f
Interface	port2

iv. Select *OK*.
v. Repeat the first two steps and configure the following settings for the route to the remote protected network:

Destination	2001:db8:d0c:4::/64
Interface	to_HQ1

vi. Select *OK*.
vii. Repeat the first two steps and configure the following settings for the blackhole route:

Destination	2001:db8:d0c:4::/64
Interface	Blackhole
Administrative Distance	254

viii. Select *OK*.

To configure the example in the CLI:

1. Configure the HQ1 FortiGate.
   a. Configure the IPv6 address on port2 and port3:

```
config system interface
    edit port2
        config ipv6
            set ip6-address 2001:db8:d0c:1::e/64
        end
    next
    edit port3
        config ipv6
            set ip6-address 2001:db8:d0c:4::e/64
        end
    next
end
```

   b. Configure IPsec settings:

```
config vpn ipsec phase1-interface
    edit "to_HQ2"
        set interface port2
        set ip-version 6
        set peertype any
        set proposal aes128-sha256 aes256-sha256 aes128-sha1 aes256-sha1
        set remote-gw6 2001:db8:d0c:2::e
```

```
        set psksecret sample
    next
end
config vpn ipsec phase2-interface
    edit "to_HQ2"
        set phase1name "to_HQ2"
        set proposal aes128-sha1 aes256-sha1 aes128-sha256 aes256-sha256 aes128gcm
aes256gcm chacha20poly1305
        set src-addr-type subnet6
        set dst-addr-type subnet6
    next
end
```

c. Configure the IPv6 firewall policy to allow IPv6 traffic between port3 to the IPsec interface:

```
config firewall policy
    edit 1
        set srcintf "port3"
        set dstintf "to_HQ2"
        set srcaddr6 "all"
        set dstaddr6 "all"
        set action accept
        set schedule "always"
        set service "ALL"
        set logtraffic "all"
    next
    edit 2
        set srcintf "to_HQ2"
        set dstintf "port3"
        set srcaddr6 "all"
        set dstaddr6 "all"
        set action accept
        set schedule "always"
        set service "ALL"
        set logtraffic "all"
    next
end
```

d. Configure the static routes:

```
config router static6
    edit 1
        set gateway 2001:db8:d0c:1::f
        set device "port2"
    next
    edit 2
        set dst 2001:db8:d0c:3::/64
        set device "to_HQ2"
    next
    edit 3
        set dst 2001:db8:d0c:3::/64
        set blackhole enable
        set distance 254
    next
end
```

2. Configure the HQ2 FortiGate.

a. Configure the IPv6 address on port2 and port3:

```
config system interface
    edit port2
        config ipv6
            set ip6-address 2001:db8:d0c:2::e/64
        end
    next
    edit port3
        config ipv6
            set ip6-address 2001:db8:d0c:3::e/64
        end
    next
end
```

b. Configure IPsec settings:

```
config vpn ipsec phase1-interface
    edit "to_HQ1"
        set interface port2
        set ip-version 6
        set peertype any
        set proposal aes128-sha256 aes256-sha256 aes128-sha1 aes256-sha1
        set remote-gw6 2001:db8:d0c:1::e
        set psksecret sample
    next
end
config vpn ipsec phase2-interface
    edit "to_HQ2"
        set phase1name "to_HQ1"
        set proposal aes128-sha1 aes256-sha1 aes128-sha256 aes256-sha256 aes128gcm
aes256gcm chacha20poly1305
        set src-addr-type subnet6
        set dst-addr-type subnet6
    next
end
```

c. Configure the IPv6 firewall policy to allow IPv6 traffic between port3 to the IPsec interface:

```
config firewall policy
    edit 1
        set srcintf "port3"
        set dstintf "to_HQ1"
        set srcaddr6 "all"
        set dstaddr6 "all"
        set action accept
        set schedule "always"
        set service "ALL"
        set logtraffic "all"
    next
    edit 2
        set srcintf "to_HQ1"
        set dstintf "port3"
        set srcaddr6 "all"
        set dstaddr6 "all"
        set action accept
        set schedule "always"
        set service "ALL"
```

```
        set logtraffic "all"
    next
end
```

d. Configure the static routes:

```
config router static6
    edit 1
        set gateway 2001:db8:d0c:2::f
        set device "port2"
    next
    edit 2
        set dst 2001:db8:d0c:4::/64
        set device "to_HQ1"
    next
    edit 3
        set dst 2001:db8:d0c:4::/64
        set blackhole enable
        set distance 254
    next
end
```

Verification

The following commands are useful to check IPsec phase1/phase2 interface status:

1. Run the `diagnose vpn ike gateway list` command on HQ1. The system should return the following:

```
vd: root/0
name: to_HQ2
version: 1
interface: port2 6
addr: 2001:db8:d0c:1::e:500 -> 2001:db8:d0c:2::e:500
tun_id: 10.0.0.1/::10.0.0.1
remote_location: 0.0.0.0
network-id: 0
created: 1537s ago
peer-id: 2001:db8:d0c:2::e
peer-id-auth: no
IKE SA: created 1/1  established 1/1  time 0/0/0 ms
IPsec SA: created 1/1  established 1/1  time 0/0/0 ms

  id/spi: 160 8d7231820bb5ffd9/6c840a4c11b57927
  direction: initiator
  status: established 1537-1537s ago = 0ms
  proposal: aes128-sha256
  key: 32d8521a77d98529-5fe4b67914d30f87
  lifetime/rekey: 86400/84562
  DPD sent/recv: 00000007/00000003
  peer-id: 2001:db8:d0c:2::e
```

2. Run the `diagnose vpn tunnel list` command on HQ1. The system should return the following:

```
list all ipsec tunnel in vd 0
------------------------------------------------------
name=to_HQ2 ver=1 serial=1 2001:db8:d0c:1::e:0->2001:db8:d0c:2::e:0 tun_id=10.0.0.1 tun_

Site-to-site IPv4 over IPv6 VPN example

In this example, two private networks with IPv4 addressing communicate securely over IPv6 infrastructure.

The following topology is used for this example:

- Port2 connects to the IPv6 public network and port3 connects to the IPv4 local network.
- HQ1 port2 IPv6 address is 2001:db8:d0c:1::e and port3 IPv4 address is 192.168.2.1.
- HQ2 port2 IPv6 address is 2001:db8:d0c:2::e and port3 IPv4 address is 192.168.3.1.

Please note that the IPv6 addresses used in this example are for illustrative purposes only and should not be used in your environment.

The 2001:db8::/32 prefix is a special IPv6 prefix designated for use in documentation examples. See RFC 3849 for more information.

To configure the example in the GUI:

1. Configure the HQ1 FortiGate.
   a. Configure the IPv6 address on port2 and IPv4 address on port3:
      i. Go to *Network* > *Interfaces* and edit port2.
      ii. Set *IPv6 addressing mode* to *Manual* and enter the *IPv6 Address/Prefix*.

IPv6 Address/Prefix	2001:db8:d0c:1::e/64

      iii. Click *OK*.
      iv. Go to *Network* > *Interfaces* and edit port3.
      v. Set *Addressing mode* to *Manual* and enter the *IP/Netmask*.

IP/Netmask	192.168.2.1/24

   b. Configure IPsec settings:
      i. Go to *VPN* > *IPsec Wizard* and enter a VPN name.
      ii. Set *Template type* to *Custom*.
      iii. Click *Next*.
      iv. Configure the following *Network* settings:

IP Version	IPv6
Remote Gateway	Static IP Address
IP Address	2001:db8:d0c:2::e
Interface	port2

      v. Configure the following *Authentication* settings:

Method	Pre-shared Key
Pre-shared Key	sample

      vi. Configure the following *New Phase 2* settings:

Local Address	addr_subnet
Remote Address	addr_subnet

   c. Configure the IPv4 firewall policy to allow IPv4 traffic from port3 to the IPsec interface:
      i. Go to *Policy & Objects* > *Firewall Policy*.
      ii. Click *Create New*.

iii. Name the policy and configure the following parameters:

Incoming Interface	port3
Outgoing Interface	to_HQ2
Source	all
Destination	all
Schedule	always
Service	ALL
Action	ACCEPT

iv. Click *OK*.

d. Configure the IPv4 firewall policy to allow IPv4 traffic from the IPsec interface to port3:

i. Go to *Policy & Objects* > *Firewall Policy*.

ii. Click *Create New*.

iii. Name the policy and configure the following parameters:

Incoming Interface	to_HQ2
Outgoing Interface	port3
Source	all
Destination	all
Schedule	always
Service	ALL
Action	ACCEPT

iv. Click *OK*.

e. Configure the static routes:

i. Go to *Network* > *Static Routes*.

ii. Click *Create New* > *IPv6 Static Route*.

iii. Configure the following settings for the default route to the remote VPN gateway:

Destination	0.0.0.0/0.0.0.0
Gateway Address	2001:db8:d0c:1::f
Interface	port2

iv. Select *OK*.

v. Repeat the first two steps for *IPv4 Static Route* and configure the following settings for the route to the remote protected network:

Destination	192.168.3.0/24
Interface	to_HQ2

vi. Select *OK*.

vii. Repeat the first two steps for *IPv4 Static Route* and configure the following settings for the blackhole route:

Destination	192.168.3.0/24
Interface	Blackhole
Administrative Distance	254

viii. Select *OK*.

2. Configure the HQ2 FortiGate:
   a. Configure the IPv6 address on port2 and IPv4 address on port3:
      i. Go to *Network* > *Interfaces* and edit port2.
      ii. Set *IPv6 addressing mode* to *Manual* and enter the *IPv6 Address/Prefix*.

IPv6 Address/Prefix	2001:db8:d0c:2::e/64

      iii. Click *OK*.
      iv. Go to *Network* > *Interfaces* and edit port3.
      v. Set *Addressing mode* to *Manual* and enter the *IP/Netmask*.

IP/Netmask	192.168.3.1/24

   b. Configure IPsec settings:
      i. Go to *VPN* > *IPsec Wizard* and enter a VPN name.
      ii. Set *Template type* to *Custom*.
      iii. Click *Next*.
      iv. Configure the following *Network* settings:

IP Version	IPv6
Remote Gateway	Static IP Address
IP Address	2001:db8:d0c:1::e
Interface	port2

      v. Configure the following *Authentication* settings:

Method	Pre-shared Key
Pre-shared Key	sample

      vi. Configure the following *New Phase 2* settings:

Local Address	addr_subnet
Remote Address	addr_subnet

   c. Configure the IPv4 firewall policy to allow IPv4 traffic from port3 to the IPsec interface:
      i. Go to *Policy & Objects* > *Firewall Policy*.
      ii. Click *Create New*.

iii. Name the policy and configure the following parameters:

Incoming Interface	port3
Outgoing Interface	to_HQ1
Source	all
Destination	all
Schedule	always
Service	ALL
Action	ACCEPT

iv. Click *OK*.

d. Configure the IPv4 firewall policy to allow IPv4 traffic from the IPsec interface to port3:

i. Go to *Policy & Objects* > *Firewall Policy*.

ii. Click *Create New*.

iii. Name the policy and configure the following parameters:

Incoming Interface	to_HQ1
Outgoing Interface	port3
Source	all
Destination	all
Schedule	always
Service	ALL
Action	ACCEPT

iv. Click *OK*.

e. Configure the static routes:

i. Go to *Network* > *Static Routes*.

ii. Click *Create New* > *IPv6 Static Route*.

iii. Configure the following settings for the default route to the remote VPN gateway:

Destination	0.0.0.0/0.0.0.0
Gateway Address	2001:db8:d0c:2::f
Interface	port2

iv. Select *OK*.

v. Repeat the first two steps for *IPv4 Static Route* and configure the following settings for the route to the remote protected network:

Destination	192.168.2.0/24
Interface	to_HQ1

vi. Select *OK*.

vii. Repeat the first two steps for *IPv4 Static Route* and configure the following settings for the blackhole route:

Destination	192.168.2.0/24
Interface	Blackhole
Administrative Distance	254

viii. Select *OK*.

To configure the example in the CLI:

1. Configure the HQ1 FortiGate.
   a. Configure the IPv6 address on port2 and IPv4 address on port3:

```
config system interface
    edit port2
        config ipv6
            set ip6-address 2001:db8:d0c:1::e/64
        end
    next
    edit port3
        set ip 192.168.2.1/24
    next
end
```

   b. Configure IPsec settings:

```
config vpn ipsec phase1-interface
    edit "to_HQ2"
        set interface port2
        set ip-version 6
        set peertype any
        set proposal aes128-sha256 aes256-sha256 aes128-sha1 aes256-sha1
        set remote-gw6 2001:db8:d0c:2::e
        set psksecret sample
    next
end
config vpn ipsec phase2-interface
    edit "to_HQ2"
        set phase1name "to_HQ2"
        set proposal aes128-sha1 aes256-sha1 aes128-sha256 aes256-sha256 aes128gcm
aes256gcm chacha20poly1305
        set src-addr-type subnet
        set dst-addr-type subnet
    next
end
```

   c. Configure the IPv4 firewall policy to allow IPv4 traffic between port3 to the IPsec interface:

```
config firewall policy
    edit 1
        set srcintf "port3"
        set dstintf "to_HQ2"
        set srcaddr "all"
        set dstaddr "all"
        set action accept
```

```
        set schedule "always"
        set service "ALL"
        set logtraffic "all"
    next
    edit 2
        set srcintf "to_HQ2"
        set dstintf "port3"
        set srcaddr "all"
        set dstaddr "all"
        set action accept
        set schedule "always"
        set service "ALL"
        set logtraffic "all"
    next
end
```

d. Configure the static routes:

```
config router static6
    edit 1
        set gateway 2001:db8:d0c:1::f
        set device "port2"
    next
end
config router static
    edit 1
        set dst 192.168.3.0 255.255.255.0
        set device "to_HQ2"
    next
    edit 2
        set dst 192.168.3.0 255.255.255.0
        set device blackhole
        set distance 254
    next
end
```

2. Configure the HQ2 FortiGate.

a. Configure the IPv6 address on port2 and IPv4 address on port3:

```
config system interface
    edit port2
        config ipv6
            set ip6-address 2001:db8:d0c:2::e/64
        end
    next
    edit port3
        set ip 192.168.3.1/24
    next
end
```

b. Configure IPsec settings:

```
config vpn ipsec phase1-interface
    edit "to_HQ1"
        set interface port2
        set ip-version 6
        set peertype any
```

```
        set proposal aes128-sha256 aes256-sha256 aes128-sha1 aes256-sha1
        set remote-gw6 2001:db8:d0c:1::e
        set psksecret sample
    next
end
config vpn ipsec phase2-interface
    edit "to_HQ2"
        set phase1name "to_HQ1"
        set proposal aes128-sha1 aes256-sha1 aes128-sha256 aes256-sha256 aes128gcm
aes256gcm chacha20poly1305
        set src-addr-type subnet
        set dst-addr-type subnet
    next
end
```

c. Configure the IPv4 firewall policy to allow IPv4 traffic between port3 to the IPsec interface:

```
config firewall policy
    edit 1
        set srcintf "port3"
        set dstintf "to_HQ1"
        set srcaddr "all"
        set dstaddr "all"
        set action accept
        set schedule "always"
        set service "ALL"
        set logtraffic "all"
    next
    edit 2
        set srcintf "to_HQ1"
        set dstintf "port3"
        set srcaddr "all"
        set dstaddr "all"
        set action accept
        set schedule "always"
        set service "ALL"
        set logtraffic "all"
    next
end
```

d. Configure the static routes:

```
config router static6
    edit 1
        set gateway 2001:db8:d0c:2::f
        set device "port2"
    next
end
config router static
    edit 1
        set dst 192.168.2.0 255.255.255.0
        set device "to_HQ1"
    next
    edit 2
        set dst 192.168.2.0 255.255.255.0
        set device blackhole
        set distance 254
```

```
        next
    end
```

Verification

The following commands are useful to check IPsec phase1/phase2 interface status:

1. Run the `diagnose vpn ike gateway list` command on HQ1. The system should return the following:

```
vd: root/0
name: to_HQ2
version: 1
interface: port2 6
addr: 2001:db8:d0c:1::e:500 -> 2001:db8:d0c:2::e:500

Site-to-site IPv6 over IPv4 VPN example

In this example, IPv6-addressed networks communicate securely over IPv4 public infrastructure.

The following topology is used for this example:

- Port2 connects to the IPv4 public network and port3 connects to the IPv6 local network.
- HQ1 port2 IPv4 address is 10.0.0.1 and port3 IPv6 address is 2001:db8:d0c:4::e.
- HQ2 port2 IPv4 address is 10.0.1.1 and port3 IPv6 address is 2001:db8:d0c:3::e.

Please note that the IPv6 addresses used in this example are for illustrative purposes only and should not be used in your environment.

The 2001:db8::/32 prefix is a special IPv6 prefix designated for use in documentation examples. See RFC 3849 for more information.

To configure the example in the GUI:

1. Configure the HQ1 FortiGate.
   a. Configure the IPv4 address on port2 and IPv6 address on port3:
      i. Go to *Network* > *Interfaces* and edit port2.
      ii. Set *Addressing mode* to *Manual* and enter the *IP/Netmask*.

IP/Netmask	10.0.0.1/24

      iii. Click *OK*.
      iv. Go to *Network* > *Interfaces* and edit port3.
      v. Set *IPv6 addressing mode* to *Manual* and enter the *IPv6 Address/Prefix*.

IPv6 Address/Prefix	2001:db8:d0c:4::e/64

   b. Configure IPsec settings:
      i. Go to *VPN* > *IPsec Wizard* and enter a VPN name.
      ii. Set *Template type* to *Custom*.
      iii. Click *Next*.
      iv. Configure the following *Network* settings:

IP Version	IPv4
Remote Gateway	Static IP Address
IP Address	10.0.1.1
Interface	port2

v. Configure the following *Authentication* settings:

Method	Pre-shared Key
Pre-shared Key	sample

vi. Configure the following *New Phase 2* settings:

Local Address	IPv6 Subnet
Remote Address	IPv6 Subnet

c. Configure the IPv6 firewall policy to allow IPv6 traffic from port3 to the IPsec interface:
   i. Go to *Policy & Objects* > *Firewall Policy*.
   ii. Click *Create New*.
   iii. Name the policy and configure the following parameters:

Incoming Interface	port3
Outgoing Interface	to_HQ2
Source	all
Destination	all
Schedule	always
Service	ALL
Action	ACCEPT

   iv. Click *OK*.
d. Configure the IPv6 firewall policy to allow IPv6 traffic from the IPsec interface to port3:
   i. Go to *Policy & Objects* > *Firewall Policy*.
   ii. Click *Create New*.

iii. Name the policy and configure the following parameters:

Incoming Interface	to_HQ2
Outgoing Interface	port3
Source	all
Destination	all
Schedule	always
Service	ALL
Action	ACCEPT

iv. Click *OK*.

e. Configure the static routes:

i. Go to *Network* > *Static Routes*.

ii. Click *Create New* > *IPv4 Static Route*.

iii. Configure the following settings for the default route to the remote VPN gateway:

Destination	0.0.0.0/0.0.0.0
Gateway Address	10.0.0.2
Interface	port2

iv. Select *OK*.

v. Repeat the first two steps for *IPv6 Static Route* and configure the following settings for the route to the remote protected network:

Destination	2001:db8:d0c:3::/64
Interface	to_HQ2

vi. Select *OK*.

vii. Repeat the first two steps for *IPv6 Static Route* and configure the following settings for the blackhole route:

Destination	2001:db8:d0c:3::/64
Interface	Blackhole
Administrative Distance	254

viii. Select *OK*.

2. Configure the HQ2 FortiGate:

a. Configure the IPv4 address on port2 and IPv6 address on port3:

i. Go to *Network* > *Interfaces* and edit port2.

ii. Set *Addressing mode* to *Manual* and enter the *IP/Netmask*.

IP/Netmask	10.0.1.1/24

iii. Click *OK*.

iv. Go to *Network* > *Interfaces* and edit port3.

v. Set *IPv6 addressing mode* to *Manual* and enter the *IPv6 Address/Prefix*.

IPv6 Address/Prefix	2001:db8:d0c:3::e/64

b. Configure IPsec settings:

i. Go to *VPN* > *IPsec Wizard* and enter a VPN name.

ii. Set *Template type* to *Custom*.

iii. Click *Next*.

iv. Configure the following *Network* settings:

IP Version	IPv4
Remote Gateway	Static IP Address
IP Address	10.0.0.1
Interface	port2

v. Configure the following *Authentication* settings:

Method	Pre-shared Key
Pre-shared Key	sample

vi. Configure the following *New Phase 2* settings:

Local Address	IPv6 Subnet
Remote Address	IPv6 Subnet

c. Configure the IPv6 firewall policy to allow IPv6 traffic from port3 to the IPsec interface:

i. Go to *Policy & Objects* > *Firewall Policy*.

ii. Click *Create New*.

iii. Name the policy and configure the following parameters:

Incoming Interface	port3
Outgoing Interface	to_HQ1
Source	all
Destination	all
Schedule	always
Service	ALL
Action	ACCEPT

iv. Click *OK*.

d. Configure the IPv6 firewall policy to allow IPv6 traffic from the IPsec interface to port3:

i. Go to *Policy & Objects* > *Firewall Policy*.

ii. Click *Create New*.

iii. Name the policy and configure the following parameters:

Incoming Interface	to_HQ1
Outgoing Interface	port3
Source	all
Destination	all
Schedule	always
Service	ALL
Action	ACCEPT

iv. Click *OK*.

e. Configure the static routes:

i. Go to *Network* > *Static Routes*.

ii. Click *Create New* > *IPv4 Static Route*.

iii. Configure the following settings for the default route to the remote VPN gateway:

Destination	0.0.0.0/0.0.0.0
Gateway Address	10.0.1.2
Interface	port2

iv. Select *OK*.

v. Repeat the first two steps for *IPv6 Static Route* and configure the following settings for the route to the remote protected network:

Destination	2001:db8:d0c:4::/64
Interface	to_HQ1

vi. Select *OK*.

vii. Repeat the first two steps for *IPv6 Static Route* and configure the following settings for the blackhole route:

Destination	2001:db8:d0c:4::/64
Interface	Blackhole
Administrative Distance	254

viii. Select *OK*.

To configure the example in the CLI:

1. Configure the HQ1 FortiGate.

a. Configure the IPv6 address on port2 and port3:

```
config system interface
    edit port2
        set ip 10.0.0.1/24
    next
```

```
    edit port3
        config ipv6
            set ip6-address 2001:db8:d0c:4::e/64
        end
    next
end
```

b. Configure IPsec settings:

```
config vpn ipsec phase1-interface
    edit "to_HQ2"
        set interface port2
        set ip-version 4
        set peertype any
        set proposal aes128-sha256 aes256-sha256 aes128-sha1 aes256-sha1
        set remote-gw 10.0.1.1
        set psksecret sample
    next
end
config vpn ipsec phase2-interface
    edit "to_HQ2"
        set phase1name "to_HQ2"
        set proposal aes128-sha1 aes256-sha1 aes128-sha256 aes256-sha256 aes128gcm
aes256gcm chacha20poly1305
        set src-addr-type subnet6
        set dst-addr-type subnet6
    next
end
```

c. Configure the IPv6 firewall policy to allow IPv6 traffic between port3 to the IPsec interface:

```
config firewall policy
    edit 1
        set srcintf "port3"
        set dstintf "to_HQ2"
        set srcaddr6 "all"
        set dstaddr6 "all"
        set action accept
        set schedule "always"
        set service "ALL"
        set logtraffic "all"
    next
    edit 2
        set srcintf "to_HQ2"
        set dstintf "port3"
        set srcaddr6 "all"
        set dstaddr6 "all"
        set action accept
        set schedule "always"
        set service "ALL"
        set logtraffic "all"
    next
end
```

d. Configure the static routes:

```
config router static
    edit 1
```

```
        set gateway 10.0.0.2
        set device "port2"
    next
end
config router static6
    edit 1
        set dst 2001:db8:d0c:3::/64
        set device "to_HQ2"
    next
    edit 2
        set dst 2001:db8:d0c:3::/64
        set device blackhole
        set distance 254
    next
end
```

2. Configure the HQ2 FortiGate.
   a. Configure the IPv6 address on port2 and port3:

```
config system interface
    edit port2
        set ip 10.0.1.1/24
    next
    edit port3
        config ipv6
            set ip6-address 2001:db8:d0c:3::e/64
        end
    next
end
```

   b. Configure IPsec settings:

```
config vpn ipsec phase1-interface
    edit "to_HQ1"
        set interface port2
        set ip-version 4
        set peertype any
        set proposal aes128-sha256 aes256-sha256 aes128-sha1 aes256-sha1
        set remote-gw 10.0.0.1
        set psksecret sample
    next
end
config vpn ipsec phase2-interface
    edit "to_HQ2"
        set phase1name "to_HQ1"
        set proposal aes128-sha1 aes256-sha1 aes128-sha256 aes256-sha256 aes128gcm
aes256gcm chacha20poly1305
        set src-addr-type subnet6
        set dst-addr-type subnet6
    next
end
```

   c. Configure the IPv6 firewall policy to allow IPv6 traffic between port3 to the IPsec interface:

```
config firewall policy
    edit 1
        set srcintf "port3"
```

```
            set dstintf "to_HQ1"
            set srcaddr6 "all"
            set dstaddr6 "all"
            set action accept
            set schedule "always"
            set service "ALL"
            set logtraffic "all"
        next
        edit 2
            set srcintf "to_HQ1"
            set dstintf "port3"
            set srcaddr6 "all"
            set dstaddr6 "all"
            set action accept
            set schedule "always"
            set service "ALL"
            set logtraffic "all"
        next
    end
```

d. Configure the static routes:

```
config router static
    edit 1
        set gateway 10.0.1.2
        set device "port2"
    next
end
config router static6
    edit 1
        set dst 2001:db8:d0c:4::/64
        set device "to_HQ1"
    next
    edit 2
        set dst 2001:db8:d0c:4::/64
        set device blackhole
        set distance 254
    next
end
```

Verification

The following commands are useful to check IPsec phase1/phase2 interface status:

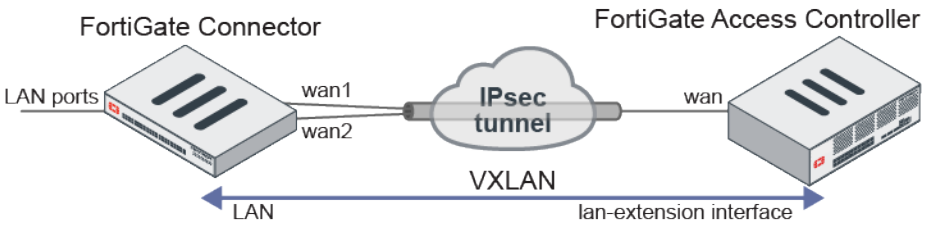
1. Run the `diagnose vpn ike gateway list` command on HQ1. The system should return the following:

```
vd: root/0
name: to_HQ2
version: 1
interface: port2 6
addr: 10.0.0.1:500 -> 10.0.0.2:500
tun_id: 10.0.0.2/::10.0.0.2
remote_location: 0.0.0.0
network-id: 0
created: 576319s ago
peer-id: 10.0.0.2
peer-id-auth: no
```

```
IKE SA: created 1/8  established 1/8  time 0/1127/9000 ms
IPsec SA: created 1/7  established 1/7  time 0/5/10 ms

  id/spi: 8 c04ab0ead989f579/267813e164d4ec22
  direction: initiator
  status: established 59710-59710s ago = 0ms
  proposal: aes128-sha256
  key: 034a0c3bf3deb551-8d647af9b6f76578
  lifetime/rekey: 86400/26389
  DPD sent/recv: 00000044/00000047
  peer-id: 10.0.0.2
```

2. Run the `diagnose vpn tunnel list` command on HQ1. The system should return the following:



```
list all ipsec tunnel in vd 0
------------------------------------------------------
name=to_HQ2 ver=1 serial=1 10.0.0.1:0->10.0.0.2:0 tun_id=10.0.0.2 tun_id6=::10.0.0.2

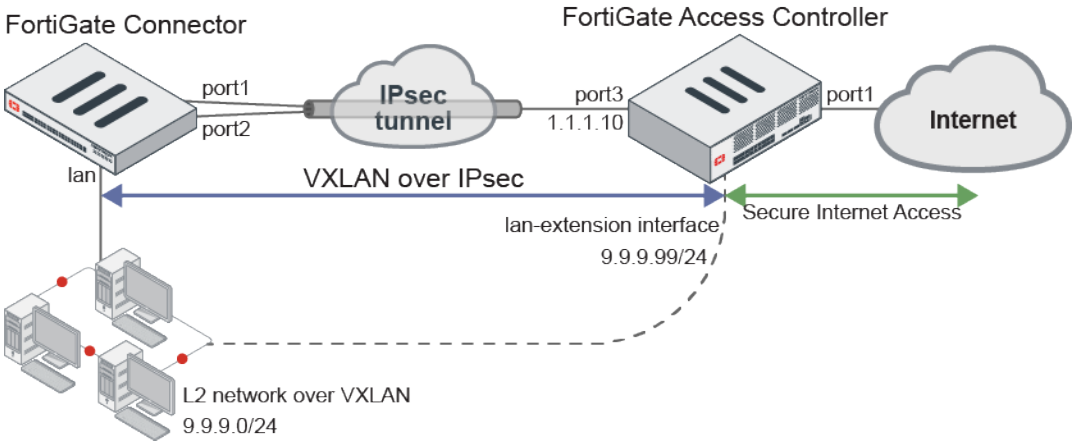
```

FortiGate LAN extension



LAN extension mode allows a remote FortiGate to provide remote connectivity to a local FortiGate over a backhaul connection.

The remote FortiGate, called the FortiGate Connector, discovers the local FortiGate, called the FortiGate Controller, and forms one or more IPsec tunnels back to the FortiGate Controller. A VXLAN is established over the IPsec tunnels creating an L2 network between the FortiGate Controller and the network behind the FortiGate Connector.

In this example, the Controller provides secure internet access to the remote network behind the Connector. The Controller has two WAN connections: an inbound backhaul connection and an outbound internet connection. The Connector has two wired WAN/uplink ports that are connected to the internet.

After the Connector discovers the Controller and is authorized by the Controller, the Controller pushes a FortiGate LAN extension profile to the Connector. The Connector uses the profile configurations to form two IPsec tunnels back to the Controller. Additional VXLAN aggregate interfaces are automatically configured to create an L2 network between the Connector LAN port and a virtual LAN extension interface on the Controller. Clients behind the Connector can then connect to the internet through the Controller that is securing the internet connection.

To discover and authorize the FortiGate Controller:

1. On the FortiGate Controller:
   a. For high-end models (1000 series and higher), enable the FortiExtender setting:

```
config system global
    set fortiextender enable
end
```

   This command is configured by default on low- and medium-end models (900 series and lower).

   b. Enable security fabric connections on port3 to allow the Connector to connect over CAPWAP:

```
config system interface
    edit "port3"
        set vdom "root"
        set ip 1.1.1.10 255.255.255.0
        set allowaccess fabric ping
```

```
        set ip-managed-by-fortiipam enable
    next
end
```

2. On the FortiGate Connector:
   a. Enable VDOMs:

```
config system global
    set vdom-mode multi-vdom
end
```

   You will be logged out of the device when VDOM mode is enabled.

   b. For high-end models (1000 series and higher), enable the FortiExtender setting in the global VDOM:

```
config global
    config system global
        set fortiextender enable
    end
end
```

This command is configured by default on low- and medium-end models (900 series and lower).

   c. Create the lan-ext VDOM while setting the VDOM type to LAN extension (making the VDOM act as a FortiExtender in LAN extension mode), and add the Controller IP address:

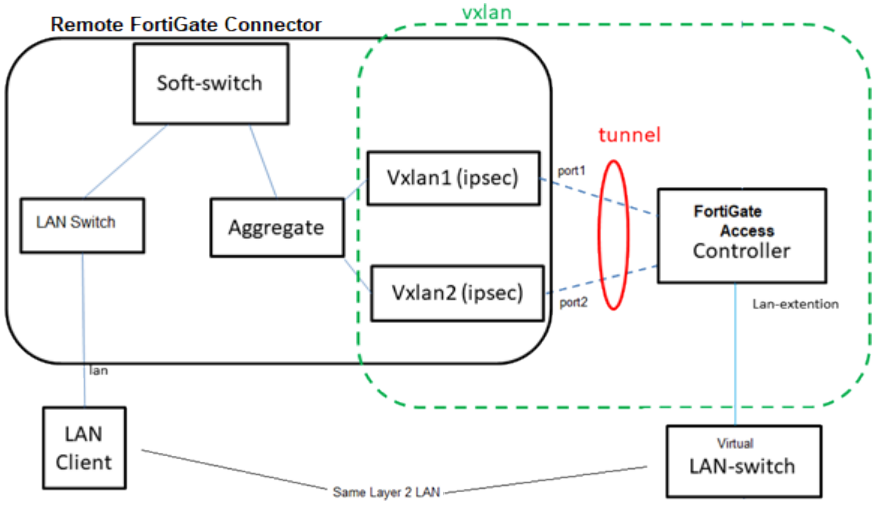
```
config vdom
    edit lan-ext
        config system settings
            set vdom-type lan-extension
            set lan-extension-controller-addr "1.1.1.10"
            set ike-port 4500
        end
    next
end
```

   d. Configure port1 and port2 to access the Controller:

```
config system interface
    edit "port1"
        set vdom "lan-ext"
        set ip 5.5.5.1 255.255.255.0
        set allowaccess ping fabric
        set type physical
        set lldp-reception enable
        set role wan
    next
    edit "port2"
        set vdom "lan-ext"
        set ip 6.6.6.1 255.255.255.0
        set allowaccess ping fabric
        set type physical
        set lldp-reception enable
        set role wan
```

```
    next
end
```

3. On the FortiGate Controller:
   a. Extension controller configurations are automatically initialized:



```
config extension-controller fortigate-profile
    edit "FGCONN-lanext-default"
        set id 0
        config lan-extension
            set ipsec-tunnel "fg-ipsec-XdSpij"
            set backhaul-interface "port3"
        end
    next
end

config extension-controller fortigate
    edit "FGT60E0000000001"
        set id "FG5H1E0000000001"
        set device-id 0
        set profile "FGCONN-lanext-default"
    next
end
```

   b. Enable FortiGate administration to authorize the Connector:

```
config extension-controller fortigate
    edit "FGT60E0000000001"
        set authorized enable
    next
end
```

4. After the FortiGate Connector has been authorized, the Controller pushes the IPsec tunnel configuration to the Connector, forcing it to establish the tunnel and form the VXLAN mechanism.

The VXLANs are built on the IPsec tunnels between the Connector and Controller. The VXLAN interfaces are aggregated for load balancing and redundancy. A softswitch combines the aggregate interface with the local LAN ports, allowing the LAN ports to be part of the VXLAN. This combines the local LAN ports with the virtual LAN extension interface on the FortiGate Controller.

a. The Connector receives the IPsec configurations from the Controller, and creates tunnels for each uplink:

```
config vpn ipsec phase1-interface
    edit "ul-port1"
        set interface "port1"
        set ike-version 2
        set peertype any
        set net-device disable
        set proposal aes128-sha256 aes256-sha256 aes128-sha1 aes256-sha1
        set localid "peerid-T4YLv2rp62SU6JhoCPIv02MzjLtS7P5HlxRER1Qpi6O9ZsAsbPSpvoiE"
        set dpd on-idle
        set comments "[FGCONN] Do NOT edit. Automatically generated by extension
controller."
        set remote-gw 1.1.1.10
        set psksecret ******
    next
    edit "ul-port2"
        set interface "port2"
        set ike-version 2
        set peertype any
        set net-device disable
        set proposal aes128-sha256 aes256-sha256 aes128-sha1 aes256-sha1
        set localid "peerid-T4YLv2rp62SU6JhoCPIv02MzjLtS7P5HlxRER1Qpi6O9ZsAsbPSpvoiE"
        set dpd on-idle
        set comments "[FGCONN] Do NOT edit. Automatically generated by extension
controller."
        set remote-gw 1.1.1.10
        set psksecret ******
    next
end
```

b. VXLAN interfaces are formed over each tunnel:

```
config system vxlan
    edit "vx-port1"
        set interface "ul-port1"
        set vni 1
        set dstport 9999
        set remote-ip "10.252.0.1"
    next
    edit "vx-port2"
        set interface "ul-port2"
        set vni 1
        set dstport 9999
        set remote-ip "10.252.0.1"
    next
end
```

c. An aggregate interface is configured to load balance between the two VXLAN interfaces, using the source MAC and providing link redundancy:

```
config system interface
    edit "le-agg-link"
        set vdom "lan-ext"
        set type aggregate
        set member "vx-port1" "vx-port2"
        set snmp-index 35
        set lacp-mode static
```

```
        set algorithm Source-MAC
    next
end
```

d. The softswitch bridges the aggregate interface and the local LAN to connect the LAN to the VXLAN bridged L2 network that goes to the FortiGate LAN extension interface:

```
config system switch-interface
    edit "le-switch"
        set vdom "lan-ext"
        set member "le-agg-link" "lan"
    next
end
```

e. After the IPsec tunnel is setup and the VXLAN is created over the tunnel, the LAN extension interface is automatically created on the Controller:

```
config system interface
    edit "FGT60E0000000001"
        set vdom "root"
        set ip 192.168.0.254 255.255.255.0
        set allowaccess ping ssh
        set type lan-extension
        set role lan
        set snmp-index 27
        set ip-managed-by-fortiipam enable
        set interface "fg-ipsec-XdSpij"
    next
end
```

To configure the LAN extension interface and firewall policy on the FortiGate Controller:

1. Set the IP address and netmask of the LAN extension interface:

```
config system interface
    edit "FGT60E0000000001"
        set ip 9.9.9.99 255.255.255.0
        set ip-managed-by-fortiipam enable
    next
end
```

Devices on the remote LAN network will use this as their gateway.

2. Optionally, enable DHCP on the interface to assign IP addresses to the remote devices:

```
config system dhcp server
    edit 3
        set dns-service default
        set default-gateway 9.9.9.99
        set netmask 255.255.255.0
        set interface "FGT60E0000000001"
        config ip-range
            edit 1
                set start-ip 9.9.9.100
                set end-ip 9.9.9.254
            next
        end
        set dhcp-settings-from-fortiipam enable
        config exclude-range
```

```
            edit 1
                set start-ip 9.9.9.254
                set end-ip 9.9.9.254
            next
        end
    next
end
```

3. Configure the firewall policy to allow traffic from the LAN extension interface to the WAN interface (port1):

```
config firewall policy
    edit "lan-ext"
        set name "qsaf"
        set srcintf "FGT60E0000000001"
        set dstintf "port1"
        set action accept
        set srcaddr "all"
        set dstaddr "all"
        set schedule "always"
        set service "ALL"
        set nat enable
    next
end
```

Optionally, security profiles and other settings can be configured.

The policy allows remote LAN clients to access the internet through the backhaul channel. Clients in the remote LAN behind the Connector receive an IP address over DHCP and access the internet securely through the Controller.

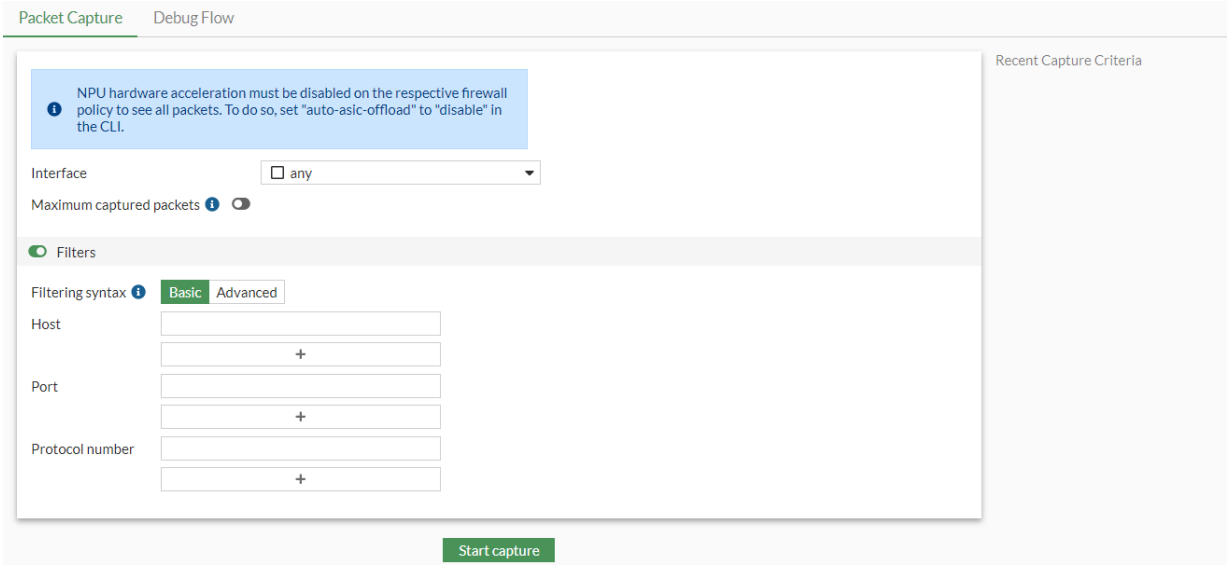
Diagnostics

Administrators can use the *Diagnostics* page to access the following tools:

Capture packet	Captures packet streams in real-time to let you view header and payload information. See Using the packet capture tool on page 619.
Debug flow	Traces packet flow through FortiOS to help you diagnose and debug issues. See Using the debug flow tool on page 623.

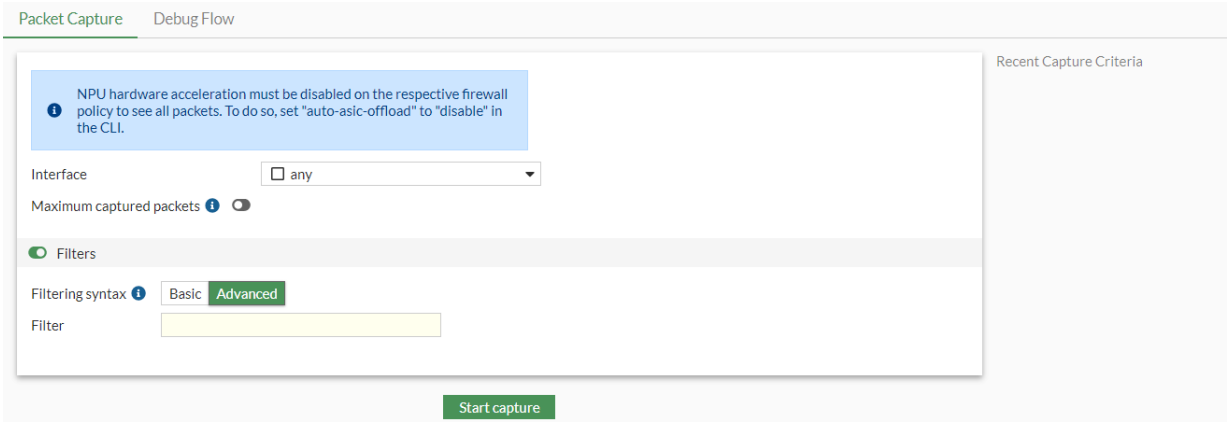
See also Performing a sniffer trace or packet capture on page 3131 and Debugging the packet flow on page 3133.

Using the packet capture tool



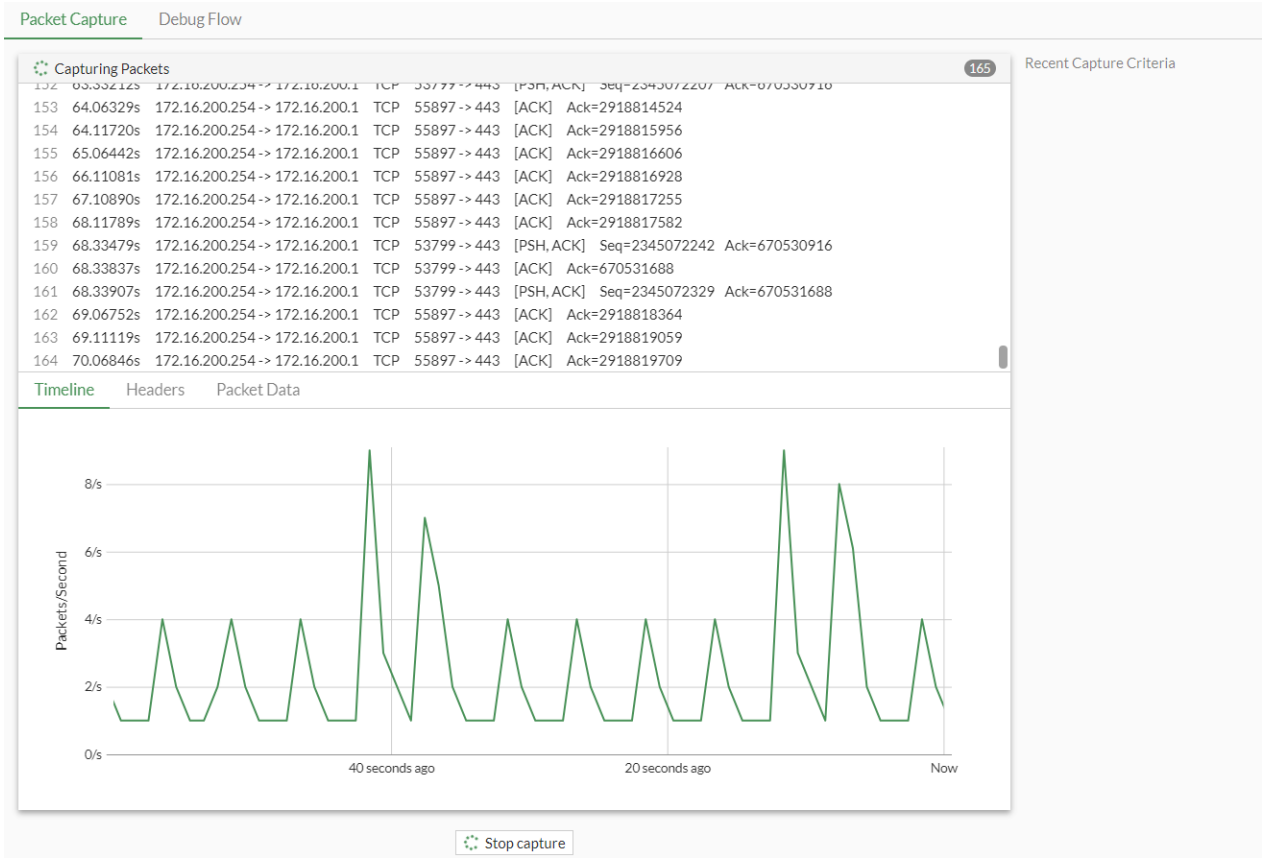
Administrators can use the packet capture tool to select a packet and view its header and payload information in real-time. Once completed, packets can be filtered by various fields or through the search bar. The capture can be saved as a PCAP file that you can use with a third-party application, such as Wireshark, for further analysis.

Recent capture criteria is saved after the packet capture, and you can select and use the same criteria again.



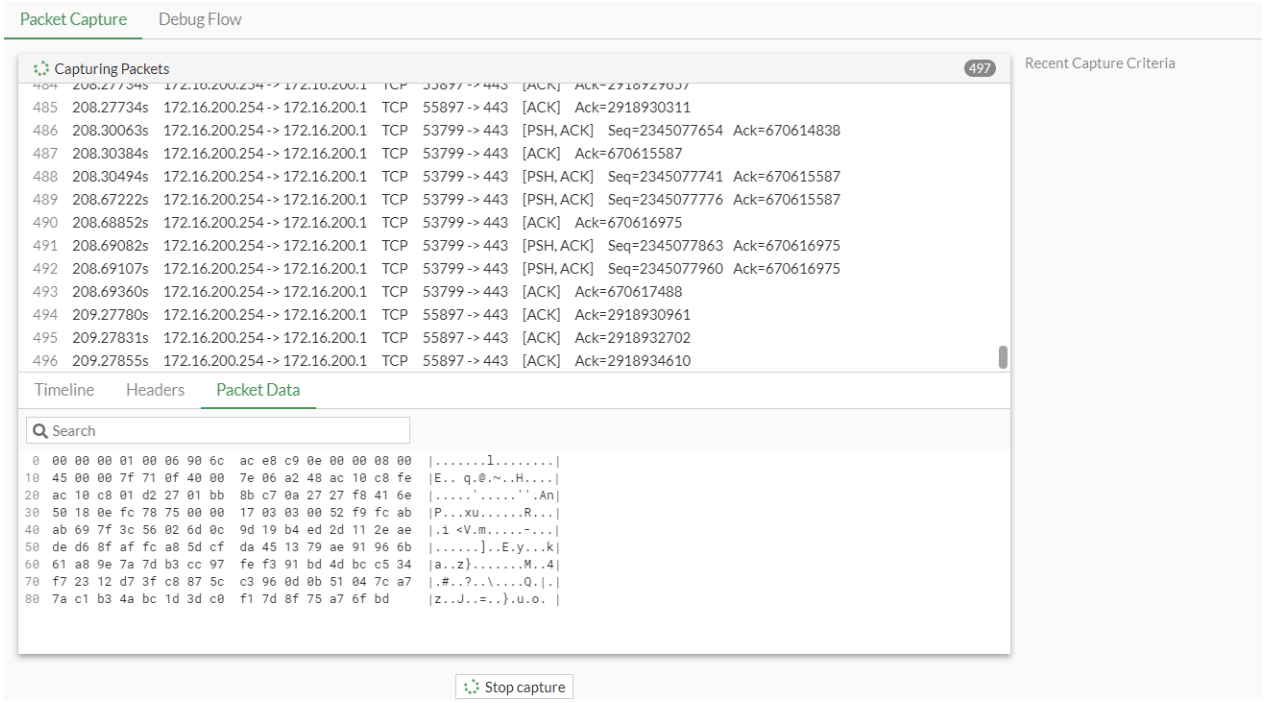
For information about running a packet capture in the CLI, see Performing a sniffer trace or packet capture on page 3131.

To use the packet capture tool in the GUI:

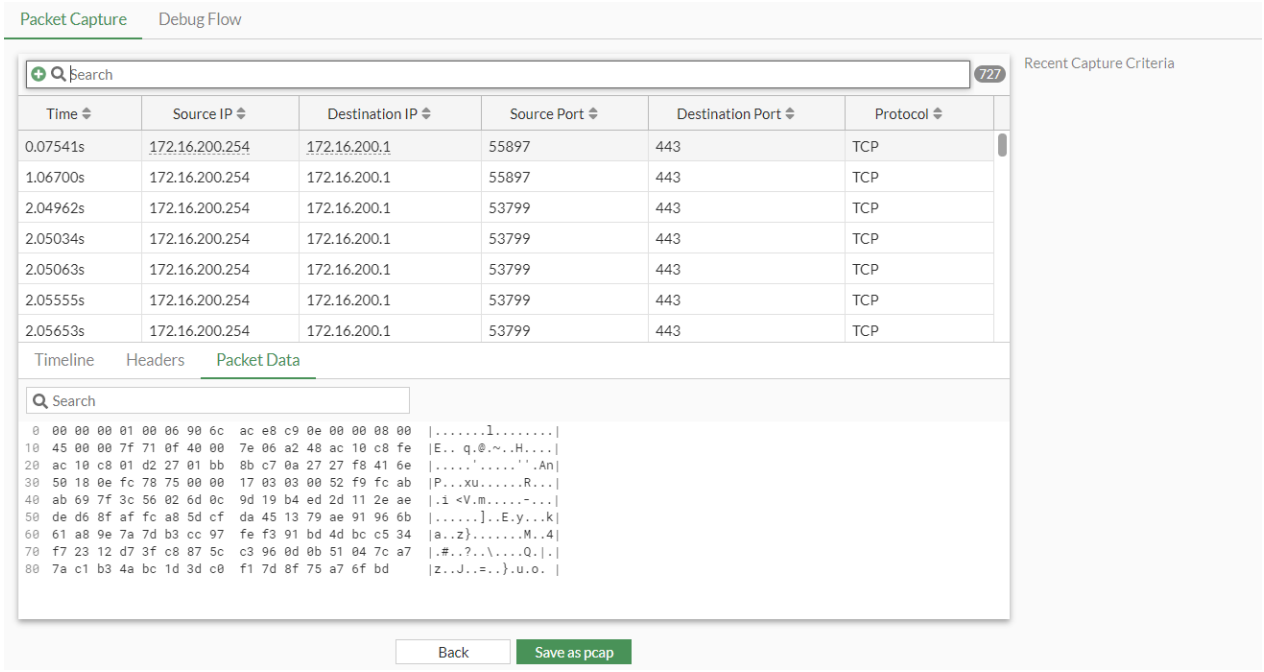


1. Go to *Network* > *Diagnostics* and select the *Packet Capture* tab.
2. Optionally, select an *Interface* (*any* is the default).
3. Optionally, enable *Filters* and select a *Filtering syntax*:
   a. *Basic*: enter criteria for the *Host*, *Port*, and *Protocol number*.

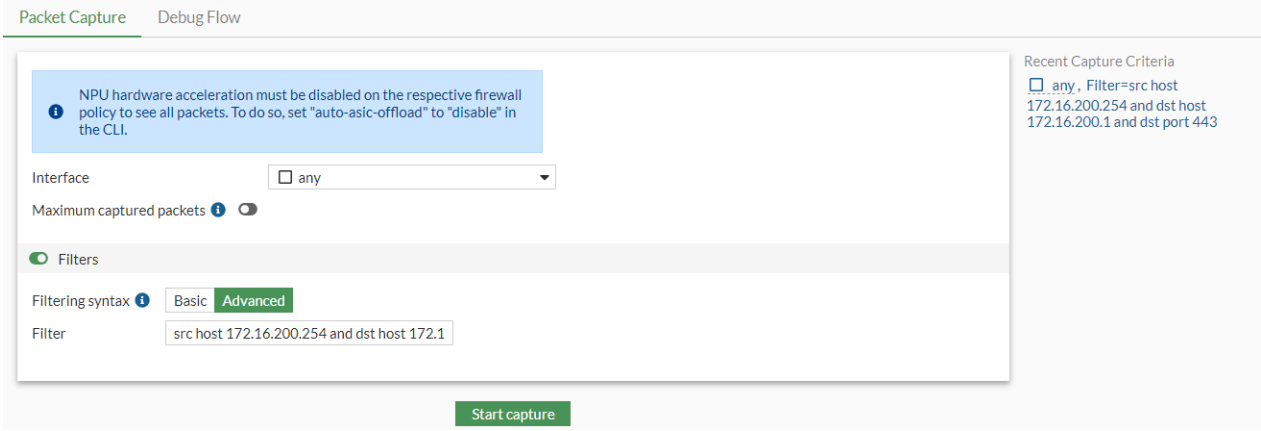
   b. *Advanced*: enter a string, such as *src host 172.16.200.254 and dst host 172.16.200.1 and dst port 443*.



4. Click *Start capture*. The capture is visible in real-time.



5. While the capture is running, select a packet, then click the *Headers* or *Packet Data* tabs to view more information.



6. When the capture is finished, click *Save as pcap*. The PCAP file is automatically downloaded.

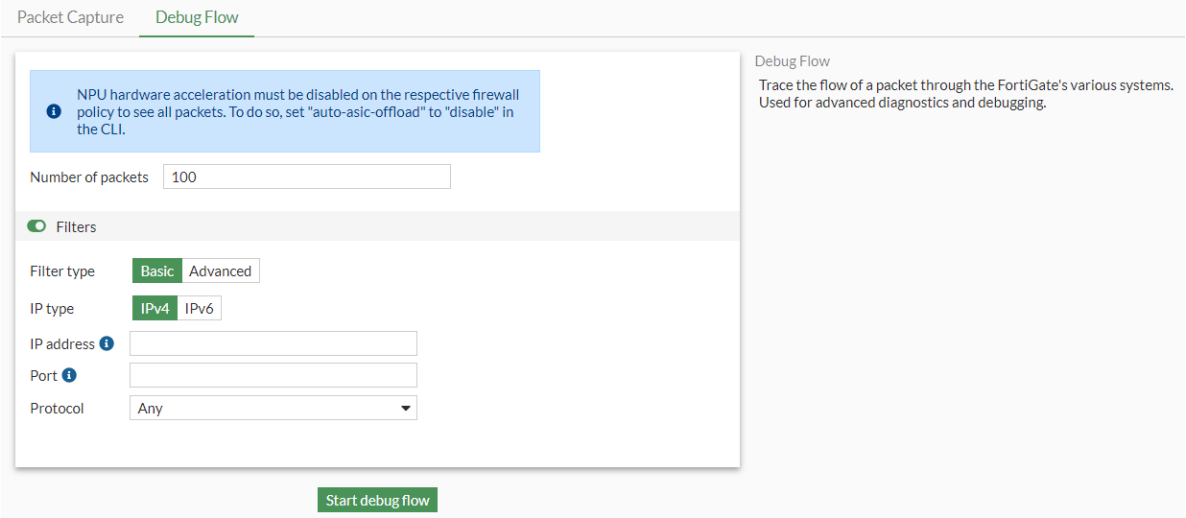
7. Optionally, use the *Search* bar or the column headers to filter the results further.

   The packet capture history is listed under *Recent Capture Criteria* in the right-side of the screen. Clicking the hyperlink will take you back to the main page with the interface and filter settings already populated.

For more granular sniffer output with various verbose settings, use `diagnose sniffer packet <interface> <'filter'> <verbose> <count> <tsformat>`. See Performing a sniffer trace or packet capture on page 3131.

To use recent capture criteria:

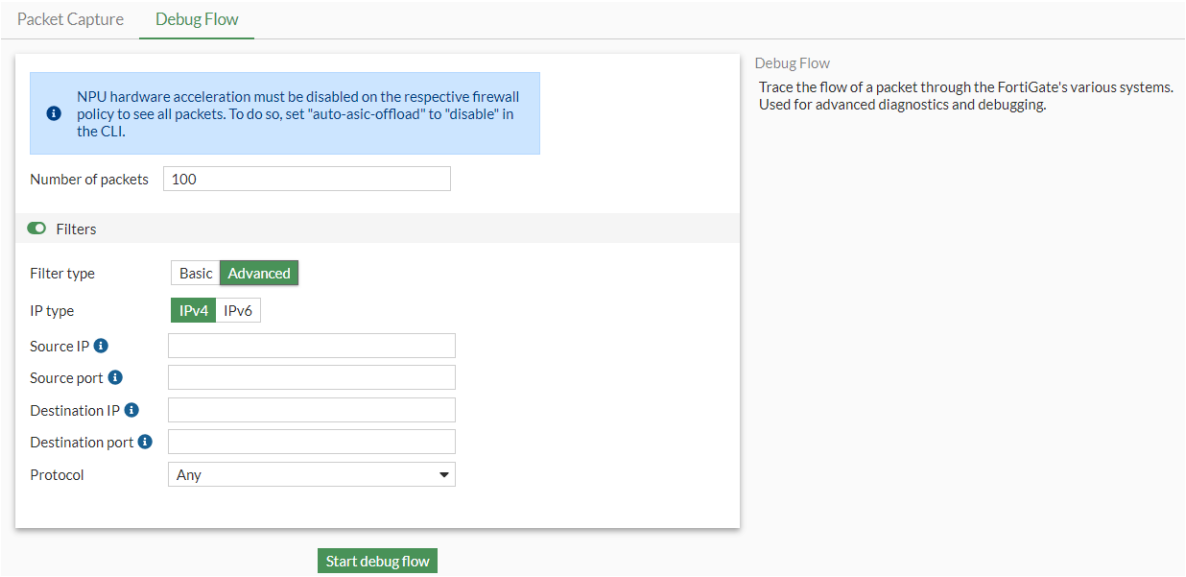
1. Go to *Network* > *Diagnostics* and select the *Packet Capture* tab.
2. Under *Recent Capture Criteria*, click one of the saved capture criteria. The criteria populate the fields.
3. Click *Start Capture*.



Using the debug flow tool

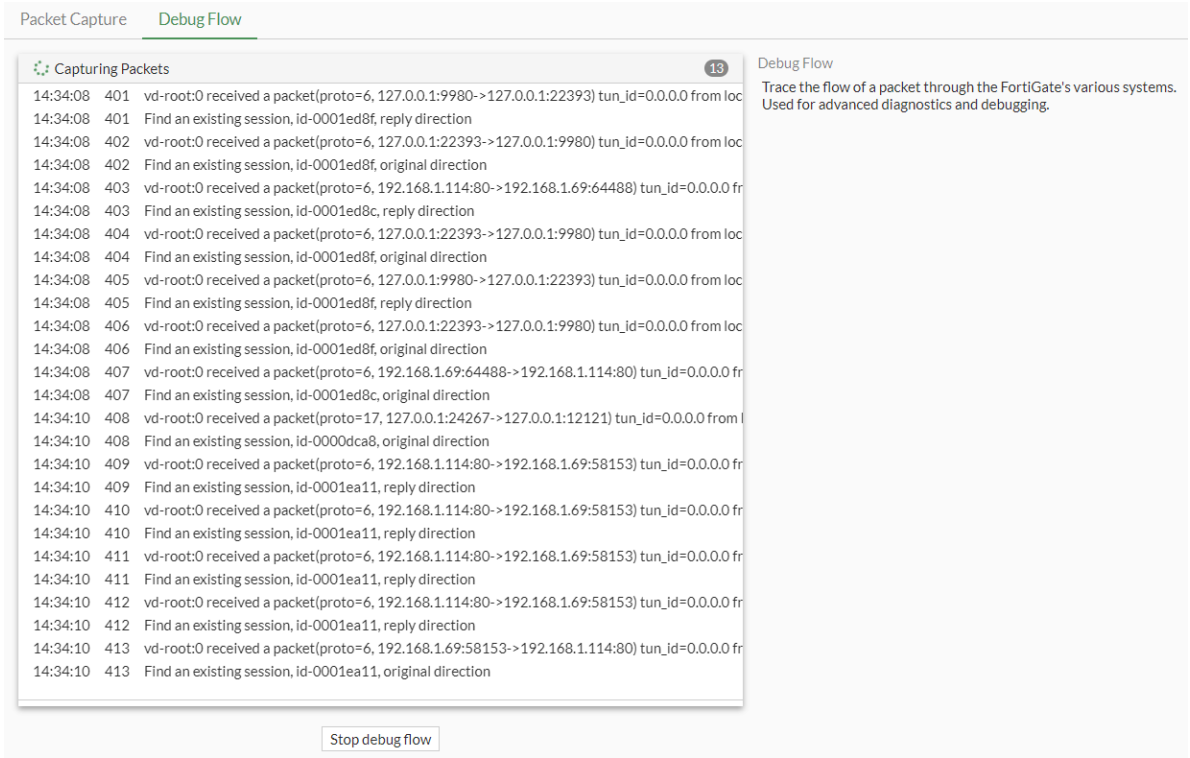
Administrators can use the debug flow tool to display debug flow output in real-time until it is stopped. The completed output can be filtered by time, message, or function. The output can be exported as a CSV file.

For information about using the debug flow tool in the CLI, see Debugging the packet flow on page 3133.

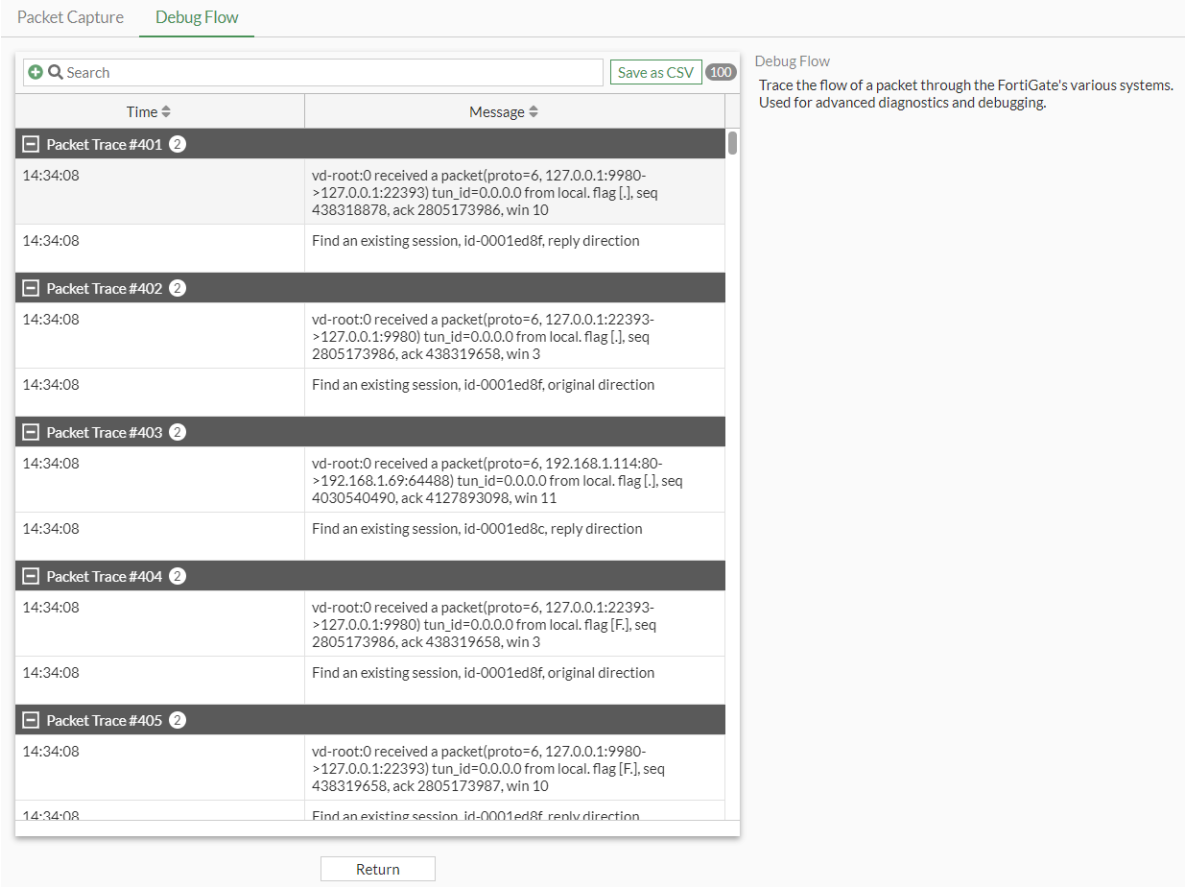


To run a debug flow:

1. Go to *Network* > *Diagnostics* and select the *Debug Flow* tab.
2. Optionally, enable *Filters* and select a *Filter type*:
   a. *Basic*: filter by *IP address*, *Port*, and *Protocol*, which is the equivalent of:
      - `# diagnose debug flow filter addr <addr/range>`
      - `# diagnose debug flow filter port <port/range>`
      - `# diagnose debug flow filter proto <protocol>`

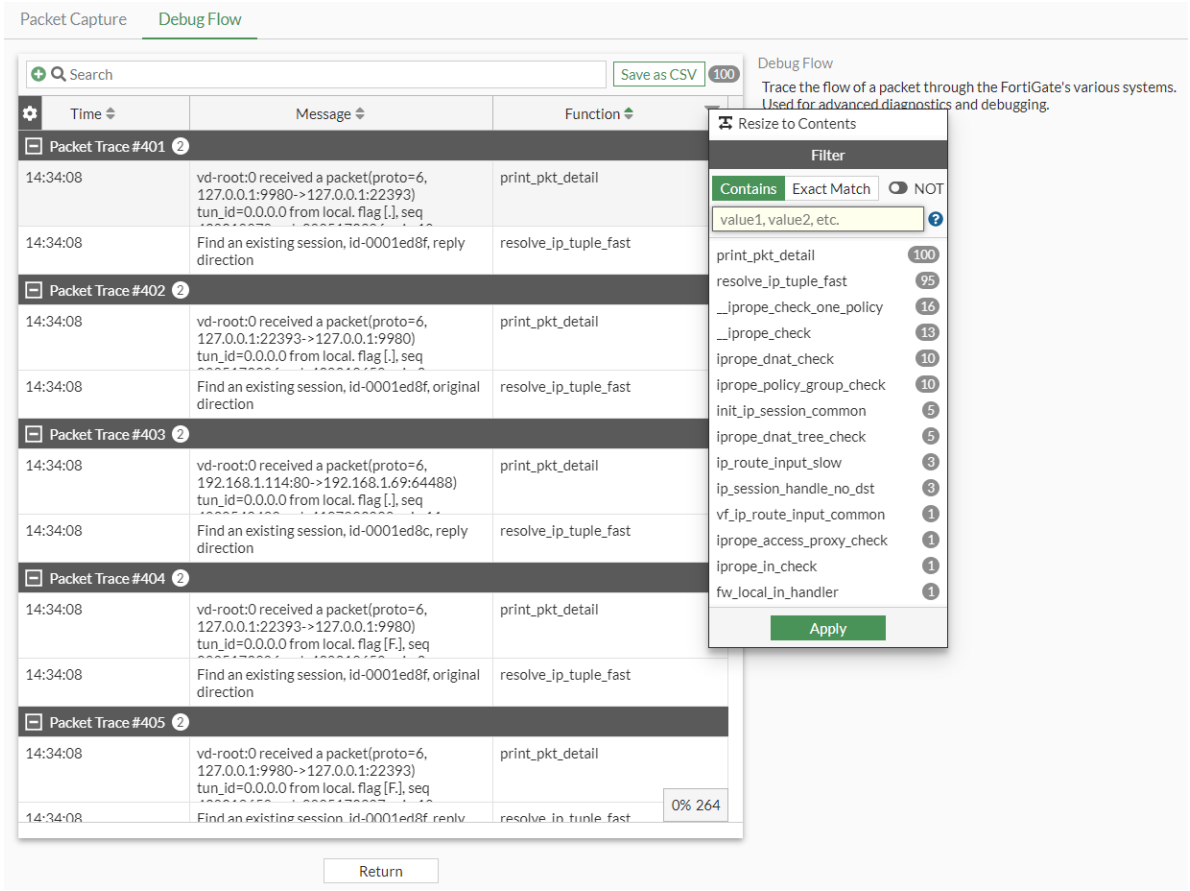


b. *Advanced*: filter by *Source IP*, *Source port*, *Destination IP*, *Destination port*, and *Protocol*, which is the equivalent of:



- `# diagnose debug flow filter saddr <addr/range>`
- `# diagnose debug flow filter sport <port/range>`
- `# diagnose debug flow filter daddr <addr/range>`
- `# diagnose debug flow filter dport <port/range>`
- `# diagnose debug flow filter proto <protocol>`

3. Click *Start debug flow*. The debug messages are visible in real-time.



4. When the debug flow is finished (or you click *Stop debug flow*), click *Save as CSV*. The CSV file is automatically downloaded.

The current output can be filtered by *Time* and *Message*. The *Function* field can be added.

5. Hover over the table header and click the gear icon (*Configure Table*).
6. Select *Function* and click *Apply*. The *Function* column is displayed and can be used to filter the output for further analysis.

SD-WAN

The following topics provide information about SD-WAN:

- SD-WAN overview on page 628
- SD-WAN quick start on page 632
- SD-WAN members and zones on page 642
- Performance SLA on page 653
- SD-WAN rules on page 688
- Advanced routing on page 752
- VPN overlay on page 782
- Advanced configuration on page 836
- SD-WAN cloud on-ramp on page 876
- Troubleshooting SD-WAN on page 898

SD-WAN overview

SD-WAN is a software-defined approach to managing Wide-Area Networks (WAN). It consolidates the physical transport connections, or underlays, and monitors and load-balances traffic across the links. VPN overlay networks can be built on top of the underlays to control traffic across different sites.

Health checks and SD-WAN rules define the expected performance and business priorities, allowing the FortiGate to automatically and intelligently route traffic based on the application, internet service, or health of a particular connection.

WAN security and intelligence can be extended into the LAN by incorporating wired and wireless networks under the same domain. FortiSwitch and FortiAP devices integrate seamlessly with the FortiGate to form the foundation of an SD-Branch.

Some of the key benefits of SD-WAN include:

- Reduced cost with transport independence across MPLS, 4G/5G LTE, and others.
- Reduced complexity with a single vendor and single-pane-of-glass management.
- Improve business application performance thanks to increased availability and agility.
- Optimized user experience and efficiency with SaaS and public cloud applications.

SD-WAN components and design principles

SD-WAN can be broken down into three layers:

- Management and orchestration
- Control, data plane, and security
- Network access

The control, data plane, and security layer can only be deployed on a FortiGate. The other two layers can help to scale and enhance the solution. For large deployments, FortiManager and FortiAnalyzer provide the management and orchestration capabilities FortiSwitch and FortiAP provide the components to deploy an SD-Branch.

Layer	Functions	Devices	
Management and orchestration	• Unified management • Template based solution • Zero touch provisioning • Logging, monitoring, and analysis • Automated orchestration using the REST API	FortiManager 	FortiAnalyzer 
Control, data plane, and security	• Consolidation of underlays and overlays into SD-WAN zones • Underlay and Overlay • Scalable VPN solutions using ADVPN • Overlay • Static and dynamic routing definition • Routing • NGFW firewalling • Security • SD-WAN health-checks and monitoring • SD-WAN • Application-aware steering and intelligence • SD-WAN	FortiGate 	
Network access	• Wired and wireless network segmentation • Built-in network access control	FortiSwitch 	FortiAP 

Design principles

The Five-pillar approach, described in the SD-WAN / SD-Branch Architecture for MSSPs guide, is recommended when designing a secure SD-WAN solution.

Underlay

Determine the WAN links that will be used for the underlay network, such as your broadband link, MPLS, 4G/5G LTE connection, and others.

For each link, determine the bandwidth, quality and reliability (packet loss, latency, and jitter), and cost. Use this information to determine which link to prefer, what type of traffic to send across the each link, and to help you the baselines for health-checks.

Overlay

VPN overlays are needed when traffic must travel across multiple sites. These are usually site-to-site IPsec tunnels that interconnect branches, datacenters, and the cloud, forming a hub-and-spoke topology.

The management and maintenance of the tunnels should be considered when determining the overlay network requirements. Manual tunnel configuration might be sufficient in a small environment, but could become unmanageable as the environment size increases. ADVPN can be used to help scale the solution; see ADVPN on page 1777 for more information.

Routing

Traditional routing designs manipulate routes to steer traffic to different links. SD-WAN uses traditional routing to build the basic routing table to reach different destinations, but uses SD-WAN rules to steer traffic. This allows the steering to be based on criteria such as destination, internet service, application, route tag, and the health of the link. Routing in an SD-WAN solution is used to identify all possible routes across the underlays and overlays, which the FortiGate balances using ECMP.

In the most basic configuration, static gateways that are configured on an SD-WAN member interface automatically provide the basic routing needed for the FortiGate to balance traffic across the links. As the number of sites and destinations increases, manually maintaining routes to each destination becomes difficult. Using dynamic routing to advertise routes across overlay tunnels should be considered when you have many sites to interconnect.

Security

Security involves defining policies for access control and applying the appropriate protection using the FortiGate's NGFW features. Efficiently grouping SD-WAN members into SD-WAN zones must also be considered. Typically, underlays provide direct internet access and overlays provide remote internet or network access. Grouping the underlays together into one zone, and the overlays into one or more zones could be an effective method.

SD-WAN

The SD-WAN pillar is the intelligence that is applied to traffic steering decisions. It is comprised of four primary elements:

- **SD-WAN zones**

  SD-WAN is divided into zones. SD-WAN member interfaces are assigned to zones, and zones are used in policies as source and destination interfaces. You can define multiple zones to group SD-WAN interfaces together, allowing logical groupings for overlay and underlay interfaces. Routing can be configured per zone.

  See SD-WAN members and zones on page 642.
- **SD-WAN members**

  Also called interfaces, SD-WAN members are the ports and interfaces that are used to run traffic. At least one interface must be configured for SD-WAN to function.

  See Configuring the SD-WAN interface on page 633.
- **Performance SLAs**

  Also called health-checks, performance SLAs are used to monitor member interface link quality, and to detect link failures. When the SLA falls below a configured threshold, the route can be removed, and traffic can be steered to different links in the SD-WAN rule.

  SLA health-checks use active or passive probing:

- Active probing requires manually defining the server to be probed, and generates consistent probing traffic.
- Passive probing uses active sessions that are passing through firewall policies used by the related SD-WAN interfaces to derive health measurements. It reduces the amount of configuration, and eliminates probing traffic. See Passive WAN health measurement on page 665 for details.

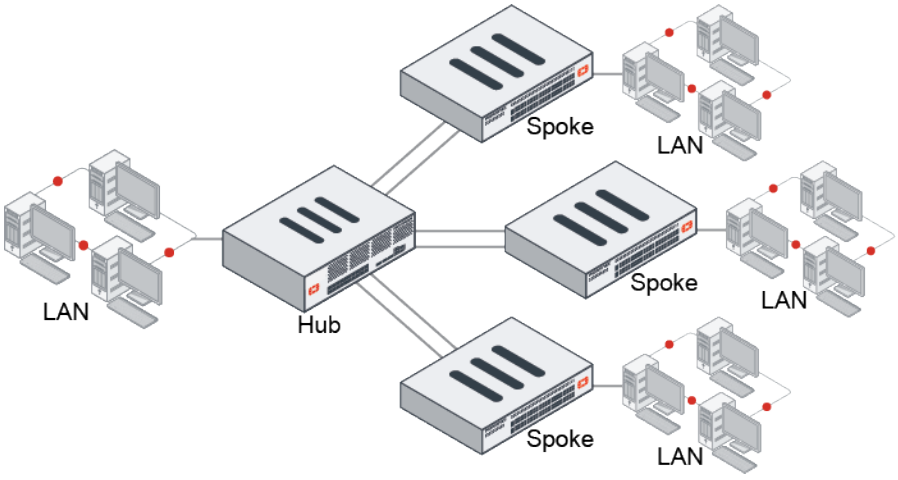
See Performance SLA on page 653.

- **SD-WAN rules**

  Also called services, SD-WAN rules control path selection. Specific traffic can be dynamically sent to the best link, or use a specific route.

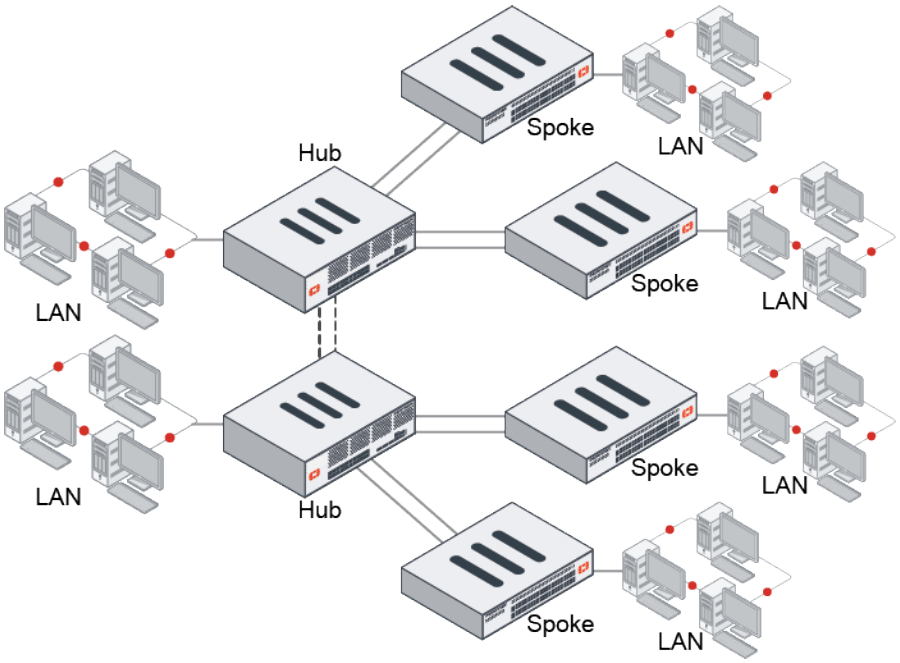
  Rules control the strategy that the FortiGate uses when selecting the outbound traffic interface, the SLAs that are monitored when selecting the outgoing interface, and the criteria for selecting the traffic that adheres to the rule. When no SD-WAN rules match the traffic, the implicit rule applies.

  See SD-WAN rules on page 688.



SD-WAN designs and architectures

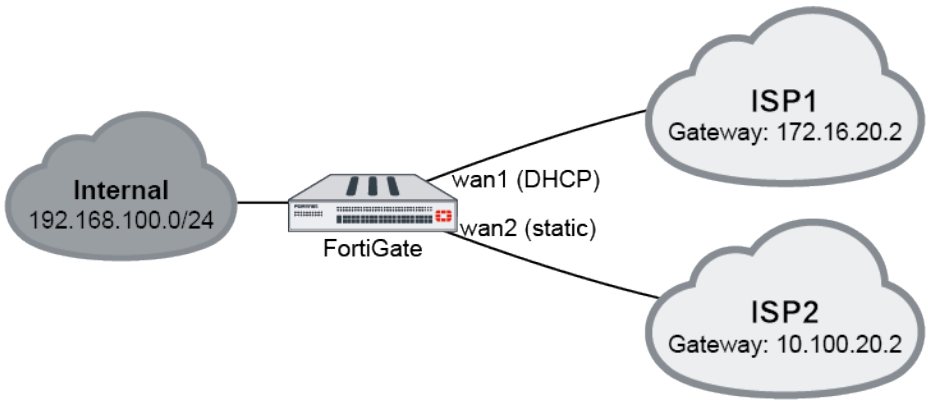
The core functionalities of Fortinet's SD-WAN solution are built into the FortiGate. Whether the environment contains one FortiGate, or one hundred, you can use SD-WAN by enabling it on the individual FortiGates.



At a basic level, SD-WAN can be deployed on a single device in a single site environment:

At a more advanced level, SD-WAN can be deployed in a multi-site, hub and spoke environment:

At an enterprise or MSSP level, the network can include multiple hubs, possibly across multiple regions:



For more details, see the SD-WAN / SD-Branch Architecture for MSSPs guide.

SD-WAN quick start

This section provides an example of how to start using SD-WAN for load balancing and redundancy.

In this example, two ISP internet connections, wan1 (DHCP) and wan2 (static), use SD-WAN to balance traffic between them at 50% each.

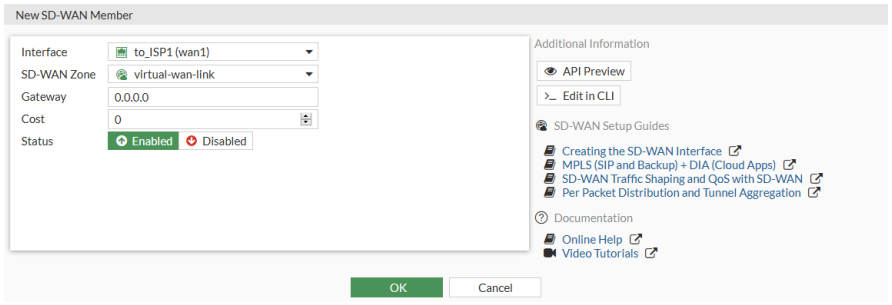
1. Configuring the SD-WAN interface on page 633
2. Adding a static route on page 634
3. Selecting the implicit SD-WAN algorithm on page 634
4. Configuring firewall policies for SD-WAN on page 635
5. Link monitoring and failover on page 635
6. Results on page 637
7. Configuring SD-WAN in the CLI on page 640

Configuring the SD-WAN interface

First, SD-WAN must be enabled and member interfaces must be selected and added to a zone. The selected FortiGate interfaces can be of any type (physical, aggregate, VLAN, IPsec, and others), but must be removed from any other configurations on the FortiGate.

In this step, two interfaces are configured and added to the default SD-WAN zone (virtual-wan-link) as SD-WAN member interfaces. This example uses a mix of static and dynamic IP addresses; your deployment could also use only one or the other.

Once the SD-WAN members are created and added to a zone, the zone can be used in firewall policies, and the whole SD-WAN can be used in static routes.



To configure SD-WAN members:

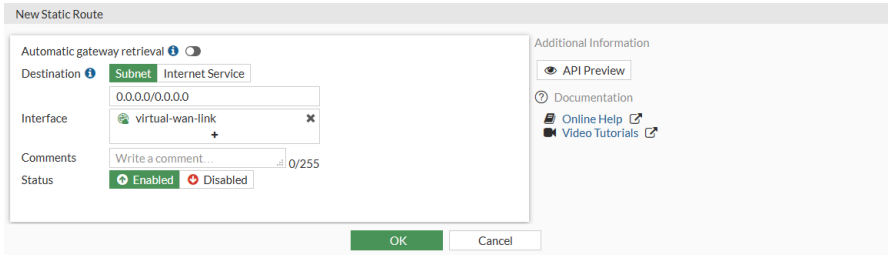
1. Configure the wan1 and wan2 interfaces. See Interface settings on page 150 for details.
   a. Set the wan1 interface *Addressing mode* to *DHCP* and *Distance* to *10*.

   By default, a DHCP interface has a distance of 5, and a static route has a distance of 10. It is important to account for this when configuring your SD-WAN for 50/50 load balancing by setting the DHCP interface's distance to 10.

   b. Set the wan2 interface *IP/Netmask* to *10.100.20.1 255.255.255.0*.
2. Go to *Network* > *SD-WAN*, select the *SD-WAN Zones* tab, and click *Create New* > *SD-WAN Member*.
3. Set the *Interface* to *wan1*.
4. Leave *SD-WAN Zone* as *virtual-wan-link*.
5. As wan1 uses DHCP, leave *Gateway* set to *0.0.0.0*.
   If IPv6 visibility is enabled in the GUI, an IPv6 gateway can also be added for each member. See Feature visibility on page 2517 for details.
6. Leave *Cost* as *0*.
   The *Cost* field is used by the Lowest Cost (SLA) strategy. The link with the lowest cost is chosen to pass traffic. The lowest possible *Cost* is *0*.

7. Set *Status* to *Enable*, and click *OK*.

8. Repeat the above steps for wan2, setting *Gateway* to the ISP's gateway: *10.100.20.2*.



Adding a static route

You must configure a default route for the SD-WAN. The default gateways for each SD-WAN member interface do not need to be defined in the static routes table. FortiGate will decide what route or routes are preferred using Equal Cost Multi-Path (ECMP) based on distance and priority.

To create a static route for SD-WAN:

1. Go to *Network* > *Static Routes*.
2. Click *Create New*. The *New Static Route* page opens.
3. Set *Destination* to *Subnet*, and leave the IP address and subnet mask as *0.0.0.0/0.0.0.0*.
4. In the *Interface* field select an SD-WAN zone.

5. Ensure that *Status* is *Enabled*.
6. Click *OK*.

Selecting the implicit SD-WAN algorithm

SD-WAN rules define specific routing options to route traffic to an SD-WAN member.

If no routing rules are defined, the default *Implicit* rule is used. It can be configured to use one of five different load balancing algorithms. See Implicit rule on page 696 for more details and examples.

This example shows four methods to equally balance traffic between the two WAN connections. Go to *Network* > *SD-WAN*, select the *SD-WAN Rules* tab, and edit the *sd-wan* rule to select the method that is appropriate for your requirements.

- *Source IP* (CLI command: `source-ip-based`):
  Select this option to balance traffic equally between the SD-WAN members according to a hash algorithm based on the source IP addresses.

- *Session* (`weight-based`):
  Select this option to balance traffic equally between the SD-WAN members by the session numbers ratio among its members. Use weight 50 for each of the 2 members.
- *Source-Destination IP* (`source-dest-ip-based`):
  Select this option to balance traffic equally between the SD-WAN members according to a hash algorithm based on the source and destination IP addresses.
- *Volume* (`measured-volume-based`):
  Select this option to balance traffic equally between the SD-WAN members according to the bandwidth ratio among its members.

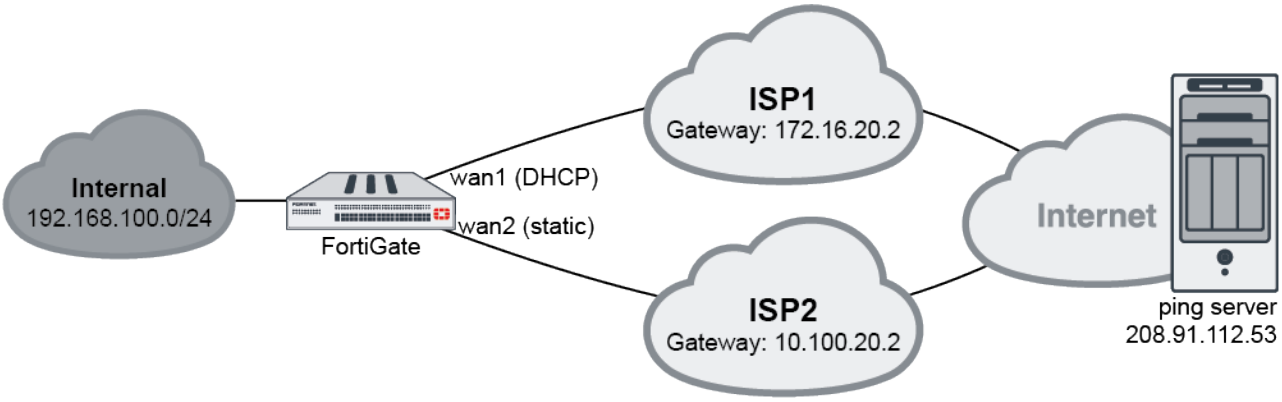
Configuring firewall policies for SD-WAN

SD-WAN zones can be used in policies as source and destination interfaces. Individual SD-WAN members cannot be used in policies.

You must configure a policy that allows traffic from your organization's internal network to the SD-WAN zone. Policies configured with the SD-WAN zone apply to all SD-WAN interface members in that zone.

To create a firewall policy for SD-WAN:

1. Go to *Policy & Objects* > *Firewall Policy*.
2. Click *Create New*. The *New Policy* page opens.
3. Configure the following:

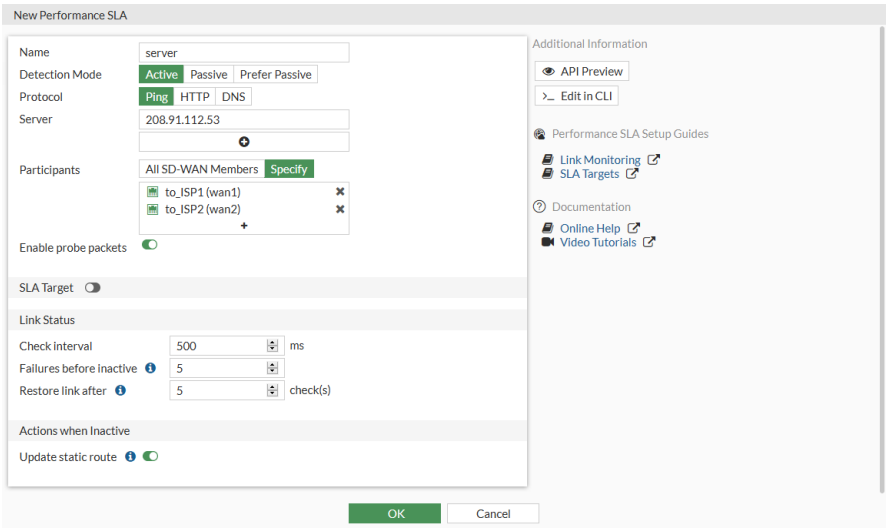


Name	Enter a name for the policy.
Incoming Interface	*internal*
Outgoing Interface	*virtual-wan-link*
Source	*all*
Destination	*all*
Schedule	*always*
Service	*ALL*
Action	*ACCEPT*
Firewall / Network Options	Enable *NAT* and set *IP Pool Configuration* to *Use Outgoing Interface Address*.
Security Profiles	Apply profiles as required.
Logging Options	Enable *Log Allowed Traffic* and select *All Sessions*. This allows you to verify results later.

4. Enable the policy, then click *OK*.

Link monitoring and failover

Performance SLA link monitoring measures the health of links that are connected to SD-WAN member interfaces by sending probing signals through each link to a server, and then measuring the link quality based on latency, jitter, and



packet loss. If a link is broken, the routes on that link are removed and traffic is routed through other links. When the link is working again, the routes are re-enabled. This prevents traffic being sent to a broken link and lost.

In this example, the detection server IP address is 208.91.112.53. A performance SLA is created so that, if ping fails per the metrics defined, the routes to that interface are removed and traffic is detoured to the other interface. The ping protocol is used, but other protocols could also be selected as required.

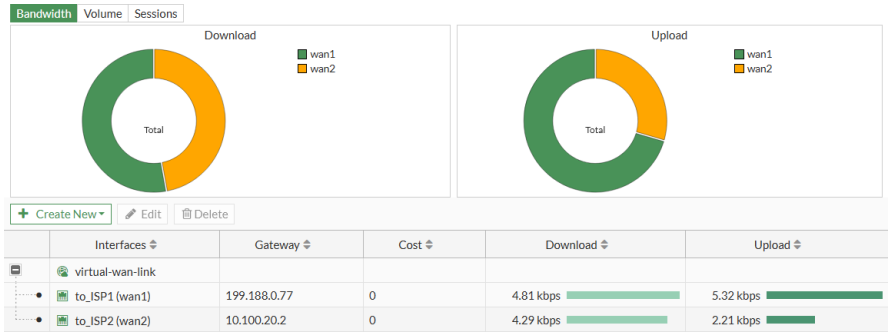
To configure a performance SLA:

1. Go to *Network* > *SD-WAN*, select the *Performance SLAs* tab, and click *Create New*.
2. Enter a name for the SLA and set *Protocol* to *Ping*.
3. In the *Server* field, enter the detection server IP address (208.91.112.53 in this example).
4. In the *Participants* field, select *Specify* and add wan1 and wan2.

   SLA targets are not required for link monitoring.
5. Configure the required metrics in *Link Status*.
6. Ensure that *Update static route* is enabled. This disables static routes for the inactive interface and restores routes on recovery.
7. Click *OK*.

Results

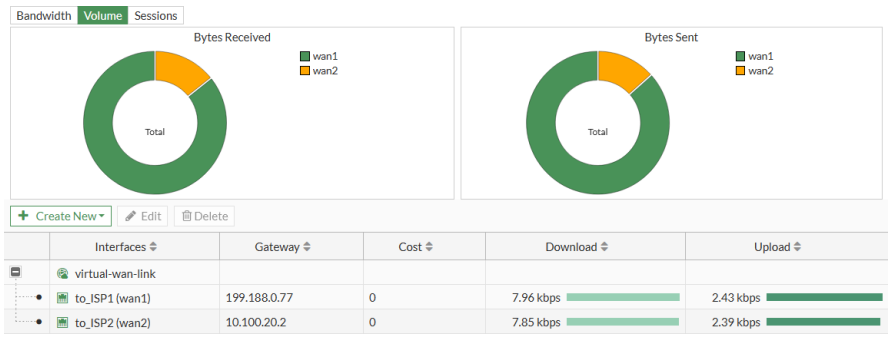
The following GUI pages show the function of the SD-WAN and can be used to confirm that it is setup and running correctly:



- Interface usage on page 637
- Performance SLA on page 638
- Routing table on page 639
- Firewall policy on page 640

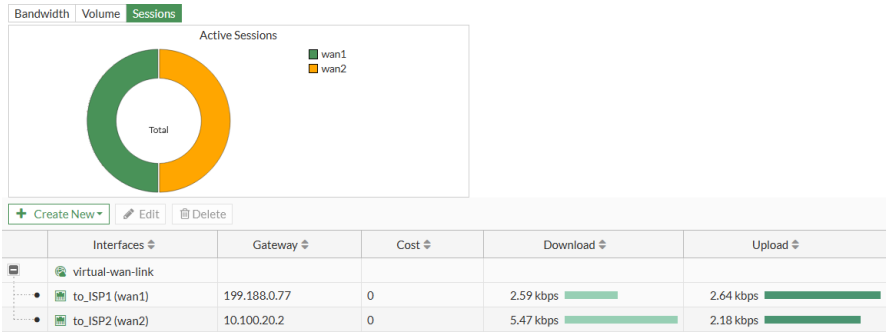
Interface usage

Go to *Network* > *SD-WAN* and select the *SD-WAN Zones* tab to review the SD-WAN interfaces' usage.



Bandwidth

Select *Bandwidth* to view the amount of downloaded and uploaded data for each interface.

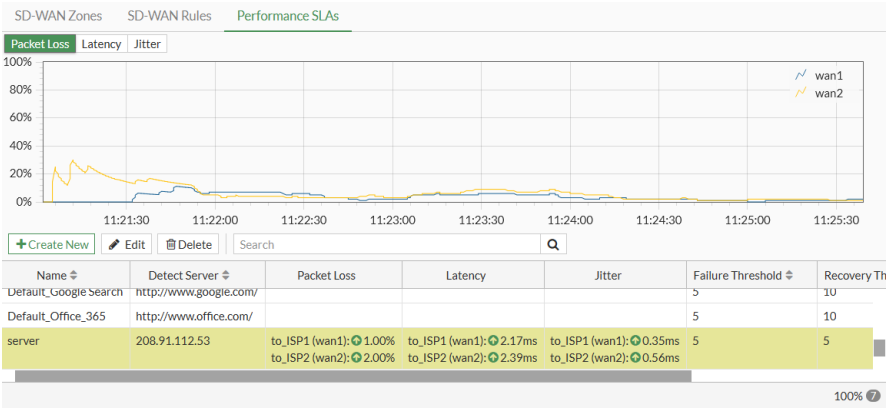


Volume

Select *Volume* to see donut charts of the received and sent bytes on the interfaces.

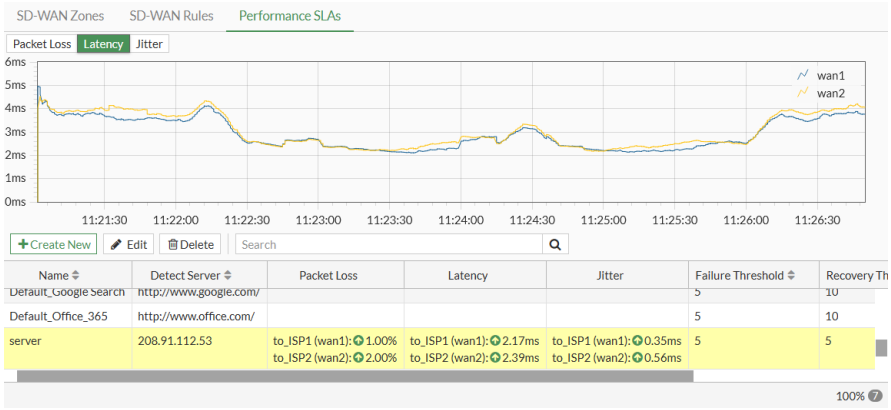
Sessions

Select *Sessions* to see a donut chart of the number of active sessions on each interface.



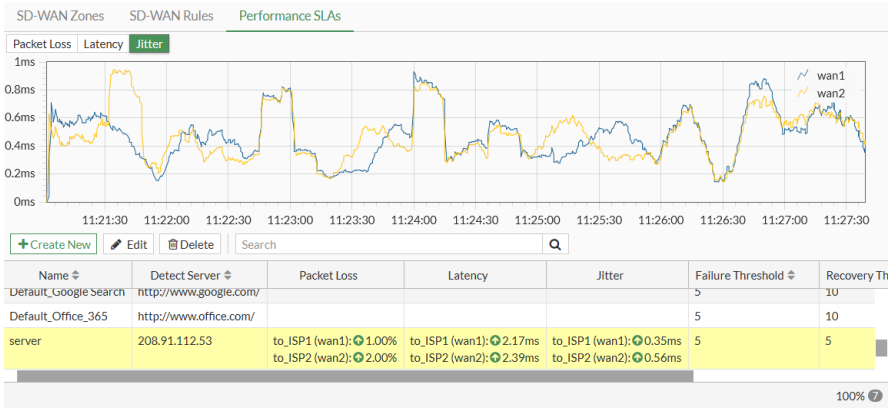
Performance SLA

Go to *Network* > *SD-WAN*, select the *Performance SLAs* tab, and select the SLA from the table (*server* in this example) to view the packet loss, latency, and jitter on each SD-WAN member in the health check server.



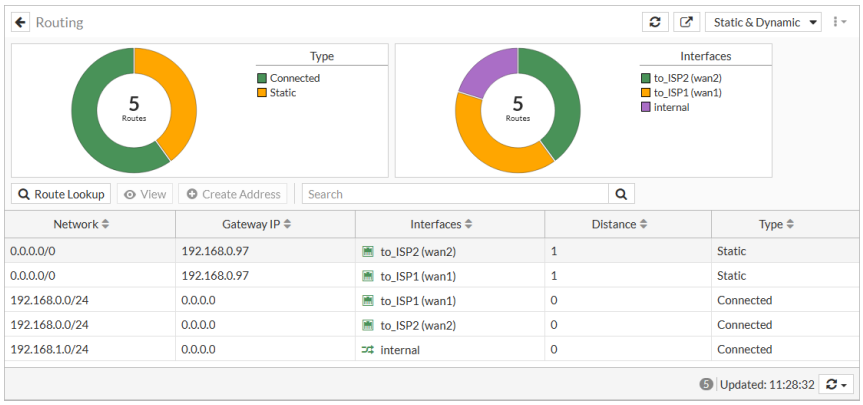
Packet loss

Select *Packet Loss* to see the percentage of packets lost for each member.



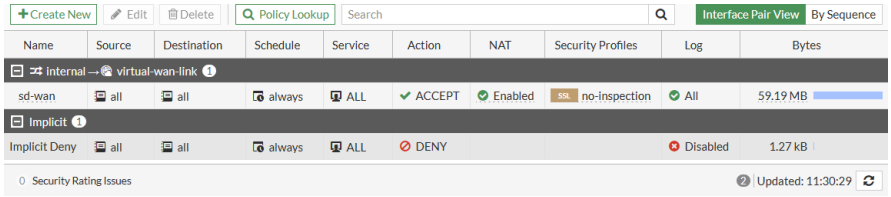
Latency

Select *Latency* to see the current latency, in milliseconds, for each member.



Jitter

Select *Jitter* to see the jitter, in milliseconds, for each member.



Routing table

Go to *Dashboard* > *Network*, expand the *Routing* widget, and select *Static & Dynamic* to review all static and dynamic routes. For more information about the widget, see Static & Dynamic Routing monitor on page 101.

Firewall policy

Go to *Policy & Objects* > *Firewall Policy* to review the SD-WAN policy.

Configuring SD-WAN in the CLI

This example can be entirely configured using the CLI.

To configure SD-WAN in the CLI:

1. Configure the wan1 and wan2 interfaces:

```
config system interface
    edit "wan1"
        set alias to_ISP1
        set mode dhcp
        set distance 10
    next
    edit "wan2"
        set alias to_ISP2
        set ip 10.100.20.1 255.255.255.0
    next
end
```

2. Enable SD-WAN and add the interfaces as members:

```
config system sdwan
    set status enable
    config members
        edit 1
            set interface "wan1"
        next
        edit 2
            set interface "wan2"
            set gateway 10.100.20.2
        next
    end
end
```

If no SD-WAN zone is specified, members are added to the default *virtual-wan-link* zone.

3. Create a static route for SD-WAN:

```
config router static
    edit 1
        set sdwan-zone "virtual-wan-link"
    next
end
```

4. Select the implicit SD-WAN algorithm:

```
config system sdwan
    set load-balance-mode {source-ip-based | weight-based | source-dest-ip-based |
measured-volume-based}
end
```

5. Create a firewall policy for SD-WAN:

```
config firewall policy
    edit <policy_id>
        set name <policy_name>
        set srcintf "internal"
        set dstintf "virtual-wan-link"
        set srcaddr all
        set dstaddr all
        set action accept
        set schedule always
        set service ALL
        set utm-status enable
        set ssl-ssh-profile <profile_name>
        set av-profile <profile_name>
        set webfilter-profile <profile_name>
        set dnsfilter-profile <profile_name>
        set emailfilter-profile <profile_name>
        set ips_sensor <sensor_name>
        set application-list <app_list>
        set voip-profile <profile_name>
        set logtraffic all
        set nat enable
        set status enable
    next
end
```

6. Configure a performance SLA:

```
config system sdwan
    config health-check
        edit "server"
            set server "208.91.112.53"
            set update-static-route enable
            set members 1 2
        next
    end
end
```

Results

To view the routing table:

```
# get router info routing-table all

Routing table for VRF=0
Codes: K - kernel, C - connected, S - static, R - RIP, B - BGP
       O - OSPF, IA - OSPF inter area
       N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
       E1 - OSPF external type 1, E2 - OSPF external type 2
       i - IS-IS, L1 - IS-IS level-1, L2 - IS-IS level-2, ia - IS-IS inter area
       * - candidate default

S*      0.0.0.0/0 [1/0] via 172.16.20.2, wan1
                  [1/0] via 10.100.20.2, wan2
C       10.100.20.0/24 is directly connected, wan2
C       172.16.20.2/24 is directly connected, wan1
C       192.168.0.0/24 is directly connected, internal
```

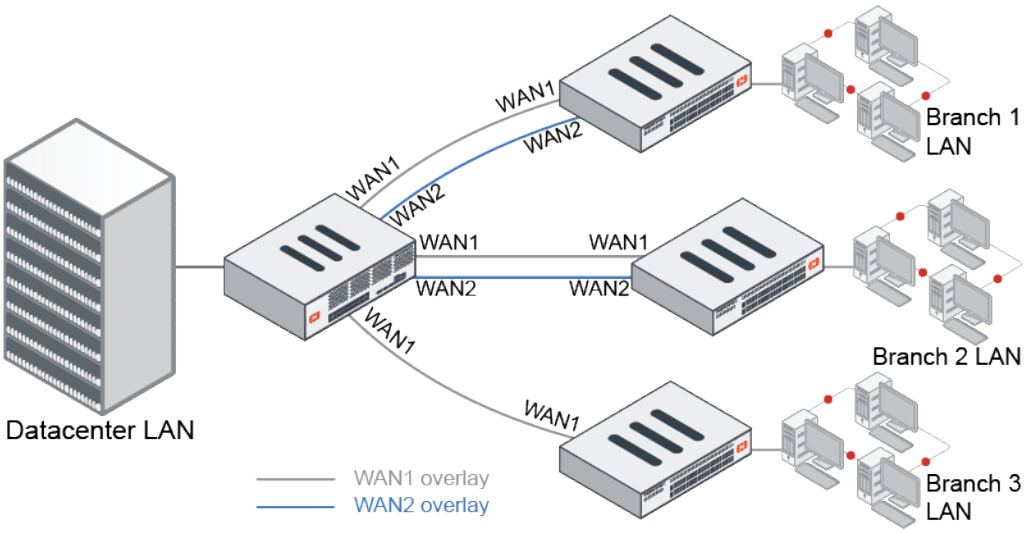
To diagnose the Performance SLA status:

```
FGT # diagnose sys sdwan health-check
Health Check(server):
Seq(1): state(alive), packet-loss(0.000%) latency(15.247), jitter(5.231) sla_map=0x0
Seq(2): state(alive), packet-loss(0.000%) latency(13.621), jitter(6.905) sla_map=0x0
```

SD-WAN members and zones

SD-WAN bundles interfaces together into zones. Interfaces are first configured as SD-WAN members. This does not change the interface, it just allows SD-WAN to reference the interface as a member. SD-WAN member interfaces can be any interface supported by FortiGates, such as physical ports, VLAN interfaces, LAGs, IPsec tunnels, GRE tunnels, IPIP tunnels, and FortiExtender interfaces. Once SD-WAN members are configured, they can be assigned to a zone. Zones are used in policies as source and destination interfaces, in static routes, and in SD-WAN rules.

Multiple zones can be used to group SD-WAN interfaces for logical scenarios, such as overlay and underlay interfaces. Using multiple zones in policies allows for more granular control over functions like resource access and UTM access. Individual SD-WAN member interfaces cannot be used directly in policies, but they can be moved between SD-WAN zones at any time. If a member interface requires a special SD-WAN consideration, it can be put into an SD-WAN zone by itself.



SD-WAN zones and members can be used in IPv4 and IPv6 static routes to make route configurations more flexible. SD-WAN zones and members can be used in SD-WAN rules to simplify the rule configuration. See Specify an SD-WAN zone in static routes and SD-WAN rules on page 648 for more information.

When the Security Fabric is configured, SD-WAN zones are included in the Security Fabric topology views.

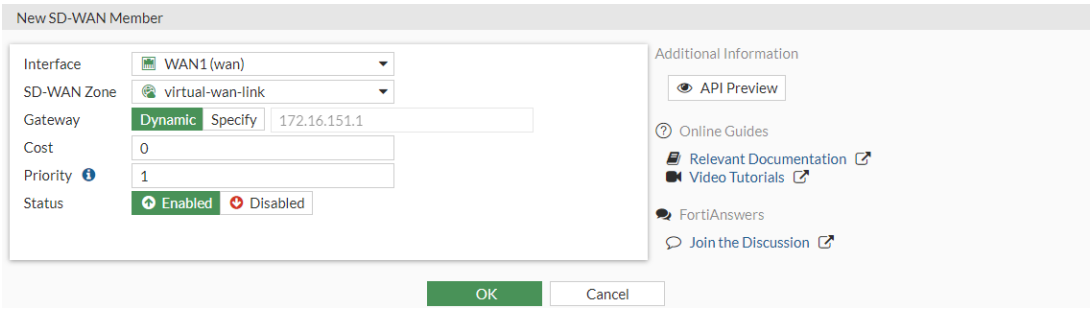
Topology

This topology is used in the following procedures:

- Configuring SD-WAN member interfaces
- Configuring SD-WAN zones
- Using SD-WAN zones

Configuring SD-WAN member interfaces

When configuring SD-WAN zones and members, it does not matter what order they are defined. In this example, the members are defined first, and they will be placed temporarily in the default zone called virtual-wan-link. A zone must be defined when creating a member, and the overlay and underlay zones will created in the next procedure. It is standard practice to create SD-WAN members for each underlay and overlay interface, as most SD-WAN implementations apply SD-WAN intelligence to both underlay and overlay networks.



The following options can be configured for SD-WAN members:

GUI option	CLI option	Description
Interface	`interface`	Select the interface to use as an SD-WAN member. Optionally, select *None* in the GUI to not use an interface yet.
SD-WAN Zone	`zone`	Select the destination zone if it exists at the time of member creation. Otherwise, the default virtual-wan-link zone is applied. A new zone can be created within the GUI dropdown field.

GUI option	CLI option	Description
Gateway/IPv6 Gateway	`gateway/gateway6`	Enter the default gateway for the interface. For interfaces that already have a default gateway, such as those configured using DHCP, this field is pre-populated in the GUI.
Cost	`cost`	Enter the cost of the interface for services in SLA mode (0 - 4294967295, default = 0). A lower cost has a higher preference.
Priority	`priority`	Enter the priority of the interface for IPv4 (1 - 65535, default = 1). The priority is used in the static route created for the SD-WAN member interface and in SD-WAN rules (including the implicit rule). When priority is used to determine the best route, the lower value takes precedence.
Status	`status`	Enable or disable the interface in SD-WAN.
n/a	`source/source6`	Set the source IP address used in the health check packet to the server.

To configure the SD-WAN members and add them to the default zone in the GUI:

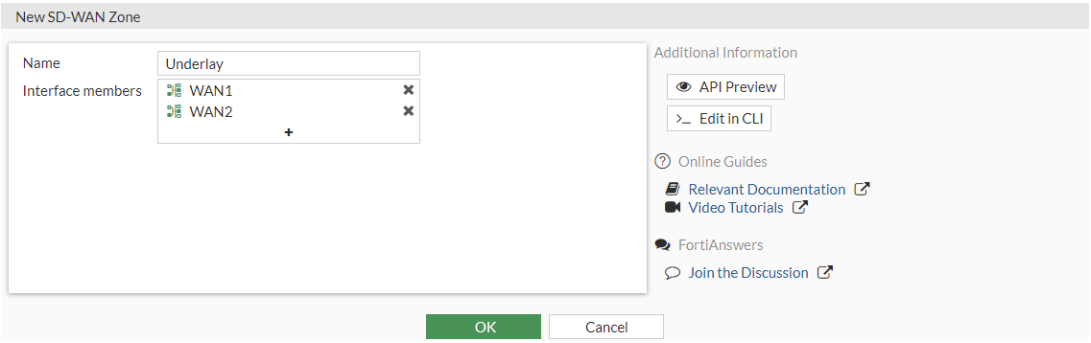
1. Go to *Network* > *SD-WAN*, select the *SD-WAN Zones* tab, and click *Create New* > *SD-WAN Member*.
2. Set the *Interface* to *WAN1*.
3. Leave the *SD-WAN Zone* as *virtual-wan-link*.

4. Click *OK*.
5. Repeat these steps to create SD-WAN members for the WAN2, VPN1, and VPN2 interfaces.

To configure the SD-WAN members and add them to the default zone in the CLI:

```
config system sdwan
    config members
        edit 1
            set interface "WAN1"
            set zone "virtual-wan-link"
        next
        edit 2
            set interface "WAN2"
```

```
            set zone "virtual-wan-link"
        next
        edit 3
            set interface "VPN1"
            set zone "virtual-wan-link"
        next
        edit 4
            set interface "VPN2"
            set zone "virtual-wan-link"
        next
    end
end
```



Configuring SD-WAN zones

While SD-WAN zones are primarily used to logically group interfaces that are often used for the same purpose (such as WAN1 and WAN2), sometimes an SD-WAN zone can have a single member. This is due to the constraint that SD-WAN members may not be referenced directly in policies; however, SD-WAN members can be referenced directly in SD-WAN rules.

In this example, two zones named Overlay and Underlay are configured, and the member interfaces are added to their respective zones.

To configure the SD-WAN zones in the GUI:

1. Go to *Network* > *SD-WAN* and select the *SD-WAN Zones* tab.
2. Click *Create New* > *SD-WAN Zone*.
3. Enter the *Name*, *Underlay*.
4. Set the *Interface members* to *WAN1* and *WAN2*.

5. Click *OK*.
6. Repeat these steps to configure the *Overlay* zone with members VPN1 and VPN2.

To configure the SD-WAN zones in the CLI:

1. Configure the SD-WAN zones:

```
config system sdwan
    config zone
        edit "Overlay"
        next
```

```
        edit "Underlay"
        next
    end
end
```

2. Add the member interfaces to their respective zones:

```
config system sdwan
    config members
        edit 1
            set interface WAN1
            set zone "Underlay"
        next
        edit 2
            set interface WAN2
            set zone "Underlay"
        next
        edit 3
            set interface VPN1
            set zone "Overlay"
        next
        edit 4
            set interface VPN2
            set zone "Overlay"
        next
    end
end
```

In the `config zone` settings, there is a `service-sla-tie-break` parameter that includes three options for the tie-break method used when multiple interfaces in a zone are eligible for traffic:

- `cfg-order`: members that meet the SLA are selected in the order they are configured (default).
- `fib-best-match`: members that meet the SLA are selected that match the longest prefix in the routing table.
- `input-device`: members that meet the SLA are selected by matching the input device.

See Overlay stickiness on page 854 for more information.

Using SD-WAN zones

Once SD-WAN zones are defined, they can be used in firewall policies. This section covers three policy scenarios:

- Datacenter resource access
- Direct internet access
- Remote internet access

SD-WAN zones are a critical component of SD-WAN rules. See Fields for configuring WAN intelligence on page 692 for more information.

Datacenter resource access

Datacenter resources are made available through the VPN branches or overlay. In this example, there are two SD-WAN members in the overlay zone that the branch FortiGate can use to route traffic to and from the datacenter resource. The overlay zone is used as the destination in the firewall policy.

To configure the firewall policy:

1. Go to *Policy & Objects* > *Firewall Policy* and click *Create New*.
2. Configure the following settings:

Name	*DC_Access*
Incoming Interface	*LAN*
Outgoing Interface	*Overlay*
Source	*Branch_LAN*
Destination	*DC_LAN*
Action	*ACCEPT*

3. Configure the other settings as needed.
4. Click *OK*.

This firewall policy allows traffic to any interfaces included in the zone. The SD-WAN rules contain the intelligence used to select which members in the zone to use.

Direct internet access

Direct internet access (DIA) is how a branch may access resources contained on the public internet. This can be non-business resources (such as video streaming sites), or publically available business resources (such as vendor portals).

To configure the firewall policy:

1. Go to *Policy & Objects* > *Firewall Policy* and click *Create New*.
2. Configure the following settings:

Name	*DIA*
Incoming Interface	*LAN*
Outgoing Interface	*Underlay*
Source	*Branch_LAN*
Destination	*all*
Action	*ACCEPT*

3. Configure the other settings as needed.
4. Click *OK*.

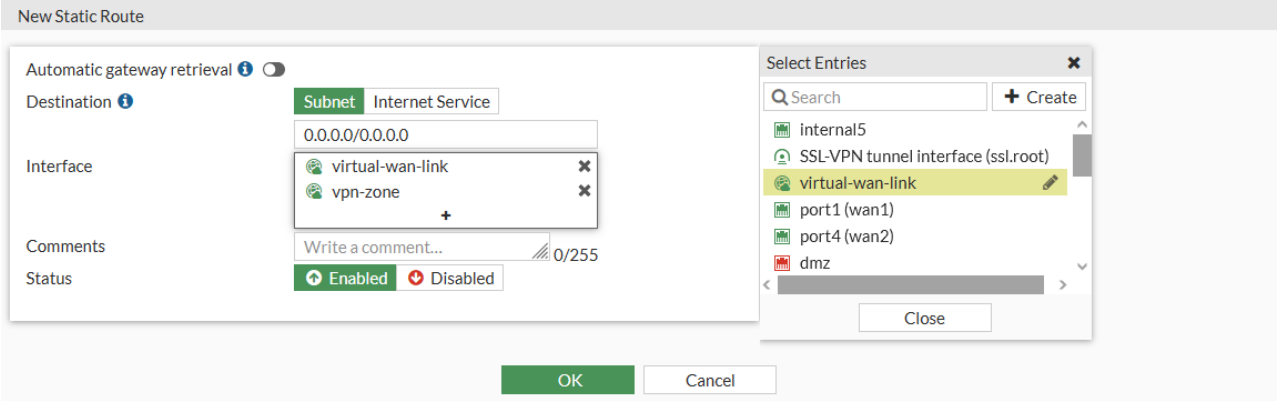
Remote internet access

Remote internet access (RIA) is the ability for a branch location to route public internet access requests across the overlay and out one of the hub's (or datacenter's) WAN interfaces. This option is effective when a branch has a WAN circuit with a local ISP and a second circuit that is private, such as MPLS. When the WAN circuit goes down, it is possible to send traffic through the hub using the MPLS overlay.

To configure the firewall policy:

1. Go to *Policy & Objects* > *Firewall Policy* and click *Create New*.
2. Configure the following settings:

Name	*RIA*
Incoming Interface	*LAN*
Outgoing Interface	*Overlay*
Source	*Branch_LAN*
Destination	*all*
Action	*ACCEPT*



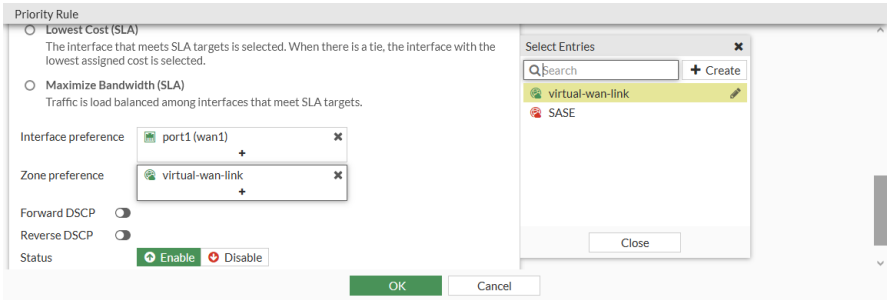
3. Configure the other settings as needed.
4. Click *OK*.

Specify an SD-WAN zone in static routes and SD-WAN rules

SD-WAN zones can be used in IPv4 and IPv6 static routes, and in SD-WAN service rules. This makes route configuration more flexible, and simplifies SD-WAN rule configuration.

To configure an SD-WAN zone in a static route in the GUI:

1. Go to *Network* > *Static Routes*
2. Edit an existing static route, or click *Create New* to create a new route.
3. Set *Interface* to one or more SD-WAN zones.



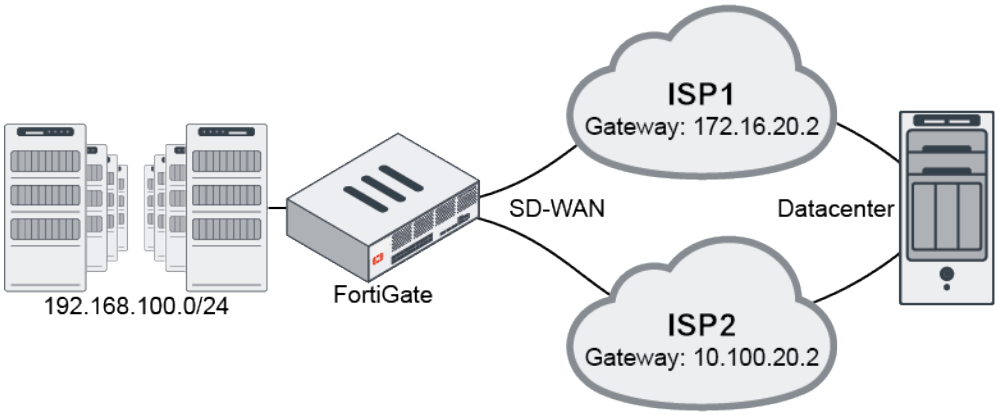
4. Configure the remaining settings are required.
5. Click *OK*.

To configure an SD-WAN zone in a static route in the CLI:

```
config router {static | static6}
    edit 1
        set sdwan-zone <zone> <zone> ...
    next
end
```

To configure an SD-WAN zone in an SD-WAN rule in the GUI:

1. Go to *Network* > *SD-WAN* and select the *SD-WAN Rules* tab
2. Edit an existing rule, or click *Create New* to create a new rule.
3. In the *Zone preference* field add one or more SD-WAN zones.



4. Configure the remaining settings are needed.
5. Click *OK*.

To configure an SD-WAN zone in an SD-WAN rule in the CLI:

```
config system sdwan
    config service
        edit 1
            set priority-zone <zone>
        next
    end
end
```

Examples

In these two examples, three SD-WAN members are created. Two members, port13 and port15, are in the default zone (*virtual-wan-link*), and the third member, to_FG_B_root, is in the *SASE* zone.

Example 1

In this example:

- Two service rules are created. Rule 1 uses the *virtual-wan-link* zone, and rule 2 uses the *SASE* zone.
- Two IPv4 static routes are created. The first route uses the *virtual-wan-link* zone, and the second route uses the *SASE* zone.

To configure the SD-WAN:

1. Assign port13 and port15 to the *virtual-wan-link* zone and to_FG_B_root to the *SASE* zone:

```
config system sdwan
    set status enable
    config members
        edit 1
            set interface "port13"
            set zone "virtual-wan-link"
            set gateway 10.100.1.1
        next
        edit 2
            set interface "port15"
            set zone "virtual-wan-link"
            set gateway 10.100.1.5
        next
        edit 3
            set interface "to_FG_B_root"
            set zone "SASE"
        next
    end
end
```

2. Create two service rules, one for each SD-WAN zone:

```
config system sdwan
    config service
```

```
        edit 1
            set dst "10.100.20.0"
            set priority-zone "virtual-wan-link"
        next
        edit 2
            set internet-service enable
            set internet-service-name "Fortinet-FortiGuard"
            set priority-zone "SASE"
        next
    end
end
```

3. Configure static routes for each of the SD-WAN zones:

```
config router static
    edit 1
        set distance 1
        set sdwan-zone "virtual-wan-link"
    next
    edit 2
        set dst 172.16.109.0 255.255.255.0
        set distance 1
        set sdwan-zone "SASE"
    next
end
```

To verify the results:

1. Check the service rule 1 diagnostics:

```
# diagnose sys sdwan service 1

Service(1): Address Mode(IPV4) flags=0x200 use-shortcut-sla
  Gen(1), TOS(0x0/0x0), Protocol(0: 1->65535), Mode(manual)
  Members(2):
    1: Seq_num(1 port13), alive, selected
    2: Seq_num(2 port15), alive, selected
  Dst address(1):
        10.100.20.0-10.100.20.255
```

Both members of the *virtual-wan-link* zone are selected. In manual mode, the interface members are selected based on the member configuration order. In SLA and priority mode, the order depends on the link status. If all of the link statuses pass, then the members are selected based on the member configuration order.

2. Check the service rule 2 diagnostics:

```
# diagnose sys sdwan service 2

Service(2): Address Mode(IPV4) flags=0x200 use-shortcut-sla
  Gen(1), TOS(0x0/0x0), Protocol(0: 1->65535), Mode(manual)
  Members(1):
    1: Seq_num(3 to_FG_B_root), alive, selected
  Internet Service(1): Fortinet-FortiGuard(1245324,0,0,0)
```

The member of the *SASE* zone is selected.

3. Review the routing table:

```
# get router info routing-table static
Routing table for VRF=0
S*      0.0.0.0/0 [1/0] via 10.100.1.1, port13
                  [1/0] via 10.100.1.5, port15
S       172.16.109.0/24 [1/0] via 172.16.206.2, to_FG_B_root
```

The default gateway has the members from the *virtual-wan-link* zone, and the route to 172.16.10.9.0/24 has the single member from the *SASE* zone.

Example 2

In this example, two IPv6 static routes are created. The first route uses the *virtual-wan-link* zone, and the second route uses the *SASE* zone.

To configure the SD-WAN:

1. Configure port13 and port15 with IPv6 addresses and assign them to the *virtual-wan-link* zone, and assign to_FG_B_root to the *SASE* zone:

```
config system sdwan
    set status enable
    config members
        edit 1
            set interface "port13"
            set zone "virtual-wan-link"
            set gateway6 2004:10:100:1::1
            set source6 2004:10:100:1::2
        next
        edit 2
            set interface "port15"
            set zone "virtual-wan-link"
            set gateway6 2004:10:100:1::5
            set source6 2004:10:100:1::6
        next
        edit 3
            set interface "to_FG_B_root"
            set zone "SASE"
        next
    end
end
```

2. Configure IPv6 static routes for each of the SD-WAN zones:

```
config router static6
    edit 1
        set distance 1
        set sdwan-zone "virtual-wan-link"
    next
    edit 2
        set dst 2003:172:16:109::/64
        set distance 1
        set sdwan-zone "SASE"
    next
end
```

To verify the results:

1. Review the routing table:

```
# get router info6 routing-table static
Routing table for VRF=0
S*      ::/0 [1/0] via 2004:10:100:1::1, port13, 00:20:51, [1024/0]
             [1/0] via 2004:10:100:1::5, port15, 00:20:51, [1024/0]
S       2003:172:16:109::/64 [1/0] via ::ac10:ce02, to_FG_B_root, 00:20:51, [1024/0]
S       2003:172:16:209::/64 [5/0] via ::ac10:ce02, to_FG_B_root, 14:40:14, [1024/0]
```

   The IPv6 default route includes the members from the *virtual-wan-link* zone, and the route to 2003:172:16:109::/64 has the single member from the *SASE* zone.

Performance SLA

Performance SLAs are used to measure the health of links that are connected to SD-WAN member interfaces by either sending probing signals through each link to a server, or using session information that is captured by firewall policies (see Passive WAN health measurement on page 665 for information), and measuring the link quality based on latency, jitter, and packet loss. If a link fails all of the health checks, the routes on that link are removed from the SD-WAN link load balancing group, and traffic is routed through other links. When the link passes SLA, the routes are reestablished. This prevents traffic from being sent to a broken link and getting lost.

The following topics provide instructions on configuring performance SLA:

- Performance SLA overview on page 653
- Link health monitor on page 658
- Monitoring performance SLA on page 660
- Passive WAN health measurement on page 665
- Passive health-check measurement by internet service and application on page 670
- Mean opinion score calculation and logging in performance SLA health checks on page 674
- Embedded SD-WAN SLA information in ICMP probes on page 677
- SD-WAN application monitor using FortiMonitor on page 685

Performance SLA overview

Performance SLAs consist of three parts:

- Health checks
- SLA targets
- Link status

Health checks

A health check is defined by a probe mode, protocol, and server. These three options specify what resource is being evaluated and how the evaluation is done. Each health check should be configured specifically for that resource, so the probe mode, protocol and server should be tailored for the particular service. For example, the health check for a VoIP service will differ than one for a database replication service.

Performance SLA participants are the interfaces that will be evaluated for a given health check. They must be SD-WAN member interfaces, but do not have to belong to the same zone. When selecting participants, only select participants that you expect the service communications to use. For example, a health check for a corporate resource might only use the overlay to access the service. Therefore, you would only add the VPN interfaces as participants.

There are six predefined performance SLA profiles for newly created VDOMs or factory reset FortiGate devices: AWS, DNS, FortiGuard, Gmail, Google Search, and Office 365. These performance SLA profiles provide Fortinet recommended settings for common services. To complete the performance SLA configuration, add the participants for the service. You can adjust the default settings to suit your needs.

Probe mode

The probe mode can be set to active, passive, or prefer passive.

In active mode, the FortiGate sends a packet of the type specified by the protocol setting towards the defined server. This allows you to evaluate the path to the destination server using the protocol that matches the service provided by the server. Active probing does add some overhead in the form of health check probes (and additional configurations to define the probe type and server), but it has the benefit of constantly measuring the performance of the path to the server. This can be beneficial when reviewing historical data.

In passive mode, session information captured by firewall policies is used to determine latency, jitter, and packet loss. This has the added benefit of not generating additional traffic, and does not require the performance SLA to define a specific server for measurement. Instead, the SD-WAN rule must define the traffic to evaluate, and the firewall policy permitting the traffic must have a setting enabled. See Passive WAN health measurement on page 665 and Passive health-check measurement by internet service and application on page 670 for more information.

Prefer passive mode is a combination of active and passive modes. Health is measured using traffic when there is traffic, and using probes when there is no traffic. A protocol and server must be configured.

Protocol

Health checks support a variety of protocols and protocol specific options. The most commonly used protocols (ping, HTTP, and DNS) can be configured in the GUI when creating a new performance SLA on the *Network* > *SD-WAN* > *Performance SLAs* page. The following protocols and options can be configured in the CLI using the `set protocol <option>` parameter:

`ping`	Use PING to test the link with the server.
`tcp-echo`	Use TCP echo to test the link with the server.
`udp-echo`	Use UDP echo to test the link with the server.
`http`	Use HTTP-GET to test the link with the server.
`twamp`	Use TWAMP to test the link with the server.
`dns`	Use DNS query to test the link with the server. The FortiGate sends a DNS query for an A Record and the response matches the expected IP address.
`tcp-connect`	Use a full TCP connection to test the link with the server. The method to measure the quality of the TCP connection can be: • `half-open`: FortiGate sends SYN and gets SYN-ACK. The latency is based on the round trip between SYN and SYN-ACK (default).

	• `half-close`: FortiGate sends FIN and gets FIN-ACK. The latency is based on the round trip between FIN and FIN-ACK.
`ftp`	Use FTP to test the link with the server. The FTP mode can be: • `passive`: The FTP health-check initiates and establishes the data connection (default). • `port`: The FTP server initiates and establishes the data connection.

SD-WAN health checks can generate traffic that becomes quite high as deployments grow. Take this into consideration when setting DoS policy thresholds. For details on setting DoS policy thresholds, refer to DoS policy on page 1066.

To use UDP-echo and TCP-echo as health checks:

```
config system sdwan
    set status enable
    config health-check
        edit "h4_udp1"
            set protocol udp-echo
            set port 7
            set server <server>
        next
        edit "h4_tcp1"
            set protocol tcp-echo
            set port 7
            set server <server>
        next
        edit "h6_udp1"
            set addr-mode ipv6
            set server "2032::12"
            set protocol udp-echo
            set port 7
        next
    end
end
```

To use DNS as a health check, and define the IP address that the response must match:

```
config system sdwan
    set status enable
    config health-check
        edit "h4_dns1"
            set protocol dns
            set dns-request-domain "ip41.forti2.com"
            set dns-match-ip 1.1.1.1
        next
        edit "h6_dns1"
            set addr-mode ipv6
            set server "2000::15.1.1.4"
            set protocol dns
            set port 53
            set dns-request-domain "ip61.xxx.com"
        next
```

```
    end
end
```

To use TCP Open (SYN/SYN-ACK) and TCP Close (FIN/FIN-ACK) to verify connections:

```
config system sdwan
    set status enable
    config health-check
        edit "h4_tcpconnect1"
            set protocol tcp-connect
            set port 443
            set quality-measured-method {half-open | half-close}
            set server <server>
        next
        edit "h6_tcpconnect1"
            set addr-mode ipv6
            set server "2032::13"
            set protocol tcp-connect
            set port 444
            set quality-measured-method {half-open | half-close}
        next
    end
end
```

To use active or passive mode FTP to verify connections:

```
config system sdwan
    set status enable
    config health-check
        edit "h4_ftp1"
            set protocol ftp
            set port 21
            set user "root"
            set password ***********
            set ftp-mode {passive | port}
            set ftp-file "1.txt"
            set server <server>
        next
        edit "h6_ftp1"
            set addr-mode ipv6
            set server "2032::11"
            set protocol ftp
            set port 21
            set user "root"
            set password ***********
            set ftp-mode {passive | port}
            set ftp-file "2.txt"
        next
    end
end
```

Health check probe packets support DSCP markers for accurate link performance evaluation for high priority applications. This allows the probe packet to match the real traffic it is providing measurements for, including how that traffic is shaped by upstream devices based on the DSCP markers.

To mark health check packets with DSCP:

```
config system sdwan
    config health-check
        edit <name>
            set diffservcode <6-bits_binary, 000000-111111>
            set protocol <option>
        next
    end
end
```

Server

An IP address or FQDN can be defined as the server that the probe packets will be sent to. Up to two servers can be defined this way. When two servers are provided, both must fail in order for the health check to fail. This is to avoid a scenario where one remote server is down and causes a false positive that the link is down. The FortiGate can still use the interface associated with this health check to reach the remaining healthy server.

The purpose of the server is not simply to measure the health of the link, but rather the health of the path to a resource. It is highly recommended to use an IP address or FQDN that reflects the resource so the traffic path is considered.

A server can only be used in one performance SLA at any given time.

SLA targets

SLA targets are a set of constraints that are used in SD-WAN rules to control the paths that traffic takes. The constraints are:

- Latency threshold: latency for SLA to make a decision, in milliseconds (0 - 10000000, default = 5).
- Jitter threshold: jitter for SLA to make a decision, in milliseconds (0 - 10000000, default = 5).
- Packet loss threshold: packet loss for SLA to make a decision, in percentage (0 - 100, default = 0).

These settings should be specific to the service whose performance is being considered. You should attempt to configure the constraints to be just under the maximum values for the application or service to function well. For example, if your application requires less than 100 ms latency, then you should configure the SLA target to be 90 ms. Misconfiguring these settings will cause the performance SLA to lose value. If the values are too tight, then you may have traffic flipping between links before necessary. If the values are too loose, then performance may be impacted and the FortiGate will do nothing about it.

In the GUI, one SLA target can be configured, but additional targets can be configured in the CLI. Once a second target is configured in the CLI, additional targets can be configured from the GUI. Multiple SLA targets can be configured where a server provides multiple services that have different values for acceptable performance. For example, Google provides a DNS service and entertainment services (YouTube), so it is necessary to configure multiple SLA targets in this case since you can only configure a server in one performance SLA.

Link status

The *Link Status* section of the performance SLA configuration consists of three settings that determine the frequency that the link is evaluated, and the requirements to be considered valid or invalid:

- *Check interval*: the interval in which the FortiGate checks the interface, in milliseconds (500 - 3600000, default = 500).
- *Failures before inactive*: the number of failed status checks before the interface shows as inactive (1 - 3600, default =5). This setting helps prevent flapping, where the system continuously transfers traffic back and forth between links.
- *Restore link after*: the number of successful status checks before the interface shows as active (1 - 3600, default = 5). This setting also helps prevent flapping.

When a participant becomes inactive, the performance SLA causes the FortiGate to withdraw all static routes associated with that interface. If there are multiple static routes using the same interface, they will all be withdrawn when the link monitor is failing.

Link health monitor

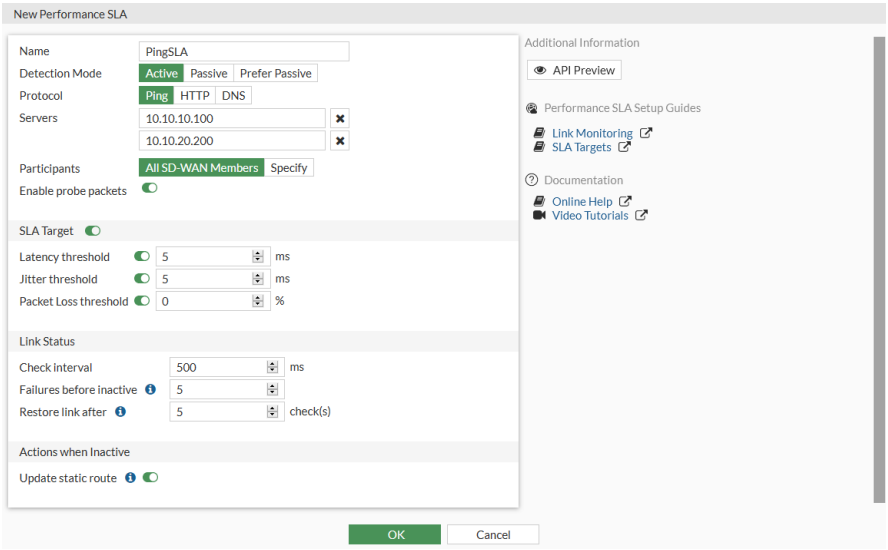
Performance SLA link health monitoring measures the health of links that are connected to SD-WAN member interfaces by either sending probing signals through each link to a server, or using session information that is captured on firewall policies (see Passive WAN health measurement on page 665 for information), and measuring the link quality based on latency, jitter, and packet loss. If a link fails all of the health checks, the routes on that link are removed from the SD-WAN link load balancing group, and traffic is routed through other links. When the link is working again the routes are reestablished. This prevents traffic being sent to a broken link and lost.

When an SD-WAN member has multiple health checks configured, all of the checks must fail for the routes on that link to be removed from the SD-WAN link load balancing group.

Two health check servers can be configured to ensure that, if there is a connectivity issue, the interface is at fault and not the server. A server can only be used in one health check.

The FortiGate uses the first server configured in the health check server list to perform the health check. If the first server is unavailable, then the second server is used. The second server continues to be used until it becomes unavailable, and then the FortiGate returns to the first server, if it is available. If both servers are unavailable, then the health check fails.

You can configure the protocol that is used for status checks, including: Ping, HTTP, DNS, TCP echo, UDP echo, two-way active measurement protocol (TWAMP), TCP connect, and FTP. In the GUI, only Ping, HTTP, and DNS are available.



You can view link quality measurements by going to *Network* > *SD-WAN* and selecting the *Performance SLAs* tab. The table shows the default health checks, the health checks that you configured, and information about each health check. The values shown in the *Packet Loss*, *Latency*, and *Jitter* columns are for the health check server that the FortiGate is currently using. The green up arrows indicate that the server is responding, and does not indicate if the health checks are being met. See Results on page 637 for more information.

To configure a link health monitor in the GUI:

1. Go to *Network* > *SD-WAN*, select the *Performance SLAs* tab, and click *Create New*.
2. Set a *Name* for the SLA.
3. Set the *Protocol* that you need to use for status checks: *Ping*, *HTTP*, or *DNS*.
4. Set *Server* to the IP addresses of up to two servers that all of the SD-WAN members in the performance SLA can reach.
5. Set *Participants* to *All SD-WAN Members*, or select *Specify* to choose specific SD-WAN members.
6. Set *Enable probe packets* to enable or disable sending probe packets.

7. Configure *SLA Target*:
   If the health check is used in an SD-WAN rule that uses *Manual* or *Best Quality* strategies, enabling *SLA Target* is optional. If the health check is used in an SD-WAN rule that uses *Lowest Cost (SLA)* or *Maximum Bandwidth (SLA)* strategies, then *SLA Target* is enabled.

   When *SLA Target* is enabled, configure the following:
   - *Latency threshold*: Calculated based on last 30 probes (default = 5ms).
   - *Jitter threshold*: Calculated based on last 30 probes (default = 5ms).
   - *Packet Loss threshold*: Calculated based on last 100 probes (default = 0%).
8. In the *Link Status* section configure the following:
   - *Check interval*: The interval in which the FortiGate checks the interface, in milliseconds (500 - 3600000, default = 500).
   - *Failures before inactive*: The number of failed status checks before the interface shows as inactive (1 - 3600, default =5). This setting helps prevent flapping, where the system continuously transfers traffic back and forth between links
   - *Restore link after*: The number of successful status checks before the interface shows as active (1 - 3600, default = 5). This setting helps prevent flapping, where the system continuously transfers traffic back and forth between links
9. In the *Actions when Inactive* section, enable *Update static route* to disable static routes for inactive interfaces and restore routes when interfaces recover.

10. Click *OK*.

To configure a link health monitor in the CLI:

```
config system sdwan
    config health-check
        edit "PingSLA"
            set addr-mode {ipv4 | ipv6}
            set server <server1_IP_address> <server2_IP_address>
            set detect-mode {active | passive | prefer-passive}
            set protocol {ping | tcp-echo | udp-echo | http | twamp | dns | tcp-connect |
ftp}
            set ha-priority <integer>
            set probe-timeout <integer>
            set probe-count <integer>
```

```
            set probe-packets {enable | disable}
            set interval <integer>
            set failtime <integer>
            set recoverytime <integer>
            set diffservcode <binary>
            set update-static-route {enable | disable}
            set update-cascade-interface {enable | disable}
            set sla-fail-log-period <integer>
            set sla-pass-log-period <integer>
            set threshold-warning-packetloss <integer>
            set threshold-alert-packetloss <integer>
            set threshold-warning-latency <integer>
            set threshold-alert-latency <integer>
            set threshold-warning-jitter <integer>
            set threshold-alert-jitter <integer>
            set members <member_number> ... <member_number>
            config sla
                edit 1
                    set link-cost-factor {latency jitter packet-loss}
                    set latency-threshold <integer>
                    set jitter-threshold <integer>
                    set packetloss-threshold <integer>
                next
            end
        next
    end
end
```

Additional settings are available for some of the protocols:

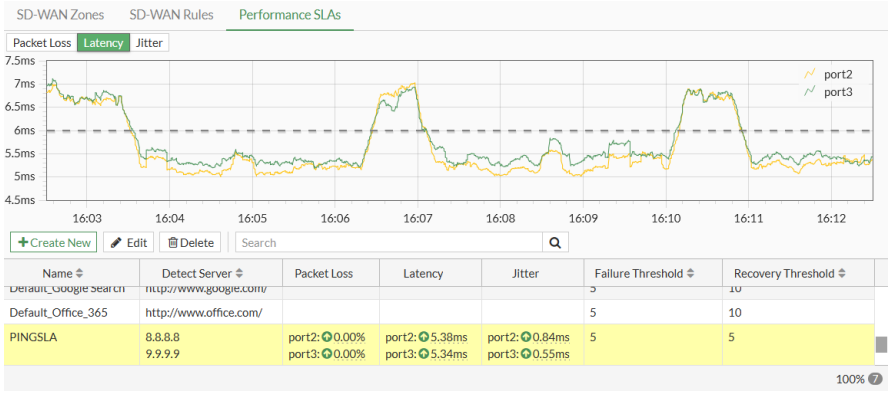
Protocol	Additional options

http	`port <port_number>`
	`http-get <url>`
	`http-match <response_string>`

twamp	`port <port_number>`
	`security mode {none | authentication}`
	`password <password>`
	`packet-size <size>`

ftp	`ftp {passive | port}` `ftp-file <path>`

For more examples see Protocol.



Monitoring performance SLA

SD-WAN diagnostics can be used to help maintain your SD-WAN solution.

Monitoring SD-WAN link quality status

Link quality plays a significant role in link selection for SD-WAN. Investigate any prolonged issues with packet loss, latency, or jitter to ensure that your network does not experience degraded performance or an outage.

You can monitor the link quality status of SD-WAN interface members by going to *Network* > *SD-WAN* and selecting the *Performance SLAs* tab.

The live charts show the packet loss, latency, or jitter for the selected health check. Hover the cursor over a line in the chart to see the specific value for that interface at that specific time.

The table shows information about each health check, including the configured servers, link quality data, and thresholds. The colored arrow indicates the status of the interface when the last status check was performed: green means that the interface was active, and red means that the interface was inactive. Hover the cursor over the arrow for additional information.

Monitoring system event logs

The features adds an SD-WAN daemon function to keep a short, 10 minute history of SLA that can be viewed in the CLI.

Performance SLA results related to interface selection, session failover, and other information, can be logged. These logs can then be used for long-term monitoring of traffic issues at remote sites, and for reports and views in FortiAnalyzer.

The time intervals that Performance SLA fail and pass logs are generated in can be configured.

To configure the fail and pass logs' generation time interval:

```
config system sdwan
    config health-check
        edit "PingSLA"
            set sla-fail-log-period 30
            set sla-pass-log-period 60
        next
    end
end
```

To view the 10 minute Performance SLA link status history:

```
FGDocs # diagnose sys sdwan sla-log PingSLA 1
Timestamp: Fri Sep  4 10:32:37 2020, vdom root, health-check PingSLA, interface: wan2,
status: up, latency: 4.455, jitter: 0.430, packet loss: 0.000%.

In the FortiAnalyzer GUI:

Monitoring using the REST API

SLA log and interface information can be monitored using the REST API. This feature is also used by FortiManager as part of its detailed SLA monitoring and drilldown features.

API call	URL
Interface log	`https://172.172.172.9/api/v2/monitor/virtual-wan/interface-log`
SLA log	`https://172.172.172.9/api/v2/monitor/virtual-wan/sla-log`
Health check log	`https://172.172.172.9/api/v2/monitor/virtual-wan/health-check`

A comprehensive list of API calls with sample output is available on the Fortinet Developer Network.

CLI diagnose commands:

```
# diagnose sys sdwan intf-sla-log port13

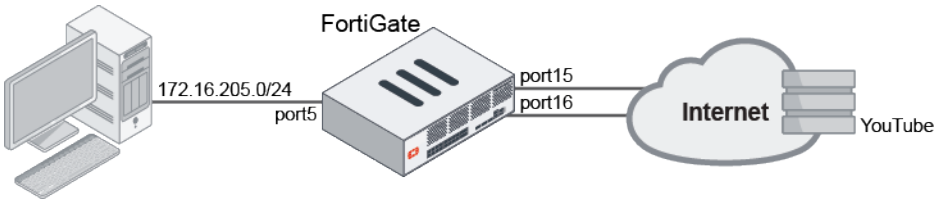
Passive WAN health measurement

SD-WAN passive WAN health measurement determines the health check measurements using session information that is captured on firewall policies that have *Passive Health Check* (`passive-wan-health-measurement`) enabled. Passive measurements analyze session information that is gathered from various TCP sessions to determine the jitter, latency, and packet loss.

Using passive WAN health measurement reduces the amount of configuration required and decreases the traffic that is produced by health check monitor probes doing active measurements. Passive WAN health measurement analyzes real-life traffic; active WAN health measurement using a detection server might not reflect the real-life traffic.

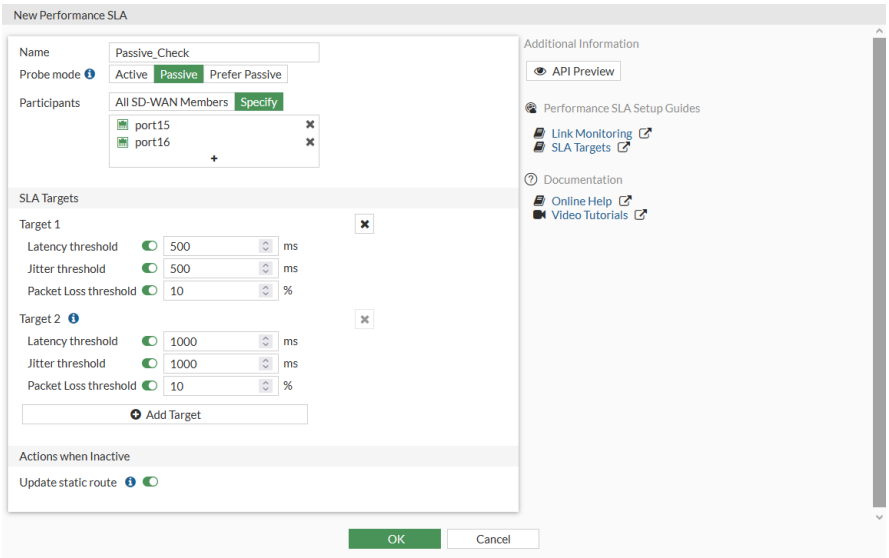
By default, active WAN health measurement is enabled when a new health check is created. It can be changed to passive or prefer passive:

passive	Health is measured using traffic, without probes. No link health monitor needs to be configured.
prefer-passive	Health is measured using traffic when there is traffic, and using probes when there is no traffic. A link health monitor must be configured, see Link health monitor for details.



When `passive-wan-health-measurement` is enabled, `auto-asic-offload` will be disabled.

Example



In this example, the FortiGate is configured to load-balance between two WAN interfaces, port15 and port16. A health check is configured in passive mode, and SLA thresholds are set. Passive WAN health measurement is enabled on the SD-WAN policy.

Measurements are taken from YouTube traffic generated by the PC. When latency is introduced to the traffic on port15, the passive health check trigger threshold is exceeded and traffic is rerouted to port16.

To configure the SD-WAN in the GUI:

1. Create the SD-WAN zone:
   a. Go to *Network* > *SD-WAN* and select the *SD-WAN Zones* tab.
   b. Click *Create New* > *SD-WAN Zone*.
   c. Enter a name for the zone, such as *SD-WAN*.
   d. Click *OK*.
2. Create the SD-WAN members:
   a. Go to *Network* > *SD-WAN* and select the *SD-WAN Zones* tab.
   b. Click *Create New* > *SD-WAN Member*.
   c. Set *Interface* to *port15*, *SD-WAN Zone* to *SD-WAN*, and *Gateway* set to *172.16.209.2*.
   d. Click *OK*.
   e. Click *Create New* > *SD-WAN Member* again.
   f. Set *Interface* to *port16*, *SD-WAN Zone* to *SD-WAN*, and *Gateway* set to *172.16.210.2*.
   g. Click *OK*.
3. Create a performance SLA:
   a. Go to *Network* > *SD-WAN* and select the *Performance SLAs* tab.
   b. Edit an existing health check, or create a new one.
   c. Set *Probe mode* to *Passive*.
   d. Set *Participants* to *Specify* and add *port15* and *port16*.
   e. Configure two SLA targets. Note that the second SLA target must be configured in the CLI.

   f. Configure the remaining settings as needed.

g. Click *OK*.
The SLA list shows the probe mode in the *Detect Server* column, if the probe mode is passive or prefer passive.

Probe packets can only be disabled in the CLI and when the probe mode is not passive.

4. Create SD-WAN rules:
   a. Go to *Network* > *SD-WAN*, select the *SD-WAN Rules* tab, and click *Create New*.
   b. Configure the first rule:

Name	Background_Traffic
Source address	172.16.205.0
Application	Click in the field, and in the *Select Entries* pane search for *YouTube* and select all of the entries
Strategy	Maximize Bandwidth (SLA)
Interface preference	port15 and port16
Required SLA target	Passive_Check#2

   c. Click *OK*.
   d. Click *Create New* again and configure the second rule:

Name	Foreground_Traffic
Source address	172.16.205.0
Address	all
Protocol number	Specify - 1
Strategy	Lowest Cost (SLA)
Interface preference	port15 and port16
Required SLA target	Passive_Check#1

   e. Click *OK*.

To configure the firewall policy in the GUI:

1. Go to *Policy & Objects* > *Firewall Policy* and click *Create New*.
2. Configure the policy:

Name	SD-WAN-HC-policy
Incoming Interface	port5
Outgoing Interface	SD-WAN
Source	all
Destination	all

Schedule	always
Service	ALL
Action	ACCEPT
Passive Health Check	Enabled Passive health check can only be enabled in a policy when the outgoing interface is an SD-WAN zone.

3. Click *OK*.

To configure the SD-WAN in the CLI:

```
config system sdwan
    set status enable
    config zone
        edit "SD-WAN"
        next
    end
    config members
        edit 1
            set zone "SD-WAN"
            set interface "port15"
            set gateway 172.16.209.2
        next
        edit 2
            set zone "SD-WAN"
            set interface "port16"
            set gateway 172.16.210.2
        next
    end
    config health-check
        edit "Passive_Check"
            set detect-mode passive
            set members 1 2
            config sla
                edit 1
                    set latency-threshold 500
                    set jitter-threshold 500
                    set packetloss-threshold 10
                next
                edit 2
                    set latency-threshold 1000
                    set jitter-threshold 1000
                    set packetloss-threshold 10
                next
            end
        next
    end
    config service
        edit 1
            set name "Background_Traffic"
            set mode load-balance
            set src "172.16.205.0"
            set internet-service enable
```

```
            set internet-service-app-ctrl 31077 33321 41598 31076 33104 23397 30201 16420
17396 38569 25564
            config sla
                edit "Passive_Check"
                    set id 2
                next
            end
            set priority-member 1 2
        next
        edit 2
            set name "Foreground_Traffic"
            set mode sla
            set src "172.16.205.0"
            set protocol 1
            set dst "all"
            config sla
                edit "Passive_Check"
                    set id 1
                next
            end
            set priority-member 1 2
        next
    end
end
```

To configure the firewall policy in the CLI:

```
config firewall policy
    edit 1
        set name "SD-WAN-HC-policy"
        set srcintf "port5"
        set dstintf "SD-WAN"
        set nat enable
        set srcaddr "all"
        set dstaddr "all"
        set action accept
        set schedule "always"
        set service "ALL"
        set passive-wan-health-measurement enable
        set auto-asic-offload disable
    next
end
```

Results

When both links pass the SLA:

```
# diagnose sys link-monitor-passive interface
Interface port16 (28):
  Latency 10.000 Jitter 5.000 Packet_loss 0.000% Last_updated Fri Mar 5 10:09:21 2021

Interface port15 (27):
  Latency 60.000 Jitter 0.000 Packet_loss 0.000% Last_updated Fri Mar 5 10:39:24 2021
```

```
# diagnose sys sdwan health-check
Health Check(Passive_Check):
```

```
Seq(1 port15): state(alive), packet-loss(0.000%) latency(60.000), jitter(0.750) sla_map=0x3
Seq(2 port16): state(alive), packet-loss(0.000%) latency(10.000), jitter(5.000) sla_map=0x3
```

```
# diagnose sys sdwan service 2

Service(2): Address Mode(IPV4) flags=0x200
  Gen(1), TOS(0x0/0x0), Protocol(1: 1->65535), Mode(sla), sla-compare-order
  Members(2):
    1: Seq_num(1 port15), alive, sla(0x1), gid(0), cfg_order(0), cost(0), selected
    2: Seq_num(2 port16), alive, sla(0x1), gid(0), cfg_order(1), cost(0), selected
  Src address(1):

```

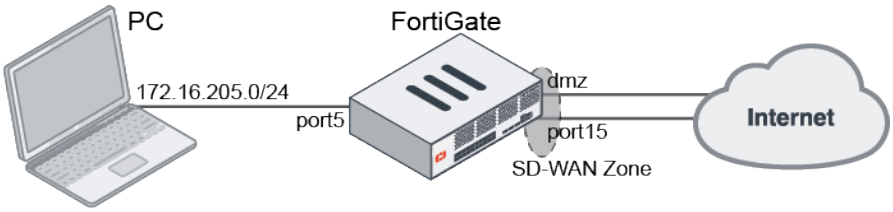
Passive health-check measurement by internet service and application



Passive health measurement supports passive detection for each internet service and application.

If internet services or applications are defined in an SD-WAN rule with passive health check, SLA information for each service or application will be differentiated and collected. SLA metrics (latency, jitter, and packet loss) on each SD-WAN member in the rule are then calculated based on the relevant internet service's or application's SLA information.

In this example, three SD-WAN rules are created:

- Rule 1: Best quality (latency) using passive SLA for the internet services Alibaba and Amazon.
- Rule 2: Best quality (latency) using passive SLA for the applications Netflix and YouTube.
- Rule 3: Best quality (latency) using passive SLA for all other traffic.

After passive application measurement is enabled for rules one and two, the SLA metric of rule one is the average latency of the internet services Alibaba and Amazon, and the SLA metric of rule two is the average latency of the applications Netflix and YouTube.

To configure the SD-WAN:

1. Configure the SD-WAN members:

```
config system sdwan
    set status enable
    config zone
        edit "virtual-wan-link"
        next
    end
    config members
        edit 1
            set interface "dmz"
            set gateway 172.16.208.2
        next
        edit 2
            set interface "port15"
            set gateway 172.16.209.2
        next
    end
end
```

2. Configure the passive mode health check:

```
config health-check
    edit "Passive_HC"
        set detect-mode passive
        set members 1 2
    next
end
```

3. Configure SD-WAN service rules:

```
config service
    edit 1
        set name "1"
        set mode priority
        set src "172.16.205.0"
        set internet-service enable
        set internet-service-name "Alibaba-Web" "Amazon-Web"
        set health-check "Passive_HC"
        set priority-members 1 2
        set passive-measurement enable    //Enable "passive application measurement", it
is a new command which is introduced in this project.
    next
    edit 2
        set name "2"
        set mode priority
        set src "172.16.205.0"
```

```
        set internet-service enable
        set internet-service-app-ctrl 18155 31077
        set health-check "Passive_HC"
        set priority-members 1 2
        set passive-measurement enable    ////Enable "passive application measurement"
    next
    edit 3
        set name "3"
        set mode priority
        set dst "all"
        set src "172.16.205.0"
        set health-check "Passive_HC"
        set priority-members 1 2
    next
end
```

4. Configure SD-WAN routes:

```
config router static
    edit 1
        set distance 1
        set sdwan-zone "virtual-wan-link"
    next
end
```

5. Configure the firewall policy with passive WAN health measurement enabled:

```
config firewall policy
    edit 1
        set uuid 972345c6-1595-51ec-66c5-d705d266f712
        set srcintf "port5"
        set dstintf "virtual-wan-link"
        set action accept
        set srcaddr "172.16.205.0"
        set dstaddr "all"
        set schedule "always"
        set service "ALL"
        set passive-wan-health-measurement enable
        set utm-status enable
        set ssl-ssh-profile "certificate-inspection"
        set application-list "g-default"
        set auto-asic-offload disable
    next
end
```

To verify the results:

1. On the PC, open the browser and visit the internet services and applications.
2. On the FortiGate, check the collected SLA information to confirm that each server or application on the SD-WAN members was measured individually:

```
# diagnose sys link-monitor-passive interface

Interface dmz (5):
       Default(0x00000000): latency=3080.0  11:57:54, jitter=5.0     11:58:08,
pktloss=0.0  % NA
   Alibaba-Web(0x00690001): latency=30.0    11:30:06, jitter=25.0    11:29:13,
```

```
pktloss=0.0  % NA
       YouTube(0x00007965): latency=100.0   12:00:35, jitter=2.5     12:00:30,
pktloss=0.0  % NA
       Netflix(0x000046eb): latency=10.0    11:31:24, jitter=10.0    11:30:30,
pktloss=0.0  % NA
    Amazon-Web(0x00060001): latency=80.0    11:31:52, jitter=35.0    11:32:07,
pktloss=0.0  % NA

Interface port15 (27):
       Default(0x00000000): latency=100.0   12:00:42, jitter=0.0     12:00:42,
pktloss=0.0  % NA
    Amazon-Web(0x00060001): latency=30.0    11:56:05, jitter=0.0     11:55:21,
pktloss=0.0  % NA
   Alibaba-Web(0x00690001): latency=0.0     11:26:08, jitter=35.0    11:27:08,
pktloss=0.0  % NA
       YouTube(0x00007965): latency=100.0   11:33:34, jitter=0.0     11:33:50,
pktloss=0.0  % NA
       Netflix(0x000046eb): latency=0.0     11:26:29, jitter=0.0     11:29:03,
pktloss=0.0  % NA
```

3. Verify that the SLA metrics on the members are calculated as expected:

```
# diagnose sys sdwan service

Service(1): Address Mode(IPV4) flags=0x600 use-shortcut-sla
  Gen(1), TOS(0x0/0x0), Protocol(0: 1->65535), Mode(priority), link-cost-factor

```

Mean opinion score calculation and logging in performance SLA health checks

The mean opinion score (MOS) is a method of measuring voice quality using a formula that takes latency, jitter, packet loss, and the codec into account to produce a score from zero to five (0 - 5). The G.711, G.729, and G.722 codecs can be selected in the health check configurations, and an MOS threshold can be entered to indicate the minimum MOS score for the SLA to pass. The maximum MOS score will depend on which codec is used, since each codec has a theoretical maximum limit.

```
config system sdwan
    config health-check
          edit <name>
            set mos-codec {g711 | g729 | g722}
            config sla
                edit <id>
                    set link-cost-factor {latency jitter packet-loss mos}
                    set mos-threshold <value>
                next
            end
        next
    end
end
```

`mos-codec {g711 | g729 | g722}`	Set the VoIP codec to use for the MOS calculation (default = g711).
`link-cost-factor {latency jitter packet-loss mos}`	Set the criteria to base the link selection on.
`mos-threshold <value>`	Set the minimum MOS for the SLA to be marked as pass (1.0 - 5.0, default = 3.6).

To configure a health check to calculate the MOS:

```
config system sdwan
    set status enable
    config zone
        edit "virtual-wan-link"
        next
    end
    config members
        edit 1
            set interface "dmz"
            set gateway 172.16.208.2
        next
        edit 2
            set interface "port15"
            set gateway 172.16.209.2
        next
    end
    config health-check
```

```
        edit "Test_MOS"
            set server "2.2.2.2"
            set sla-fail-log-period 30
            set sla-pass-log-period 30
            set members 0
            set mos-codec g729
            config sla
                edit 1
                    set link-cost-factor mos
                    set mos-threshold "4.0"
                next
            end
        next
    end
end
```

To use an MOS SLA to steer traffic in an SD-WAN rule:

```
config system sdwan
    config service
        edit 1
            set name "MOS_traffic_steering"
            set mode sla
            set dst "HQ_LAN"
            set src "Branch_LAN"
            config sla
                edit "Test_MOS"
                    set id 1
                next
            end
            set priority-members 0
        next
    end
end
```

The MOS currently cannot be used to steer traffic when the `mode` is set to `priority`.

To verify the MOS calculation results:

1. Verify the health check diagnostics:

```
# diagnose sys sdwan health-check
Health Check(Test_MOS):
Seq(1 dmz): state(alive), packet-loss(0.000%) latency(0.114), jitter(0.026), mos(4.123),
bandwidth-up(999999), bandwidth-dw(999997), bandwidth-bi(1999996) sla_map=0x1
Seq(2 port15): state(alive), packet-loss(0.000%) latency(0.100), jitter(0.008), mos
(4.123), bandwidth-up(999999), bandwidth-dw(999999), bandwidth-bi(1999998) sla_map=0x1

# diagnose sys sdwan sla-log Test_MOS 1
Timestamp: Tue Jan  4 11:23:06 2022, vdom root, health-check Test_MOS, interface: dmz,
status: up, latency: 0.151, jitter: 0.040, packet loss: 0.000%, mos: 4.123.
Timestamp: Tue Jan  4 11:23:07 2022, vdom root, health-check Test_MOS, interface: dmz,
status: up, latency: 0.149, jitter: 0.041, packet loss: 0.000%, mos: 4.123.
```

```
# diagnose sys sdwan sla-log Test_MOS 2
Timestamp: Tue Jan  4 11:25:09 2022, vdom root, health-check Test_MOS, interface:
port15, status: up, latency: 0.097, jitter: 0.009, packet loss: 0.000%, mos: 4.123.
Timestamp: Tue Jan  4 11:25:10 2022, vdom root, health-check Test_MOS, interface:
port15, status: up, latency: 0.097, jitter: 0.008, packet loss: 0.000%, mos: 4.123.
```

2. Change the `mos-codec` to `g722`. The diagnostics will now display different MOS values:

```
# diagnose sys sdwan health-check
Health Check(Test_MOS):
Seq(1 dmz): state(alive), packet-loss(0.000%) latency(0.150), jitter(0.031), mos(4.453),
bandwidth-up(999999), bandwidth-dw(999997), bandwidth-bi(1999996) sla_map=0x1
Seq(2 port15): state(alive), packet-loss(0.000%) latency(0.104), jitter(0.008), mos
(4.453), bandwidth-up(999999), bandwidth-dw(999999), bandwidth-bi(1999998) sla_map=0x1
```

3. Increase the latency on the link in port15. The calculated MOS value will decrease accordingly. In this example, port15 is out of SLA since its MOS value is now less than the 4.0 minimum:

```
# diagnose sys sdwan  health-check
Health Check(Test_MOS):
Seq(1 dmz): state(alive), packet-loss(0.000%) latency(0.106), jitter(0.022), mos(4.453),
bandwidth-up(999999), bandwidth-dw(999997), bandwidth-bi(1999996) sla_map=0x1
Seq(2 port15): state(alive), packet-loss(0.000%) latency(300.119), jitter(0.012), mos
(3.905), bandwidth-up(999999), bandwidth-dw(999999), bandwidth-bi(1999998) sla_map=0x0
```

Sample logs

Embedded SD-WAN SLA information in ICMP probes

In the hub and spoke SD-WAN design, in order for traffic to pass symmetrically from spoke to hub and hub to spoke, it is essential for the hub to know which IPsec overlay is in SLA and out of SLA. Prior to introducing embedded SLA information in ICMP probes, it is common practice for spokes to use the SD-WAN neighbor feature and `route-map-out-preferable` setting to signal the health of each overlay to the hub. However, this requires BGP to be configured per overlay, and to manipulate BGP routes using custom BGP communities.

With embedded SLA information in ICMP probes, spokes can communicate their SLA for each overlay directly through ICMP probes to the hub. The hub learns these SLAs and maps the status for each spoke and its corresponding overlays.

The hub uses the SLA status to apply priorities to the IKE routes, giving routes over IPsec overlays that are within SLAs a lower priority value and routes over overlays out of SLAs a higher priority value. If BGP is used, recursively resolved BGP routes can inherit the priority from its parent.

Embedded SLA information in ICMP probes allows hub and spoke SD-WAN to be designed with a BGP on loopback topology, or without BGP at all. The following topology outlines an example of the BGP on loopback design where each spoke is peered with the hub and route reflector on the loopback interface.

In this topology, each FortiGate's BGP router ID is based on its Loopback0 interface. Each spoke has SLA health checks defined to send ICMP probes to the server's Lo_HC interface on 172.31.100.100. The ICMP probes include embedded SLA information for each SD-WAN overlay member.

Related SD-WAN settings:

```
config system sdwan
    config health-check
        edit <name>
            set detect-mode {active | passive | prefer-passive | remote}
            set embed-measured-health {enable | disable}
            config sla
                edit <id>
                    set priority-in-sla <integer>
                    set priority-out-sla <integer>
                next
            end
            set sla-id-redistribute <id>
        next
    end
end
```

`detect-mode {active | passive | prefer-passive | remote}`	Set the mode that determines how to detect the server: • `active`: the probes are sent actively (default). • `passive`: the traffic measures health without probes. • `prefer-passive`: the probes are sent in case of no new traffic. • `remote`: the link health is obtained from remote peers.
`embed-measured-health {enable | disable}`	Enable/disable embedding SLA information in ICMP probes (default = disable).
`set priority-in-sla <integer>`	Set the priority that will be set to the IKE route when the corresponding overlay is in SLA (0 - 65535).
`set priority-out-sla <integer>`	Set the priority that will be set to the IKE route when the corresponding overlay is out of SLA (0 - 65535).
`sla-id-redistribute <id>`	Set the SLA entry (ID) that will be applied to the IKE routes (0 - 32, default = 0).

Related BGP setting:

```
config router bgp
    set recursive-inherit-priority {enable | disable}
end
```

`recursive-inherit-priority {enable | disable}`	Enable/disable allowing recursive resolved BGP routes to inherit priority from its parent (default = disable).

Example with BGP on loopback SD-WAN

This example demonstrates the configurations needed to configure the SD-WAN and BGP settings for the preceding topology. It is assumed that IPsec VPN overlays are already configured per the topology, and that loopback interfaces

are already configured on each FortiGate.

Configuring the Spoke_1 FortiGate

In the SD-WAN settings, note the following requirements:

1. Configure the SD-WAN zones and members. For each SD-WAN member, define the source of its probes to be the Loopback0 interface IP.
2. Configure the SLA health check to point to the Hub's Lo_HC interface and IP. Enable `embed-measured-health`.
3. Configure an SD-WAN service rule to route traffic based on the maximize bandwidth (SLA) algorithm to prefer member H1_T11 over H1_T22.
4. Configure `set exchange-interface-ip enable` and `set exchange-ip-addr4` to the Loopback0 interface IP. The `exchange-interface-ip option` is automatically turned on when ADVPN has already been configured. If ADVPN has not been configured, then `set exchange-interface-ip enable` must be configured before `set exchange-ip-addr4` can be configured.

To configure the SD-WAN settings:

```
config system sdwan
    set status enable
    config zone
        edit "virtual-wan-link"
        next
        edit "overlay"
        next
    end
    config members
        edit 1
            set interface "H1_T11"
            set zone "overlay"
            set source 172.31.0.65
        next
        edit 4
            set interface "H1_T22"
            set zone "overlay"
            set source 172.31.0.65
        next
    end
    config health-check
        edit "HUB"
            set server "172.31.100.100"
            set embed-measured-health enable
            set members 0
            config sla
                edit 1
                    set link-cost-factor latency
                    set latency-threshold 100
                next
            end
        next
    end
    config service
        edit 1
            set mode sla
            set dst "CORP_LAN"
```

```
            set src "CORP_LAN"
            config sla
                edit "HUB"
                    set id 1
                next
            end
            set priority-members 1 4
        next
    end
end
```

To configure the BGP settings:

```
config router bgp
    set as 65001
    set router-id 172.31.0.65
    config neighbor
        edit "172.31.0.1"
            set remote-as 65001
            set update-source "Loopback0"
        next
    end
    config network
        edit 1
            set prefix 10.0.3.0 255.255.255.0
        next
    end
end
```

To add the loopback IP to the IPsec interface settings:

```
config vpn ipsec phase1-interface
    edit "H1_T11"
        set exchange-interface-ip enable
        set exchange-ip-addr4 172.31.0.65
    next
    edit "H1_T22"
        set exchange-interface-ip enable
        set exchange-ip-addr4 172.31.0.65
    next
end
```

Configuring the hub FortiGate

In the SD-WAN settings, note the following requirements:

1. Configure the SD-WAN zone and members.
2. Configure the SLA health checks to detect SLAs based on the remote site (spoke). This must be defined for each SD-WAN member:
   a. For the SLA, specify the same link cost factor and metric as the spoke (100).
   b. Define the IKE route priority for in and out of SLA. Lower priority values have higher priority than higher priority values.
3. Define the SLA entry ID that will be applied to the IKE routes.

4. Configure `set exchange-interface-ip enable` and `set exchange-ip-addr4` to the Loopback0 interface IP. The `exchange-interface-ip option` is automatically turned on when ADVPN has already been configured. If ADVPN has not been configured, then `set exchange-interface-ip enable` must be configured before `set exchange-ip-addr4` can be configured.

To configure the SD-WAN settings:

```
config system sdwan
    set status enable
    config zone
        edit "virtual-wan-link"
        next
    end
    config members
        edit 1
            set interface "EDGE_T1"
        next
        edit 2
            set interface "EDGE_T2"
        next
    end
    config health-check
        edit "1"
            set detect-mode remote
            set sla-id-redistribute 1
            set members 1
            config sla
                edit 1
                    set link-cost-factor latency
                    set latency-threshold 100
                    set priority-in-sla 10
                    set priority-out-sla 20
                next
            end
        next
        edit "2"
            set detect-mode remote
            set sla-id-redistribute 1
            set members 2
            config sla
                edit 1
                    set link-cost-factor latency
                    set latency-threshold 100
                    set priority-in-sla 15
                    set priority-out-sla 25
                next
            end
        next
    end
end
```

In the BGP settings, note the following requirements:

1. Enable `recursive-inherit-priority` to inherit the route priority from its parent, which is the priority defined in the health check SLA settings.
2. Configure the other BGP settings similar to a regular BGP hub.

To configure the BGP settings:

```
config router bgp
    set as 65001
    set router-id 172.31.0.1
    set recursive-inherit-priority enable
    config neighbor-group
        edit "EDGE"
            set remote-as 65001
            set update-source "Loopback0"
            set route-reflector-client enable
        next
    end
    config neighbor-range
        edit 1
            set prefix 172.31.0.64 255.255.255.192
            set neighbor-group "EDGE"
        next
    end
end
```

To add the loopback IP to the IPsec interface settings:

```
config vpn ipsec phase1-interface
    edit "EDGE_T1"
        set exchange-interface-ip enable
        set exchange-ip-addr4 172.31.0.1
    next
    edit "EDGE_T2"
        set exchange-interface-ip enable
        set exchange-ip-addr4 172.31.0.1
    next
end
```

Testing and verification

Once the hub and spokes are configured, verify that SLA statuses are passed from the spoke to the hub.

To verify that the SLA statuses are passed from the spoke to the hub:

1. On Spoke_1, display the status of the health-checks for H1_T11 and H1_T22:

```
# diagnose sys sdwan  health-check
Health Check(HUB):
Seq(1 H1_T11): state(alive), packet-loss(0.000%) latency(0.228), jitter(0.018), mos
(4.404), bandwidth-up(999999), bandwidth-dw(1000000), bandwidth-bi(1999999) sla_map=0x1
Seq(4 H1_T22): state(alive), packet-loss(0.000%) latency(0.205), jitter(0.007), mos
(4.404), bandwidth-up(999998), bandwidth-dw(1000000), bandwidth-bi(1999998) sla_map=0x1
```

2. On Spoke_1, display the status and order of the overlays in the SD-WAN service rule:

```
# diagnose sys sdwan service
Service(1): Address Mode(IPV4) flags=0x200 use-shortcut-sla
 Tie break: cfg
  Gen(1), TOS(0x0/0x0), Protocol(0: 1->65535), Mode(sla), sla-compare-order
  Members(2):
```

```
    1: Seq_num(1 H1_T11), alive, sla(0x1), gid(0), cfg_order(0), local cost(0), selected

    2: Seq_num(4 H1_T22), alive, sla(0x1), gid(0), cfg_order(3), local cost(0), selected

  Src address(1):
        10.0.0.0-10.255.255.255
  Dst address(1):
        10.0.0.0-10.255.255.255
```

Both overlays are within SLA, so H1_T11 is preferred due to its `cfg-order`.

Spoke_1's SLA information for H1_T11 and H1_T22 is embedded into the ICMP probes destined for the hub's Lo_HC interface. The hub receives this information and maps the SLAs correspondingly per spoke and overlay based on the same SLA targets.

As a result, since all SLAs are within target, the hub sets the routes over each overlay as follows:

Hub SD-WAN member	Overlay	SLA status	Priority for IKE routes
1	EDGE_T1	0x1 – within SLA	10
2	EDGE_T2	0x1 – within SLA	15

3. Verify that the spoke has sent its health check result to hub.
   a. On the hub, display the status of the health checks for EDGE_T1 and EDGE_T2:

```
# diagnose sys sdwan health-check remote
Remote Health Check: 2(2)
  Passive remote statistics of EDGE_T2(22):
EDGE_T2_0(172.31.3.5): timestamp=02-09 16:19:11, latency=1.056, jitter=0.582,
pktloss=0.000%
Remote Health Check: 1(1)
  Passive remote statistics of EDGE_T1(21):
EDGE_T1_0(172.31.3.1): timestamp=02-09 16:19:11, latency=1.269, jitter=0.675,
pktloss=0.000%
```

4. When there are multiple spokes, additional options can be used to filter a spoke by health check name, or health check name and the member's sequence number (`diagnose system sdwan health-check remote <hc_name> <seq_num>`).
   a. To filter the health check by health check name:

```
# diagnose sys sdwan health-check remote 1
Remote Health Check: 1(1)
  Passive remote statistics of EDGE_T1(21):
EDGE_T1_0(172.31.3.1): timestamp=02-09 16:43:37, latency=1.114, jitter=0.473,
pktloss=0.000%
```

   When this method is used, the output displays all the members of the specified health check name.

   b. To filter the health check by health check name and the member's sequence number:

```
# diagnose sys sdwan health-check remote 1 1
Remote Health Check: 1(1)
  Passive remote statistics of EDGE_T1(21):
EDGE_T1_0(172.31.3.1): timestamp=02-09 16:43:41, latency=1.178, jitter=0.497,
pktloss=0.000%
```

   When this method is used, the output displays the specified member of the specified health check name.

If the `detect-mode` is set to `remote`, use `diagnose sys sdwan health-check remote` in lieu of `diagnose sys sdwan health-check`.

5. Simultaneously, BGP recursive routes inherit the priority based on the parent IKE routes. The recursively resolved BGP routes that pass through EDGE_T1 will have a priority of 10, and routes that pass through EDGE_T2 will have a priority of 15. Therefore, traffic from the hub to the spoke will be routed to EDGE_T1.

   Verify the routing tables.

   a. Static:

```
# get router info routing-table static
Routing table for VRF=0
S       172.31.0.65/32 [15/0] via EDGE_T1 tunnel 10.0.0.69 vrf 0, [10/0]
                              [15/0] via EDGE_T2 tunnel 172.31.0.65 vrf 0, [15/0]
```

   b. BGP:

```
# get router info routing-table bgp
Routing table for VRF=0
B       10.0.3.0/24 [200/0] via 172.31.0.65 (recursive via EDGE_T1 tunnel 10.0.0.69
vrf 0 [10]), 04:32:53
                                            (recursive via EDGE_T2 tunnel 172.31.0.65
vrf 0 [15]), 04:32:53, [1/0]
```

Next, test by making the health checks over the spokes' H1_T11 tunnel out of SLA. This should trigger traffic to start flowing from the spokes' H1_T22 tunnel. Consequently, the SLA statuses are passed from the spoke to the hub, and the hub will start routing traffic to EDGE_T2.

To verify that the hub will start routing traffic to EDGE_T2 when the spoke H1_T11 tunnel is out of SLA:

1. On Spoke_1, display the status of the health checks for H1_T11 and H1_T22:

```
# diagnose sys sdwan health-check
Health Check(HUB):
Seq(1 H1_T11): state(alive), packet-loss(0.000%) latency(120.228), jitter(0.013), mos
(4.338), bandwidth-up(999999), bandwidth-dw(1000000), bandwidth-bi(1999999) sla_map=0x0
Seq(4 H1_T22): state(alive), packet-loss(0.000%) latency(0.220), jitter(0.008), mos
(4.404), bandwidth-up(999998), bandwidth-dw(1000000), bandwidth-bi(1999998) sla_map=0x1
```

2. Verify the routing tables.

   a. Static:

```
# get router info routing-table static
Routing table for VRF=0
S       172.31.0.65/32 [15/0] via EDGE_T2 tunnel 172.31.0.65 vrf 0, [15/0]
                       [15/0] via EDGE_T1 tunnel 10.0.0.69 vrf 0, [20/0]
```

   The priority for EDGE_T1 has changed from 10 to 20.

   b. BGP:

```
# get router info routing-table bgp
Routing table for VRF=0
B       10.0.3.0/24 [200/0] via 172.31.0.65 (recursive via EDGE_T2 tunnel 172.31.0.65
vrf 0 [15]), 00:01:19
```

```
                                                (recursive via EDGE_T1 tunnel 10.0.0.69
      vrf 0 [20]), 00:01:19, [1/0]
```

EDGE_T2 is now preferred. The priority for EDGE_T1 has changed from 10 to 20.

Spoke_1's SLA information for H1_T11 embedded into the ICMP probes has now changed.

As a result, the hub sets the routes over each overlay as follows:

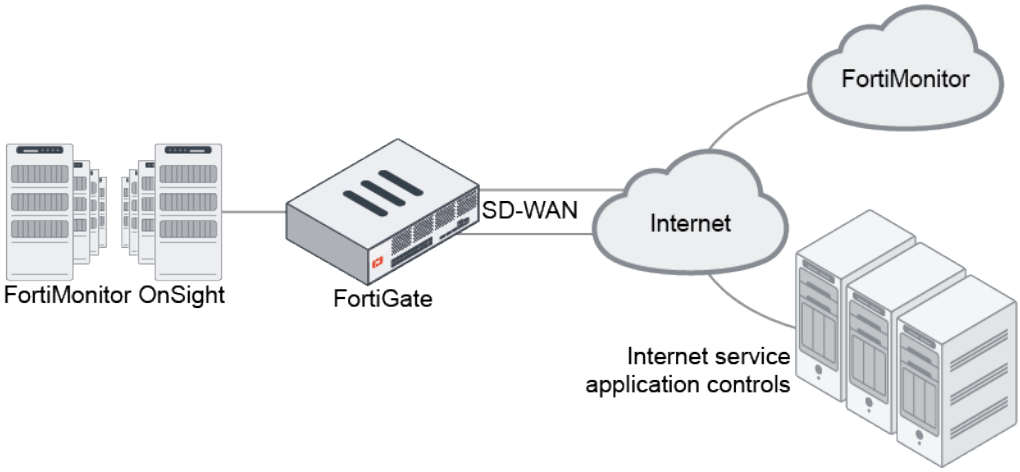
Hub SD-WAN member	Overlay	SLA status	Priority for IKE routes
1	EDGE_T1	0x0 – out of SLA	20
2	EDGE_T2	0x1 – within SLA	15

The BGP recursive routes inherit the priority based on the parent IKE routes. Since priority for IKE routes on EDGE_T1 has changed to 20, recursively resolved BGP routes passing through EDGE_T1 has also dropped to 20. As a result, hub to spoke_1 traffic will go over EDGE_T2.

SD-WAN application monitor using FortiMonitor

The agent-based health check detection mode works with FortiMonitor to provide more accurate user level performance statistics. FortiMonitor acts as an agent and sends health check probes on behalf of the monitored FortiGate interface. FortiMonitor mimics a real user, and the probes return a more accurate application level performance. The SLA information collected from FortiMonitor is sent back to the FortiGate as the monitored interface's SLA information. These statistics can be used to gain a deeper insight into the SD-WAN traffic performance.

```
config system sdwan
    config health-check
        edit <name>
            set detect-mode agent-based
        next
    end
    config service
        edit <id>
            set agent-exclusive {enable | disable}
        next
    end
end
```



The following diagnostic commands can be used to view agent related metrics:

```
# diagnose sys link-monitor-passive agent <option>
```

`list`	List all the collected reports.
`list-app`	List the details of each application.
`flush`	Flush all the collected reports.
`flush-app`	Flush the details of all the applications.
`agent-oif-map`	List the agent and interface maps.

Example

In this example, routing is achieved through SD-WAN rules. The agent-based health check detection mode creates the FortiMonitor IP address and FortiGate SD-WAN interface map.

This example assumes that the FortiMonitor has already been added to the Security Fabric (see Configuring FortiMonitor on page 2644 for detailed instructions). The FortiMonitor OnSight (client) can be configured for two or more IP addresses, and each IP address is capable of sending application probes to user-specified applications.

Specific routing is implemented on the FortiGate to ensure each FortiMonitor client collects performance statistics for only one SD-WAN member interface. The FortiMonitor is configured to send application-specific probes to measure that application's performance on a given SD-WAN member. The FortiGate uses the FortiMonitor performance statistics to determine link quality based on application performance by mapping the health check. The link quality for a given application can then be used to steer the matching application traffic with greater accuracy.

To configure the FortiGate:

1. Configure the address objects for each FortiMonitor client:

```
config firewall address
    edit "FMR_OnSight1"
        set subnet 10.2.1.80 255.255.255.255
    next
    edit "MR_OnSight2"
        set subnet 10.2.1.81 255.255.255.255
    next
end
```

2. Configure the SD-WAN rules to ensure each OnSight client uses only one SD-WAN member, and map the FortiMonitor IP to an SD-WAN member (interface):

```
config system sdwan
    config service
        edit 1
            set dst "all"
            set src "FMR_OnSight1"
            set priority-members 1
            set agent-exclusive enable
        next
```

```
        edit 2
            set dst "all"
            set src "FMR_OnSight2"
            set priority-members 2
            set agent-exclusive enable
        next
    end
end
```

3. Configure the SD-WAN health check:

```
config health-check
    edit "FMR"
        set detect-mode agent-based
        set members 1 2
        config sla
            edit 1
            next
        end
    next
end
```

To verify the SD-WAN member performance:

1. Verify the health check diagnostics:

```
# diagnose sys sdwan health-check
Health Check(FMR):
Seq(1 v1236): state(alive), packet-loss(0.000%) latency(183.214), jitter(0.124), mos
(4.225), bandwidth-up(999992), bandwidth-dw(999976), bandwidth-bi(1999968) sla_map=0x0
Seq(2 v1237): state(alive), packet-loss(0.000%) latency(182.946), jitter(0.100), mos
(4.226), bandwidth-up(999998), bandwidth-dw(999993), bandwidth-bi(1999991) sla_map=0x0
```

2. Verify the collected reports:

```
# diagnose sys link-monitor-passive agent list
       v1236( 23) | src=10.2.1.80 | latency=183.2   20:27:24 | jitter=0.1     20:27:24 |
pktloss=0.0  % 20:27:24
       v1237( 24) | src=10.2.1.81 | latency=182.9   20:27:24 | jitter=0.1     20:27:24 |
pktloss=0.0  % 20:27:24
```

3. Verify the details of each application:

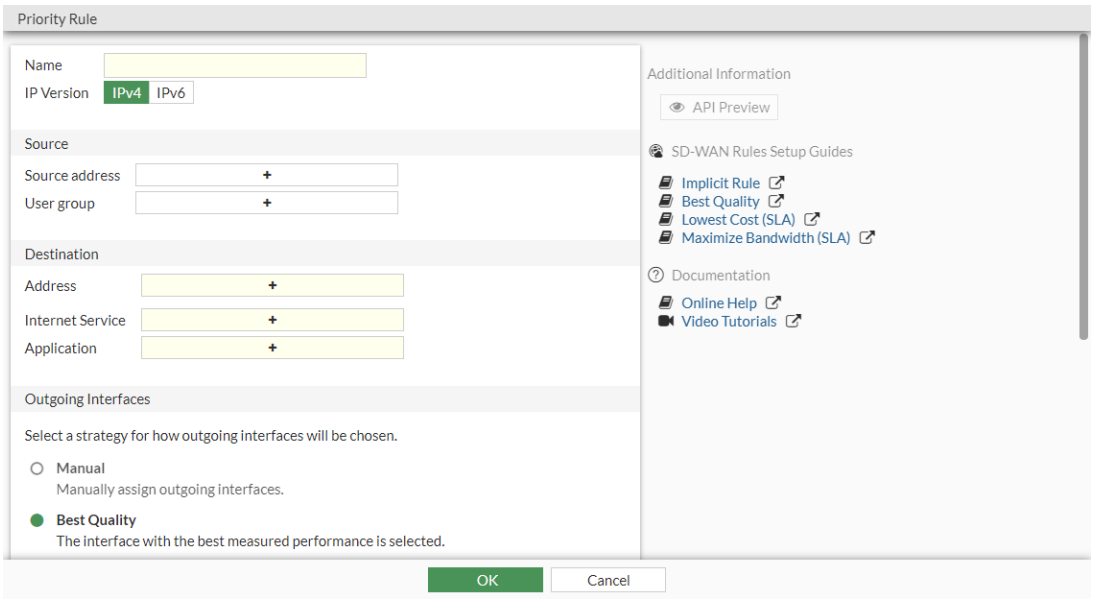
```
# diagnose sys link-monitor-passive agent list-app
app_id=0x00000000, app=fortinet.com, dev=v1236(23)
        latency=183.2, jitter=0.1, pktloss=0.0,ntt=99.2,srt=384.8,app_err=0.0, 20:28:25
app_id=0x00000000, app=fortinet.com, dev=v1237(24)
        latency=183.1, jitter=0.5, pktloss=0.0,ntt=104.4,srt=377.8,app_err=0.0, 20:28:25
```

4. Verify the agent and interface maps:

```
# diagnose sys link-monitor-passive agent agent-oif-map
oif=v1236(23), src=10.2.1.80
oif=v1237(24), src=10.2.1.81
```

SD-WAN rules

SD-WAN rules, which are sometimes called *service rules*, identify traffic of interest, and then route the traffic based on a strategy and the condition of the route or *link* between two devices. You can use many strategies to select the outgoing interface and many performance service level agreements (SLAs) to evaluate the link conditions.



Use the following topics to learn about and create SD-WAN rules for your needs:

- SD-WAN rules overview on page 688
- Implicit rule on page 696
- Automatic strategy on page 700
- Manual strategy on page 701
- Best quality strategy on page 702
- Lowest cost (SLA) strategy on page 706
- Maximize bandwidth (SLA) strategy on page 709
- Manual interface speedtest on page 712
- Scheduled interface speedtest on page 713
- SD-WAN traffic shaping and QoS on page 715
- SDN dynamic connector addresses in SD-WAN rules on page 720
- Application steering using SD-WAN rules on page 723
- DSCP tag-based traffic steering in SD-WAN on page 736
- ECMP support for the longest match in SD-WAN rule matching on page 743
- Override quality comparisons in SD-WAN longest match rule matching on page 745
- Use an application category as an SD-WAN rule destination on page 748

SD-WAN rules overview

SD-WAN rules control how sessions are distributed to SD-WAN members. You can configure SD-WAN rules from the GUI and CLI.

From the GUI, go to *Network* > *SD-WAN* > *SD-WAN Rules*. When creating a new SD-WAN rule, or editing an existing SD-WAN rule, use the *Source* and *Destination* sections to identify traffic, and use the *Outgoing interfaces* section to configure WAN intelligence for routing traffic.

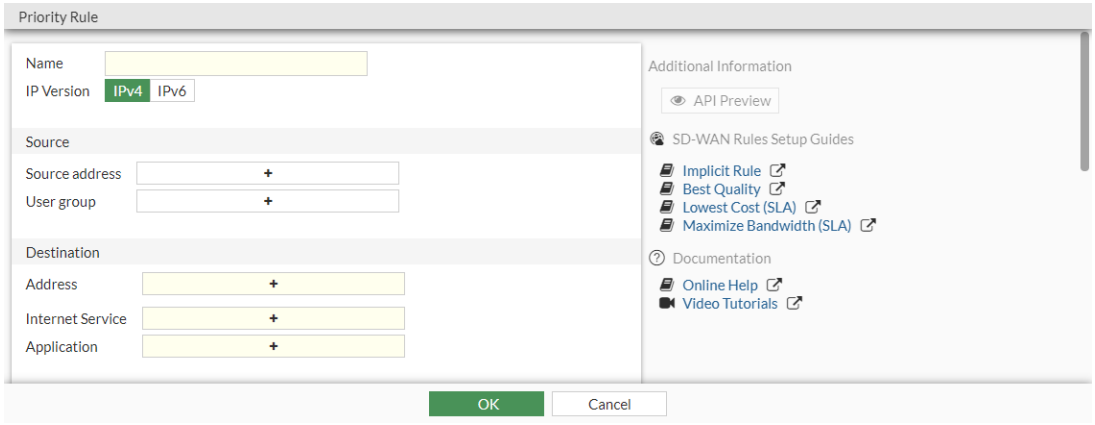
From the CLI, use the following command to configure SD-WAN rules:

```
config system sdwan
    config service
        edit <ID>
        next
    end
end
```

The following topics describe the fields used to configure SD-WAN rules:

- Fields for identifying traffic on page 689
- Fields for configuring WAN intelligence on page 692
- Additional fields for configuring WAN intelligence on page 695

Fields for identifying traffic



This topic describes the fields in an SD-WAN rule used for defining the traffic to which the rule applies. Some fields are available only in the CLI.

SD-WAN rules can identify traffic by a variety of means:

Address type	Source	Destination
IPv4/6	✓	✓
MAC	✓	✓
Group	✓	✓
FABRIC_DEVICE dynamic address	✓	✓
Users	✓	✓
User groups	✓	✓

Address type	Source	Destination
Application control (application aware routing)		✓
Internet service database (ISDB)		✓
BGP route tags		✓
Differentiated Services Code Point (DSCP) tags		✓

In the GUI, go to *Network* > *SD-WAN* > *SD-WAN Rules*. Click *Create New*, or double-click an existing rule to open it for editing. The *Source* and *Destination* sections are used to identify traffic for the rule:

In the CLI, edit the service definition ID number to identify traffic for the rule:

```
config system sdwan
    config service
        edit <ID>
        <CLI commands from the following tables>
        ...
    end
end
```

The following table describes the fields used for the name, ID, and IP version of the SD-WAN rule:

ID, Name, and IP version		
Field	**CLI**	**Description**

ID	`config system sdwan`
	`  config service`
	`  edit <ID>`
	`  next`
	`  end`
	`end`
		ID is generated when the rule is created. You can only specify the ID from the CLI.

Name	`set name <string>`	The name does not need to relate to the traffic being matched, but it is good practice to have intuitive rule names.
IP version	`set addr-mode <ipv4 | ipv6>`	The addressing mode can be IPv4 or IPv6.

ID, Name, and IP version		
Field	**CLI**	**Description**
		To configure in the GUI, IPv6 must be enabled from *System* > *Feature Visibility* page.

The following table describes the fields used for source section of the SD-WAN rule:

Source		
Field	**CLI**	**Description**
Source address	`set src <object>` Can be negated from the CLI with `set src-negate`.	One or more address objects.
User group	`set users <user object>` `set groups <group object>`	Individual users or user groups
Source interface (`input-device`)	`set input-device <interface name>` Can be negated with `set input-device-negate enable`.	CLI only. Select one or more source interfaces.

The following table describes the fields used for the destination section of the SD-WAN rule:

Destination		
Field	**CLI**	**Description**

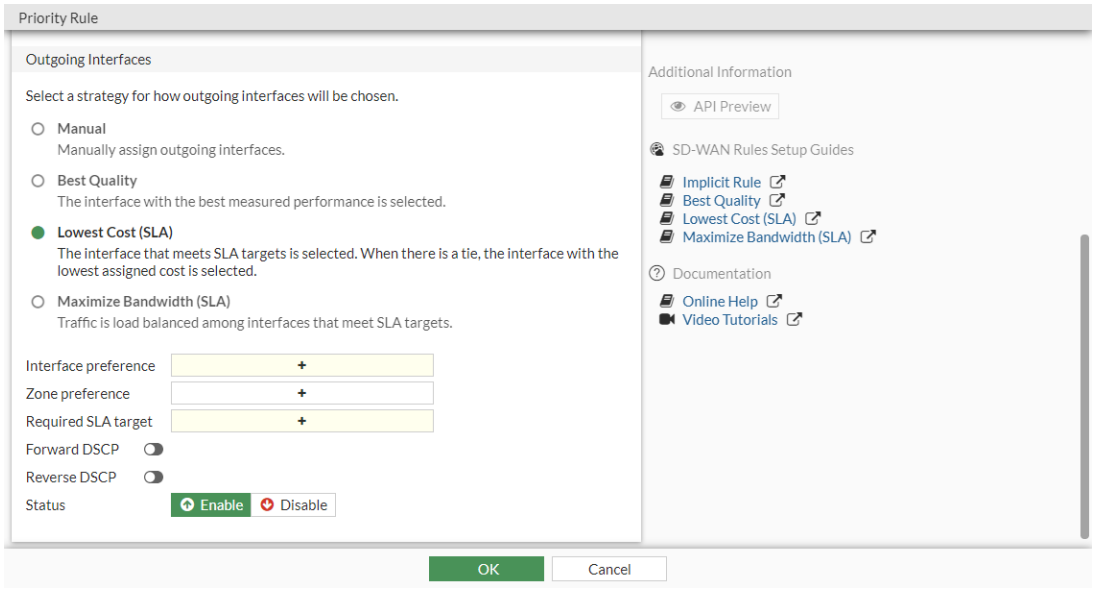
Address	`set dst <object>`
	`set protocol <integer>`
	`set start-port <integer>`
	`set end-port <integer>`
	Use `set dst-negate enable` to negate the address object.
		One or more address objects.
		One protocol and one port range can be combined with the address object.
		If it is necessary for an SD-WAN rule to match multiple protocols or multiple port ranges, you can create a custom Internet Service.

Internet Service	`set internet-service enable`
	`set internet-service-custom <name_1> <name_2> ... <name_n>`
	`set internet-service-custom-group <name_1> <name_2> ... <name_n>`
	`set internet-service-name <name_1> <name_2> ... <name_n>`
	`set internet-service-group <name_1> <name_2> ... <name_n>`
		One or more internet services or service groups.

Destination		
Field	**CLI**	**Description**

Application	`set internet-service-app-ctrl <id_1> <id_2> ... <id_n>`
	`set internet-service-app-ctrl-group <name_1> <name_2> ... <name_n>`
	`set internet-service-app-ctrl-category <id_1> <id_2> ... <id_n>`
		One or more applications or application groups.
		Can be used with internet services or service group.

Route tag (`route-tag`)	`set route-tag <integer>`	CLI only. This replaces the `dst` field (if previously configured) and matches a BGP route tag configured in a route map. See Using BGP tags with SD-WAN rules on page 758.
TOS mask (`tos-mask`)	`set tos-mask <8-bit hex value>`	CLI only. In order to leverage type of service (TOS) matching or DSCP matching on the IP header, the SD-WAN rule must specify the bit mask of the byte holding the TOS value. For example, a TOS mask of 0xe0 (11100000) matches the upper 3 bits.
TOS (`tos`)	`set tos <8 bit hex value>`	CLI only. The value specified here is matched after the `tos-mask` is applied. For example, the FortiGate receives DSCP values 110000 and 111011. (DSCP is the upper 6 bits of the TOS field – 11000000 and 11101100 respectively). Using the TOS value 0xe0 (11100000), only the second DSCP value is matched.



By default, individual applications and application groups cannot be selected in SD-WAN rules. To enable this functionality in the GUI, go to *System* > *Feature Visibility* and enable *Application Detection Based SD-WAN*. In the CLI, enter:

```
config system global
    set gui-app-detection-sdwan enable
end
```

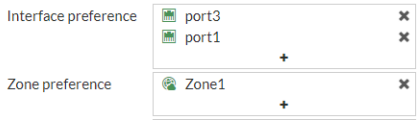
Fields for configuring WAN intelligence

This topic describes the fields in an SD-WAN rule used for configuring WAN intelligence, which processes and routes traffic that matches the SD-WAN rule.

In the GUI, go to *Network* > *SD-WAN* > *SD-WAN Rules*. Click *Create New*, or double-click an existing rule to open it for editing. The *Outgoing Interfaces* section is used to configure WAN intelligence for the rule:

WAN intelligence is comprised of the following parts:

- Interface or zone preference on page 693
- Strategy on page 694
- Performance SLA on page 694



Interface or zone preference

By default, the configured order of interfaces and/or zones in a rule are used. Interfaces and zones that are selected first have precedence over interfaces selected second and so on.

You can specify both interfaces and zones. When a zone is specified in the *Zone preference* field, it is equivalent to selecting each of the contained interface members in the *Interface preference* section. Interface members in a zone have lower priority than interfaces configured in the *Interface preference* section.

For example:

- There are 3 interfaces: port1, port2 and port3.
  - Port2 is in Zone1
  - Port1 and port3 belong to the default *virtual-wan-link* zone.
- An SD-WAN rule is created with *Interface preference* set to *port3* and *port1*, and *Zone preference* set to *Zone1*.

The SD-WAN rule prefers the interfaces in the following order:

1. port3
2. port1
3. port2

You can configure the interface and zone preference in the CLI:

```
config system sdwan
    config service
        edit <ID>
            set priority-members <integer>
            set priority-zone <interface>
        next
    end
end
```

Strategy

Strategy dictates how the interface and/or zone order changes as link conditions change. You can use the following strategies:

- Automatic (`auto`): interfaces are assigned a priority based on quality. See Automatic strategy on page 700.
- Manual (`manual`): interfaces are manually assigned a priority. See Manual strategy on page 701.
- Best Quality (`priority`): interfaces are assigned a priority based on the `link-cost-factor` of the interface. See Best quality strategy on page 702.
- Lowest cost (SLA) (`sla`): interfaces are assigned a priority based on selected SLA settings. See Lowest cost (SLA) strategy on page 706.
- Maximize Bandwidth (SLA) (`load-balance`): traffic is distributed among all available links based on the selected load balancing algorithm. See Maximize bandwidth (SLA) strategy on page 709.

Performance SLA

The best quality, lowest cost, and maximize bandwidth strategies are the most intelligent modes, and they leverage SLA health checks to provide meaningful metrics for a given link. FortiGate uses the metrics to make intelligent decisions to route traffic.

Automatic and manual strategies have pre-configured logic that do not leverage SLA health checks.

The goal of the performance SLA is to measure the quality of each SD-WAN member link. The following methods can be used to measure the quality of a link:

- Active measurement
  - Health-check traffic is sent to a server with a variety of protocols options.
  - The following SLA metrics are measured on this probe traffic:
    - Latency
    - Jitter
    - Packet loss
- Passive measurement
  - SLA metrics are measured on real or live traffic, reducing the amount of probe traffic that is sent and received.
  - There is the option (prefer passive) to initiate probe traffic when no live traffic is present.

Performance SLA is utilized by `auto`, *Lowest Cost (SLA)*, *Maximize Bandwidth (SLA)*, and *Best Quality* strategies. *Lowest Cost (SLA)* and *Maximize Bandwidth SLA* use SLA targets in a pass or fail style to evaluate whether a link is considered for traffic. *Best Quality* compares a specific metric of the SLA to pick the best result.

Therefore it is integral to select or create an SLA target(s) that relates to the traffic targeted by the rule. It does not make sense to evaluate a public resource, such as YouTube, when the rule matches Azure traffic.

See Performance SLA on page 653 for more details.

Additional fields for configuring WAN intelligence

This topic describes the fields in an SD-WAN rule used for configuring WAN intelligence for egress traffic:

- Forward and/or reverse differentiated services code point (DSCP) on page 695
- Default and gateway options on page 695

For information about accessing fields for configuring WAN intelligence, see Fields for configuring WAN intelligence on page 692.

Forward and/or reverse differentiated services code point (DSCP)

The FortiGate differentiated services feature can be used to change the DSCP value for all packets accepted by a policy.

The packet's `DSCP` field for traffic initiating a session (forward) or for reply traffic (reverse) can be changed and enabled in each direction separately by configuring it in the firewall policy using the *Forward DSCP* and *Reverse DSCP* fields.

From the CLI:

```
config system sdwan
    config service
        edit <ID>
            ...
            set dscp-forward enable
            ...
        next
    end
end
```

`set dscp-forward enable`	Enable use of forward DSCP tag.
`set dscp-forward-tag 000000`	Forward traffic DSCP tag.
`set dscp-reverse enable`	Enable use of reverse DSCP tag.
`set dscp-reverse-tag 000000`	Reverse traffic DSCP tag.

Default and gateway options

Following are additional gateway options that can be set only in the CLI:

```
config system sdwan
    config service
        edit <ID>
            ...
            set default enable
            ...
        next
    end
end
```

`set default [enable|disable]`	Enable or disable use of SD-WAN as default service.
`set gateway [enable|disable]`	Enable or disable SD-WAN service gateway.

By default, these settings are set to `disable`.

These two commands help adjust FortiGate route selection by affecting how the FortiGate consults the Forward Information Base (FIB).

In order to decide whether an SD-WAN policy-route can be matched, FortiGate performs the following FIB lookups:

- FIB best match for the destination must return an SD-WAN member.
- FIB route to the destination must exist over the desired SD-WAN member.

When `set default enable` is used with `set gateway enable`, FortiGate bypasses the FIB checks, and instead routes any matching traffic of the SD-WAN rule to the chosen SD-WAN member using the member's configured gateway. SD-WAN members must have a gateway configured.

When `set default disable` is used with `set gateway enable`, FortiGate keeps the first rule in effect but causes the second rule to change to:

- FIB route to the gateway IP address must exist over any interface.

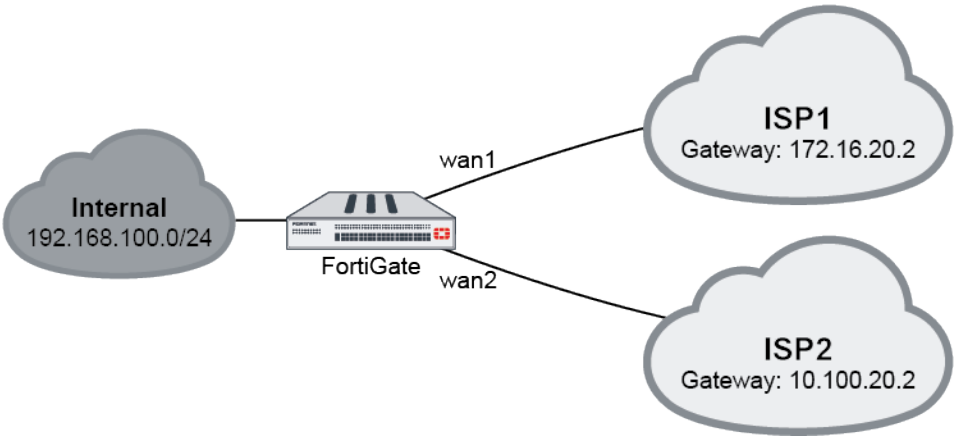
See also Fields for configuring WAN intelligence on page 692.

Implicit rule

SD-WAN rules define specific policy routing options to route traffic to an SD-WAN member. When no explicit SD-WAN rules are defined, or if none of the rules are matched, then the default implicit rule is used.

In an SD-WAN configuration, the default route usually points to the SD-WAN interface, so each active member's gateway is added to the routing table's default route. FortiOS uses equal-cost multipath (ECMP) to balance traffic between the interfaces. One of five load balancing algorithms can be selected:

Source IP (`source-ip-based`)	Traffic is divided equally between the interfaces, including the SD-WAN interface. Sessions that start at the same source IP address use the same path. This is the default selection.
Sessions (`weight-based`)	The workload is distributing based on the number of sessions that are connected through the interface. The weight that you assign to each interface is used to calculate the percentage of the total sessions that are allowed to connect through an interface, and the sessions are distributed to the interfaces accordingly. The sessions with the same source and destination IP are forwarded to the same path if the device model and kernel version supports route cache. However, it is not guaranteed and the route cache could be refreshed in case network events take place. In most cases where route cache is not supported, the sessions with the same source and destination IP will be load balanced between SD-WAN member interfaces. An interface's weight value cannot be zero.
Spillover (`usage-based`)	The interface is used until the traffic bandwidth exceeds the ingress and egress thresholds that you set for that interface. Additional traffic is then sent through the next SD-WAN interface member.
Source-Destination IP (`source-dest-ip-based`)	Traffic is divided equally between the interfaces. Sessions that start at the same source IP address and go to the same destination IP address use the same path.



Volume (`measured-volume-based`)	The workload is distributing based on the number of packets that are going through the interface. The volume weight that you assign to each interface is used to calculate the percentage of the total bandwidth that is allowed to go through an interface, and the bandwidth is distributed to the interfaces accordingly. An interface's volume value cannot be zero.

You cannot exclude an interface from participating in load balancing using the implicit rule. If the weight or volume were set to zero in a previous FortiOS version, the value is treated as a one.

Interfaces with static routes can be excluded from ECMP if they are configured with a lower priority than other static routes.

Examples

The following four examples demonstrate how to use the implicit rules (load-balance mode).

If no SD-WAN zone is specified, members are added to the default *virtual-wan-link* zone.

Example 1

Outgoing traffic is equally balanced between wan1 and wan2, using *source-ip-based* or *source-dest-ip-based* mode.

Using the GUI:

1. On the FortiGate, enable SD-WAN and add wan1 and wan2 as SD-WAN members, then add a policy and static route. See SD-WAN quick start on page 632 for details.
2. Go to *Network* > *SD-WAN* and select the *SD-WAN Rules* tab.
3. Edit the *sd-wan* rule (the last default rule).
4. For the *Load Balancing Algorithm*, select either *Source IP* or *Source-Destination IP*.
5. Click *OK*.

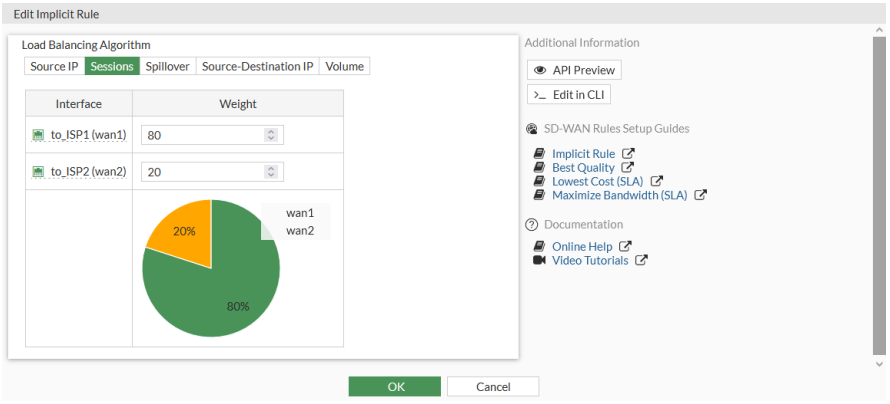
Using the CLI:

1. Enable SD-WAN and add wan1 and wan2 as SD-WAN members, then add a policy and static route. See SD-WAN quick start on page 632 for details.
2. Set the load balancing algorithm:
   Source IP based:

```
config system sdwan
    set load-balance-mode source-ip-based
end
```

   Source-Destination IP based:

```
config system sdwan
    set load-balance-mode source-dest-ip-based
end
```



Example 2

Outgoing traffic is balanced between wan1 and wan2 with a customized ratio, using *weight-based* mode: wan1 runs 80% of the sessions, and wan2 runs 20% of the sessions.

Sessions with the same source and destination IP addresses (`src-ip` and `dst-ip`) will be forwarded to the same path, but will still be considered in later session ratio calculations.

Using the GUI:

1. Go to *Network* > *SD-WAN* and select the *SD-WAN Rules* tab.
2. Edit the *sd-wan* rule (the last default rule).
3. For the *Load Balancing Algorithm*, select *Sessions*.
4. Enter 80 in the *wan1* field, and 20 in the *wan2* field.

5. Click *OK*.

Using the CLI:

```
config system sdwan
    set load-balance-mode weight-based
    config members
        edit 1
            set interface "wan1"
            set weight 80
```

```
        next
        edit 2
            set interface "wan2"
            set weight 20
        next
    end
end
```

Example 3

Outgoing traffic is balanced between wan1 and wan2 with a customized ratio, using *measured-volume-based* mode: wan1 runs 80% of the volume, and wan2 runs 20% of the volume.

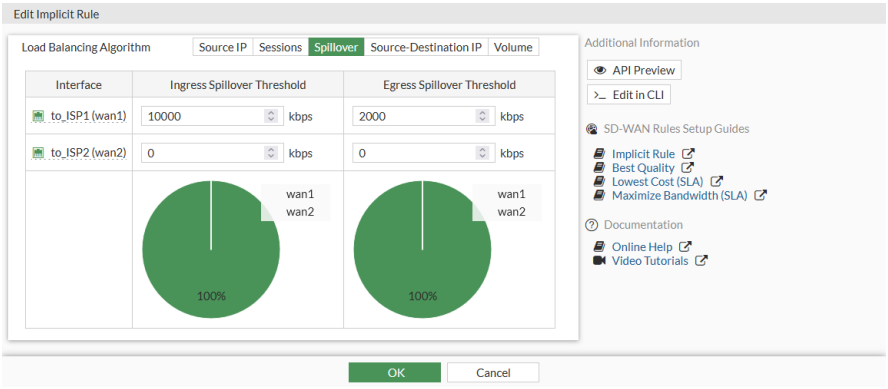
Using the GUI:

1. Go to *Network* > *SD-WAN* and select the *SD-WAN Rules* tab.
2. Edit the *sd-wan* rule (the last default rule).
3. For the *Load Balancing Algorithm*, select *Volume*.
4. Enter 80 in the *wan1* field, and 20 in the *wan2* field.
5. Click *OK*.

Using the CLI:

```
config system sdwan
    set load-balance-mode measured-volume-based
    config members
        edit 1
            set interface "wan1"
            set volume-ratio 80
        next
        edit 2
            set interface "wan2"
            set volume-ratio 20
        next
    end
end
```

Example 4



Load balancing can be used to reduce costs when internet connections are charged at different rates. For example, if wan2 charges based on volume usage and wan1 charges a fixed monthly fee, we can use wan1 at its maximum bandwidth, and use wan2 for overflow.

In this example, wan1's bandwidth is 10Mbps down and 2Mbps up. Traffic will use wan1 until it reaches its spillover limit, then it will start to use wan2. Note that `auto-asic-offload` must be disabled in the firewall policy.

Using the GUI:

1. On the FortiGate, enable SD-WAN and add wan1 and wan2 as SD-WAN members, then add a policy and static route. See SD-WAN quick start on page 632 for details.
2. Go to *Network* > *SD-WAN* and select the *SD-WAN Rules* tab.
3. Edit the *sd-wan* rule (the last default rule).
4. For the *Load Balancing Algorithm*, select *Spillover*.

5. Enter 10000 in the *wan1 Ingress Spillover Threshold* field, and 2000 in the *wan1 Egress Spillover Threshold* field.

6. Click *OK*.

Using the CLI:

```
config system sdwan
    set load-balance-mode usage-based
    config members
        edit 1
            set interface "wan1"
            set spillover-threshold 2000
            set ingress-spillover-threshold 10000
        next
    end
end
```

Automatic strategy

The automatic strategy is a legacy rule that lets you select an outgoing interface based on its performance ranking compared to the other SD-WAN interfaces. This is achieved by applying a performance SLA to rank the interfaces, and then selecting the desired rank.

In this example, you have three SD-WAN interfaces to three different ISPs that all go to the public internet. WAN1 is your highest quality link and should be reserved for business critical traffic. WAN2 and WAN3 are redundant backup links. You noticed one non-critical application is taking up a lot of bandwidth and want to prioritize it to the lowest quality link at any given time.

To configure automatic SD-WAN rules from the CLI:

```
config system sdwan
    config members
        edit 1
            set interface "wan1"
        next
        edit 2
            set interface "wan2"
        next
        edit 3
            set interface "wan3"
        next
```

```
    end
    config health-check
        edit "non-critical application"
            set server "noncritical.application.com"
            set members 1 2 3
            config sla
                edit 1
                    set latency-threshold 250
                    set jitter-threshold 50
                    set packletloss-threshold 3
                next
            end
        next
    end
    config service
        edit 1
            set name "non-critical application"
            set mode auto
            set quality-link 3
            set dst "non-critical-app-address-object"
            set health-check "non-critical application"
        next
    end
end
```

The `auto` option is only available in the CLI. If you use the GUI to edit the rule, the `auto` option will be overwritten because you cannot select *auto* in the GUI.

Manual strategy

In manual mode, no health checks are used. As a result, the decision making closer resembles logic than intelligence. SD-WAN manual rules are similar to regular policy-based routes, but have the added features of application-aware routing and BGP-tag routing. A manual strategy rule is comprised of the following parts:

- Defining the interfaces to be used
- Ordering the interfaces based on preference

To configure manual SD-WAN rules from the GUI:

1. Go to *Network* > *SD-WAN*.
2. Select the *SD-WAN Rules* tab, and click *Create New*.

3. Set the following options to create a manual rule:

Name	Type a name for the rule.
Source	(Optional) Specify a *Source address* and/or *User group*.
Destination	Specify the destination using an *Address* object or an *Internet Service* or an *Application*.
Zone preference	Specify one or more SD-WAN interfaces or zones. The order in which the interfaces or zones are specified determines their priority when the rule is matched.

4. Set the remaining options as desired, and click *OK* to create the rule.

To configure manual SD-WAN rules from the CLI:

```
config system sdwan
    config members
        edit 1
            set interface "wan1"
        next
        edit 2
            set interface "wan2"
        next
    end
    config service
        edit 1
            set name "manual"
            set mode manual
            set priority-members 2 1
            set dst "DC_net"
            set hold-down-time 60
        next
    end
end
```

- The command `set mode manual` will not appear in the configuration because it is the default mode.
- The command `set hold-down-time <integer>` is an optional command that controls how long to wait before switching back to the primary interface in the event of a failover.

Best quality strategy

When using *Best Quality* mode, SD-WAN will choose the best link to forward traffic by comparing the *link-cost-factor*. A link-cost factor is a specific metric of participating link(s) (such as, latency, packet loss, and so on) evaluated against a target that you define (such as a health-check server), for example, the latency of WAN1 and WAN2 to your datacenter. Below is a list of link-cost factors available to you:

GUI	CLI	Description
Latency	`latency`	Select a link based on latency.
Jitter	`jitter`	Select a link based on jitter.
Packet Loss	`packet-loss`	Select a link based on packet loss.
Downstream	`inbandwidth`	Select a link based on available bandwidth of incoming traffic.
Upstream	`outbandwidth`	Select a link based on available bandwidth of outgoing traffic.
Bandwidth	`bibandwidth`	Select a link based on available bandwidth of bidirectional traffic.
Customized profile	`custom-profile-1`	Select link based on customized profile. If selected, set the following weights: • packet-loss-weight: Coefficient of packet-loss. • latency-weight: Coefficient of latency. • jitter-weight: Coefficient of jitter. • bandwidth-weight: Coefficient of reciprocal of available bidirectional bandwidth.

Although SD-WAN intelligence selects the best quality link according to the selected metric, by default a preference or advantage is given to the first configured SD-WAN member. This default is 10% and may be configured with the CLI command `set link-cost-threshold 10`.

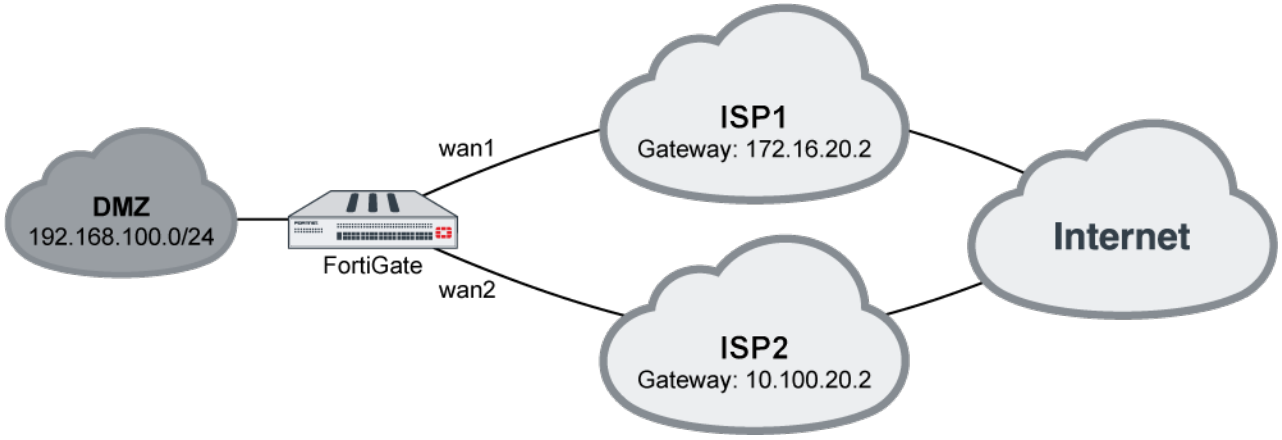
Example of how `link-cost-threshold` works:

```
config system sdwan
    config members
        edit 1
            set interface "wan1"
        next
        edit 2
            set interface "wan2"
        next
    end
    config service
        edit 1
            set name "Best_Quality"
            set mode priority
            set priority-members 2 1
            set dst "DC_net"
            set health-check "DC_HealthCheck"
            set link-cost-factor latency
            set link-cost-threshold 10
        next
    end
end
```

In this example both WAN1 and WAN2 are assumed to have 200ms latency to the health-check server named `DC_HealthCheck`. Because WAN2 is specified before WAN1 in priority-members, SD-WAN parses the two interfaces metric as follows:

- WAN1: 200ms
- WAN2: 200ms / (1+10%) = ~182ms

As a result, WAN2 is selected because the latency is lower.

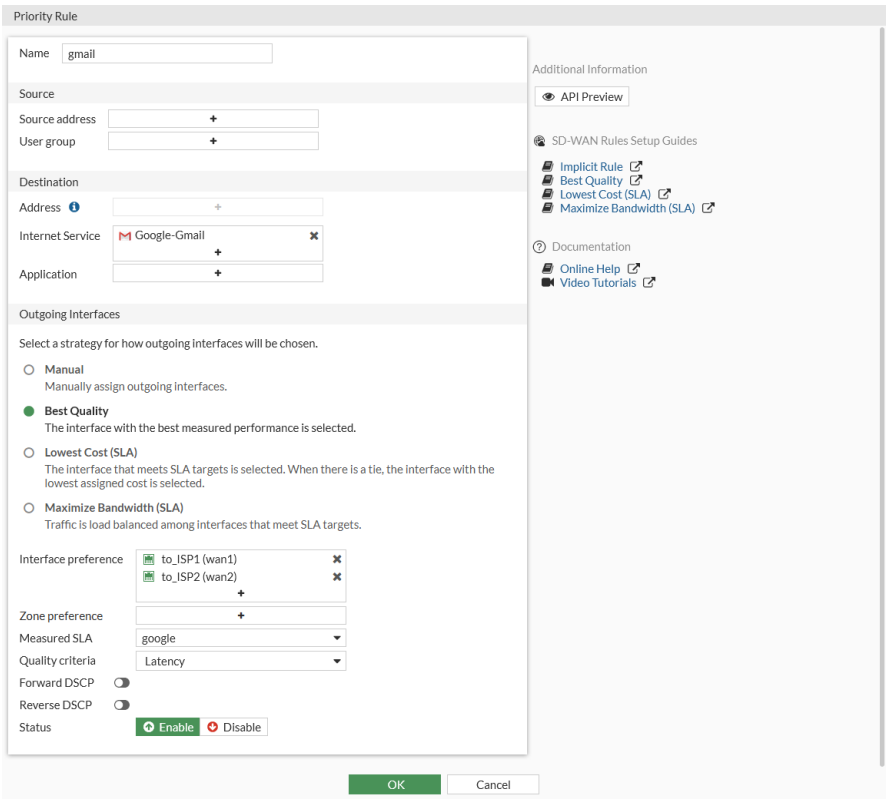


If the *Downstream* (`inbandwidth`), *Upstream* (`outbandwidth`), or *Bandwidth* (`bibandwidth`) quality criteria is used, the FortiGate uses the upstream and downstream bandwidth values configured on the member interfaces to calculate bandwidth.

The interface bandwidth configuration can be done manually, or the interface speedtest can be used to populate the bandwidth values based on the speedtest results. See Manual interface speedtest on page 712 for details.

To manually configure the upstream and downstream interface bandwidth values:

```
config system interface
    edit <interface>
        set estimated-upstream-bandwidth <speed in kbps>
        set estimated-downstream-bandwidth <speed in kbps>
    next
end
```



Example

In this example, your wan1 and wan2 SD-WAN interfaces connect to two ISPs that both go to the public internet, and you want Gmail services to use the link with the least latency.

To configure an SD-WAN rule to use Best Quality:

1. On the FortiGate, add wan1 and wan2 as SD-WAN members, then add a policy and static route. See SD-WAN quick start on page 632 for more details.
2. Go to *Network* > *SD-WAN*, select the *Performance SLAs* tab, and click *Create New*.
3. Enter a name for the performance SLA, such as *google*, and set the *Server* to *google.com*. See Health checks for more details.
4. Click *OK*.
5. Go to *Network* > *SD-WAN*, select the *SD-WAN Rules* tab, and click *Create New*.
6. Enter a name for the rule, such as *gmail*.
7. Configure the following settings:

Internet Service	Google-Gmail
Strategy	Best Quality
Interface preference	wan1 and wan2
Measured SLA	google
Quality criteria	Latency

8. Click *OK*.

To configure an SD-WAN rule to use priority:

```
config system sdwan
    config health-check
        edit "google"
            set server "google.com"
            set members 1 2
        next
    end
    config service
        edit 1
            set name "gmail"
            set mode priority
            set internet-service enable
            set internet-service-id 65646
            set health-check "google"
```

```
            set link-cost-factor latency
            set priority-members 1 2
        next
    end
end
```

To diagnose the Performance SLA status:

```
FGT # diagnose sys sdwan health-check google
Health Check(google):
Seq(1): state(alive), packet-loss(0.000%) latency(14.563), jitter(4.334) sla_map=0x0
Seq(2): state(alive), packet-loss(0.000%) latency(12.633), jitter(6.265) sla_map=0x0

FGT # diagnose sys sdwan service 1
Service(1):

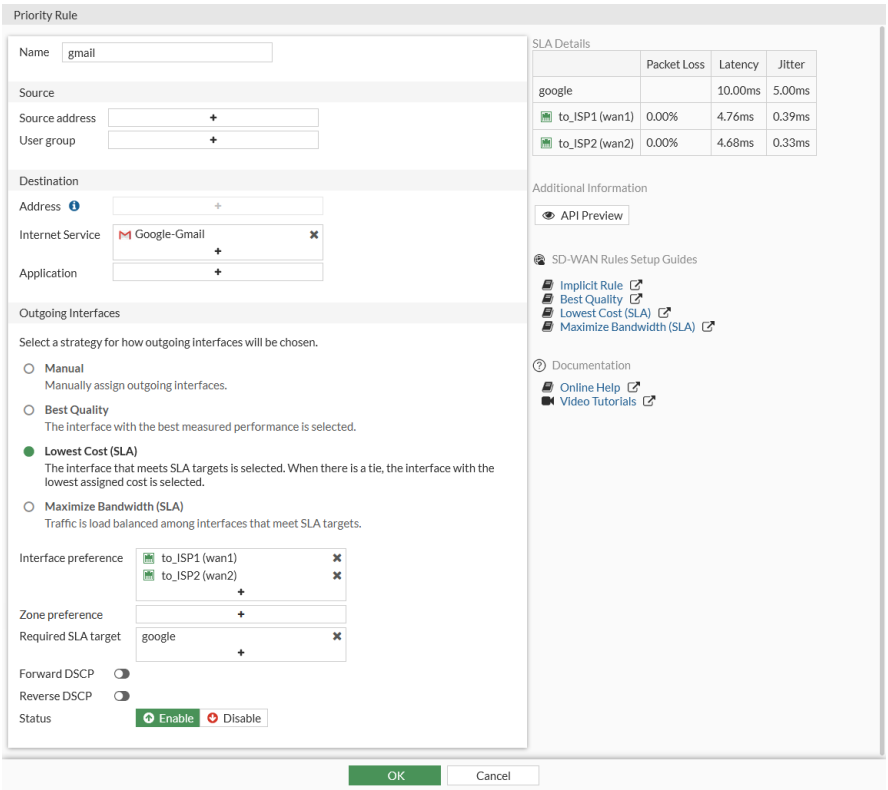
    TOS(0x0/0x0), protocol(0: 1->65535), Mode(priority), link-cost-facotr(latency), link-
cost-threshold(10), health-check(google) Members:

        1: Seq_num(2), alive, latency: 12.633, selected
        2: Seq_num(1), alive, latency: 14.563, selected

    Internet Service: Google-Gmail(65646)
```

As wan2 has a smaller latency, SD-WAN will put Seq_num(2) on top of Seq_num(1) and wan2 will be used to forward Gmail traffic.

Lowest cost (SLA) strategy



When using *Lowest Cost (SLA)* mode (`sla` in the CLI), SD-WAN will choose the lowest cost link that satisfies SLA to forward traffic. The lowest possible cost is `0`. If multiple eligible links have the same cost, the *Interface preference* order will be used to select a link.

In this example, your wan1 and wan2 SD-WAN interfaces connect to two ISPs that both go to the public internet. The cost of wan2 is less than that of wan1. You want to configure Gmail services to use the lowest cost interface, but the link quality must meet a standard of latency: 10ms, and jitter: 5ms.

To configure an SD-WAN rule to use Lowest Cost (SLA):

1. On the FortiGate, add wan1 and wan2 as SD-WAN members, then add a policy and static route. See SD-WAN quick start on page 632 for details.
2. Go to *Network* > *SD-WAN*, select the *Performance SLAs* tab, and click *Create New*.
3. Enter a name for the performance SLA, such as *google*, and set the *Server* to *google.com*.
4. Enable *SLA Target*. Set the *Latency threshold* to *10 ms*, and the *Jitter threshold* to *5 ms*. See Health checks for more details.
5. Click *OK*.
6. Go to *Network* > *SD-WAN*, select the *SD-WAN Rules* tab, and click *Create New*.
7. Enter a name for the rule, such as *gmail*.
8. Configure the following settings:

Internet Service	Google-Gmail
Strategy	Lowest Cost (SLA)
Interface preference	wan1 and wan2
Required SLA target	google

9. Click *OK*.

To configure an SD-WAN rule to use SLA:

```
config system sdwan
    config members
        edit 1
            set interface "wan1"
            set cost 10
        next
        edit 2
            set interface "wan2"
            set cost 5
        next
    end
    config health-check
        edit "google"
            set server "google.com"
            set members 1 2
            config sla
                edit 1
                    set latency-threshold 10
                    set jitter-threshold 5
                next
            end
        next
    end
    config service
        edit 1
            set name "gmail"
            set mode sla
            set internet-service enable
            set internet-service-id 65646
            config sla
                edit "google"
                    set id 1
                next
            end
            set priority-members 1 2
        next
    end
end
```

If no SD-WAN zone is specified, members are added to the default *virtual-wan-link* zone.

The CLI command `set minimum-sla-meet-members` allows you to specify the number of links that must meet SLA for the rule to take effect. If the number of members is less than the minimum set with this command, the rule will not take effect.

To diagnose the Performance SLA status:

```
FGT # diagnose sys sdwan health-check google
Health Check(google):
```

```
Seq(1): state(alive), packet-loss(0.000%) latency(14.563), jitter(4.334) sla_map=0x0
Seq(2): state(alive), packet-loss(0.000%) latency(12.633), jitter(6.265) sla_map=0x0

FGT # diagnose sys sdwan service 1
Service(1): Address Mode(IPV4) flags=0x0

    TOS(0x0/0x0), Protocol(0: 1->65535), Mode(sla)
    Members:<<BR>>

        1: Seq_num(2), alive, sla(0x1), cfg_order(1), selected
        2: Seq_num(1), alive, sla(0x1), cfg_order(0), selected

    Internet Service: Google.Gmail(65646)
```

When both wan1 and wan2 meet the SLA requirements, Gmail traffic will only use wan2. If only wan1 meets the SLA requirements, Gmail traffic will only use wan1, even though it has a higher cost. If neither interface meets the requirements, wan2 will be used.

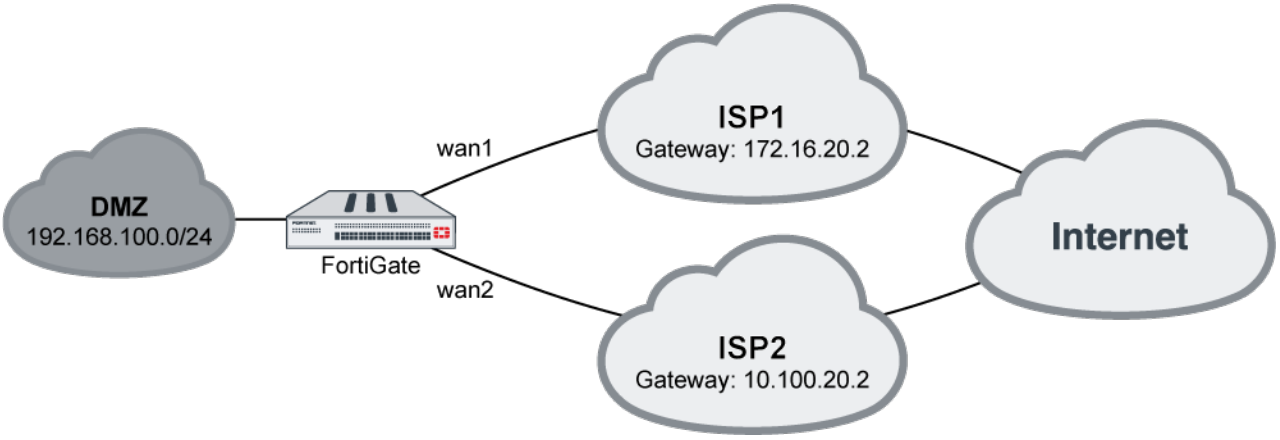
If both interface had the same cost and both met the SLA requirements, the first link configured in `set priority-members` would be used.

Maximize bandwidth (SLA) strategy

When using *Maximize Bandwidth* mode (`load-balance` in the CLI), SD-WAN will choose all of the links that satisfies SLA to forward traffic based on a load balancing algorithm. The load balancing algorithm, or hash method, can be one of the following:

round-robin	All traffic are distributed to selected interfaces in equal portions and circular order. This is the default method, and the only option available when using the GUI.
source-ip-based	All traffic from a source IP is sent to the same interface.
source-dest-ip-based	All traffic from a source IP to a destination IP is sent to the same interface.
inbandwidth	All traffic are distributed to a selected interface with most available bandwidth for incoming traffic.
outbandwidth	All traffic are distributed to a selected interface with most available bandwidth for outgoing traffic.
bibandwidth	All traffic are distributed to a selected interface with most available bandwidth for both incoming and outgoing traffic.

When the `inbandwidth`, `outbandwidth`), or `bibandwidth` load balancing algorithm is used, the FortiGate will compare the bandwidth based on the configured upstream and downstream bandwidth values.



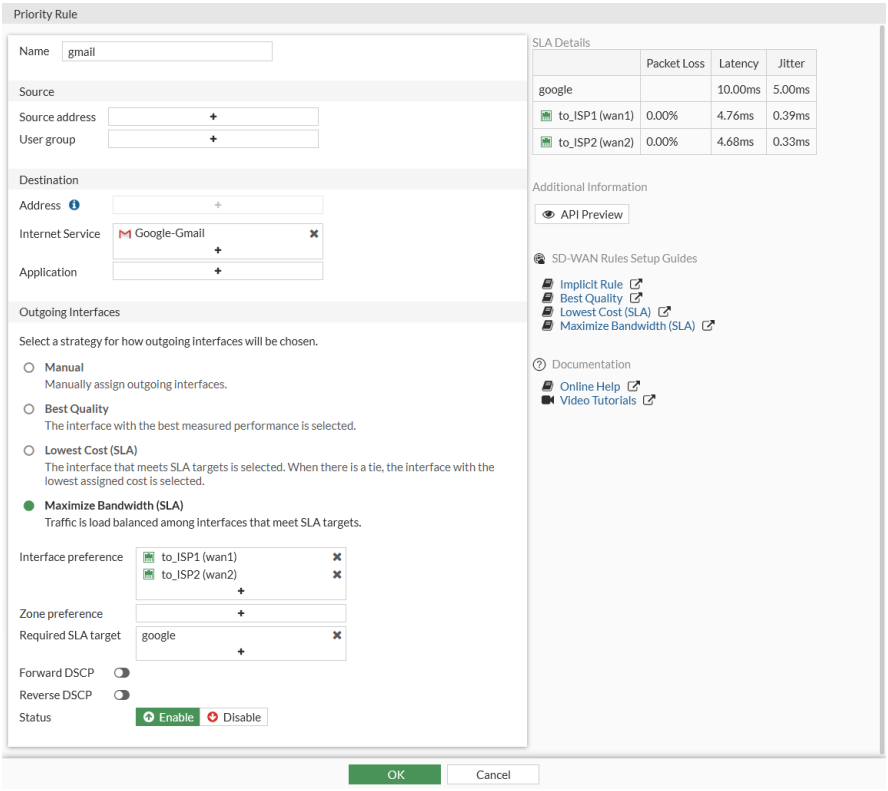
The interface speedtest can be used to populate the bandwidth values based on the speedtest results. See Manual interface speedtest on page 712 for details.

To manually configure the upstream and downstream bandwidth values:

```
config system interface
    edit <interface>
        set estimated-upstream-bandwidth <speed in kbps>
        set estimated-downstream-bandwidth <speed in kbps>
```

```
    next
end
```

ADVPN is not supported in this mode.



In this example, your wan1 and wan2 SD-WAN interfaces connect to two ISPs that both go to the public internet. You want to configure Gmail services to use both of the interface, but the link quality must meet a standard of latency: 10ms, and jitter: 5ms. This can maximize the bandwidth usage.

To configure an SD-WAN rule to use Maximize Bandwidth (SLA):

1. On the FortiGate, add wan1 and wan2 as SD-WAN members, then add a policy and static route. See SD-WAN quick start on page 632 for details.
2. Go to *Network* > *SD-WAN*, select the *Performance SLAs* tab, and click *Create New*.
3. Enter a name for the performance SLA, such as *google*, and set the *Server* to *google.com*.
4. Enable *SLA Target*. Set the *Latency threshold* to *10 ms*, and the *Jitter threshold* to *5 ms*. See Health checks for more details.
5. Click *OK*.
6. Go to *Network* > *SD-WAN*, select the *SD-WAN Rules* tab, and click *Create New*.
7. Enter a name for the rule, such as *gmail*.

8. Configure the following settings:

Field	Setting
Internet Service	Google-Gmail
Strategy	Maximize Bandwidth (SLA)
Interface preference	wan1 and wan2
Required SLA target	google

9. Click *OK*.

To configure an SD-WAN rule to use SLA:

```
config system sdwan
    config health-check
        edit "google"
            set server "google.com"
            set members 1 2
            config sla
                edit 1
                    set latency-threshold 10
                    set jitter-threshold 5
                next
            end
        next
    end
    config service
```

```
        edit 1
            set name "gmail"
            set addr-mode ipv4
            set mode load-balance
            set hash-mode round-robin
            set internet-service enable
            set internet-service-name Google-Gmail
            config sla
                edit "google"
                    set id 1
                next
            end
            set priority-members 1 2
        next
    end
end
```

The CLI command `set minimum-sla-meet-members` allows you to specify the number of links that must meet SLA for the rule to take effect. If the number of members is less than the minimum set with this command, the rule will not take effect.

To diagnose the performance SLA status:

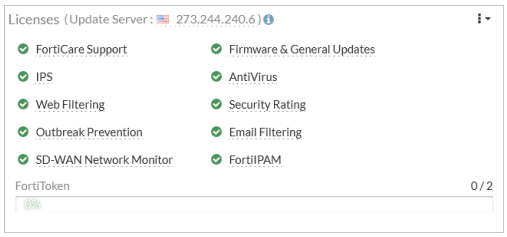
```
FGT # diagnose sys sdwan health-check google
Health Check(google):
Seq(1): state(alive), packet-loss(0.000%) latency(14.563), jitter(4.334) sla_map=0x0
Seq(2): state(alive), packet-loss(0.000%) latency(12.633), jitter(6.265) sla_map=0x0

FGT # diagnose sys sdwan service 1
Service(1): Address Mode(IPV4) flags=0x0

    TOS(0x0/0x0), Protocol(0: 1->65535), Mode(load-balance)
    Members:<<BR>>

        1: Seq_num(1), alive, sla(0x1), num of pass(1), selected
        2: Seq_num(2), alive, sla(0x1), num of pass(1), selected

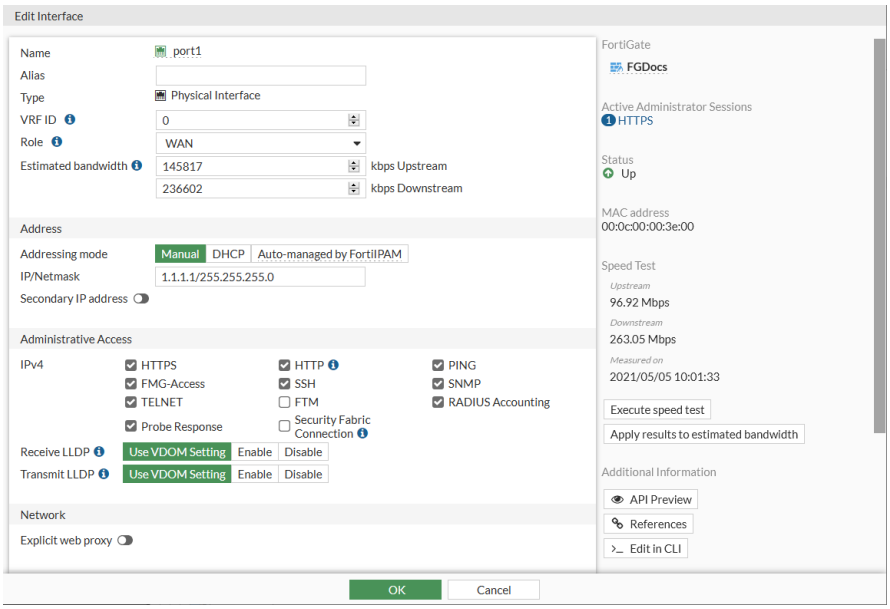
    Internet Service: Google.Gmail(65646)
```



When both wan1 and wan2 meet the SLA requirements, Gmail traffic will use both wan1 and wan2. If only one of the interfaces meets the SLA requirements, Gmail traffic will only use that interface.

If neither interface meets the requirements but health-check is still alive, then wan1 and wan2 tie. The traffic will try to balance between wan1 and wan2, using both interfaces to forward traffic.

Manual interface speedtest



An interface speedtest can be manually performed on WAN interfaces in the GUI. The results of the test can be added to the interface's *Estimated bandwidth*. The estimated upstream and downstream bandwidths can be used in SD-WAN service rules to determine the best link to use when either Maximize Bandwidth or Best Quality strategies are selected.

An SD-WAN Network Monitor license is required to use the speedtest. The *License* widget and the *System* > *FortiGuard* page show the license status.

To run an interface speedtest in the GUI:

1. Go to *Network* > *Interfaces*.
2. Edit a WAN interface. The interfaces can be grouped by role using the grouping dropdown on the right side of the toolbar.
3. Click *Execute speed test* in the right pane.

4. When the test completes, click *OK* in the *Confirm* pane to apply the results to the estimated bandwidth. The results can also be applied later by clicking *Apply results to estimated bandwidth*.

   The speedtest results are used to populate the *Estimated bandwidth* fields.
5. Click *OK*.

The FortiGate must be connected to FortiGuard, and able to reach either the AWS or Google speedtest servers.

Scheduled interface speedtest

The SD-WAN Network Monitor service supports running a speed test based on a schedule. The test results are automatically updated in the interface `measured-upstream-bandwidth` and `measured-downstream-bandwidth` fields. These fields do not impact the interface inbound bandwidth, outbound bandwidth, estimated upstream bandwidth, or estimated downstream bandwidth settings.

An SD-WAN Network Monitor license is required to use the speedtest. The *License* widget and the *System* > *FortiGuard* page show the license status.

When the scheduled speed tests run, it is possible to temporarily bypass the bandwidth limits set on the interface and configure custom maximum or minimum bandwidth limits. These configurations are optional.

```
config system speed-test-schedule
    edit <interface>
        set schedules <schedule> ...
        set update-inbandwidth enable {enable | disable}
        set update-outbandwidth enable {enable | disable}
        set update-inbandwidth-maximum <integer>
        set update-inbandwidth-minimum <integer>
        set update-outbandwidth-maximum <integer>
        set update-outbandwidth-minimum <integer>
    next
end
```

`update-inbandwidth enable {enable | disable}`	Enable/disable bypassing the interface's inbound bandwidth setting.
`update-outbandwidth enable {enable | disable}`	Enable/disable bypassing the interface's outbound bandwidth setting.
`update-inbandwidth-maximum <integer>`	Maximum downloading bandwidth to be used in a speed test, in Kbps (0 - 16776000).
`update-inbandwidth-minimum <integer>`	Minimum downloading bandwidth to be considered effective, in Kbps (0 - 16776000).
`update-outbandwidth-maximum <integer>`	Maximum uploading bandwidth to be used in a speed test, in Kbps (0 - 16776000).
`update-outbandwidth-minimum <integer>`	Minimum uploading bandwidth to be considered effective, in Kbps (0 - 16776000).

In the following example, a speed test is scheduled on port1 at 10:00 AM, and another one at 14:00 PM.

To run a speed test based on a schedule:

1. Configure the recurring schedules:

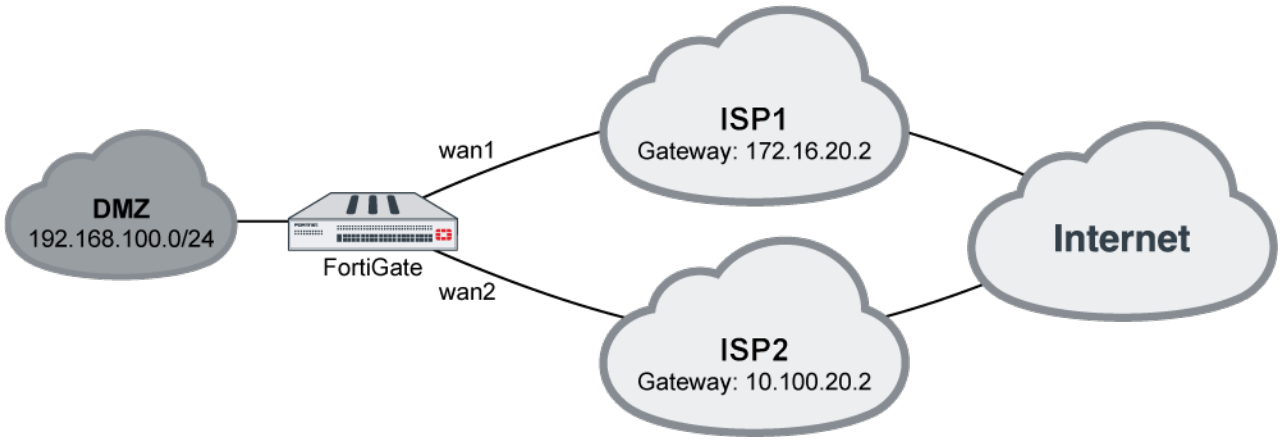
```
config firewall schedule recurring
    edit "10"
        set start 10:00
        set end 12:00
        set day monday tuesday wednesday thursday friday
    next
    edit "14"
        set start 14:00
        set end 16:00
        set day monday tuesday wednesday thursday friday
    next
end
```

2. Configure the speed test schedule:

```
config system speed-test-schedule
    edit "port1"
        set schedules "10" "14"
        set update-inbandwidth enable
        set update-outbandwidth enable
        set update-inbandwidth-maximum 60000
        set update-inbandwidth-minimum 10000
        set update-outbandwidth-maximum 50000
        set update-outbandwidth-minimum 10000
    next
end
```

3. View the speed test results:

```
config system interface
    edit port1
        get | grep measure
            measured-upstream-bandwidth: 23691
            measured-downstream-bandwidth: 48862
            bandwidth-measure-time:  Wed Jan 27 14:00:39 2021
    next
end
```



SD-WAN traffic shaping and QoS

Use a traffic shaper in a firewall shaping policy to control traffic flow. You can use it to control maximum and guaranteed bandwidth, or put certain traffic to one of the three different traffic priorities: high, medium, or low.

An advanced shaping policy can classify traffic into 30 groups. Use a shaping profile to define the percentage of the interface bandwidth that is allocated to each group. Each group of traffic is shaped to the assigned speed limit based on the outgoing bandwidth limit configured on the interface.

For more information, see Traffic shaping on page 1189.

Sample topology

Sample configuration

This example shows a typical customer usage where the customer's SD-WAN uses the default zone, and has two member: wan1 and wan2, each set to 10Mb/s.

An overview of the procedures to configure SD-WAN traffic shaping and QoS with SD-WAN includes:

1. Give HTTP/HTTPS traffic high priority and give FTP low priority so that if there are conflicts, FortiGate will forward HTTP/HTTPS traffic first.
2. Even though FTP has low priority, configure FortiGate to give it a 1Mb/s guaranteed bandwidth on each SD-WAN member so that if there is no FTP traffic, other traffic can use all the bandwidth. If there is heavy FTP traffic, it can still be guaranteed a 1Mb/s bandwidth.
3. Traffic going to specific destinations such as a VOIP server uses wan1 to forward, and SD-WAN forwards with an Expedited Forwarding (EF) DSCP tag 101110.

To configure SD-WAN traffic shaping and QoS with SD-WAN in the GUI:

1. On the FortiGate, add wan1 and wan2 as SD-WAN members, then add a policy and static route.
   See SD-WAN quick start on page 632.
2. Add a firewall policy with *Application Control* enabled. See Configuring firewall policies for SD-WAN on page 635.
3. Go to *Policy & Objects* > *Traffic Shaping*, select the *Traffic Shapers* tab, and edit *low-priority*.
   a. Enable *Guaranteed Bandwidth* and set it to *1000* kbps.
4. Go to *Policy & Objects* > *Traffic Shaping*, select the *Traffic Shaping Policies* tab, and click *Create New*.
   a. Name the traffic shaping policy, for example, *HTTP-HTTPS*.
   b. Set the following:

Source	*all*
Destination	*all*
Service	*HTTP* and *HTTPS*
Outgoing interface	*virtual-wan-link*
Shared Shaper	Enable and set to *high-priority*
Reverse Shaper	Enable and set to *high-priority*

   c. Click *OK*.
5. Go to *Policy & Objects* > *Traffic Shaping*, select the *Traffic Shaping Policies* tab, and click *Create New*.
   a. Name the traffic shaping policy, for example, *FTP*.
   b. Set the following:

Source	*all*
Destination	*all*
Service	*FTP*, *FTP_GET*, and *FTP_PUT*
Outgoing interface	*virtual-wan-link*
Shared Shaper	Enable and set to *low-priority*
Reverse Shaper	Enable and set to *low-priority*

   c. Click *OK*

6. Go to *Network* > *SD-WAN*, select the *SD-WAN Rules* tab, and click *Create New*.
   a. Enter a name for the rule, such as *Internet*.
   b. In the *Destination* section, click *Address* and select the VoIP server that you created in the firewall address.
   c. Under *Outgoing Interfaces* select *Manual*.
   d. For *Interface preference* select *wan1*.
   e. Click *OK*.
7. Use CLI commands to modify DSCP settings. See the DSCP CLI commands below.

To configure the firewall policy using the CLI:

```
config firewall policy
    edit 1
        set name "1"
        set srcintf "dmz"
        set dstintf "virtual-wan-link"
        set srcaddr "all"
        set dstaddr "all"
        set action accept
        set schedule "always"
        set service "ALL"
        set utm-status enable
        set ssl-ssh-profile "certificate-inspection"
        set application-list "default"
        set nat enable
    next
end
```

To configure the firewall traffic shaper priority using the CLI:

```
config firewall shaper traffic-shaper
    edit "high-priority"
        set maximum-bandwidth 1048576
        set per-policy enable
    next
    edit "low-priority"
        set guaranteed-bandwidth 1000
        set maximum-bandwidth 1048576
        set priority low
        set per-policy enable
    next
end
```

To configure the firewall traffic shaping policy using the CLI:

```
config firewall shaping-policy
    edit 1
        set name "http-https"
        set service "HTTP" "HTTPS"
        set dstintf "virtual-wan-link"
        set traffic-shaper "high-priority"
        set traffic-shaper-reverse "high-priority"
        set srcaddr "all"
        set dstaddr "all"
    next
```

```
    edit 2
        set name "FTP"
        set service "FTP" "FTP_GET" "FTP_PUT"
        set dstintf "virtual-wan-link"
        set traffic-shaper "low-priority"
        set traffic-shaper-reverse "low-priority"
        set srcaddr "all"
        set dstaddr "all"
    next
end
```

To configure SD-WAN traffic shaping and QoS with SD-WAN in the CLI:

```
config system sdwan
    set status enable
    config members
        edit 1
            set interface "wan1"
            set gateway 172.16.20.2
        next
        edit 2
            set interface "wan2"
            set gateway 10.100.20.2
        next
    end
    config service
        edit 1
            set name "SIP"
            set priority-members 1
            set dst "voip-server"
            set dscp-forward enable
            set dscp-forward-tag 101110
        next
    end
end
```

If no SD-WAN zone is specified, members are added to the default *virtual-wan-link* zone.

To use the diagnose command to check if specific traffic is attached to the correct traffic shaper:

```
# diagnose firewall iprope list 100015

policy index=1 uuid_idx=0 action=accept
flag (0):
shapers: orig=high-priority(2/0/134217728) reply=high-priority(2/0/134217728)
cos_fwd=0  cos_rev=0
group=00100015 av=00000000 au=00000000 split=00000000
host=0 chk_client_info=0x0 app_list=0 ips_view=0
misc=0 dd_type=0 dd_mode=0
zone(1): 0 -> zone(2): 36 38
source(1): 0.0.0.0-255.255.255.255, uuid_idx=6,
dest(1): 0.0.0.0-255.255.255.255, uuid_idx=6,
```

```
service(2):
        [6:0x0:0/(1,65535)->(80,80)] helper:auto
        [6:0x0:0/(1,65535)->(443,443)] helper:auto

policy index=2 uuid_idx=0 action=accept
flag (0):
shapers: orig=low-priority(4/128000/134217728) reply=low-priority(4/128000/134217728)
cos_fwd=0  cos_rev=0
group=00100015 av=00000000 au=00000000 split=00000000
host=0 chk_client_info=0x0 app_list=0 ips_view=0
misc=0 dd_type=0 dd_mode=0
zone(1): 0 -> zone(2): 36 38
source(1): 0.0.0.0-255.255.255.255, uuid_idx=6,
dest(1): 0.0.0.0-255.255.255.255, uuid_idx=6,
service(3):
        [6:0x0:0/(1,65535)->(21,21)] helper:auto
        [6:0x0:0/(1,65535)->(21,21)] helper:auto
        [6:0x0:0/(1,65535)->(21,21)] helper:auto
```

To use the diagnose command to check if the correct traffic shaper is applied to the session:

```
# diagnose sys session list
session info: proto=6 proto_state=01 duration=11 expire=3599 timeout=3600 flags=00000000
sockflag=00000000 sockport=0 av_idx=0 use=5
origin-shaper=low-priority prio=4 guarantee 128000Bps max 1280000Bps traffic 1050Bps drops
0B

bytes dropped 0
```

SDN dynamic connector addresses in SD-WAN rules

SDN dynamic connector addresses can be used in SD-WAN rules. FortiGate supports both public (AWS, Azure, GCP, OCI, AliCloud) and private (Kubernetes, VMware ESXi and NSX, OpenStack, ACI, Nuage) SDN connectors.

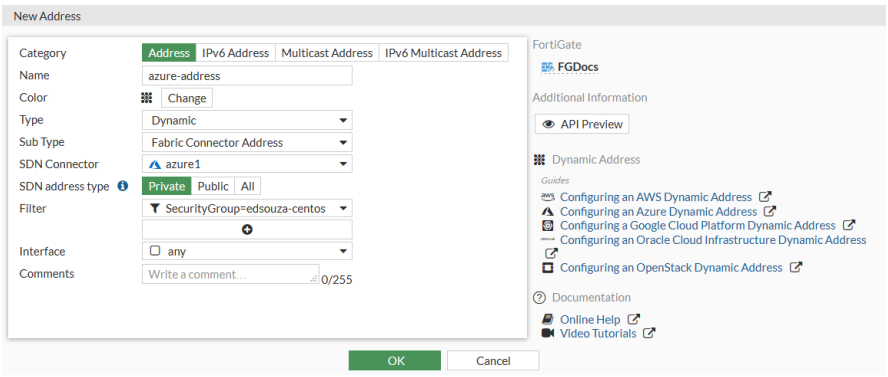
The configuration procedure for all of the supported SDN connector types is the same. This example uses an Azure public SDN connector.

There are four steps to create and use an SDN connector address in an SD-WAN rule:

1. Configure the FortiGate IP address and network gateway so that it can reach the Internet.
2. Create an Azure SDN connector.
3. Create a firewall address to associate with the configured SDN connector.
4. Use the firewall address in an SD-WAN service rule.

To create an Azure SDN connector:

1. Go to *Security Fabric* > *External Connectors*.
2. Click *Create New*.
3. In the *Public SDN* section, click *Microsoft Azure*.
4. Enter the following:



Name	azure1
Status	Enabled
Update Interval	Use Default
Server region	Global
Directory ID	942b80cd-1b14-42a1-8dcf-4b21dece61ba
Application ID	14dbd5c5-307e-4ea4-8133-68738141feb1
Client secret	xxxxxx
Resource path	disabled

5. Click *OK*.

To create a firewall address to associate with the configured SDN connector:

1. Go to *Policy & Objects* > *Addresses*.
2. Click *Create New* > *Address*.
3. Enter the following:

Category	Address
Name	azure-address
Type	Dynamic
Sub Type	Fabric Connector Address
SDN Connector	azure1
SDN address type	Private
Filter	SecurityGroup=edsouza-centos
Interface	Any

4. Click *OK*.

To use the firewall address in an SD-WAN service rule:

1. Go to *Network* > *SD-WAN*, select the *SD-WAN Rules* tab, and click *Create New*.
2. Set the *Name* to *Azure1*.
3. For the *Destination Address* select *azure-address*.
4. Configure the remaining settings as needed. See SD-WAN rules on page 688 for details.
5. Click *OK*.

Diagnostics

Use the following CLI commands to check the status of and troubleshoot the connector.

To see the status of the SDN connector:

```
# diagnose sys sdn status
SDN Connector           Type        Status          Updating        Last update
-------------------------------------------------------------------------------------
azure1                  azure       connected       no              n/a
```

To debug the SDN connector to resolve the firewall address:

```
# diagnose debug application azd -1
    Debug messages will be on for 30 minutes.

    ...
    azd sdn connector azure1 start updating IP addresses
    azd checking firewall address object azure-address-1, vd 0
     IP address change, new list:
      10.18.0.4
      10.18.0.12
      ...
      ...
# diagnose sys sdwan service

    Service(2): Address Mode(IPV4) flags=0x0
      TOS(0x0/0x0), Protocol(0: 1->65535), Mode(manual)
      Service role: standalone
```

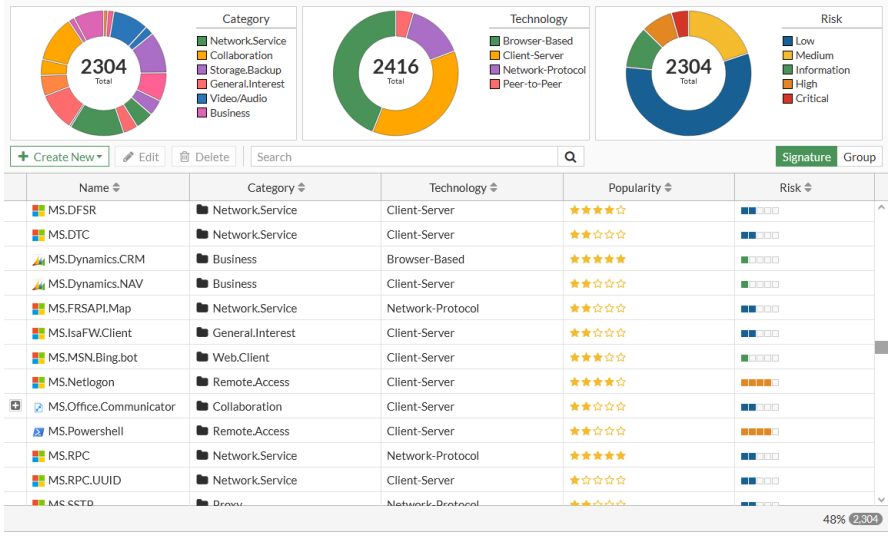
```
Member sub interface:
Members:
  1: Seq_num(1), alive, selected
Dst address:
      10.18.0.4 - 10.18.0.4
      10.18.0.12 - 10.18.0.12
       ... ...
       ... ...
       ... ...
```

Application steering using SD-WAN rules

This topic covers how to use application steering in a topology with multiple WAN links. The following examples illustrate how to use different strategies to perform application steering to accommodate different business needs:

- Application matching on page 723
- Static application steering with a manual strategy on page 724
- Dynamic application steering with lowest cost and best quality strategies on page 727

By default, individual applications and application groups cannot be selected in SD-WAN rules. To enable this functionality in the GUI, go to *System* > *Feature Visibility* and enable *Application Detection Based SD-WAN*. In the CLI, enter:



```
config system global
    set gui-app-detection-sdwan enable
end
```

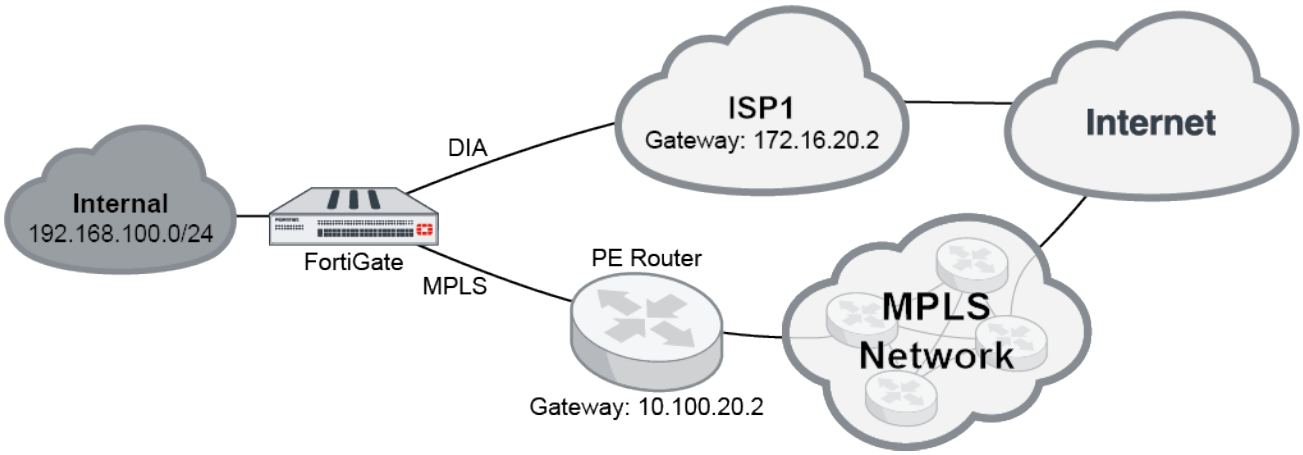
For application based steering to work, application control must be enabled in a policy. See Application control on page 1397.

Application matching

To apply application steering, SD-WAN service rules match traffic based on the applications that are in the application signature database. To view the signatures, go to *Security Profiles* > *Application Signatures* and select *Signature*.

On the first session that passes through, the IPS engine processes the traffic in the application layer to match it to a signature in the application signature database. The first session does not match any SD-WAN rules because the signature has not been recognized yet. When the IPS engine recognizes the application, it records the 3-tuple IP address, protocol, and port in the application control Internet Service ID list. To view the application and corresponding 3-tuple:

```
# diagnose sys sdwan internet-service-app-ctrl-list [app ID]
52.114.142.254
Microsoft.Teams(43541 4294837333): 52.114.142.254 6 443 Fri Jun 18 13:52:18 2021
```



The recognized application and 3-tuple stay in the application control list for future matches to occur. If there are no hits on the entry for eight hours, the entry is deleted.

For services with multiple IP addresses, traffic might not match the expected SD-WAN rule because the traffic is destined for an IP address that hat no previously been recognized by the FortiGate. The `diagnose sys sdwan internet-service-app-ctrl-list` command can be used to help troubleshoot such situations.

Static application steering with a manual strategy

This example covers a typical usage scenario where the SD-WAN has two members: MPLS and DIA. DIA is primarily used for direct internet access to internet applications, such as Office365, Google applications, Amazon, and Dropbox. MPLS is primarily used for SIP, and works as a backup when DIA is not working.

This example configures all SIP traffic to use MPLS while all other traffic uses DIA. If DIA is not working, the traffic will use MPLS.

By default, individual applications and application groups cannot be selected in SD-WAN rules. To enable this functionality in the GUI, go to *System* > *Feature Visibility* and enable *Application Detection Based SD-WAN*. In the CLI, enter:

```
config system global
    set gui-app-detection-sdwan enable
end
```

To configure an SD-WAN rule to use SIP and DIA in the GUI:

1. Add port1 (DIA) and port2 (MPLS) as SD-WAN members, and configure a static route. See Configuring the SD-WAN interface on page 633 for details.
2. Create a firewall policy with an *Application Control* profile configured. See Configuring firewall policies for SD-WAN on page 635 for details.
3. Go to *Network* > *SD-WAN*, select the *SD-WAN Rules* tab, and click *Create New*.
4. Enter a name for the rule, such as *SIP*.
5. Click the *Application* field and select the applicable SIP applications from the *Select Entries* panel.
6. Under *Outgoing Interfaces*, select *Manual*.
7. For *Interface preference*, select *MPLS*.
8. Click *OK*.
9. Click *Create New* to create another rule.
10. Enter a name for the rule, such as *Internet*.
11. Click the *Address* field and select *all* from the panel.
12. Under *Outgoing Interfaces*, select *Manual*.
13. For *Interface preference*, select *DIA*.
14. Click *OK*.

To configure the firewall policy using the CLI:

```
config firewall policy
    edit 1
        set name "1"
        set srcintf "dmz"
        set dstintf "virtual-wan-link"
```

```
        set srcaddr "all"
        set dstaddr "all"
        set action accept
        set schedule "always"
        set service "ALL"
        set utm-status enable
        set fsso disable
        set application-list "default"
        set ssl-ssh-profile "certificate-inspection"
        set nat enable
    next
end
```

To configure an SD-WAN rule to use SIP and DIA using the CLI:

```
config system sdwan
    set status enable
    config members
        edit 1
            set interface "MPLS"
        next
        edit 2
            set interface "DIA"
        next
    end
    config service
        edit 1
            set name "SIP"
            set internet-service enable
            set internet-service-app-ctrl 34640 152305677 38938 26180 26179 30251
            set priority-members 2
        next
        edit 2
            set name "Internet"
            set dst "all"
            set priority-members 1
        next
    end
end
```

All SIP traffic uses MPLS. All other traffic goes to DIA. If DIA is broken, the traffic uses MPLS. If you use VPN instead of MPLS to run SIP traffic, you must configure a VPN interface, for example vpn1, and then replace member 1 from MPLS to vpn1 for SD-WAN member.

If no SD-WAN zone is specified, members are added to the default *virtual-wan-link* zone.

To use the diagnose command to check performance SLA status using the CLI:

```
# diagnose sys sdwan service 1

Service(1): Address Mode(IPV4) flags=0x0
```

```
TOS(0x0/0x0), Protocol(0: 1->65535), Mode(manual)
Members:<<BR>>

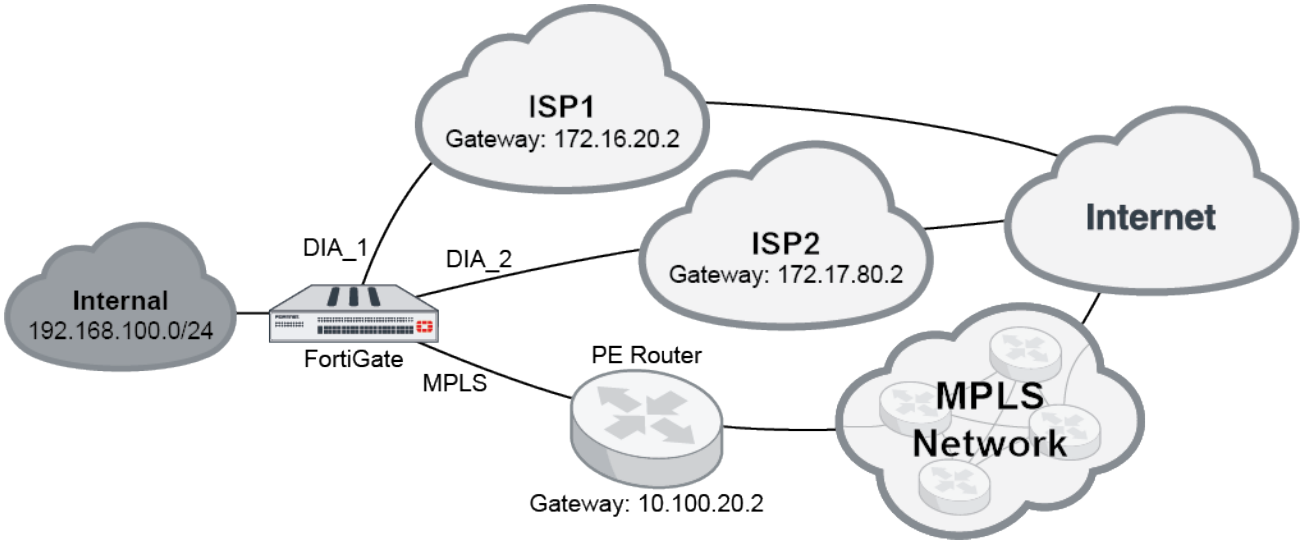
1: Seq_num(1), alive, selected

Internet Service: SIP(4294836224 34640) SIP.Method(4294836225 152305677) SIP.Via.NAT
(4294836226 38938) SIP_Media.Type.Application(4294836227 26180) SIP_Message(4294836228
26179) SIP_Voice(4294836229 30251)
```

```
# diagnose sys sdwan service 2

Service(2): Address Mode(IPV4) flags=0x0

TOS(0x0/0x0), Protocol(0: 1->65535), Mode(manual)
Members:<<BR>>



1: Seq_num(2), alive, selected

Dst address: 0.0.0.0-255.255.255.255
```

```
# diagnose sys sdwan internet-service-app-ctrl-list
Ctrl application(SIP 34640):Internet Service ID(4294836224)
Ctrl application(SIP.Method 152305677):Internet Service ID(4294836225)
Ctrl application(SIP.Via.NAT 38938):Internet Service ID(4294836226)
Ctrl application(SIP_Media.Type.Application 26180):Internet Service ID(4294836227)
Ctrl application(SIP_Message 26179):Internet Service ID(4294836228)
Ctrl application(SIP_Voice 30251):Internet Service ID(4294836229)
```

Dynamic application steering with lowest cost and best quality strategies

In this example, the SD-WAN has three members: two ISPs (DIA_1 and DIA_2) that are used for access to internet applications, and an MPLS link that is used exclusively as a backup for business critical applications.

Business applications, such as Office365, Google, Dropbox, and SIP, use the *Lowest Cost (SLA)* strategy to provide application steering, and traffic falls back to MPLS only if both ISP1 and ISP2 are down. Non-business applications, such as Facebook and Youtube, use the *Best Quality* strategy to choose between the ISPs.

By default, individual applications and application groups cannot be selected in SD-WAN rules. To enable this functionality in the GUI, go to *System* > *Feature Visibility* and enable *Application Detection Based SD-WAN*. In the CLI, enter:

```
config system global
    set gui-app-detection-sdwan enable
end
```

To configure the SD-WAN members, static route, and firewall policy in the GUI:

1. Add port1 (DIA_1), port2 (DIA_2), and port3 (MPLS) as SD-WAN members. Set the cost of DIA_1 and DIA_2 to *0*, and MPLS to *20*. See Configuring the SD-WAN interface on page 633 for details.
2. Configure a static route. See Adding a static route on page 634 for details.
3. Create a firewall policy to allow traffic out on SD-WAN, with an *Application Control* profile configured. See Configuring firewall policies for SD-WAN on page 635 for details.

To configure the SD-WAN rule and performance SLA checks for business critical application in the GUI:

1. Go to *Network* > *SD-WAN*, select the *SD-WAN Rules* tab, and click *Create New*.
2. Set the name to *BusinessCriticalApps*.

   This rule will steer your business critical traffic to the appropriate link based on the *Lowest Cost (SLA)*.
3. Set *Source address* to *all*.
4. Under *Destination*, set *Application* to your required applications. In this example: *Microsoft.Office.365*, *Microsoft.Office.Online*, *Google.Docs*, *Dropbox*, and *SIP*.
5. Under *Outgoing Interfaces*, select *Lowest Cost (SLA)*.

   The lowest cost is defined in the SD-WAN member interface settings (see Configuring the SD-WAN interface on page 633). The lowest possible cost is *0*, which represents the most preferred link. In this example, DIA_1 and DIA_2 both have a cost of *0*, while MPLS has a cost of *20* because it is used for backup.
6. In *Interface preference*, add the interfaces in order of preference when the cost of the links is tied. In this example, DIA_1, DIA_2, then MPLS.

   MPLS will always be chosen last, because it has the highest cost. DIA_1 and DIA_2 have the same cost, so an interface is selected based on their order in the *Interface preference* list.
7. Set *Required SLA target* to ensure that only links that pass your SLA target are chosen in this SD-WAN rule:
   a. Click in the *Required SLA target* field.
   b. In the *Select Entries* pane, click *Create*. The *New Performace SLA* pane opens.
   c. Set *Name* to *BusinessCriticalApps_HC*.

      This health check is used for business critical applications in your SD-WAN rule.
   d. Leave *Protocol* set to *Ping*, and add up to two servers, such as *office.com* and *google.com*.
   e. Set *Participants* to *Specify*, and add all three interfaces: DIA_1, DIA_2, and MPLS.
   f. Enable *SLA Target*.

      The attributes in your target determine the quality of your link. The SLA target of each link is compared when determining which link to use based on the lowest cost. Links that meet the SLA target are preferred over links that fail, and move to the next step of selection based on cost. If no links meet the SLA target, then they all move to the next step.

      In this example, disable *Latency threshold* and *Jitter threshold*, and set *Packet loss threshold* to *1*.
   g. Click *OK*.
   h. Select the new performance SLA to set it as the *Required SLA target*.

When multiple SLA targets are added, you can choose which target to use in the SD-WAN rule.

8. Click *OK* to create the SD-WAN rule.

To configure the SD-WAN rule and performance SLA checks for non-business critical application in the GUI:

1. Go to *Network* > *SD-WAN*, select the *SD-WAN Rules* tab, and click *Create New*.
2. Set the name to *NonBusinessCriticalApps*.

   This rule will steer your non-business critical traffic to the appropriate link based on the *Best Quality*. No SLA target must be met, as the best link is selected based on the configured quality criteria and interface preference order.
3. Set *Source address* to *all*.
4. Under *Destination*, set *Application* to your required applications. In this example: *Facebook*, and *Youtube*.
5. Under *Outgoing Interfaces*, select *Best Quality*.
6. In *Interface preference*, add the interfaces in order of preference.

   By default, a more preferred link has an advantage of 10% over a less preferred link. For example, when latency is used, the preferred link's calculated latency = real latency / (1+10%).

The preferred link advantage can be customized in the CLI when the mode is `priority` (*Best Quality*) or `auto`:

```
config system sdwan
    config service
        edit <id>
            set link-cost-threshold <integer>
        next
    end
end
```

7. Create and apply a new performance SLA profile:
   a. Click in the *Measured SLA* field.
   b. In the drop-down list, click *Create*. The *New Performace SLA* pane opens.
   c. Set *Name* to *NonBusinessCritical_HC*.
      This health check is used for non-business critical applications in your SD-WAN rule.
   d. Leave *Protocol* set to *Ping*, and add up to two servers, such as *youtube.com* and *facebook.com*.
   e. Set *Participants* to *Specify*, and add the DIA_1 and DIA_2 interfaces. In this example, MPLS is not used for non-business critical applications.
   f. Leave *SLA Target* disabled.
   g. Click *OK*.
   h. Select the new performance SLA from the list to set it as the *Measured SLA*.
8. Set *Quality criteria* as required. In this example, *Latency* is selected.
   For bandwidth related criteria, such as *Downstream*, *Upstream*, and *Bandwidth* (bi-directional), the selection is based on available bandwidth. An estimated bandwidth should be configured on the interface to provide a baseline, maximum available bandwidth.

9. Click *OK* to create the SD-WAN rule.

To configure the SD-WAN members, static route, and firewall policy in the CLI:

1. Configure the interfaces:

```
config system interface
    edit "port1"
        set ip <class_ip&net_netmask>
        set alias "DIA_1"
        set role wan
    next
    edit "port2"
        set ip <class_ip&net_netmask>
        set alias "DIA_2"
        set role wan
    next
    edit "port3"
        set ip <class_ip&net_netmask>
        set alias "MPLS"
        set role wan
    next
end
```

2. Configure the SD-WAN members:

```
config system sdwan
    set status enable
```

```
    config members
        edit 1
            set interface "port1"
            set gateway 172.16.20.2
        next
        edit 2
            set interface "port2"
            set gateway 172.17.80.2
        next
        edit 3
            set interface "port3"
            set gateway 10.100.20.2
            set cost 20
        next
    end
end
```

If no SD-WAN zone is specified, members are added to the default *virtual-wan-link* zone.

3. Configure a static route. See Adding a static route on page 634 for details.
4. Create a firewall policy to allow traffic out on SD-WAN, with an *Application Control* profile configured. See Configuring firewall policies for SD-WAN on page 635 for details.

To configure the SD-WAN rule and performance SLA checks for business critical application in the CLI:

1. Configure the *BusinessCriticalApps_HC* health-check:

```
config system sdwan
    config health-check
        edit "BusinessCriticalApps_HC"
            set server "office.com" "google.com"
            set members 1 2 3
            config sla
                edit 1
                    set link-cost-factor packet-loss
                    set packetloss-threshold 1
                next
            end
        next
    end
end
```

2. Configure the *BusinessCriticalApps* service to use *Lowest Cost (SLA)*:

```
config system sdwan
    config service
        edit 1
            set name "BusinessCriticalApps"
            set mode sla
            set src "all"
            set internet-service enable
            set internet-service-app-ctrl 17459 16541 33182 16177 34640
            config sla
```

```
                edit "BusinessCriticalApps_HC"
                    set id 1
                next
            end
            set priority-members 1 2 3
        next
    end
end
```

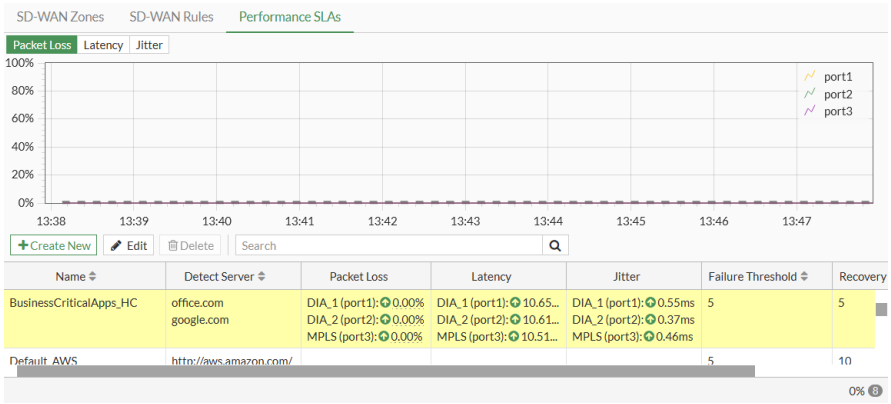
To configure the SD-WAN rule and performance SLA checks for non-business critical application in the CLI:

1. Configure the *nonBusinessCriticalApps_HC* health-check:

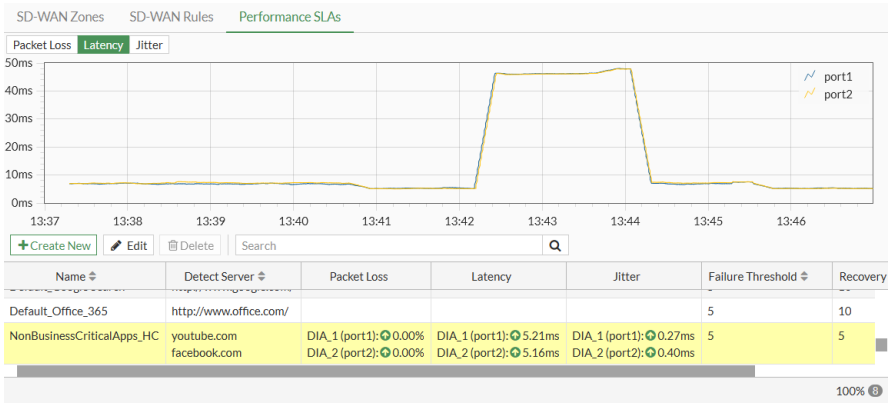
```
config system sdwan
    config health-check
        edit "NonBusinessCriticalApps_HC"
            set server "youtube.com" "facebook.com"
            set members 1 2
        next
    end
end
```

2. Configure the *NonBusinessCriticalApps* service to use *Lowest Cost (SLA)*:

```
config system sdwan
    config service
        edit 4
            set name "NonBusinessCriticalApps"
            set mode priority
            set src "all"
            set internet-service enable
            set internet-service-app-ctrl 15832 31077
            set health-check "NonBusinessCriticalApps_HC"
            set priority-members 1 2
        next
    end
end
```



Verification

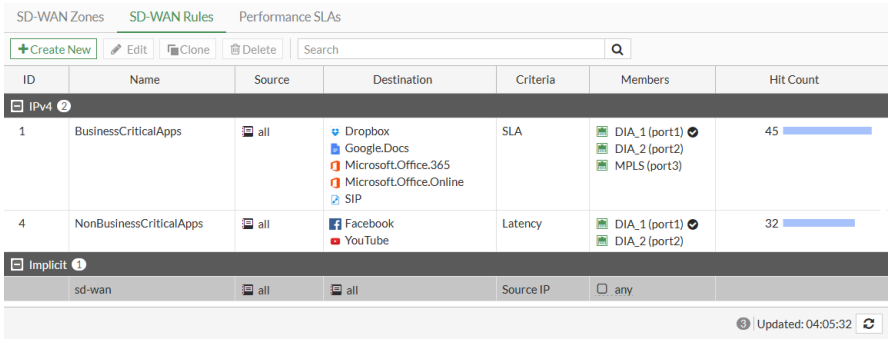


Check the following GUI pages, and run the following CLI commands to confirm that your traffic is being steered by the SD-WAN rules.

Health checks

To verify the status of each of the health checks in the GUI:

1. Go to *Network* > *SD-WAN*, select the *Performance SLAs* tab, and select each of the health checks from the list.



To verify the status of each of the health checks in the CLI:

```
# diagnose sys sdwan health-check
Health Check(BusinessCritical_HC):
Seq(1 port1): state(alive), packet-loss(0.000%) latency(12.884), jitter(0.919) sla_map=0x1
Seq(2 port2): state(alive), packet-loss(0.000%) latency(13.018), jitter(0.723) sla_map=0x1
Seq(3 port3): state(alive), packet-loss(0.000%) latency(13.018), jitter(0.923) sla_map=0x1
Health Check(NonBusinessCritical_HC):
Seq(1 port1): state(alive), packet-loss(0.000%) latency(6.888), jitter(0.953) sla_map=0x0
Seq(2 port2): state(alive), packet-loss(0.000%) latency(6.805), jitter(0.830) sla_map=0x0
```

Rule members and hit count

To verify the active members and hit count of the SD-WAN rule in the GUI:

1. Go to *Network* > *SD-WAN* and select the *SD-WAN Rules* tab.

   The interface that is currently selected by the rule has a checkmark next to its name in the *Members* column. Hover the cursor over the checkmark to open a tooltip that gives the reason why that member is selected. If multiple members are selected, only the highest ranked member is highlighted (unless the mode is *Maximize Bandwidth (SLA)*).

To verify the active members and hit count of the SD-WAN rule in the CLI:

```
# diagnose sys sdwan service

Service(3): Address Mode(IPV4) flags=0x0
  Gen(13), TOS(0x0/0x0), Protocol(0: 1->65535), Mode(sla), sla-compare-order
  Members:
    1: Seq_num(1 port1), alive, sla(0x1), cfg_order(0), cost(0), selected
    2: Seq_num(2 port2), alive, sla(0x1), cfg_order(1), cost(0), selected
    3: Seq_num(3 port3), alive, sla(0x1), cfg_order(2), cost(20), selected
  Internet Service: Dropbox(4294836727,0,0,0 17459) Google.Docs(4294836992,0,0,0 16541)

```

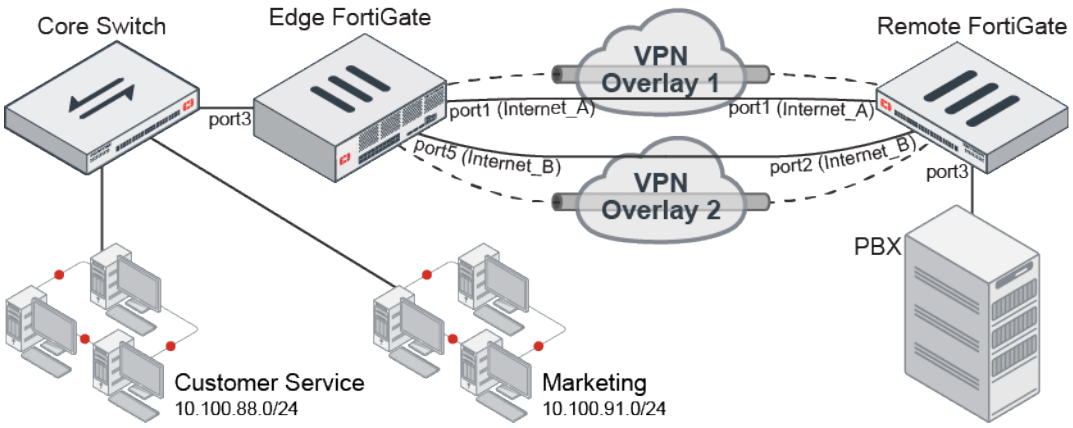
Applications and sessions

To verify sessions in FortiView:

1. Go to a dashboard and add the *FortiView Cloud Applications* widget sorted by bytes. See Cloud application view on page 137 for details.

2. Drill down on an application, such as *YouTube*, then select the *Sessions* tab.

To verify applications identified by Application Control in SD-WAN:



```
# diagnose sys sdwan internet-service-app-ctrl-list

DSCP tag-based traffic steering in SD-WAN

Differentiated Services Code Point (DSCP) tags can be used to categorize traffic for quality of service (QoS). SD-WAN traffic steering on an edge device can be provided based on the DSCP tags.

This section provides an example of using DSCP tag-based traffic steering using secure SD-WAN. Traffic from the customer service and marketing departments at a headquarters are marked with separate DSCP tags by the core switch and passed to the edge FortiGate. The edge FortiGate reads the tags, then steers traffic to the preferred interfaces based on the defined SD-WAN rules.

VoIP and social media traffic are steered. VoIP traffic from the customer service department is more important than social media traffic. The edge FortiGate identifies the tagged traffic based on SD-WAN rules then steers the traffic:

- VoIP traffic is marked with DSCP tag 011100 and steered to the VPN overlay with the lowest jitter, to provide the best quality voice communication with the remote PBX server.
- Social media traffic is marked with the DSCP tag 001100 and steered to the internet connection with the lowest cost.

The following is assumed to be already configured:

- Two IPsec tunnels (IPsec VPNs on page 1575):
  - Branch-HQ-A on Internet_A (port 1)
  - Branch-HQ-B on Internet_B (port 5)
- Four SD-WAN members in two zones (Configuring the SD-WAN interface on page 633):
  - Overlay zone includes members Branch-HQ-A and Branch-HQ-B
  - virtual-wan-link zone includes members Internet_A and Internet_B

    Internet_A has a cost of 0 and Internet_B has a cost of 10. When using the lowest cost strategy, Internet_A will be preferred. Both members are participants in the Default_DNS performance SLA.
- A static route that points to the SD-WAN interface (Adding a static route on page 634).
- Two firewall policies:

Name	SD-WAN-OUT	Overlay-OUT
From	port3	port3
To	virtual-wan-link	Overlay
Source	all	all
Destination	all	all
Schedule	always	always
Service	all	all
Action	Accept	Accept
NAT	enabled	enabled

After the topology is configured, you can proceed with the configuration of the edge FortiGate:

- Configuring SD-WAN rules on page 738
- Results on page 739

Configuring SD-WAN rules

Configure SD-WAN rules to govern the steering of DSCP tag-based traffic to the appropriate interfaces. Traffic is steered based on the criteria that are configured in the SD-WAN rules.

In this example, three SD-WAN rules are configured to govern DSCP tagged traffic:

- *VoIP-Steer* for VoIP traffic.
- *Facebook-DSCP-steer* for Social media traffic.
- *All-traffic* for all of the Other web traffic.

After configuring the rules, go to *Network* > *SD-WAN* and select the *SD-WAN Rules* tab to check the rules.

VoIP traffic

VoIP traffic is steered to the *Overlay* zone.

DSCP values are usually 6-bit binary numbers that are padded with zeros at the end. VoIP traffic with DSCP tag 011100 will become 01110000. This 8-bit binary number is represented in its hexadecimal form, 0x70, as the type of service bit pattern (`tos`) value. The type of service evaluated bits (`tos-mask`) hexadecimal value of 0xf0 (11110000 in binary) is used to check the four most significant bits in the `tos` value. The four most significant bits of the `tos` (0111) are used to match the first four bits of the DSCP tag. Only the non-zero bit positions in the `tos-mask` are used for comparison; the zero bit positions are ignored.

The *Best quality* (`priority` mode) strategy is used to select the preferred interface, with the *Quality criteria* (`link-cost-members`) set to *Jitter*. The interface with the lowest amount of jitter is selected. For more information about configuring SD-WAN rules with the *Best Quality* strategy, see Best quality strategy on page 702.

To configure the rule for DSCP tagged VoIP traffic using the CLI:

```
config sys sdwan
    config service
        edit 5
            set name "VoIP-Steer"
            set mode priority
            set tos 0x70
            set tos-mask 0xf0
            set dst "all"
            set health-check "Default_DNS"
            set link-cost-factor jitter
            set priority-members 4 3
        next
    end
end
```

Social media traffic

Social media traffic is steered to the *virtual-wan-link* zone.

DSCP values are usually 6-bit binary numbers that are padded with zeros at the end. Social media traffic traffic with DSCP tag 001100 will become 00110000. This 8-bit binary number is represented in its hexadecimal form, 0x30, as the `tos` value. The `tos-mask` hexadecimal value of 0xf0 (11110000 in binary) is used to check the four most significant bits in the tos value. The four most significant bits of the `tos` (0011) are used to match the first four bits of the DSCP tag. Only the non-zero bit positions in the `tos-mask` are used for comparison; the zero bit positions are ignored.

The *Manual* (`manual` mode) strategy is used to select the preferred interface. Internet_B (port5, priority member 2) is set as the preferred interface to steer all social media traffic to. For more information about configuring SD-WAN rules with the manual strategy, see Manual strategy on page 701.

To configure SD-WAN rule for DSCP tagged social media traffic using the CLI:

```
config system sdwan
    config service
        edit 3
            set name "Facebook-DSCP-steer"
            set mode manual
            set tos 0x30
            set tos-mask 0xf0
            set dst "all"
            set priority-members 2 1
        next
    end
end
```

Other web traffic

Other web traffic is steered to the *virtual-wan-link* zone.

The *Lowest Cost (SLA)* strategy (`sla` mode) is used to select the preferred interface. The interface that meets the defined SLA targets (*Default_DNS* in this case) is selected. If there is a tie, the interface with the lowest cost is selected, Internet_A (port1) in this case.

For more information about configuring SD-WAN rules with the *Lowest Cost (SLA)* strategy, see Lowest cost (SLA) strategy on page 706.

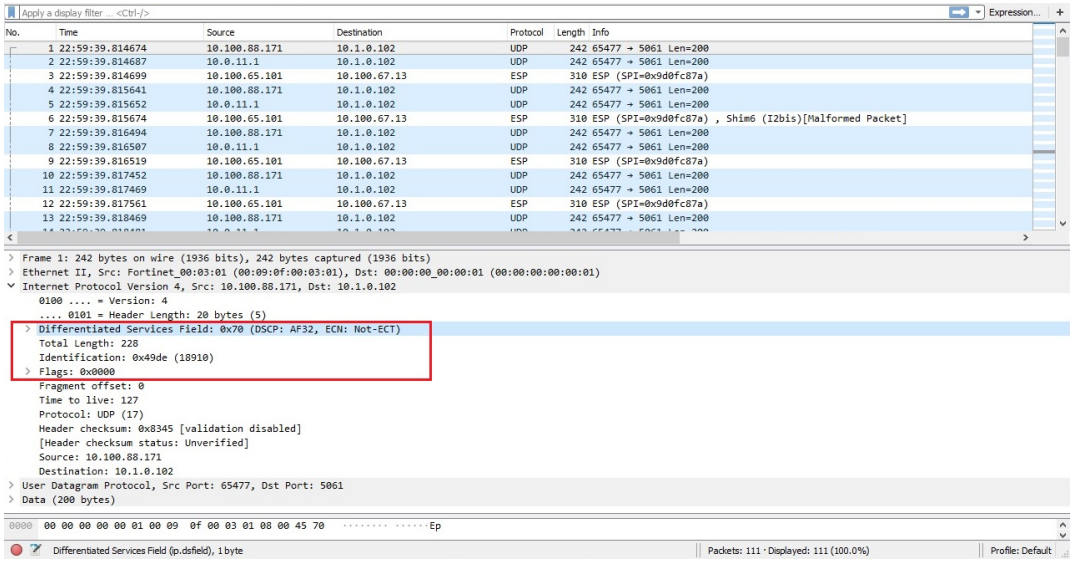
To configure SD-WAN rule for all other web traffic using the CLI:

```
config system sdwan
    config service
        edit 2
            set name "All-traffic"
            set mode sla
            set dst "all"
            config sla
                edit "Default_DNS"
                    set id 1
                next
            end
            set priority-members 1 2
        next
    end
end
```

Results

These sections show the function of SD-WAN with respect to DSCP tagged traffic steering, and can help confirm that it is running as expected:

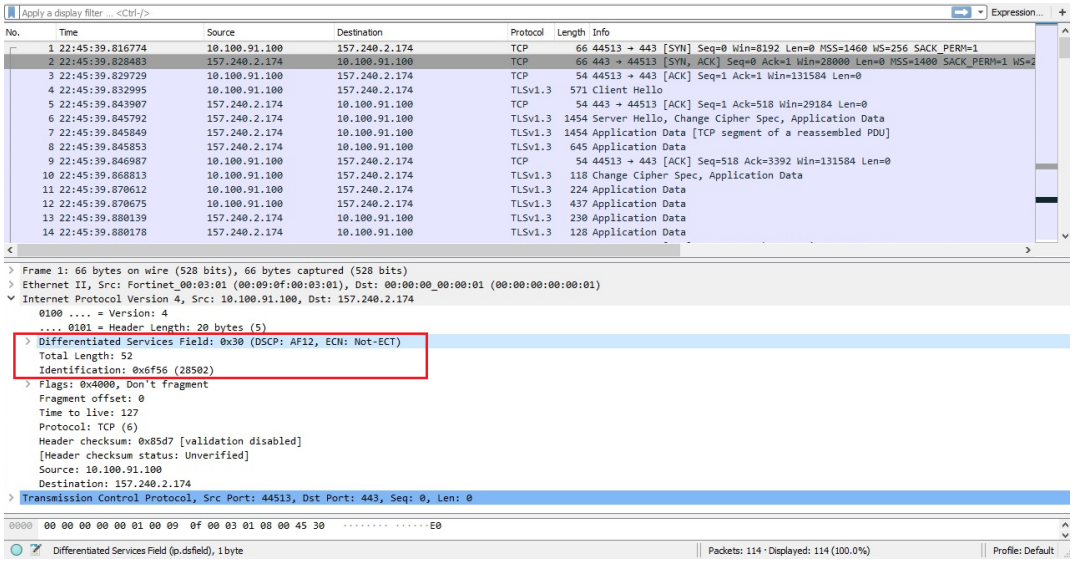
- Verifying the DSCP tagged traffic on FortiGate on page 740
- Verifying the service rules on page 741
- Verifying traffic steering on the SD-WAN rules on page 741
- Verifying that steered traffic is leaving from the expected interface on page 742



Verifying the DSCP tagged traffic on FortiGate

Packet sniffing is used to verify the incoming DSCP tagged traffic. See Using the FortiOS built-in packet sniffer for more information.

Wireshark is used to verify that VoIP traffic is tagged with the expected DSCP tag, 0x70 or 0x30.



VoIP traffic marked with DSCP tag 0x70:

```
# diagnose sniffer packet any '(ip and ip[1] & 0xfc == 0x70)' 6 0 l
```

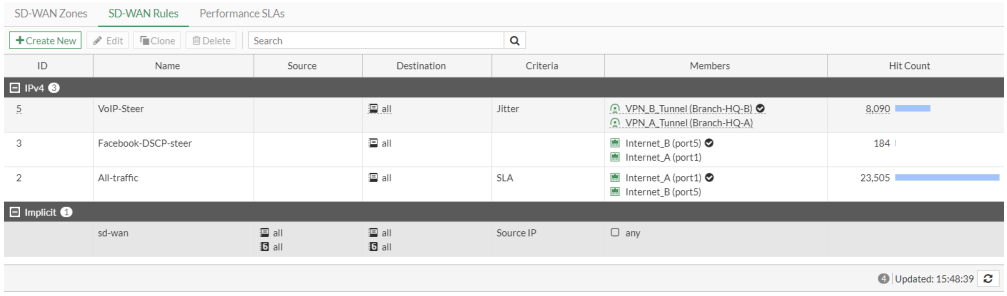
Web traffic marked with DSCP tag 0x30:

```
# diagnose sniffer packet any '(ip and ip[1] & 0xfc == 0x30)' 6 0 l
```

Verifying the service rules

To check that the expected DSCP tags and corresponding interfaces are used by the SD-WAN rules to steer traffic:

```
# diagnose sys sdwan service

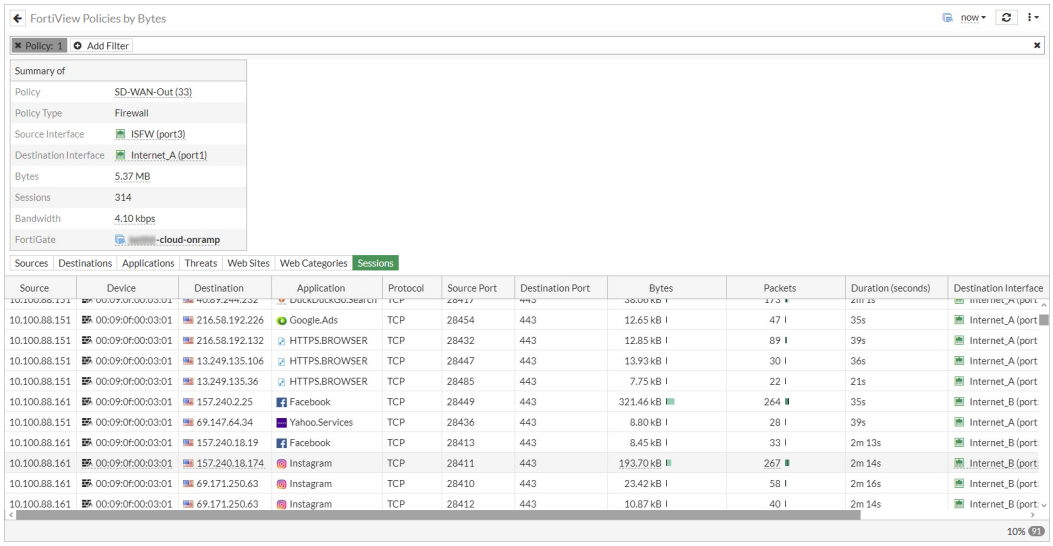


Service(5): Address Mode(IPV4) flags=0x0
   Gen(1), TOS(0x70/0xf0), Protocol(0: 1->65535), Mode(manual)
   Members:
      1: Seq_num(4 Branch-HQ-B), alive, selected
   Dst address:
         0.0.0.0-255.255.255.255

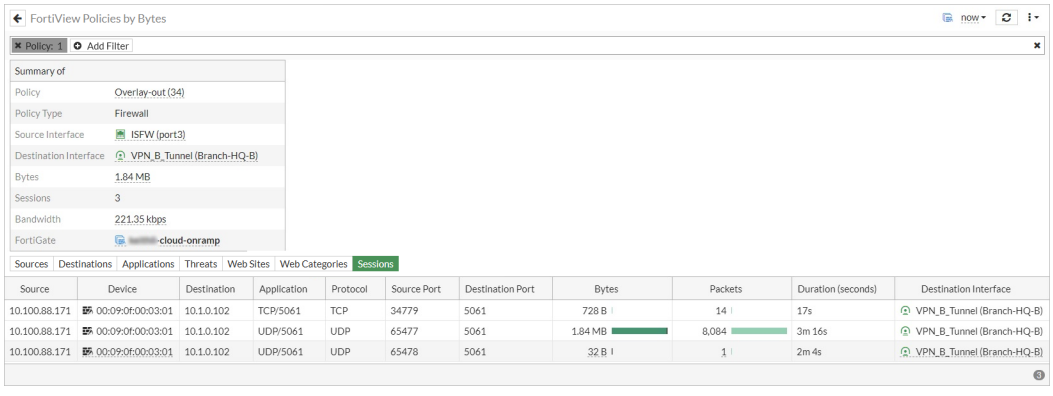
Service(3): Address Mode(IPV4) flags=0x0
   Gen(1), TOS(0x30/0xf0), Protocol(0: 1->65535), Mode(manual)
   Members:
      1: Seq_num(2 port5), alive, selected
   Dst address:
         0.0.0.0-255.255.255.255

Service(2): Address Mode(IPV4) flags=0x0
   Gen(1), TOS(0x0/0x0), Protocol(0: 1->65535), Mode(sla), sla-compare-order
   Members:
      1: Seq_num(1 port1), alive, sla(0x1), cfg_order(0), cost(0), selected
      2: Seq_num(2 port5), alive, sla(0x1), cfg_order(1), cost(10), selected
   Dst address:
         0.0.0.0-255.255.255.255
```

Verifying traffic steering on the SD-WAN rules



Go to *Network* > *SD-WAN* and select the *SD-WAN Rules* tab to check the *Hit Count* on the SD-WAN interfaces.



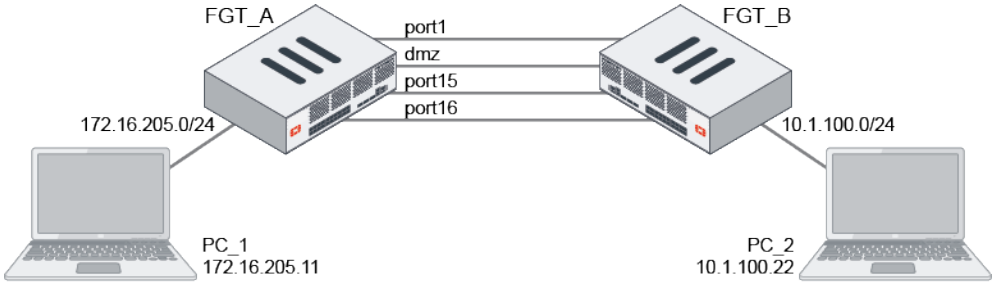
Verifying that steered traffic is leaving from the expected interface

To confirm that web traffic (port 443) flows through the correct underlay interface members, and VoIP traffic flows through the correct overlay interface members, go to *Dashboard* > *FortiView Policies* and double click on the policy name.

Web traffic is expected to leave on *Interface_A (port1)* or *Interface_B (port5)*:

VoIP traffic is expected to leave on the preferred *VPN_B_Tunnel (Branch-HQ-B)* interface:

ECMP support for the longest match in SD-WAN rule matching



The longest match SD-WAN rule can match ECMP best routes. The rule will select the egress ports on ECMP specific routes, and not the less specific routes, to transport traffic.

The service mode determines which egress port on the ECMP specific routes is selected to forward traffic:

- Manual (`manual`): The first configured alive port is selected.
- Best Quality (`priority`): The best quality port is selected.
- Lowest Cost (`sla`): The first configured or lower cost port in SLA is selected.

Example

By default, SD-WAN selects the outgoing interface from all of the links that have valid routes to the destination. In some cases, it is required that only the links that have the best (or longest match) routes (single or ECMP) to the destination are considered.

In this example, four SD-WAN members in two zones are configured. The remote PC (PC_2 - 10.1.100.22) is accessible on port15 and port16, even though there are valid routes for all of the SD-WAN members. A single SD-WAN service rule is configured that allows traffic to balanced between all four of the members, but only chooses between port15 and port16 for the specific 10.1.100.22 address.

A performance SLA health check is configured to monitor 10.1.100.2. An SD-WAN service rule in Lowest Cost (SLA) mode is configured to select the best interface to steer the traffic. In the rule, the method of selecting a member if more than one meets the SLA (`tie-break`) is configured to select members that meet the SLA and match the longest prefix in the routing table (`fib-best-match`). If there are multiple ECMP routes with the same destination, the FortiGate will take the longest (or best) match in the routing table, and choose from those interface members.

To configure the SD-WAN:

```
config system sdwan
    config zone
        edit "virtual-wan-link"
        next
        edit "z1"
        next
    end
    config members
        edit 1
            set interface "port1"
            set gateway 172.16.200.2
        next
        edit 2
```

```
            set interface "dmz"
            set gateway 172.16.208.2
        next
        edit 3
            set interface "port15"
            set zone "z1"
            set gateway 172.16.209.2
        next
        edit 4
            set interface "port16"
            set zone "z1"
            set gateway 172.16.210.2
        next
    end
    config health-check
        edit "1"
            set server "10.1.100.2"
            set members 0
            config sla
                edit 1
                next
            end
        next
    end
    config service
        edit 1
            set name "1"
            set mode sla
            set dst "all"
            set src "172.16.205.0"
            config sla
                edit "1"
                    set id 1
                next
            end
            set priority-members 1 2 3 4
            set tie-break fib-best-match
        next
    end
end
```

To check the results:

1. The debug shows the SD-WAN service rule. All of the members meet SLA, and because no specific costs are attached to the members, the egress interface is selected based on the interface priority order that is configured in the rule:

```
FGT_A (root) # diagnose sys sdwan service

Service(1): Address Mode(IPV4) flags=0x200 use-shortcut-sla
  Gen(4), TOS(0x0/0x0), Protocol(0: 1->65535), Mode(sla), sla-compare-order
  Members(4):
    1: Seq_num(1 port1), alive, sla(0x1), gid(0), cfg_order(0), cost(0), selected
    2: Seq_num(2 dmz), alive, sla(0x1), gid(0), cfg_order(1), cost(0), selected
    3: Seq_num(3 port15), alive, sla(0x1), gid(0), cfg_order(2), cost(0), selected
    4: Seq_num(4 port16), alive, sla(0x1), gid(0), cfg_order(3), cost(0), selected
```

```
  Src address(1):
        172.16.205.0-172.16.205.255
  Dst address(1):
        0.0.0.0-255.255.255.255
```

2. The routing table shows that there are ECMP default routes on all of the members, and ECMP specific (or best) routes only on port15 and port16:

```
FGT_A (root) # get router info routing-table static
Routing table for VRF=0
S*      0.0.0.0/0 [1/0] via 172.16.200.2, port1
                        [1/0] via 172.16.208.2, dmz
                        [1/0] via 172.16.209.2, port15
                        [1/0] via 172.16.210.2, port16
S       10.1.100.22/32 [10/0] via 172.16.209.2, port15
                                [10/0] via 172.16.210.2, port16
```

   Because `tie-break` is set to `fib-best-match`, the first configured member from port15 and port16 is selected to forward traffic to PC_2. For all other traffic, the first configured member from all four of the interfaces is selected to forward traffic.

3. On PC-1, generate traffic to PC-2:

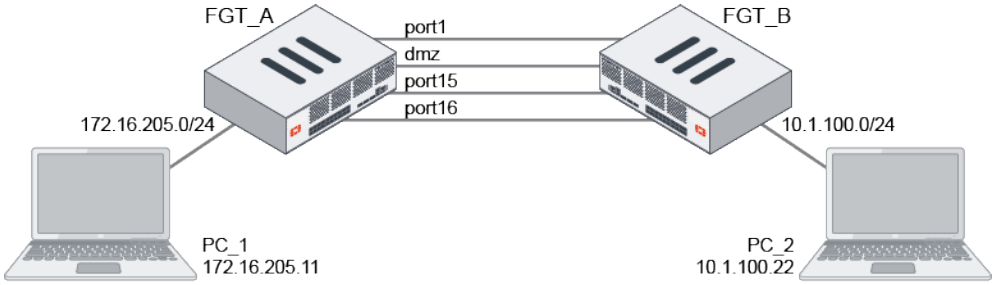
```
ping 10.1.100.22
```

4. On FGT_A, sniff for traffic sent to PC_2:

```
# diagnose sniffer packet any 'host 10.1.100.22' 4
interfaces=[any]
filters=[host 10.1.100.22]
2.831299 port5 in 172.16.205.11 -> 10.1.100.22: icmp: echo request
2.831400 port15 out 172.16.205.11 -> 10.1.100.22: icmp: echo request
```

   Traffic is leaving on port15, the first configured member from port15 and port16.

Override quality comparisons in SD-WAN longest match rule matching



In SD-WAN rules, the longest match routes will override the quality comparisons when all of the specific routes are out of SLA.

With this feature in an SD-WAN rule:

- Lowest Cost (`sla`): Even though all of the egress ports on specific routes (longest matched routes) are out of SLA, the SD-WAN rule still selects the first configured or lower-cost port from the egress ports to forward traffic.
- Best Quality (`priority`): Even though the egress ports on specific routes (longest matched routes) have worse quality that all other ports on less specific routes, the SD-WAN rule still selects the best quality port from the ports on specific routes to forward traffic.

This features avoids a situation where, if the members on specific routes (longest matched routes) are out of SLA or have worse quality, the traffic might be forwarded to the wrong members in SLA (higher quality) on the default or aggregate routes.

Example

In this example, four SD-WAN members in two zones are configured. The remote PC (PC_2 - 10.1.100.22) is accessible on port15 and port16, even though there are valid routes for all of the SD-WAN members. A single SD-WAN service rule is configured that allows traffic to balanced between all four of the members, but only chooses between port15 and port16 for the specific 10.1.100.22 address. If neither port15 nor port16 meet the SLAs, traffic will be forwarded on one of these interfaces, instead of on port1 or dmz.

A performance SLA health check is configured to monitor 10.1.100.2. An SD-WAN service rule in Lowest Cost (SLA) mode is configured to select the best interface to steer the traffic. In the rule, the method of selecting a member if more than one meets the SLA (`tie-break`) is configured to select members that meet the SLA and match the longest prefix in the routing table (`fib-best-match`). If there are multiple ECMP routes with the same destination, the FortiGate will take the longest (or best) match in the routing table, and choose from those interface members.

To configure the SD-WAN:

```
config system sdwan
    config zone
        edit "virtual-wan-link"
        next
        edit "z1"
        next
    end
    config members
        edit 1
            set interface "port1"
            set gateway 172.16.200.2
        next
        edit 2
            set interface "dmz"
            set gateway 172.16.208.2
        next
        edit 3
            set interface "port15"
            set zone "z1"
            set gateway 172.16.209.2
        next
        edit 4
            set interface "port16"
            set zone "z1"
            set gateway 172.16.210.2
        next
    end
    config health-check
```

```
        edit "1"
            set server "10.1.100.2"
            set members 0
            config sla
                edit 1
                next
            end
        next
    end
    config service
        edit 1
            set name "1"
            set mode sla
            set dst "all"
            set src "172.16.205.0"
            config sla
                edit "1"
                    set id 1
                next
            end
            set priority-members 1 2 3 4
            set tie-break fib-best-match
        next
    end
end
```

To check the results:

1. The debug shows the SD-WAN service rule. Both port15 and port16 are up, but out of SLA:

```
FGT_A (root) # diagnose sys sdwan service
Service(1): Address Mode(IPV4) flags=0x200 use-shortcut-sla
  Gen(3), TOS(0x0/0x0), Protocol(0: 1->65535), Mode(sla), sla-compare-order
  Members(4):
    1: Seq_num(1 port1), alive, sla(0x1), gid(0), cfg_order(0), cost(0), selected
    2: Seq_num(2 dmz), alive, sla(0x1), gid(0), cfg_order(1), cost(0), selected
    3: Seq_num(3 port15), alive, sla(0x0), gid(0), cfg_order(2), cost(0), selected
    4: Seq_num(4 port16), alive, sla(0x0), gid(0), cfg_order(3), cost(0), selected
  Src address(1):
        172.16.205.0-172.16.205.255

  Dst address(1):
        0.0.0.0-255.255.255.255
```

2. The routing table shows that there are ECMP default routes on all of the members, and ECMP specific (or best) routes only on port15 and port16:

```
FGT_A (root) # get router info routing-table static
Routing table for VRF=0
S*      0.0.0.0/0 [1/0] via 172.16.200.2, port1
                        [1/0] via 172.16.208.2, dmz
                        [1/0] via 172.16.209.2, port15
                        [1/0] via 172.16.210.2, port16
S       10.1.100.22/32 [10/0] via 172.16.209.2, port15
                               [10/0] via 172.16.210.2, port16
```

Because `tie-break` is set to `fib-best-match`, even though both port15 and port16 are out of SLA, the first configured member of the two (port15) is selected to forward traffic to PC_2. For all other traffic, the first configured member from all of the interfaces that are in SLA is selected to forward traffic (port1).

3. On PC-1, generate traffic to PC-2:

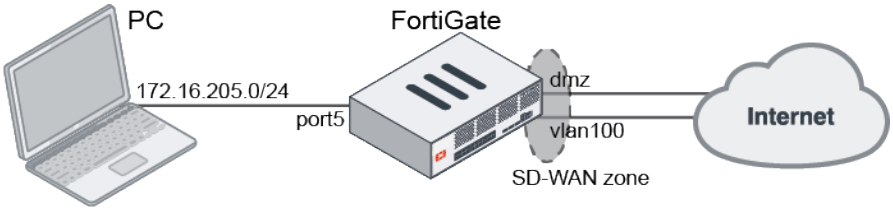
```
ping 10.1.100.22
```

4. On FGT_A, sniff for traffic sent to PC_2:

```
# diagnose sniffer packet any 'host 10.1.100.22' 4
interfaces=[any]
filters=[host 10.1.100.22]
2.831299 port5 in 172.16.205.11 -> 10.1.100.22: icmp: echo request
2.831400 port15 out 172.16.205.11 -> 10.1.100.22: icmp: echo request
```

Traffic is leaving on port15, the first configured member from port15 and port16, even though both are out of SLA.

Use an application category as an SD-WAN rule destination



An application category can be selected as an SD-WAN service rule destination criterion. Previously, only application groups or individual applications could be selected.

```
config system sdwan
    config service
        edit <id>
            set internet-service enable
            set internet-service-app-ctrl-category <id_1> <id_2> ... <id_n>
        next
    end
end
```

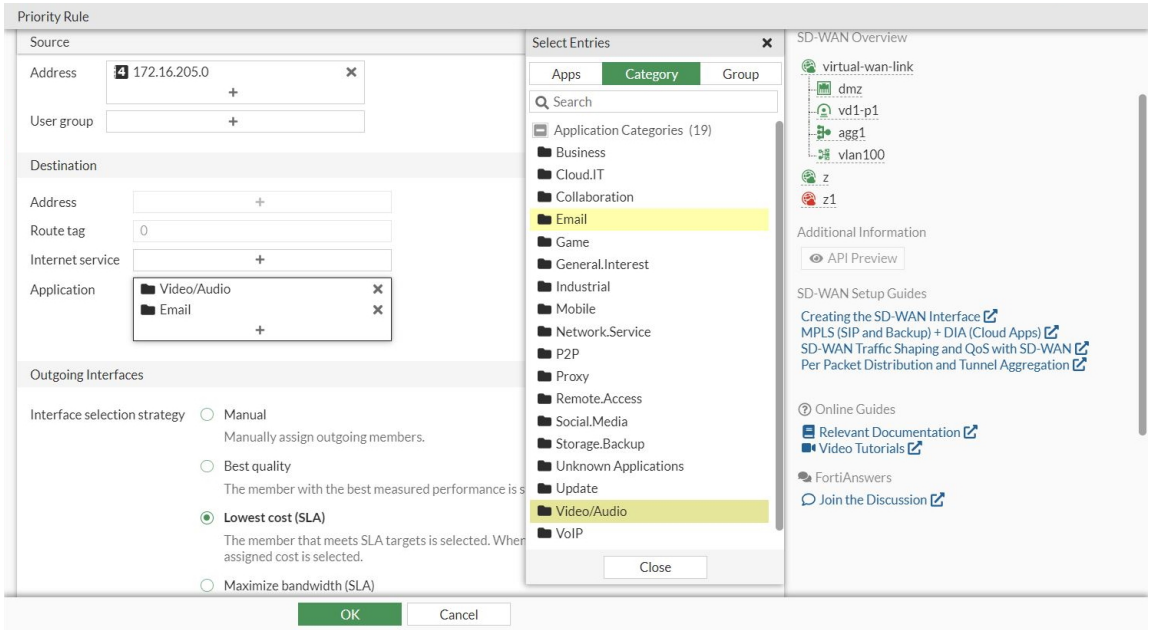
To view the detected application categories details based on category ID, use `diagnose sys sdwan internet-service-app-ctrl-category-list <id>`.

Example

In this example, traffic steering is applied to traffic detected as video/audio (category ID 5) or email (category ID 21) and applies the lowest cost (SLA) strategy to this traffic. When costs are tied, the priority goes to member 1, dmz.

To configure application categories as an SD-WAN rule destination in the GUI:

1. Enable the feature visibility:
   a. Go to *System* > *Feature Visibility*.
   b. In the *Additional Features* section, enable *Application Detection Based SD-WAN*.
   c. Click *Apply*.



To enable GUI visibility of application detection based SD-WAN in the CLI:

```
config system global
    set gui-app-detection-sdwan enable
end
```

2. Configure the SD-WAN members:
   a. Go to *Network* > *SD-WAN*, select the *SD-WAN Zones* tab, and click *Create New* > *SD-WAN Member*.
   b. Set the *Interface* to *dmz*, and set the *Gateway* to *172.16.208.2*.
   c. Click *OK*.
   d. Repeat these steps to create another member for the *vlan100* interface with gateway *172.16.206.2*.
3. Configure the performance SLA (health check):
   a. Go to *Network* > *SD-WAN*, and select the *Performance SLAs* tab, and click *Create New*.
   b. Configure the following settings:

Name	*1*
Protocol	*DNS*
Server	*8.8.8.8*
SLA Target	Enable

   c. Click *OK*.
4. Configure the SD-WAN rule to use the video/audio and email application categories:
   a. Go to *Network* > *SD-WAN*, select the *SD-WAN Rules* tab, and click *Create New*.
   b. In the *Destination* section, click the + in the *Application* field.
   c. Click *Category*, and select *Video/Audio* and *Email*.

   d. Configure the other settings as needed.
   e. Click *OK*.

5. Configure the firewall policy:
   a. Go to *Policy & Objects* > *Firewall Policy* and click *Create New*.
   b. Configure the following settings:

Incoming Interface	*port5*
Outgoing Interface	*virtual-wan-link*
Source	*172.16.205.0*
Destination	*all*
Schedule	*always*
Service	*ALL*
Action	*ACCEPT*
Application Control	*g-default*
SSL Inspection	*certificate-inspection*

   c. Click *OK*.

To configure application categories as an SD-WAN rule destination in the CLI:

1. Configure the SD-WAN settings:

```
config system sdwan
    set status enable
    config zone
        edit "virtual-wan-link"
        next
    end
    config members
        edit 1
            set interface "dmz"
            set gateway 172.16.208.2
        next
        edit 2
            set interface "vlan100"
            set gateway 172.16.206.2
        next
    end
    config health-check
        edit "1"
            set server "8.8.8.8"
            set protocol dns
            set members 0
            config sla
                edit 1
                next
            end
        next
    end
end
```

2. Configure the SD-WAN rule to use application categories 5 and 21:

```
config system sdwan
    config service
        edit 1
            set name "1"
            set mode sla
            set src "172.16.205.0"
            set internet-service enable
            set internet-service-app-ctrl-category 5 21
            config sla
                edit "1"
                    set id 1
                next
            end
            set priority-members 1 2
        next
    end
end
```

3. Configure the firewall policy:

```
config firewall policy
    edit 1
        set srcintf "port5"
        set dstintf "virtual-wan-link"
        set action accept
        set srcaddr 172.16.205.0
        set dstaddr "all"
        set schedule "always"
        set service "ALL"
        set utm-status enable
        set ssl-ssh-profile "certificate-inspection"
        set application-list "g-default"
    next
end
```

To test the configuration:

1. Verify that the traffic is sent over dmz:

```
# diagnose firewall proute list
list route policy info(vf=root):
id=2133590017(0x7f2c0001) vwl_service=1(1) vwl_mbr_seq=1 2 dscp_tag=0xff 0xff flags=0x0
tos=0x00 tos_mask=0x00 protocol=0 sport=0-65535 iif=0 dport=1-65535 path(2) oif=5(dmz)
oif=95(vlan100)
source(1): 172.16.205.0-172.16.205.255
destination wildcard(1): 0.0.0.0/0.0.0.0
internet service(2): (null)(0,5,0,0,0) (null)(0,21,0,0,0)
hit_count=469 last_used=2021-12-15 15:06:05
```

2. View some videos and emails on the PC, then verify the detected application details for each category:

```
# diagnose sys sdwan internet-service-app-ctrl-category-list 5
YouTube(31077 4294838537): 142.250.217.110 6 443 Wed Dec 15 15:39:50 2021
YouTube(31077 4294838537): 173.194.152.89 6 443 Wed Dec 15 15:37:20 2021
YouTube(31077 4294838537): 173.194.152.170 6 443 Wed Dec 15 15:37:37 2021
YouTube(31077 4294838537): 209.52.146.205 6 443 Wed Dec 15 15:37:19 2021
```

```
# diagnose sys sdwan internet-service-app-ctrl-category-list 21
Gmail(15817 4294836957): 172.217.14.197 6 443 Wed Dec 15 15:39:47 2021
```

3. Verify that the captured email traffic is sent over dmz:

```
# diagnose sniffer packet any 'host 172.217.14.197' 4
interfaces=[any]
filters=[host 172.217.14.197]
5.079814 dmz out 172.16.205.100.60592 -> 172.217.14.197.443: psh 2961561240 ack
2277134591
```

4. Edit the SD-WAN rule so that dmz has a higher cost and vlan100 is preferred.
5. Verify that the traffic is now sent over vlan100:

```
# diagnose firewall proute list
list route policy info(vf=root):
id=2134048769(0x7f330001) vwl_service=1(1) vwl_mbr_seq=2 1 dscp_tag=0xff 0xff flags=0x0
tos=0x00 tos_mask=0x00 protocol=0 sport=0-65535 iif=0 dport=1-65535 path(2) oif=95
(vlan100) oif=5(dmz)
source(1): 172.16.205.0-172.16.205.255
destination wildcard(1): 0.0.0.0/0.0.0.0
internet service(2): (null)(0,5,0,0,0) (null)(0,21,0,0,0)
hit_count=635 last_used=2021-12-15 15:55:43
```

```
# diagnose sniffer packet any 'host 172.217.14.197' 4
interfaces=[any]
filters=[host 172.217.14.197]
304.625168 vlan100 in 172.16.205.100.60592 -> 172.217.14.197.443: psh 2961572711 ack
2277139565
```

Advanced routing

The following topics provide instructions on SD-WAN advanced routing:

- Local out traffic on page 752
- Using BGP tags with SD-WAN rules on page 758
- BGP multiple path support on page 762
- Controlling traffic with BGP route mapping and service rules on page 764
- Applying BGP route-map to multiple BGP neighbors on page 771
- Using multiple members per SD-WAN neighbor configuration on page 776

Local out traffic

Local out, or self-originating, traffic is traffic that originates from the FortiGate going to external servers and services. The traffic can be from Syslog, FortiAnalyzer logging, FortiGuard services, remote authentication, and others.

By default, local out traffic relies on routing table lookups to determine the egress interface that is used to initiate the connection. However, many types of local out traffic support selecting the egress interface based on SD-WAN or manually specified interfaces. When manually specifying the egress interface, the source IP address can also be manually configured.

Go to *Network* > *Local Out Routing* to configure the available types of local out traffic. Some types of traffic can only be configured in the CLI.

By default *Local Out Routing* is not visible in the GUI. Go to *System* > *Feature Visibility* to enable it. See Feature visibility on page 2517 for more information.

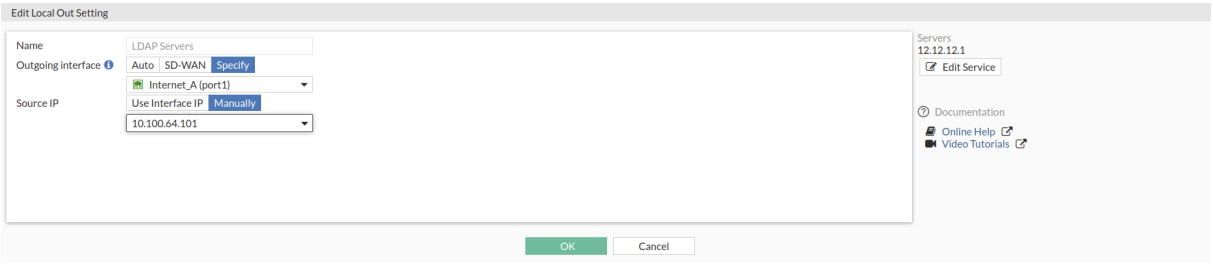
When VDOMs are enabled, the following entries are available on the local out routing page:

Global view	VDOM view
External Resources	**LDAP Servers**
AWS_IP_Blacklist	ldap
AWS_Malware_Hash	**Log**
Log	Log FortiAnalyzer Override Settings
Log FortiAnalyzer Setting	Log Syslogd Override Settings
Log FortiAnalyzer Cloud Setting	**RADIUS Servers**
FortiGate Cloud Log Settings	fac_radius_server
Log Syslogd Setting	**TACACS+**
System	TACACS
System DNS	
System FortiGuard	
System FortiSandbox	

If a service is disabled, it is grayed out. To enable it, select the service and click *Enable Service*. If a service is enabled, there is a *Local Out Setting* button in the gutter of that service's edit page to directly configure the local-out settings.

Examples

To configure DNS local-out routing:

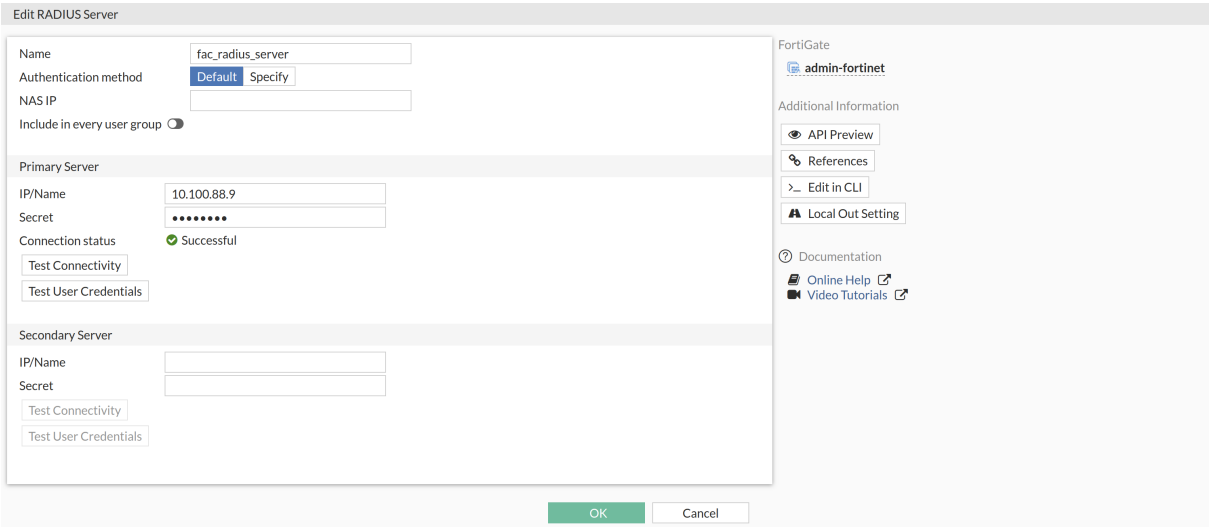


1. Go to *Network* > *Local Out Routing* and double-click *System DNS*.
2. For *Outgoing interface*, select one of the following:

Auto	Select the outgoing interface automatically based on the routing table.
SD-WAN	Select the outgoing interface using the configured SD-WAN interfaces and rules.
Specify	Select the outgoing interface from the dropdown.
Use Interface IP	Use the primary IP, which cannot be configured by the user.

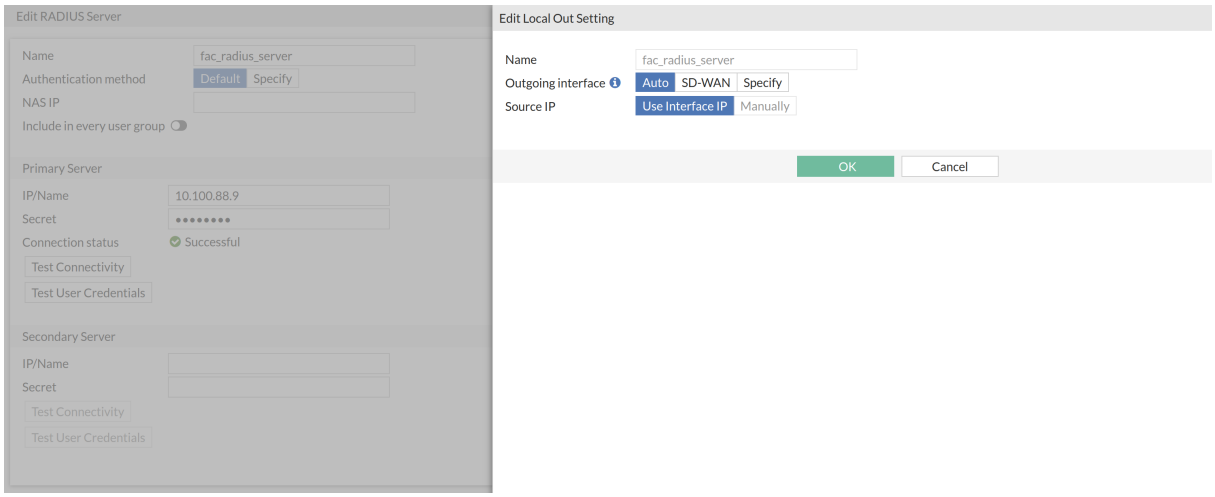
3.

Manually	Selected an IP from the list, if the selected interface has multiple IPs configured.



If *Specify* is selected, select a setting for *Source IP*:

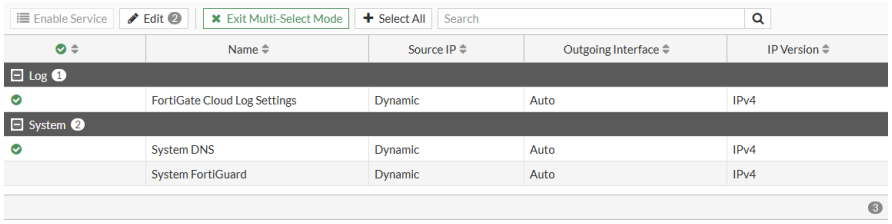
4. Click *OK*.



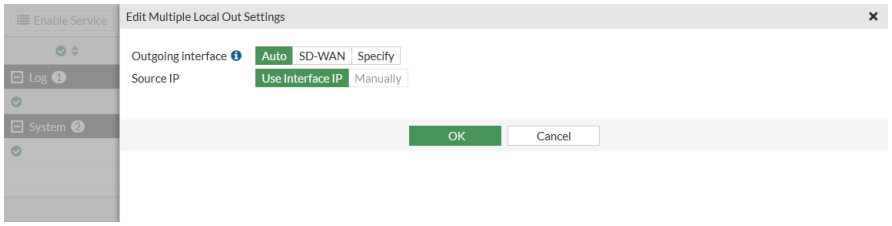
To edit local-out settings from a RADIUS server entry:

1. Go to *User & Authentication* > *RADIUS Servers* and double-click an entry to edit it.
2. Click *Local Out Setting*.

The *Edit Local Out Setting* pane opens.



3. Configure the settings for *Outgoing interface* and *Source IP*.



4. Click *OK*.

To edit multiple entries concurrently:

1. Go to *Network* > *Local Out Routing*.
2. If applicable, select *IPv4* or *IPv6*. *IPv4+IPv6* does not support multi-select.
3. Click *Multi-Select Mode*. All of the local out settings that can be edited concurrently are shown.
4. Select the specific entries, or click *Select All* to select all of the entries.

5. Click *Edit* and configure the local out settings as required.

6. Click *OK*.
7. Click *Exit Multi-Select Mode* to return to the normal view.

Configuring local out routing in the CLI

Some local out routing settings can only be configured using the CLI.

PING

IPv4 and IPv6 pings can be configured to use SD-WAN rules:

```
execute ping-options use-sdwan {yes | no}
execute ping6-options use-sd-wan {yes | no}
```

Traceroute

IPv4 traceroute can be configured to use SD-WAN rules:

```
execute traceroute-options use-sdwan {yes | no}
```

Central management

Central management traffic can use SD-WAN rules or a specific interface:

```
config system central-management
    set interface-select-method {auto | sdwan | specify}
    set interface <interface>
end
```

NTP server

NTP server traffic can use SD-WAN rules or a specific interface:

```
config system ntp
    config ntpserver
        edit <id>
            set interface-select-method {auto | sdwan | specify}
            set interface <interface>
        next
    end
end
```

DHCP proxy

DHCP proxy traffic can use SD-WAN rules or a specific interface:

```
config system settings
    set dhcp-proxy-interface-select-method {auto | sdwan | specify}
    set dhcp-proxy-interface <interface>
end
```

dhcp-proxy-interface-select-method {auto | sdwan | specify}	Select the interface selection method: • `auto`: Set the outgoing interface automatically (default). • `sdwan`: Set the interface by SD-WAN or policy routing rules. • `specify`: Set the interface manually.
dhcp-proxy-interface <interface>	Specify the outgoing interface. This option is only available and must be configured when `interface-select-method` is `specify`.

DHCP relay

DHCP relay traffic can use SD-WAN rules or a specific interface:

```
config system interface
    edit <interface>
        set dhcp-relay-interface-select-method {auto | sdwan | specify}
```

```
        set dhcp-relay-interface <interface>
    next
end
```

dhcp-relay-interface-select-method {auto | sdwan | specify}	Select the interface selection method: • `auto`: Set the outgoing interface automatically (default). • `sdwan`: Set the interface by SD-WAN or policy routing rules. • `specify`: Set the interface manually.
dhcp-relay-interface <interface>	Specify the outgoing interface. This option is only available and must be configured when `interface-select-method` is `specify`.

CA and local certificate renewal with SCEP

Certificate renewal with SCEP traffic can use SD-WAN rules or a specific interface:

```
config vpn certificate setting
    set interface-select-method {auto | sdwan | specify}
    set interface <interface>
end
```

IPS TLS protocol active probing

TLS active probing can use SD-WAN rules or a specific interface:

```
config ips global
    config tls-active-probe
        set interface-selection-method {auto | sdwan | specify}
        set interface <interface>
        set vdom <VDOM>
        set source-ip <IPv4 address>
        set source-ip6 <IPv6 address>
    end
end
```

interface-select-method {auto | sdwan | specify}	Select the interface selection method: • `auto`: Set the outgoing interface automatically (default). • `sdwan`: Set the interface by SD-WAN or policy routing rules. • `specify`: Set the interface manually.
interface <interface>	Specify the outgoing interface. This option is only available and must be configured when `interface-select-method` is `specify`.
vdom <VDOM>	Specify the VDOM. This option is only available and must be configured when `interface-select-method` is `sdwan` or `specify`.
source-ip <IPv4 address>	Specify the source IPv4 address. This option is only available and must be configured when `interface-select-method` is `sdwan` or `specify`.
source-ip6 <IPv6 address>	Specify the source IPv6 address. This option is only available and must be configured when `interface-select-method` is `sdwan` or `specify`.

Netflow and sflow

Netflow and sflow can use SD-WAN rules or a specific interface:

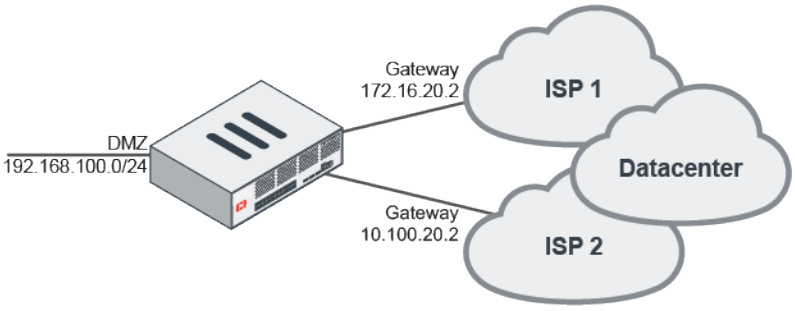
```
config system {netflow | sflow | vdom-netflow | vdom-sflow}
    set interface-select-method {auto | sdwan | specify}
    set interface <interface>
end
```

interface-select-method {auto | sdwan | specify}	Select the interface selection method: • `auto`: Set the outgoing interface automatically (default). • `sdwan`: Set the interface by SD-WAN or policy routing rules. • `specify`: Set the interface manually.
interface <interface>	Specify the outgoing interface. This option is only available and must be configured when `interface-select-method` is `specify`.

FortiClient EMS

FortiClient EMS endpoint control traffic can use SD-WAN rules or a specific interface:

```
config endpoint-control fctems
    edit fctems1
        set interface-select-method {auto | sdwan | specify}
        set interface <interface>
    end
end
```



TACACS+

System log entries can be sent to external TACACS+ accounting servers. TACACS+ traffic can use SD-WAN rules or a specific IP address:

```
config log tacacs+accounting setting
    set interface-select-method {auto | sdwan | specify}
    set source-ip <IP address>
end
```

Using BGP tags with SD-WAN rules

SD-WAN rules can use Border Gateway Protocol (BGP) learned routes as dynamic destinations.

In this example, a customer has two ISP connections, wan1 and wan2. wan1 is used primarily for direct access to internet applications, and wan2 is used primarily for traffic to the customer's data center.

The customer could create an SD-WAN rule using the data center's IP address range as the destination to force that traffic to use wan2, but the data center's IP range is not static. Instead, a BGP tag can be used.

For this example, wan2's BGP neighbor advertises the data center's network range with a community number of 30:5.

This example assumes that SD-WAN is enabled on the FortiGate, wan1 and wan2 are added as SD-WAN members in the *virtual-wan-link* SD-WAN zone, and a policy and static route have been created. See SD-WAN quick start on page 632 for details.

FortiOS supports IPv4 and IPv6 route tags.

To configure BGP tags with SD-WAN rules:

1. Configure the community list:

```
config router community-list
    edit "30:5"
        config rule
            edit 1
                set action permit
                set match "30:5"
            next
        end
    next
end
```

2. Configure the route map:

```
config router route-map
    edit "comm1"
        config rule
            edit 1
                set match-community "30:5"
                set set-route-tag 15
            next
        end
    next
end
```

3. Configure BGP:

```
config router bgp
    set as xxxxx
    set router-id xxxx
    config neighbor
        edit "10.100.20.2"
            set soft-reconfiguration enable
            set remote-as xxxxx
            set route-map-in "comm1"
        next
    end
end
```

4. Configure a firewall policy:

```
config firewall policy
    edit 1
        set name "1"
```

```
            set srcintf "dmz"
            set dstintf "virtual-wan-link"
            set srcaddr "all"
            set dstaddr "all"
            set action accept
            set schedule "always"
            set service "ALL"
            set nat enable
        next
    end
```

5. Edit the SD-WAN configuration:

```
config system sdwan
    set status enable
    config members
        edit 1
            set interface "wan1"
            set gateway 172.16.20.2
        next
        edit 2
            set interface "wan2"
        next
    end
    config service
        edit 1
            set name "DataCenter"
            set mode manual
            set route-tag 15
            set priority-members 2
        next
    end
end
```

Troubleshooting BGP tags with SD-WAN rules

Check the network community

Use the `get router info bgp network` command to check the network community:

```
# get router info bgp network
BGP table version is 5, local router ID is 1.1.1.1
Status codes: s suppressed, d damped, h history, * valid, > best, i - internal,
              S Stale
Origin codes: i - IGP, e - EGP, ? - incomplete

   Network Next Hop Metric LocPrf Weight RouteTag Path
*> 0.0.0.0/0 10.100.1.5 32768 0 ?
*> 1.1.1.1/32 0.0.0.0 32768 0 ?
*> 10.1.100.0/24 172.16.203.2 32768 0 ?
*> 10.100.1.0/30 0.0.0.0 32768 0 ?
*> 10.100.1.4/30 0.0.0.0 32768 0 ?
*> 10.100.1.248/29 0.0.0.0 32768 0 ?

```

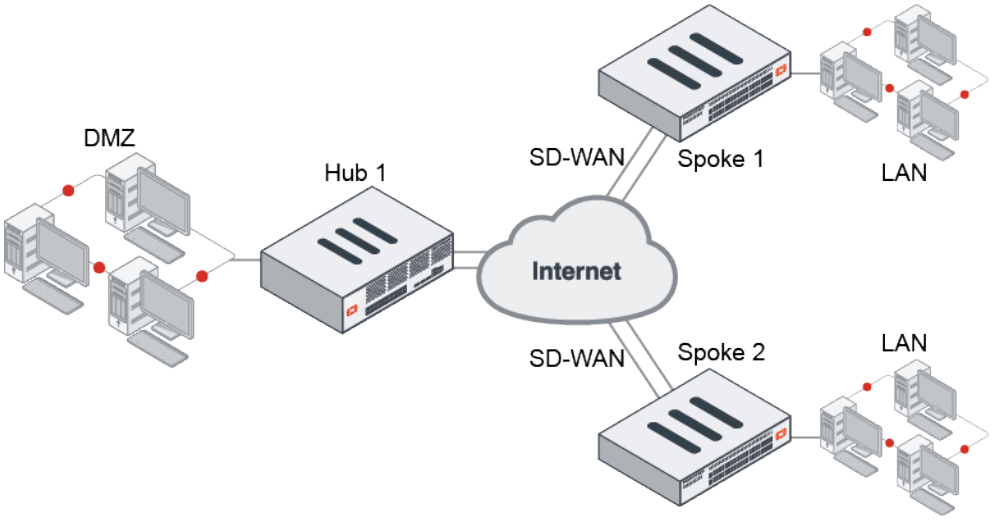
Check dynamic BGP addresses

Use the `get router info route-map-address` command to check dynamic BGP addresses:

```
# get router info route-map-address
Extend-tag: 15, interface(wan2:16)
        10.100.11.0/255.255.255.0
```

Check dynamic BGP addresses used in policy routes

Use the `diagnose firewall proute list` command to check dynamic BGP addresses used in policy routes:



```
# diagnose firewall proute list
list route policy info(vf=root):

id=4278779905 vwl_service=1(DataCenter) flags=0x0 tos=0x00 tos_mask=0x00 protocol=0
sport=0:65535 iif=0 dport=1-65535 oif=16
source wildcard(1): 0.0.0.0/0.0.0.0
destination wildcard(1): 10.100.11.0/255.255.255.0
```

BGP multiple path support

BGP supports multiple paths, allowing an ADVPN to advertise multiple paths. This allows BGP to extend and keep additional network paths according to RFC 7911.

In this example, Spoke1 and Spoke2 each have four VPN tunnels that are connected to the Hub with ADVPN. The Spoke-Hub has established four BGP neighbors on all four tunnels.

Spoke 1 and Spoke 2 can learn four different routes from each other.

To configure the hub:

```
config router bgp
    set as 65505
    set router-id 11.11.11.11
    set ibgp-multipath enable
    set additional-path enable
    set additional-path-select 4
    config neighbor-group
        edit "gr1"
            set capability-default-originate enable
            set remote-as 65505
            set additional-path both
            set adv-additional-path 4
            set route-reflector-client enable
        next
    end
    config neighbor-range
        edit 1
            set prefix 10.10.0.0 255.255.0.0
            set neighbor-group "gr1"
        next
    end
    config network
        edit 12
            set prefix 11.11.11.11 255.255.255.255
        next
```

```
    end
end
```

To configure a spoke:

```
config router bgp
    set as 65505
    set router-id 2.2.2.2
    set ibgp-multipath enable
    set additional-path enable
    set additional-path-select 4
    config neighbor
        edit "10.10.100.254"
            set soft-reconfiguration enable
            set remote-as 65505
            set additional-path both
            set adv-additional-path 4
        next
        edit "10.10.200.254"
            set soft-reconfiguration enable
            set remote-as 65505
            set additional-path both
            set adv-additional-path 4
        next
        edit "10.10.203.254"
            set soft-reconfiguration enable
            set remote-as 65505
            set additional-path both
            set adv-additional-path 4
        next
        edit "10.10.204.254"
            set soft-reconfiguration enable
            set remote-as 65505
            set additional-path both
            set adv-additional-path 4
        next
    end
    config network
        edit 3
            set prefix 22.1.1.0 255.255.255.0
        next
    end
end
```

To view the BGP routing table on a spoke:

```
Spoke1 # get router info routing-table bgp
    Routing table for VRF=0
    B*      0.0.0.0/0 [200/0] via 10.10.200.254, vd2-2, 03:57:26

    [200/0] via 10.10.100.3, vd2-1, 03:57:26
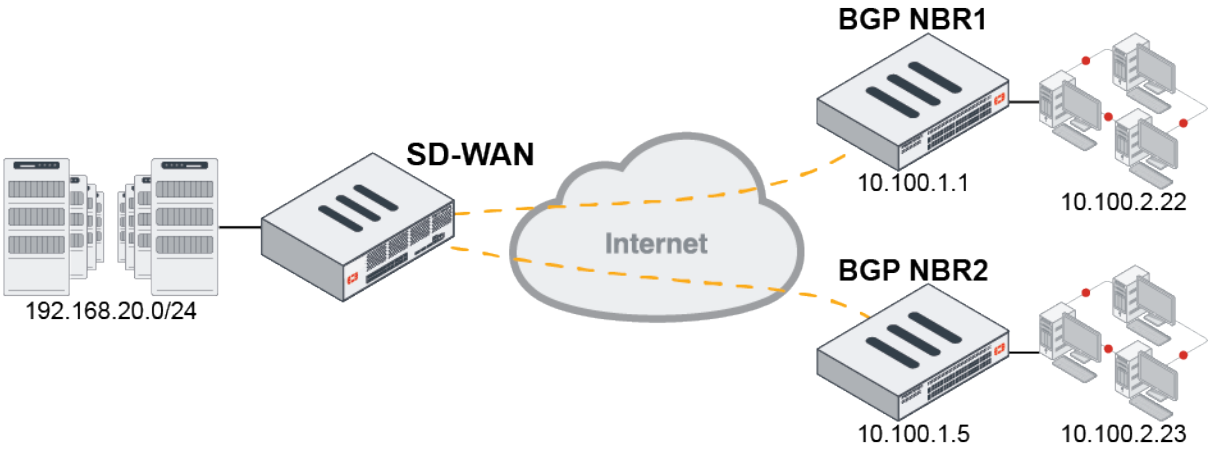
```

Controlling traffic with BGP route mapping and service rules



SD-WAN allows you to select different outbound WAN links based on performance SLAs. It is important that BGP neighbors are aware of these settings, and changes to them.

BGP can adapt to changes in SD-WAN link SLAs in the following ways:

- Applying different route-maps based on the SD-WAN's health checks. For example, different BGP community strings can be advertised to BGP neighbors when SLAs are not met.
- Traffic can be selectively forwarded based on the active BGP neighbor. If the SD-WAN service's role matches the active SD-WAN neighbor, the service is enabled. If there is no match, then the service is disabled.

Example

In this topology, a branch FortiGate has two SD-WAN gateways serving as the primary and secondary gateways. The gateways reside in different datacenters, but have a full mesh network between them.

This example shows how route-maps and service rules are selected based on performance SLAs and the member that is currently active. Traffic flows through the primary gateway unless the neighbor's health check is outside of its SLA. If that happens, traffic routes to the secondary gateway.

BGP NBR1 is the primary neighbor and BGP NBR2 is the secondary neighbor.

The branch FortiGate's wan1 and wan2 interfaces are members of the SD-WAN. When the SD-WAN neighbor status is primary, it will advertise community *20:1* to BGP NBR1 and *20:5* to BGP NBR2. When the SD-WAN neighbor status is secondary, it will advertise *20:5* to BGP NBR1 and *20:2* to BGP NBR2.

Only one of the primary or secondary neighbors can be active at one time. The SD-WAN neighbor status is used to decide which neighbor is selected:

- **Primary**: The primary neighbor takes precedence if its SLAs are met.
- **Secondary**: If the primary neighbor's SLAs are not met, the secondary neighbor becomes active if its SLAs are met.
- **Standalone**: If neither the primary or secondary neighbor's SLAs are met, the SD-WAN neighbor status becomes standalone.

Route map

SD-WAN is configured to let BGP advertise different communities when the SLA status changes. When the SLA is missed, it triggers BGP to advertise a different community to its BGP neighbor based on its route-map. The BGP neighbors can use the received community string to select the best path to reach the branch.

To configure BGP route-maps and neighbors:

1. Configure an access for the routes to be matched:

```
config router access-list
    edit "net192"
        config rule
            edit 1
                set prefix 192.168.20.0 255.255.255.0
            next
        end
    next
end
```

2. Configure the primary neighbor's preferred route-map:

```
config router route-map
    edit "comm1"
        config rule
            edit 1
                set match-ip-address "net192"
                set set-community "20:1"
            next
        end
    next
end
```

3. Configure the secondary neighbor's preferred route-map:

```
config router route-map
    edit "comm2"
        config rule
            edit 1
```

```
                set match-ip-address "net192"
                set set-community "20:2"
            next
        end
    next
end
```

4. Configure the failed route-map:

```
config router route-map
    edit "comm5"
        config rule
            edit 1
                set match-ip-address "net192"
                set set-community "20:5"
            next
        end
    next
end
```

5. Configure BGP neighbors:

```
config router bgp
    set as 65412
    set router-id 1.1.1.1
    set ibgp-multipath enable
    config neighbor
        edit "10.100.1.1"
            set soft-reconfiguration enable
            set remote-as 20
            set route-map-out "comm5"
            set route-map-out-preferable "comm1"
        next
        edit "10.100.1.5"
            set soft-reconfiguration enable
            set remote-as 20
            set route-map-out "comm5"
            set route-map-out-preferable "comm2"
        next
    end
end
```

When SLAs are met, `route-map-out-preferable` is used. When SLAs are missed, `route-map-out` is used.

To configure SD-WAN:

1. Configure the SD-WAN members:

```
config system sdwan
    set status enable
    config members
        edit 1
            set interface "port1"
        next
        edit 2
            set interface "port2"
        next
```

```
    end
end
```

2. Configure health checks for each member:

```
config system sdwan
    config health-check
        edit "ping"
            set server "10.100.2.22"
            set members 1
            config sla
                edit 1
                    set link-cost-factor packet-loss
                    set packetloss-threshold 1
                next
            end
        next
        edit "ping2"
            set server "10.100.2.23"
            set members 2
            config sla
                edit 1
                    set link-cost-factor packet-loss
                    set packetloss-threshold 1
                next
            end
        next
    end
end
```

3. Configure the SD-WAN neighbors and assign them a role and the health checks used to determine if the neighbor meets the SLA:
   SD-WAN neighbors can only be configured in the CLI.

```
config system sdwan
    config neighbor
        edit "10.100.1.1"
            set member 1
            set role primary
            set health-check "ping"
            set sla-id 1
        next
        edit "10.100.1.5"
            set member 2
            set role secondary
            set health-check "ping2"
            set sla-id 1
        next
    end
end
```

Service rules

Create SD-WAN service rules to direct traffic to the primary neighbor when its SLAs are met, and to the secondary neighbor when the primary neighbor's SLAs are missed.

To configure the SD-WAN service rules:

```
config system sdwan
    config service
        edit 1
            set name "Primary-Out"
            set role primary
            set dst "all"
            set src "all"
            set priority-members 1
        next
        edit 2
            set name "Secondary-Out"
            set role secondary
            set dst "all"
            set src "all"
            set priority-members 2
        next
    end
end
```

If neither the primary nor secondary neighbors are active, the SD-WAN neighbor status becomes standalone. Only service rules with `standalone-action` enabled will continue to pass traffic. This option is disabled by default.

Verification

To verify when the primary neighbor is passing traffic:

1. Verify the health check status:

```
FortiGate-Branch # diagnose sys sdwan health-check
Health Check(ping):
Seq(1 port1): state(alive), packet-loss(0.000%) latency(0.569), jitter(0.061) sla_
map=0x1
Health Check(ping2):
Seq(2 port2): state(alive), packet-loss(0.000%) latency(3.916), jitter(2.373) sla_
map=0x1
```

2. Verify SD-WAN neighbor status:

```
FortiGate-Branch # diagnose sys sdwan neighbor
SD-WAN neighbor status: hold-down(disable), hold-down-time(0), hold_boot_time(0)
        Selected role(primary) last_secondary_select_time/current_time in seconds 0/572
Neighbor(10.100.1.1): member(1) role(primary)
        Health-check(ping:1)  sla-pass selected alive
Neighbor(10.100.1.5): member(2) role(secondary)
        Health-check(ping2:1)  sla-pass alive
```

3. Verify service rules status:

```
FortiGate-Branch # diagnose sys sdwan service

Service(1): Address Mode(IPV4) flags=0x0
  Gen(3), TOS(0x0/0x0), Protocol(0: 1->65535), Mode(manual)
  Service role: primary
```

```
  Members:
    1: Seq_num(1 port1), alive, selected
  Src address:
        0.0.0.0-255.255.255.255

  Dst address:
        0.0.0.0-255.255.255.255

Service(2): Address Mode(IPV4) flags=0x0
  Gen(6), TOS(0x0/0x0), Protocol(0: 1->65535), Mode(manual)
  Service role: secondary, disabled by unselected.
  Members:
    1: Seq_num(2 port2), alive, selected
  Src address:
        0.0.0.0-255.255.255.255

  Dst address:
        0.0.0.0-255.255.255.255
```

4. Verify neighbor routers:
   a. Primary neighbor router:

```
FGT-NBR1 # get router info bgp network 192.168.20.0
BGP routing table entry for 192.168.20.0/24
Paths: (1 available, best #1, table Default-IP-Routing-Table)
  Not advertised to any peer
  64512
    10.100.1.2 from 10.100.1.2 (192.168.122.98)
      Origin IGP metric 0, localpref 100, valid, external, best
      Community: 20:1
      Last update: Thu Apr 30 13:41:40 2020
```

   b. Secondary neighbor router:

```
FGT-NBR2 # get router info bgp network 192.168.20.0
VRF 0 BGP routing table entry for 192.168.20.0/24
Paths: (1 available, best #1, table Default-IP-Routing-Table)
  Not advertised to any peer
  Original VRF 0
  64512
    10.100.1.6 from 10.100.1.6 (192.168.122.98)
      Origin IGP metric 0, localpref 100, valid, external, best
      Community: 20:5
      Last update: Thu Apr 30 13:41:39 2020
```

To verify when the secondary neighbor is passing traffic:

1. Verify the health check status:

```
FortiGate-Branch # diagnose sys sdwan health-check
Health Check(ping):
Seq(1 port1): state(dead), packet-loss(54.000%) sla_map=0x0
Health Check(ping2):
Seq(2 port2): state(alive), packet-loss(0.000%) latency(4.339), jitter(3.701) sla_
map=0x1
```

2. Verify SD-WAN neighbor status:

```
FortiGate-Branch # diagnose sys sdwan neighbor
SD-WAN neighbor status: hold-down(disable), hold-down-time(0), hold_boot_time(0)
        Selected role(secondary) last_secondary_select_time/current_time in seconds
936/936
Neighbor(10.100.1.1): member(1) role(primary)
        Health-check(ping:1)  sla-fail dead
Neighbor(10.100.1.5): member(2) role(secondary)
        Health-check(ping2:1)  sla-pass selected alive
```

3. Verify service rules status:

```
FortiGate-Branch # diagnose sys sdwan service

Service(1): Address Mode(IPV4) flags=0x0
  Gen(4), TOS(0x0/0x0), Protocol(0: 1->65535), Mode(manual)
  Service role: primary, disabled by unselected.
  Members:
    1: Seq_num(1 port1), alive, selected
  Src address:
        0.0.0.0-255.255.255.255

  Dst address:
        0.0.0.0-255.255.255.255

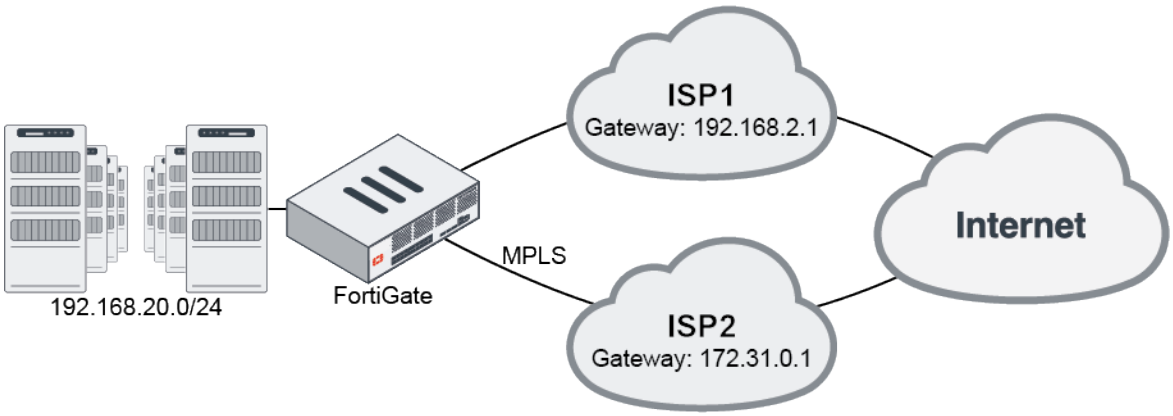
Service(2): Address Mode(IPV4) flags=0x0
  Gen(7), TOS(0x0/0x0), Protocol(0: 1->65535), Mode(manual)
  Service role: secondary
  Members:
    1: Seq_num(2 port2), alive, selected
  Src address:
        0.0.0.0-255.255.255.255

  Dst address:
        0.0.0.0-255.255.255.255
```

4. Verify neighbor routers:
   a. Primary neighbor router:

```
FGT-NBR1 # get router info bgp network 192.168.20.0
BGP routing table entry for 192.168.20.0/24
Paths: (1 available, best #1, table Default-IP-Routing-Table)
  Not advertised to any peer
  64512
    10.100.1.2 from 10.100.1.2 (192.168.122.98)
      Origin IGP metric 0, localpref 100, valid, external, best
      Community: 20:5
      Last update: Thu Apr 30 15:41:58 2020
```

   b. Secondary neighbor router:



```
FGT-NBR2 # get router info bgp network 192.168.20.0
VRF 0 BGP routing table entry for 192.168.20.0/24
Paths: (1 available, best #1, table Default-IP-Routing-Table)
  Not advertised to any peer
  Original VRF 0
  64512
    10.100.1.6 from 10.100.1.6 (192.168.122.98)
```

```
Origin IGP metric 0, localpref 100, valid, external, best
Community: 20:2
Last update: Thu Apr 30 15:42:07 2020
```

Applying BGP route-map to multiple BGP neighbors

Controlling traffic with BGP route mapping and service rules explained how BGP can apply different route-maps to the primary and secondary SD-WAN neighbors based on SLA health checks.

In this example, SD-WAN neighbors that are not bound to primary and secondary roles are configured.

The FortiGate has multiple SD-WAN links and has formed BGP neighbors with both ISPs.

ISP1 is used primarily for outbound traffic, and has an SD-WAN service rule using the lowest cost algorithm applied to it. When SLAs for ISP1 are not met, it will fail over to the MPLS line.

Inbound traffic is allowed by both WAN links, with each WAN advertising a community string when SLAs are met. When SLAs are not met, the WAN links advertise a different community string.

This example uses two SD-WAN links. The topology can be expanded to include more links as needed.

To configure BGP route-maps and neighbors:

1. Configure an access list for routes to be matched:

```
config router access-list
    edit "net192"
        config rule
            edit 1
                set prefix 192.168.20.0 255.255.255.0
            next
        end
    next
end
```

2. Configure route-maps for neighbor ISP1:

```
config router route-map
    edit "comm1"
        config rule
            edit 1
                set match-ip-address "net192"
```

```
                set set-community "64511:1"
            next
        end
    next
    edit "comm-fail1"
        config rule
            edit 1
                set match-ip-address "net192"
                set set-community "64511:5"
            next
        end
    next
end
```

3. Configure route-maps for neighbor ISP2:

```
config router route-map
    edit "comm2"
        config rule
            edit 1
                set match-ip-address "net192"
                set set-community "64522:1"
            next
        end
    next
    edit "comm-fail2"
        config rule
            edit 1
                set match-ip-address "net192"
                set set-community "64522:5"
            next
        end
    next
end
```

4. Configure the BGP neighbors:

```
config router bgp
    set as 64512
    set keepalive-timer 1
    set holdtime-timer 3
    config neighbor
        edit "192.168.2.1"
            set soft-reconfiguration enable
            set remote-as 64511
            set route-map-out "comm-fail1"
            set route-map-out-preferable "comm1"
        next
        edit "172.31.0.1"
            set soft-reconfiguration enable
            set remote-as 64522
            set route-map-out "comm-fail2"
            set route-map-out-preferable "comm2"
        next
    end
    config network
        edit 1
```

```
            set prefix 192.168.20.0 255.255.255.0
        next
    end
end
```

When SLAs are met, `route-map-out-preferable` is used. When SLAs are missed, `route-map-out` is used.

To configure SD-WAN:

1. Configure the SD-WAN members:

```
config system sdwan
    set status enable
    config members
        edit 1
            set interface "port1"
            set gateway 192.168.2.1
        next
        edit 2
            set interface "MPLS"
            set cost 20
        next
    end
end
```

2. Configure the health checks that must be met:

```
config system sdwan
    config health-check
        edit "pingserver"
            set server "8.8.8.8"
            set members 2 1
            config sla
                edit 1
                    set link-cost-factor packet-loss
                    set packetloss-threshold 2
                next
            end
        next
    end
end
```

3. Configure the SD-WAN neighbors and assign them a role and the health checks used to determine if the neighbor meets the SLA:
   When no role is defined, the default role, `standalone`, is used.

```
config system sdwan
    config neighbor
        edit "192.168.2.1"
            set member 1
            set health-check "pingserver"
            set sla-id 1
        next
        edit "172.31.0.1"
            set member 2
            set health-check "pingserver"
            set sla-id 1
        next
```

```
        end
    end
```

Service rules

Create SD-WAN service rules to direct traffic to the SD-WAN links based on the lowest cost algorithm The same SLA health check and criteria that are used for the SD-WAN neighbor are used for this SD-WAN service rule.

When no roles are defined in the service rule, the default role, `standalone`, is used.

To configure the SD-WAN service rule:

```
config system sdwan
    config service
        edit 1
            set name "OutboundAll"
            set mode sla
            set dst "all"
            set src "all"
            config sla
                edit "pingserver"
                    set id 1
                next
            end
            set priority-members 1 2
        next
    end
end
```

Verification

To verify that when both SLAs are met, port1 is selected due to its lower cost:

1. Verify the health check status:

   ```
   FortiGate-Branch # diagnose sys sdwan health-check
   Health Check(pingserver):
   Seq(2 MPLS): state(alive), packet-loss(0.000%) latency(24.709), jitter(14.996) sla_
   map=0x1
   Seq(1 port1): state(alive), packet-loss(0.000%) latency(28.771), jitter(14.840) sla_
   map=0x1
   ```

2. Verify SD-WAN neighbor status:

   ```
   FortiGate-Branch # diagnose sys sdwan neighbor
   Neighbor(192.168.2.1): member(1) role(standalone)
           Health-check(pingserver:1)  sla-pass selected alive
   Neighbor(172.31.0.1): member(2) role(standalone)
           Health-check(pingserver:1)  sla-pass selected alive
   ```

3. Verify service rules status:
   Because the service role is `standalone`, it matches both neighbors. The mode (SLA) determines that port1 is lower cost.

   ```
   FortiGate-Branch # diagnose sys sdwan service
   ```

```
Service(1): Address Mode(IPV4) flags=0x0
  Gen(1), TOS(0x0/0x0), Protocol(0: 1->65535), Mode(sla), sla-compare-order
  Service role: standalone
  Members:
    1: Seq_num(1 port1), alive, sla(0x1), cfg_order(0), cost(0), selected
    2: Seq_num(2 MPLS), alive, sla(0x1), cfg_order(1), cost(20), selected
  Src address:
        0.0.0.0-255.255.255.255

  Dst address:
        0.0.0.0-255.255.255.255
```

4. Verify neighbor routers:
   a. Primary neighbor router:

```
FGT-NBR1 # get router info bgp network 192.168.20.0
BGP routing table entry for 192.168.20.0/24
Paths: (1 available, best #1, table Default-IP-Routing-Table)
  Not advertised to any peer
  64512
    192.168.2.5 from 192.168.2.5 (192.168.122.98)
      Origin IGP metric 0, localpref 100, valid, external, best
      Community: 64511:1
      Last update: Thu Apr 30 23:59:05 2020
```

   b. Secondary neighbor router:

```
FGT-NBR2 # get router info bgp network 192.168.20.0
VRF 0 BGP routing table entry for 192.168.20.0/24
Paths: (1 available, best #1, table Default-IP-Routing-Table)
  Not advertised to any peer
  Original VRF 0
  64512
    172.31.0.2 from 172.31.0.2 (192.168.122.98)
      Origin IGP metric 0, localpref 100, valid, external, best
      Community: 64522:1
      Last update: Fri May  1 00:11:28 2020
```

To verify that when neighbor ISP1 misses SLAs, MPLS is selected and BGP advertises a different community string for ISP1:

1. Verify the health check status:

```
FortiGate-Branch # diagnose sys sdwan health-check
Health Check(pingserver):
Seq(2 MPLS): state(alive), packet-loss(0.000%) latency(25.637), jitter(17.820) sla_
map=0x1
Seq(1 port1): state(dead), packet-loss(16.000%) sla_map=0x0
```

2. Verify SD-WAN neighbor status:

```
FortiGate-Branch # diagnose sys sdwan neighbor
Neighbor(192.168.2.1): member(1) role(standalone)
        Health-check(pingserver:1)  sla-fail dead
Neighbor(172.31.0.1): member(2) role(standalone)
        Health-check(pingserver:1)  sla-pass selected alive
```

3. Verify service rules status:
   As SLA failed for neighbor ISP1, MPLS is preferred.

```
FortiGate-Branch # diagnose sys sdwan service

Service(1): Address Mode(IPV4) flags=0x0
  Gen(3), TOS(0x0/0x0), Protocol(0: 1->65535), Mode(sla), sla-compare-order
  Service role: standalone
  Members:
    1: Seq_num(2 MPLS), alive, sla(0x1), cfg_order(1), cost(20), selected
    2: Seq_num(1 port1), dead, sla(0x0), cfg_order(0), cost(0)
  Src address:
        0.0.0.0-255.255.255.255

  Dst address:
        0.0.0.0-255.255.255.255
```

4. Verify neighbor routers:
   The community received on ISP1 is updated.
   a. Primary neighbor router:

```
FGT-NBR1 # get router info bgp network 192.168.20.0
BGP routing table entry for 192.168.20.0/24
Paths: (1 available, best #1, table Default-IP-Routing-Table)
  Not advertised to any peer
  64512
    192.168.2.5 from 192.168.2.5 (192.168.122.98)
      Origin IGP metric 0, localpref 100, valid, external, best
      Community: 64511:5
      Last update: Fri May  1 00:33:26 2020
```

   b. Secondary neighbor router:

```
FGT-NBR2 # get router info bgp network 192.168.20.0
VRF 0 BGP routing table entry for 192.168.20.0/24
Paths: (1 available, best #1, table Default-IP-Routing-Table)
  Not advertised to any peer
  Original VRF 0
  64512
    172.31.0.2 from 172.31.0.2 (192.168.122.98)
      Origin IGP metric 0, localpref 100, valid, external, best
      Community: 64522:1
      Last update: Fri May  1 00:22:42 2020
```

Using multiple members per SD-WAN neighbor configuration

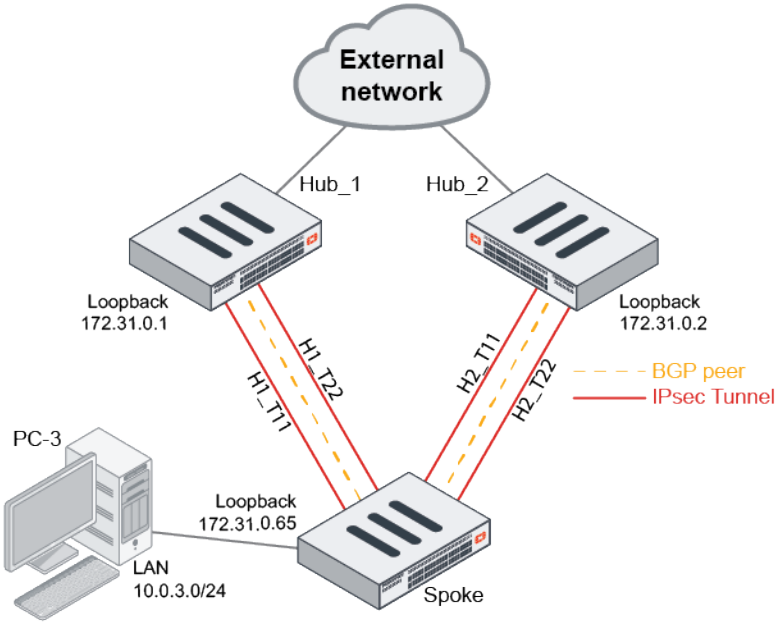
SD-WAN BGP neighbor configurations are used to define the SLA health check in which an SD-WAN member must meet to qualify as being up. When the SD-WAN member meets the SLA threshold, the FortiGate will apply the route map defined in the BGP neighbor's `route-map-out-preferable` option. If the SD-WAN member fails to meet the SLA, the FortiGate will apply the route map defined in the BGP neighbor's `route-map-out` option instead. This allows the FortiGate to advertise the health of the SD-WAN member to its BGP neighbor by advertising different community strings based on its SLA status.

For more information, refer to the following BGP examples: Controlling traffic with BGP route mapping and service rules on page 764 and Applying BGP route-map to multiple BGP neighbors on page 771.

Selecting multiple SD-WAN members allows the SD-WAN neighbor feature to support topologies where there are multiple SD-WAN overlays and/or underlays to a neighbor. The `minimum-sla-meet-members` option is used to configure the minimum number of members that must be in an SLA per neighbor for the preferable route map to be used.

```
config system sdwan
    config neighbor
        edit <ip>
            set member {<seq-num_1>} [<seq-num_2>] ... [<seq-num_n>]
            set minimum-sla-meet-members <integer>
        next
    end
end
```

`member {<seq-num_1>} [<seq-num_2>] ... [<seq-num_n>]`	Enter the member sequence number list. Multiple members can be defined.
`minimum-sla-meet-members <integer>`	Set the minimum number of members that meet SLA when the neighbor is preferred (1 - 255, default = 1). • If the number of in SLA members is less than the `minimum-sla-meet-members` value, the default route map will be used. • If the number of in SLA members is equal or larger than the `minimum-sla-meet-members` value, the preferable route map will be used.



Example

In the following example, the spoke FortiGate has four tunnels: two tunnels to Hub_1 and two tunnels to Hub_2. The spoke has two BGP neighbors: one to Hub_1 and one to Hub-2. BGP neighbors are established on loopback IPs.

The SD-WAN neighbor plus `route-map-out-preferable`configuration is deployed on the spoke to achieve the following:

- If any tunnel to Hub_1 or Hub_2 is in SLA, the preferable route map will be applied on the BGP neighbor to Hub_1 or Hub_2.
- If both tunnels to Hub_1 or Hub_2 are out of SLA, the default route map will be applied on the BGP neighbor to Hub_1 or Hub_2.

The preferable route map and default route map are used to set different custom BGP communities as the spoke advertises its LAN routes to the hub. Each hub can translate communities into different BGP MED or AS prepends and signal them to the external peers to manipulate inbound traffic, thereby routing traffic to the spoke only when the SLAs are met on at least one of two VPN overlays. In this example, community string 10:1 signals to the neighbor that SLAs are met, and 10:2 signals that SLAs are not met.

To configure the BGP route maps and neighbors:

1. Configure an access list of prefixes to be matched:

```
config router access-list
    edit "net10"
        config rule
            edit 1
                set prefix 10.0.3.0 255.255.255.0
            next
        end
    next
end
```

2. Configure route maps for neighbors in SLA (preferable) and out of SLA (default):

```
config router route-map
    edit "in_sla"
        config rule
            edit 1
                set match-ip-address "net10"
                set set-community "10:1"
            next
        end
    next
    edit "out_sla"
        config rule
            edit 1
                set match-ip-address "net10"
                set set-community "10:2"
            next
        end
    next
end
```

3. Configure the BGP neighbors:

```
config router bgp
    set router-id 172.31.0.65
    config neighbor
        edit "172.31.0.1"
            set route-map-out "out_sla"
            set route-map-out-preferable "in_sla"
            set update-source "Loopback0"
        next
        edit "172.31.0.2"
            set route-map-out "out_sla"
            set route-map-out-preferable "in_sla"
            set update-source "Loopback0"
        next
    end
    config network
        edit 1
            set prefix 10.0.3.0 255.255.255.0
        next
    end
end
```

To configure SD-WAN:

1. Configure the SD-WAN members:

```
config system sdwan
    set status enable
    config members
        edit 1
            set interface "H1_T11"
            set source 172.31.0.65
        next
        edit 4
            set interface "H1_T22"
            set source 172.31.0.65
        next
        edit 6
            set interface "H2_T11"
            set source 172.31.0.65
        next
        edit 9
            set interface "H2_T22"
            set source 172.31.0.65
        next
    end
end
```

2. Configure the health check that must be met:

```
config system sdwan
    config health-check
        edit "HUB"
            set server "172.31.100.100"
            set members 0
            config sla
```

```
                edit 1
                    set link-cost-factor latency
                    set latency-threshold 100
                next
            end
        next
    end
end
```

3. Configure the SD-WAN neighbors:

```
config system sdwan
    config neighbor
        edit "172.31.0.1"
            set member 1 4
            set health-check "HUB"
            set sla-id 1
            set minimum-sla-meet-members 1
        next
        edit "172.31.0.2"
            set member 6 9
            set health-check "HUB"
            set sla-id 1
            set minimum-sla-meet-members 1
        next
    end
end
```

To verify that when two members to Hub_1/Hub_2 are in SLA, the preferable route map is be applied on BGP neighbors to Hub_1/Hub_2:

```
Branch1_A_FGT (root) # diagnose sys sdwan health-check
Health Check(HUB):
Seq(1 H1_T11): state(alive), packet-loss(0.000%) latency(0.209), jitter(0.017), mos(4.404),
bandwidth-up(999999), bandwidth-dw(999999), bandwidth-bi(1999998) sla_map=0x1
Seq(4 H1_T22): state(alive), packet-loss(0.000%) latency(0.171), jitter(0.004), mos(4.404),
bandwidth-up(999999), bandwidth-dw(999998), bandwidth-bi(1999997) sla_map=0x1
Seq(6 H2_T11): state(alive), packet-loss(0.000%) latency(0.175), jitter(0.014), mos(4.404),
bandwidth-up(999999), bandwidth-dw(999999), bandwidth-bi(1999998) sla_map=0x1
Seq(9 H2_T22): state(alive), packet-loss(0.000%) latency(0.176), jitter(0.019), mos(4.404),
bandwidth-up(999999), bandwidth-dw(999998), bandwidth-bi(1999997) sla_map=0x1
```

```
# diagnose sys sdwan neighbor
Neighbor(172.31.0.1): member(1 4 )role(standalone)
        Health-check(HUB:1)  sla-pass selected alive
Neighbor(172.31.0.2): member(6 9 )role(standalone)
        Health-check(HUB:1)  sla-pass selected alive
```

On Hub_1 and Hub_2, the expected communities have been attached into the spoke's LAN route:

```
Hub_1_FGT (root) # get router info bgp network 10.0.3.0/24
VRF 0 BGP routing table entry for 10.0.3.0/24
Paths: (1 available, best #1, table Default-IP-Routing-Table)
  Not advertised to any peer
  Original VRF 0
  Local, (Received from a RR-client)
    172.31.0.65 from 172.31.0.65 (172.31.0.65)
      Origin IGP metric 0, localpref 100, valid, internal, best
```

```
      Community: 10:1
      Last update: Wed Dec 29 22:38:29 2021

Hub_2_FGT (root) # get router info bgp network 10.0.3.0/24
VRF 0 BGP routing table entry for 10.0.3.0/24
Paths: (1 available, best #1, table Default-IP-Routing-Table)
  Not advertised to any peer
  Original VRF 0
  Local, (Received from a RR-client)
    172.31.0.65 from 172.31.0.65 (172.31.0.65)
      Origin IGP metric 0, localpref 100, valid, internal, best
      Community: 10:1

      Last update: Wed Dec 29 22:43:10 2021
```

If one member for each neighbor becomes out of SLA, the preferable route map is still applied:

```
Branch1_A_FGT (root) # diagnose sys sdwan health-check
Health Check(HUB):
Seq(1 H1_T11): state(alive), packet-loss(0.000%) latency(120.207), jitter(0.018), mos
(4.338), bandwidth-up(999999), bandwidth-dw(999997), bandwidth-bi(1999996) sla_map=0x0
Seq(4 H1_T22): state(alive), packet-loss(0.000%) latency(0.182), jitter(0.008), mos(4.404),
bandwidth-up(999999), bandwidth-dw(999998), bandwidth-bi(1999997) sla_map=0x1
Seq(6 H2_T11): state(alive), packet-loss(0.000%) latency(120.102), jitter(0.009), mos
(4.404), bandwidth-up(999999), bandwidth-dw(999998), bandwidth-bi(1999997) sla_map=0x0
Seq(9 H2_T22): state(alive), packet-loss(0.000%) latency(0.176), jitter(0.009), mos(4.404),
bandwidth-up(999999), bandwidth-dw(999997), bandwidth-bi(1999996) sla_map=0x1

# diagnose sys sdwan neighbor
Neighbor(172.31.0.1): member(1 4 )role(standalone)
        Health-check(HUB:1)  sla-pass selected alive
Neighbor(172.31.0.2): member(6 9 )role(standalone)
        Health-check(HUB:1)  sla-pass selected alive

Hub_1_FGT (root) # get router info bgp network 10.0.3.0/24
VRF 0 BGP routing table entry for 10.0.3.0/24
Paths: (1 available, best #1, table Default-IP-Routing-Table)
  Not advertised to any peer
  Original VRF 0
  Local, (Received from a RR-client)
    172.31.0.65 from 172.31.0.65 (172.31.0.65)
      Origin IGP metric 0, localpref 100, valid, internal, best
      Community: 10:1
      Last update: Thu Dec 30 10:44:47 2021

Hub_2_FGT (root) # get router info bgp network 10.0.3.0/24
VRF 0 BGP routing table entry for 10.0.3.0/24
Paths: (1 available, best #1, table Default-IP-Routing-Table)
  Not advertised to any peer
  Original VRF 0
  Local, (Received from a RR-client)
    172.31.0.65 from 172.31.0.65 (172.31.0.65)
      Origin IGP metric 0, localpref 100, valid, internal, best
      Community: 10:1
      Last update: Wed Dec 29 22:43:10 2021
```

If both members for Hub_1 become out of SLA, the default route map is applied:

```
Branch1_A_FGT (root) # diagnose sys sdwan health-check
Health Check(HUB):
Seq(1 H1_T11): state(alive), packet-loss(0.000%) latency(120.194), jitter(0.018), mos

- Hold down time to support SD-WAN service strategies on page 797
- SD-WAN integration with OCVPN on page 799
- Adaptive Forward Error Correction on page 806
- Dual VPN tunnel wizard on page 810
- Duplicate packets on other zone members on page 811
- Duplicate packets based on SD-WAN rules on page 814
- Speed tests run from the hub to the spokes in dial-up IPsec tunnels on page 815

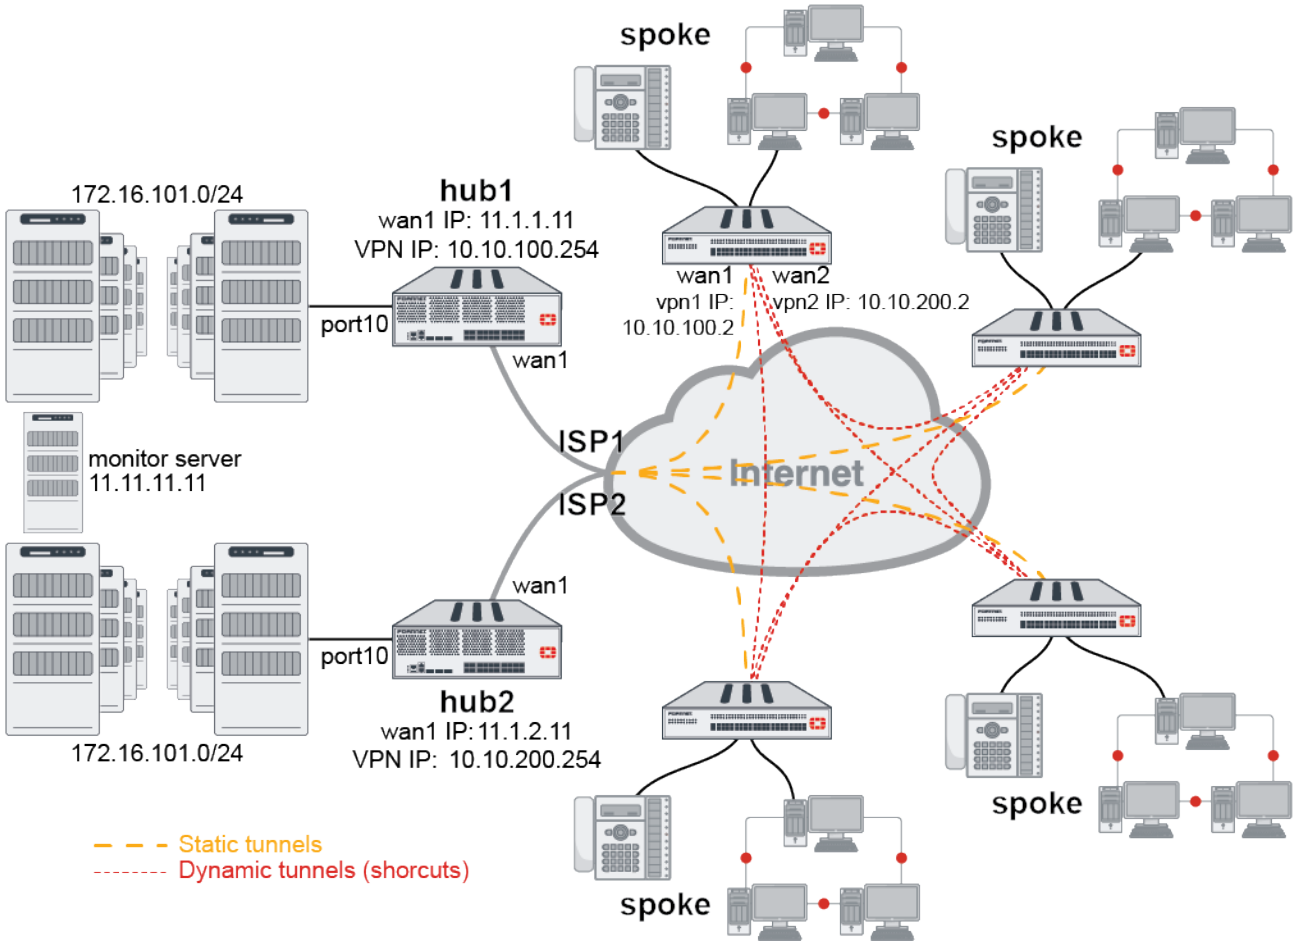
- Interface based QoS on individual child tunnels based on speed test results on page 822
- SD-WAN in large scale deployments on page 825

ADVPN and shortcut paths

This topic provides an example of how to use SD-WAN and ADVPN together.

ADVPN (Auto Discovery VPN) is an IPsec technology that allows a traditional hub-and-spoke VPN's spokes to establish dynamic, on-demand, direct tunnels between each other to avoid routing through the topology's hub device. The primary advantage is that it provides full meshing capabilities to a standard hub-and-spoke topology. This greatly reduces the provisioning effort for full spoke-to-spoke low delay reachability, and addresses the scalability issues associated with very large fully meshed VPN networks.

If a customer's head office and branch offices all have two or more internet connections, they can build a dual-hub ADVPN network. Combined with SD-WAN technology, the customer can load-balance traffic to other offices on multiple dynamic tunnels, control specific traffic using specific connections, or choose better performance connections dynamically.



SD-WAN load-balance mode rules (or services) do not support ADVPN members. Other modes' rules, such as SLA and priority, support ADVPN members.

This topic covers three parts:

1. Configure dual-hub ADVPN with multiple branches.
2. Configure BGP to exchange routing information among hubs and spokes.
3. Configure SD-WAN on spoke to do load-balancing and control traffic.

Configuration example

A typical ADVPN configuration with SD-WAN usually has two hubs, and each spoke connects to two ISPs and establishes VPN tunnels with both hubs.

This example shows a hub-and-spoke configuration using two hubs and one spoke:

- Hub1 and Hub2 both use wan1 to connect to the ISPs and port10 to connect to internal network.
- Spoke1 uses wan1 to connect to ISP1 and wan2 to connect to ISP2.
- wan1 sets up VPN to hub1.
- wan2 sets up VPN to hub2.

The SD-WAN is configured on the spoke. It uses the two VPN interfaces as members and two rules to control traffic to headquarters or other spokes using ADVPN VPN interfaces. You can create more rules if required.

For this example:

- Use SD-WAN member 1 (via ISP1) and its dynamic shortcuts for financial department traffic if member 1 meets SLA requirements. If it doesn't meet SLA requirements, it will use SD-WAN member 2 (via ISP2).
- Use SD-WAN member 2 (via ISP2) and its dynamic shortcuts for engineering department traffic.
- Load balance other traffic going to hubs and other spokes between these two members.
- Set up all other traffic to go with their original ISP connection. All other traffic does not go through SD-WAN.
- Set up basic network configuration to let all hubs and spokes connect to their ISPs and the Internet.

Hub internal network	172.16.101.0/24
Spoke1 internal network	10.1.100.0/24
ADVPN 1 network	10.10.100.0/24
ADVPN 2 network	10.10.200.0/24
Hub1 wan1 IP	11.1.1.11
Hub2 wan1 IP	11.1.2.11
Hub1 VPN IP	10.10.100.254
Hub2 VPN IP	10.10.200.254
Spoke1 to hub1 VPN IP	10.10.100.2
Spoke1 to hub2 VPN IP	10.10.200.2
Ping server in Headquarters	11.11.11.11
Internal subnet of spoke1	22.1.1.0/24
Internal subnet of spoke2	33.1.1.0/24
Firewall addresses	Configure hub_subnets and spoke_subnets before using in policies. These can be customized.

The GUI does not support some ADVPN related options, such as auto-discovery-sender, auto-discovery-receiver, auto-discovery-forwarder, and IBGP neighbor-group setting, so this example only provides CLI configuration commands.

Hub1 sample configuration

To configure the IPsec phase1 and phase2 interface:

```
config vpn ipsec phase1-interface
    edit "hub-phase1"
        set type dynamic
        set interface "wan1"
        set peertype any
        set net-device disable
        set proposal aes128-sha256 aes256-sha256 3des-sha256 aes128-sha1 aes256-sha1 3des-
sha1
        set add-route disable
        set dpd on-idle
        set auto-discovery-sender enable
        set psksecret sample
        set dpd-retryinterval 5
    next
end
config vpn ipsec phase2-interface
    edit "hub-phase2"
        set phase1name "hub-phase1"
        set proposal aes128-sha1 aes256-sha1 3des-sha1 aes128-sha256 aes256-sha256 3des-
sha256
    next
end
```

When `net-device` is disabled, a tunnel ID is generated for each dynamic tunnel. This ID, in the form of an IP address, is used as the gateway in the route entry to that tunnel. The `tunnel-search` option is removed in FortiOS 7.0.0 and later.

To configure the VPN interface and BGP:

```
config system interface
    edit "hub-phase1"
        set ip 10.10.100.254 255.255.255.255
        set remote-ip 10.10.100.253 255.255.255.0
    next
end
config router bgp
    set as 65505
    config neighbor-group
        edit "advpn"
            set link-down-failover enable
            set remote-as 65505
            set route-reflector-client enable
        next
    end
    config neighbor-range
        edit 1
            set prefix 10.10.100.0 255.255.255.0
            set neighbor-group "advpn"
        next
    end
    config network
        edit 1
            set prefix 172.16.101.0 255.255.255.0
        next
        edit 2
            set prefix 11.11.11.0 255.255.255.0
         next
    end
end
```

To configure the firewall policy:

```
config firewall policy
    edit 1
        set name "spoke2hub"
        set srcintf "hub-phase1"
        set dstintf "port10"
        set srcaddr "spoke_subnets"
        set dstaddr "hub_subnets"
        set action accept
        set schedule "always"
        set service "ALL"
        set comments "allow traffic from spokes to headquarter"
    next
    edit 2
        set name "spoke2spoke"
        set srcintf "hub-phase1"
```

```
        set dstintf "hub-phase1"
        set srcaddr "spoke_subnets"
        set dstaddr "spoke_subnets"
        set action accept
        set schedule "always"
        set service "ALL"
        set comments "allow traffic from spokes to spokes"
    next
    edit 3
        set name "internal2spoke"
        set srcintf "port10"
        set dstintf "hub-phase1"
        set srcaddr "hub_subnets"
        set dstaddr "spoke_subnets"
        set action accept
        set schedule "always"
        set service "ALL"
        set comments "allow traffic from headquarter to spokes"
    next
end
```

Hub2 sample configuration

Hub2 configuration is the same as hub1 except the wan1 IP address, VPN interface IP address, and BGP neighbor-range prefix.

To configure the IPsec phase1 and phase2 interface:

```
config vpn ipsec phase1-interface
    edit "hub-phase1"
        set type dynamic
        set interface "wan1"
        set peertype any
        set net-device disable
        set proposal aes128-sha256 aes256-sha256 3des-sha256 aes128-sha1 aes256-sha1 3des-
sha1
        set add-route disable
        set dpd on-idle
        set auto-discovery-sender enable
        set psksecret sample
        set dpd-retryinterval 5
    next
end
config vpn ipsec phase2-interface
    edit "hub-phase2"
        set phase1name "hub-phase1"
        set proposal aes128-sha1 aes256-sha1 3des-sha1 aes128-sha256 aes256-sha256 3des-
sha256
    next
end
```

To configure the VPN interface and BGP:

```
config system interface
    edit "hub-phase1"
```

```
        set ip 10.10.200.254 255.255.255.255
        set remote-ip 10.10.200.253 255.255.255.0
    next
end
config router bgp
    set as 65505
    config neighbor-group
        edit "advpn"
            set link-down-failover enable
            set remote-as 65505
            set route-reflector-client enable
        next
    end
    config neighbor-range
        edit 1
            set prefix 10.10.200.0 255.255.255.0
            set neighbor-group "advpn"
        next
    end
    config network
        edit 1
            set prefix 172.16.101.0 255.255.255.0
        next
        edit 2
            set prefix 11.11.11.0 255.255.255.0
         next
    end
end
```

To configure the firewall policy:

```
config firewall policy
    edit 1
        set name "spoke2hub"
        set srcintf "hub-phase1"
        set dstintf "port10"
        set srcaddr "spoke_subnets"
        set dstaddr "hub_subnets"
        set action accept
        set schedule "always"
        set service "ALL"
        set comments "allow traffic from spokes to headquarter"
    next
    edit 2
        set name "spoke2spoke"
        set srcintf "hub-phase1"
        set dstintf "hub-phase1"
        set srcaddr "spoke_subnets"
        set dstaddr "spoke_subnets"
        set action accept
        set schedule "always"
        set service "ALL"
        set comments "allow traffic from spokes to spokes"
    next
    edit 3
        set name "internal2spoke"
```

```
        set srcintf "port10"
        set dstintf "hub-phase1"
        set srcaddr "hub_subnets"
        set dstaddr "spoke_subnets"
        set action accept
        set schedule "always"
        set service "ALL"
        set comments "allow traffic from headquarter to spokes"
    next
end
```

Spoke1 sample configuration

To configure the IPsec phase1 and phase2 interface:

```
config vpn ipsec phase1-interface
    edit "spoke1-phase1"
        set interface "wan1"
        set peertype any
        set net-device enable
        set proposal aes128-sha256 aes256-sha256 aes128-sha1 aes256-sha1
        set add-route disable
        set dpd on-idle
        set auto-discovery-receiver enable
        set remote-gw 11.1.1.11
        set psksecret sample
        set dpd-retryinterval 5
    next
    edit "spoke1-2-phase1"
        set interface "wan2"
        set peertype any
        set net-device enable
        set proposal aes128-sha256 aes256-sha256 aes128-sha1 aes256-sha1
        set add-route disable
        set dpd on-idle
        set auto-discovery-receiver enable
        set remote-gw 11.1.2.11
        set psksecret sample
        set dpd-retryinterval 5
    next
end
config vpn ipsec phase2-interface
    edit "spoke1-phase2"
        set phase1name "spoke1-phase1"
        set proposal aes128-sha1 aes256-sha1 aes128-sha256 aes256-sha256 aes128gcm aes256gcm
chacha20poly1305
        set auto-negotiate enable
    next
    edit "spoke1-2-phase2"
        set phase1name "spoke1-2-phase1"
        set proposal aes128-sha1 aes256-sha1 aes128-sha256 aes256-sha256 aes128gcm aes256gcm
chacha20poly1305
        set auto-negotiate enable
    next
end
```

To configure the VPN interface and BGP:

```
config system interface
    edit "spoke1-phase1"
        set ip 10.10.100.2 255.255.255.255
        set remote-ip 10.10.100.254 255.255.255.0
    next
    edit "spoke1-2-phase1"
        set ip 10.10.200.2 255.255.255.255
        set remote-ip 10.10.200.254 255.255.255.0
    next
end
config router bgp
    set as 65505
    config neighbor
        edit "10.10.100.254"
            set advertisement-interval 1
            set link-down-failover enable
            set remote-as 65505
        next
        edit "10.10.200.254"
            set advertisement-interval 1
            set link-down-failover enable
            set remote-as 65505
        next
    end
    config network
        edit 1
            set prefix 10.1.100.0 255.255.255.0
        next
    end
end
```

To configure SD-WAN:

```
config system sdwan
    set status enable
    config members
        edit 1
            set interface "spoke1-phase1"
        next
        edit 2
            set interface "spoke1-2-phase1"
        next
    end
    config health-check
        edit "ping"
            set server "11.11.11.11"
            set members 1 2
            config sla
                edit 1
                    set latency-threshold 200
                    set jitter-threshold 50
                    set packetloss-threshold 5
                next
            end
```

```
        next
    end
    config service
        edit 1
            set mode sla
            set dst "financial-department"
            config sla
                edit "ping"
                    set id 1
                next
            end
            set priority-members 1 2
        next
        edit 2
            set priority-members 2
            set dst "engineering-department"
        next
    end
end
```

If no SD-WAN zone is specified, members are added to the default *virtual-wan-link* zone.

To configure the firewall policy:

```
config firewall policy
    edit 1
        set name "outbound_advpn"
        set srcintf "internal"
        set dstintf "virtual-wan-link"
        set srcaddr "spoke_subnets"
        set dstaddr "spoke_subnets" "hub_subnets"
        set action accept
        set schedule "always"
        set service "ALL"
        set comments "allow internal traffic going out to headquarter and other spokes"
    next
    edit 2
        set name "inbound_advpn"
        set srcintf "virtual-wan-link"
        set dstintf "internal"
        set srcaddr "spoke_subnets" "hub_subnets"
        set dstaddr "spoke_subnets"
        set action accept
        set schedule "always"
        set service "ALL"
        set comments "allow headquarter and other spokes traffic coming in"
    next
end
```

Troubleshooting ADVPN and shortcut paths

Before spoke vs spoke shortcut VPN is established

Use the following CLI commands to check status before spoke vs spoke shortcut VPN is established.

```
# get router info bgp summary
BGP router identifier 2.2.2.2, local AS number 65505
BGP table version is 13
3 BGP AS-PATH entries
0 BGP community entries

SD-WAN monitor on ADVPN shortcuts

SD-WAN monitors ADVPN shortcut link quality by dynamically creating link monitors for each ADVPN link. The dynamic link monitor on the spoke will use ICMP probes and the IP address of the gateway as the monitored server. These ICMP probes will not be counted as actual user traffic that keeps the spoke-to-spoke tunnel alive.

- When no shortcut is established:

```
# diagnose sys sdwan health-check
Health Check(ping):
Seq(1 tunnel-1): state(alive), packet-loss(0.000%) latency(0.038), jitter(0.006) sla_
map=0x3
Seq(2 tunnel-2): state(alive), packet-loss(0.000%) latency(0.035), jitter(0.004) sla_
map=0x3
```

- When one shortcut is established:

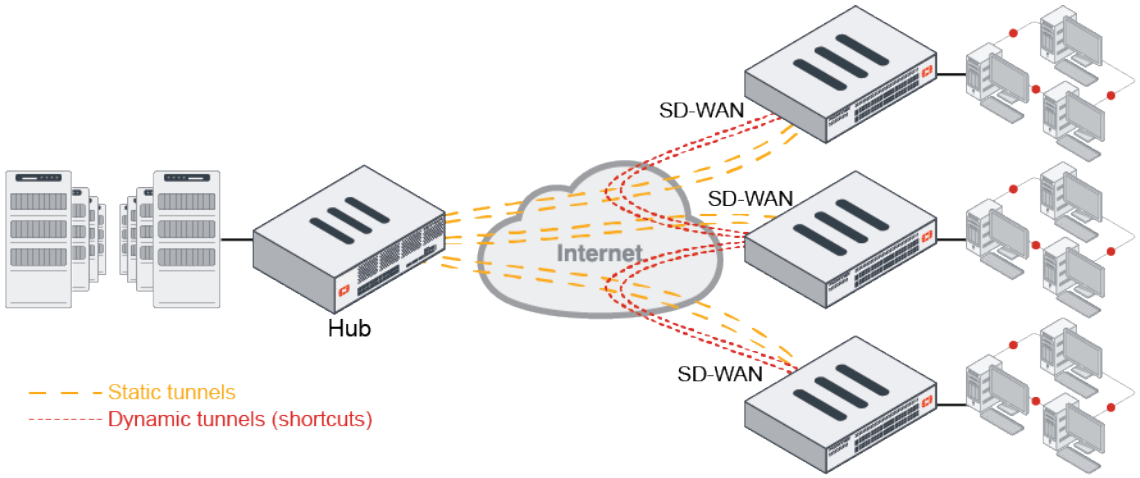
```
# diagnose sys sdwan health-check
Health Check(ping):
Seq(1 tunnel-1): state(alive), packet-loss(0.000%) latency(0.039), jitter(0.003) sla_
map=0x3
Seq(1 tunnel-1_0): state(alive), packet-loss(0.000%) latency(0.060), jitter(0.023) sla_
map=0x3
Seq(2 tunnel-2): state(alive), packet-loss(0.000%) latency(0.035), jitter(0.002) sla_
map=0x3
```

- When more than one shortcut is established:

```
# diagnose sys sdwan health-check
Health Check(ping):
Seq(1 tunnel-1): state(alive), packet-loss(0.000%) latency(0.036), jitter(0.004) sla_
map=0x3
Seq(1 tunnel-1_0): state(alive), packet-loss(0.000%) latency(0.041), jitter(0.009) sla_
map=0x3
Seq(2 tunnel-2): state(alive), packet-loss(0.000%) latency(0.030), jitter(0.005) sla_
map=0x3
Seq(2 tunnel-2_0): state(alive), packet-loss(0.000%) latency(0.031), jitter(0.004) sla_
map=0x3
```

Hold down time to support SD-WAN service strategies

In a hub and spoke SD-WAN topology with shortcuts created over ADVPN, a downed or recovered shortcut can affect which member is selected by an SD-WAN service strategy. When a downed shortcut tunnel recovers and the shortcut is added back into the service strategy, the shortcut is held at a low priority until the hold down time has elapsed.



By default, the hold down time is zero seconds. It can be set to 0 - 10000000 seconds.

To configure the hold down time:

```
config system sdwan
    config service
        edit 1
            set hold-down-time <integer>
        next
    end
end
```

Example

In this example, the hold down time is set to 15 seconds, and then the SD-WAN service is looked at before and after the hold down elapses after a downed shortcut recovers.

To configure the hold down time:

```
config system sdwan
    config service
        edit 1
            set hold-down-time 15
        next
    end
end
```

To view which SD-WAN member is selected before and after the hold down time elapses:

Before the hold down time has elapsed:

```
# diagnose sys sdwan service
Service(1): Address Mode(IPV4) flags=0x200
  Gen(34), TOS(0x0/0x0), Protocol(0: 1->65535), Mode(priority), link-cost-factor(packet-

```

SD-WAN integration with OCVPN

OCVPN has the capability to enable SD-WAN in order to dynamically add its tunnel interfaces as SD-WAN members. Users can configure SD-WAN health checks and service rules to direct traffic over the OCVPN tunnels.

The following example uses a dual hub and spoke topology. Each hub and spoke has two WAN link connections to the ISP. The spokes generate two IPsec tunnels to each hub (four tunnels in total). BGP neighbors are established over each tunnel and routes from the hubs and other spokes learned from all neighbors, which forms an ECMP scenario. All tunnels are placed as SD-WAN members, so traffic can be distributed across tunnels based on the configured SD-WAN service rules.

To integrate SD-WAN with OCVPN in the GUI:

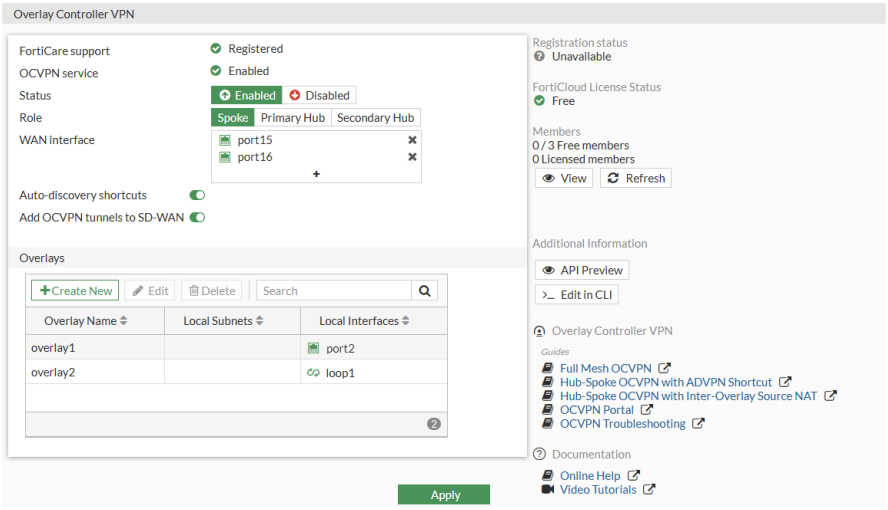
1. Configure the primary hub:
   a. Go to *VPN* > *Overlay Controller VPN* and set the *Status* to *Enable*.
   b. For *Role*, select *Primary Hub*.

c. Enter the WAN interfaces (*port15* and *port16*) and tunnel IP allocation block (*10.254.0.0/16*).

The WAN interface is position sensitive, meaning a tunnel will be created with the first position interface on the hub to the first position interface on the spoke, and so on. In this example, FGT_A (primary hub) will create two tunnels with FGT_C (spoke):

- FGT_A port15 <==> FGT_C internal1
- FGT_A port16 <==> FGT_C internal2

d. Enable *Auto-discovery shortcuts*.



e. Enable *Add OCVPN tunnels to SD-WAN*. The IPsec tunnels will be added automatically to the SD-WAN members if SD-WAN is enabled.

2. Configure the overlays on the primary hub:

a. In the *Overlays* section, click *Create New*.

b. Enter a name and add the local interface (*port2*). Note the overlay is either based on local subnets or local interfaces, but not both.
By default, inter-overlay traffic is not enabled. Toggle *Allow traffic from other overlays* to enable it.

c. Click *OK* and repeat these steps to create the second overlay (*loop1*).

d. Click *Apply*.

3. Configure the secondary hub with the same settings as the primary hub.

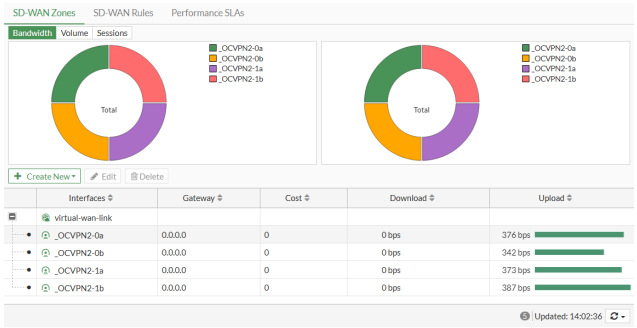
4. Configure the spoke:

a. Go to *VPN* > *Overlay Controller VPN* and set the *Status* to *Enable*.

b. For *Role*, select *Spoke*.

c. Enter the WAN interfaces (*internal1* and *internal2*).

d. Enable *Auto-discovery shortcuts*.



e. Enable *Add OCVPN tunnels to SD-WAN*. The IPsec tunnels will be added automatically to the SD-WAN members if SD-WAN is enabled.

f. Configure the overlays.

The overlay names on the spokes must match the names on the hub for the traffic to be allowed through the same overlay.

g. Click *Apply*.

5. Configure the other spoke with the same settings.
6. On a spoke, go to *Network* > *SD-WAN* and select the *SD-WAN Zones* tab to view the configuration generated by OCVPN.

Firewall policies will be automatically generated by OCVPN between the local interfaces and the SD-WAN interface. Each policy will define the proper local and remote networks for its source and destination addresses.

To integrate SD-WAN with OCVPN in the CLI:

1. Configure the primary hub:

```
config vpn ocvpn
    set role primary-hub
    set sdwan enable
    set wan-interface "port15" "port16"
    set ip-allocation-block 10.254.0.0 255.255.0.0
    config overlays
        edit "overlay1"
            config subnets
                edit 1
                    set type interface
                    set interface "port2"
                next
            end
        next
        edit "overlay2"
            config subnets
                edit 1
                    set type interface
                    set interface "loop1"
                next
            end
        next
    end
end
```

2. Configure the secondary hub with the same settings as the primary hub.
3. Configure the spoke:

```
config vpn ocvpn
    set status enable
    set sdwan enable
    set wan-interface "internal1" "internal2"
    config overlays
        edit "overlay1"
            config subnets
```

```
                edit 1
                    set type interface
                    set interface "wan2"
                next
            end
        next
        edit "overlay2"
            config subnets
                edit 1
                    set type interface
                    set interface "loop1"
                next
            end
        next
    end
end
```

4. Configure the other spoke with the same settings.
5. Configure SD-WAN:

```
config system sdwan
    set status enable
    config members
        edit 1
            set interface "_OCVPN2-0a"
        next
        edit 2
            set interface "_OCVPN2-0b"
        next
        edit 3
            set interface "_OCVPN2-1a"
        next
        edit 4
            set interface "_OCVPN2-1b"
        next
    end
end
```

Firewall policies will be automatically generated by OCVPN between the local interfaces and the SD-WAN interface. Each policy will define the proper local and remote networks for its source and destination addresses.

If no SD-WAN zone is specified, members are added to the default *virtual-wan-link* zone.

To verify the integration is working after the ADVPN shortcut is triggered:

1. Check the routing table on the spoke:

```
FGT_C # get router info routing-table all
Codes: K - kernel, C - connected, S - static, R - RIP, B - BGP
       O - OSPF, IA - OSPF inter area
       N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
       E1 - OSPF external type 1, E2 - OSPF external type 2
       i - IS-IS, L1 - IS-IS level-1, L2 - IS-IS level-2, ia - IS-IS inter area
```

```
       * - candidate default

npuid=1
```

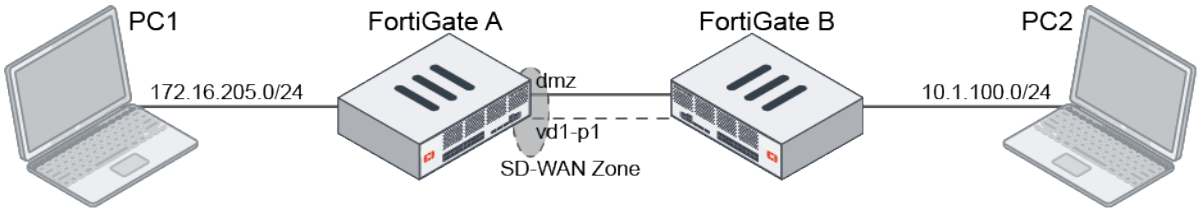
3. Check the SD-WAN state:

```
FGT_C # diagnose sys sdwan health-check
Health Check(Default_DNS):
Health Check(Default_Office_365):
Health Check(Default_Gmail):
Health Check(Default_AWS):
Health Check(Default_Google Search):
Health Check(Default_FortiGuard):
Health Check(ocvpn):
Seq(1 _OCVPN2-0a): state(alive), packet-loss(0.000%) latency(0.364), jitter(0.028) sla_
map=0x0
Seq(2 _OCVPN2-0b): state(alive), packet-loss(0.000%) latency(0.287), jitter(0.026) sla_
map=0x0
Seq(3 _OCVPN2-1a): state(dead), packet-loss(100.000%) sla_map=0x0
Seq(4 _OCVPN2-1b): state(dead), packet-loss(100.000%) sla_map=0x0
Seq(4 _OCVPN2-1b_0): state(alive), packet-loss(0.000%) latency(0.289), jitter(0.029)
sla_map=0x0
```

Adaptive Forward Error Correction



Forward Error Correction (FEC) is used to control and correct errors in data transmission by sending redundant data across the VPN in anticipation of dropped packets occurring during transit. The mechanism sends out *x* number of redundant packets for every *y* number of base packets.

Adaptive FEC considers link conditions and dynamically adjusts the FEC packet ratio:

- The FEC base and redundant packet relationship is dynamically adjusted based on changes to the network SLA metrics defined in the SD-WAN SLA health checks. For example, when there is no or low packet loss in the network, FEC can work on a low redundant level sending only one redundant packet for every 10 base packets. As packet loss increases, the number of redundant packets sent can rise accordingly.
- FEC can be applied only to streams that are sensitive to packet loss. For Example, policies that allow the UDP based VoIP protocol can enable FEC, while TCP based traffic policies do not. This reduces unnecessary bandwidth consumption by FEC.
- Because FEC does not support NPU offloading, the ability to specify streams and policies that do not require FEC allows those traffic to be offloaded. This means that not all traffic suffers a performance impact.

In this example, an IPsec tunnel is configured between two FortiGates that both have FEC enabled. The tunnel is an SD-WAN zone, and an SLA health-check is used to monitor the quality of the VPN overlay. The intention is to apply FEC to UDP traffic that is passing through the VPN overlay, while allowing all other traffic to pass through without FEC. An FEC profile is configured to adaptively increase redundant levels if the link quality exceeds a 10% packet loss threshold, or the bandwidth exceeds 950 Mbps.

The DMZ interface and IPsec tunnel vd1-p1 are SD-WAN members. FEC is enabled on vd1-p1, and health-check works on vd1-p1.

To configure the FortiGates:

1. On both FortiGates, enable FEC and NPU offloading on the IPsec tunnel vd1-p1:

```
config vpn ipsec phase1-interface
    edit "vd1-p1"
        set npu-offload enable
        set fec-egress enable
        set fec-ingress enable
    next
end
```

2. On FortiGate A, configure SD-WAN:

   The VPN overlay member (vd1-p1) must be included in the health-check and configured as the higher priority member in the SD-WAN rule.

```
config system sdwan
    set status enable
    config zone
        edit "virtual-wan-link"
        next
    end
    config members
        edit 1
            set interface "dmz"
            set gateway 172.16.208.2
        next
        edit 2
            set interface "vd1-p1"
        next
    end
    config health-check
        edit "1"
            set server "2.2.2.2"
            set members 2
            config sla
                edit 1
                next
            end
        next
    end
    config service
        edit 1
            set name "1"
            set dst "all"
            set src "172.16.205.0"
            set priority-members 2 1
```

```
        next
    end
end
```

3. On FortiGate A, create a policy to specify performing FEC on UDP traffic, and a policy for other traffic:

```
config firewall policy
    edit 1
        set srcintf "port5"
        set dstintf "virtual-wan-link"
        set action accept
        set srcaddr "172.16.205.0"
        set dstaddr "all"
        set schedule "always"
        set service "ALL_UDP"
        set fec enable
    next
    edit 2
        set srcintf "any"
        set dstintf "any"
        set action accept
        set srcaddr "all"
        set dstaddr "all"
        set schedule "always"
        set service "ALL"
    next
end
```

4. On FortiGate A, configure FEC mapping to bind network SLA metrics and FEC base and redundant packets:

```
config vpn ipsec fec
    edit "m1"
        config mappings
            edit 1
                set base 8
                set redundant 2
                set packet-loss-threshold 10
            next
            edit 2
                set base 9
                set redundant 3
                set bandwidth-up-threshold 950000
            next
        end
    next
end
```

   The mappings are matched from top to bottom: packet loss greater than 10% with eight base and two redundant packets, and then uploading bandwidth greater than 950 Mbps with nine base and three redundant packets.

5. On FortiGate A, apply the FEC mappings on vd1-p1:

```
config vpn ipsec phase1-interface
    edit "vd1-p1"
        set fec-health-check "1"
        set fec-mapping-profile "m1"
        set fec-base 10
        set fec-redundant 1
```

```
    next
end
```

The FEC base and redundant values are used when the link quality has not exceeded the limits specified in the FEC profile mapping. If `fec-codec` is set to `xor` the base and redundant packet values will not be updated.

To verify the results:

1. Send TCP and UDP traffic from PC1 to PC2, then check the sessions on FortiGate A:

```
# diagnose sys session list

session info: proto=6 proto_state=01 duration=12 expire=3587 timeout=3600 flags=00000000
socktype=0 sockport=0 av_idx=0 use=3

npu_state=0x5040000
no_ofld_reason:  non-npu-intf
```

Non-FEC protected TCP traffic is offloaded, while FEC protected UDP traffic is not offloaded

2. On FortiGate A, check the health-check result and the corresponding FEC base and redundant packets:

```
# diagnose sys sdwan health-check
Health Check(1):
Seq(2 vd1-p1): state(alive), packet-loss(0.000%) latency(0.168), jitter(0.021),
bandwidth-up(999999), bandwidth-dw(999998), bandwidth-bi(1999997) sla_map=0x1
```

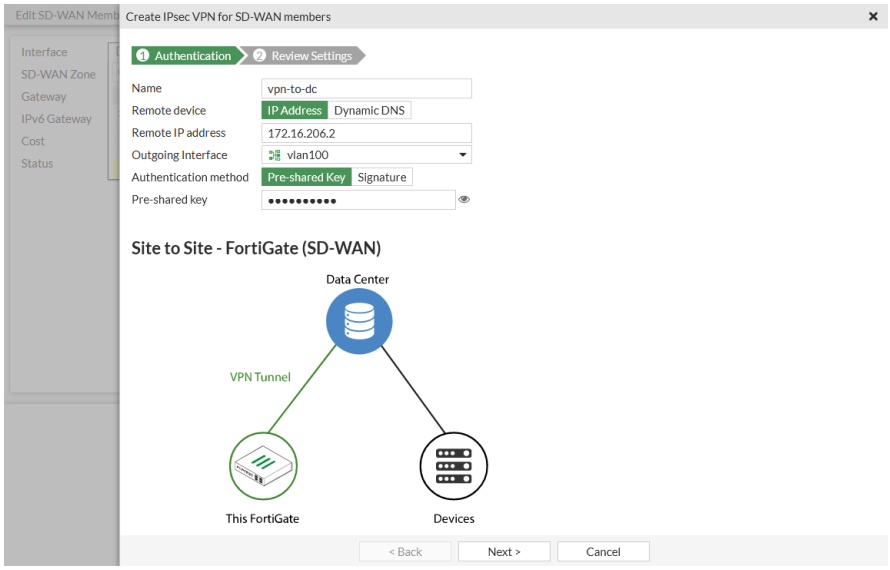
Because bandwidth-up is more than 950000kbps, base and redundant are set to 9 and 3:

```
# diagnose vpn tunnel fec vd1-p1
egress:
    enabled=1 base=9 redundant=3 codec=0 timeout=10(ms)
    encode=6621 encode_timeout=6621 encode_fail=0
    tx_data=6880 tx_parity=18601
ingress:
    enabled=1 timeout=50(ms)
    fasm_cnt=0 fasm_full=0
    ipsec_fec_chk_fail=0 complete=0
    rx_data=0 rx_parity=0
    recover=0 recover_timeout=0 recover_fail=0
    rx=0 rx_fail=0
```

3. Make packet loss more than 10%, then check the health-check result and the corresponding FEC base and redundant packets again:

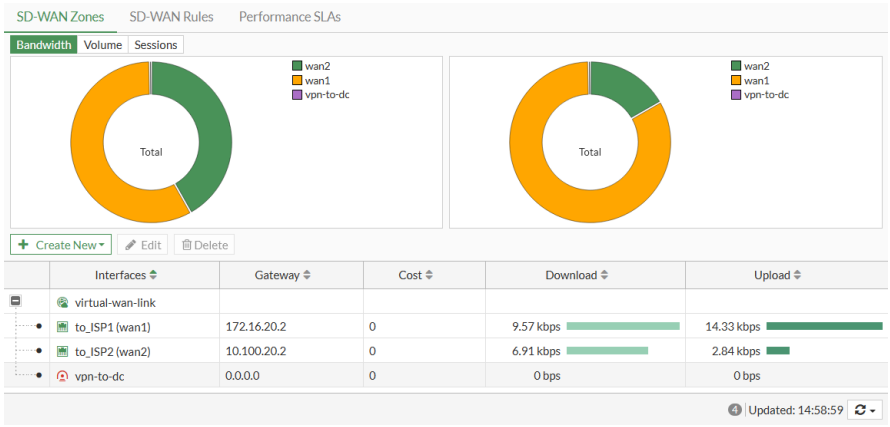
```
# diagnose sys sdwan  health-check
Health Check(1):
Seq(2 vd1-p1): state(alive), packet-loss(15.000%) latency(0.168), jitter(0.017),
bandwidth-up(999999), bandwidth-dw(999998), bandwidth-bi(1999997) sla_map=0x0
```

Because packet loss is more than 10%, entry one in FEC mapping is first matched, and base and redundant are set to 8 and 2:



```
# diagnose vpn tunnel fec  vd1-p1
egress:
    enabled=1 base=8 redundant=2 codec=0 timeout=10(ms)
    encode=6670 encode_timeout=6670 encode_fail=0
    tx_data=6976 tx_parity=18748
ingress:
    enabled=1 timeout=50(ms)
    fasm_cnt=0 fasm_full=0
    ipsec_fec_chk_fail=0 complete=0
    rx_data=0 rx_parity=0
    recover=0 recover_timeout=0 recover_fail=0
    rx=0 rx_fail=0
```

Dual VPN tunnel wizard



This wizard is used to automatically set up multiple VPN tunnels to the same destination over multiple outgoing interfaces. This includes automatically configuring IPsec, routing, and firewall settings, avoiding cumbersome and error-prone configuration steps.

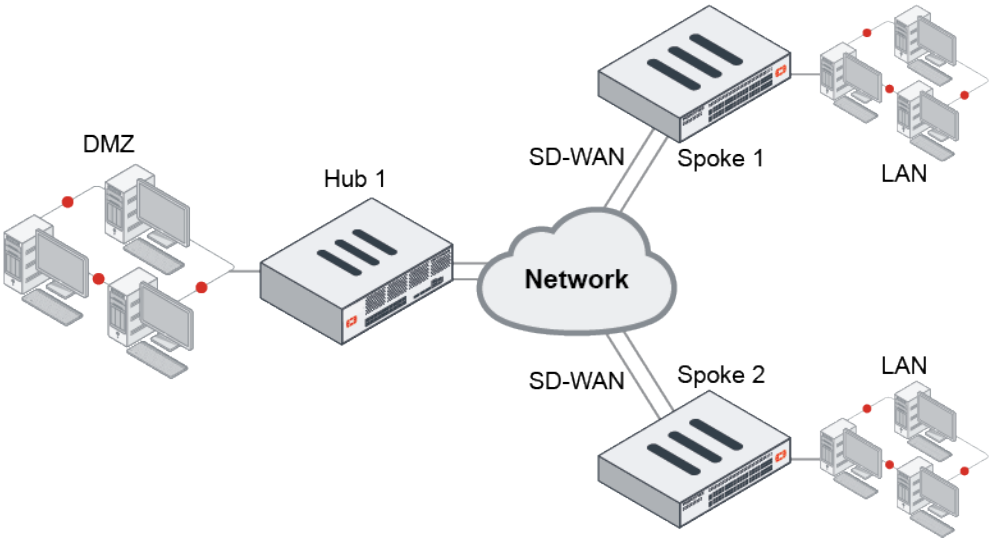
To create a new SD-WAN VPN interface using the tunnel wizard:

1. Go to *Network* > *SD-WAN*, select the *SD-WAN Zones* tab, and click *Create New* > *SD-WAN Member*.
2. In the *Interface* drop-down, click *+VPN*. The *Create IPsec VPN for SD-WAN members* pane opens.

3. Enter the required information, then click *Next*.
4. Review the settings then click *Create*.
5. Click *Close* to return to the SD-WAN page.
   The newly created VPN interface will be highlighted in the *Interface* drop-down list.
6. Select the VPN interface to add it as an SD-WAN member, then click *OK*.

Duplicate packets on other zone members

When duplication rules are used, packets are duplicated on other good links within the SD-WAN zone and de-duplicated on the destination FortiGate. Use `force` mode to force duplication on other links within the SD-WAN zone, or use `on-demand` mode to trigger duplication only when SLA fails on the selected member.



The duplication rule is configured in the CLI by using the `config duplication` command. The following options can be configured:

Parameter	Description
srcaddr	Source address or address group names.
dstaddr	Destination address or address group names.
srcaddr6	Source IPv6 address or IPv6 address group names.
dstaddr6	Destination IPv6 address or IPv6 address group names.
srcintf	Incoming (ingress) interfaces or zones.
dstintf	Outgoing (egress) interfaces or zones.
service	Service and service group names.
packet-duplication	Configure packet duplication method. • disable: Disable packet duplication (default). • force: Duplicate packets across all interface members of the SD-WAN zone. • on-demand: Duplicate packets across all interface members of the SD-WAN zone based on the link quality.
packet-de-duplication	Enable/disable discarding of packets that have been duplicated (default = disable).

The `duplication-max-num <integer>` option under `config system sdwan` is the maximum number of interface members that a packet is duplicated on in the SD-WAN zone (2 - 4, default = 2). If this value is set to 3, the original packet plus two more copies are created. If there are three member interfaces in the SD-WAN zone and the `duplication-max-num` is set to 2, the packet duplication follows the configuration order, so the packets are duplicated on the second member.

Example

The packet duplication feature works best in a spoke-spoke or hub-and-spoke topology. In this example, a hub-and-spoke ADVPN topology is used. Before shortcuts are established, Hub 1 forwards the duplicate packets from Spoke 1 to Spoke 2. Once shortcuts are established, Hub 1 is transparent, and duplicate packets are exchanged directly between the spokes.

To configure packet duplication between Spoke 1 and Spoke 2:

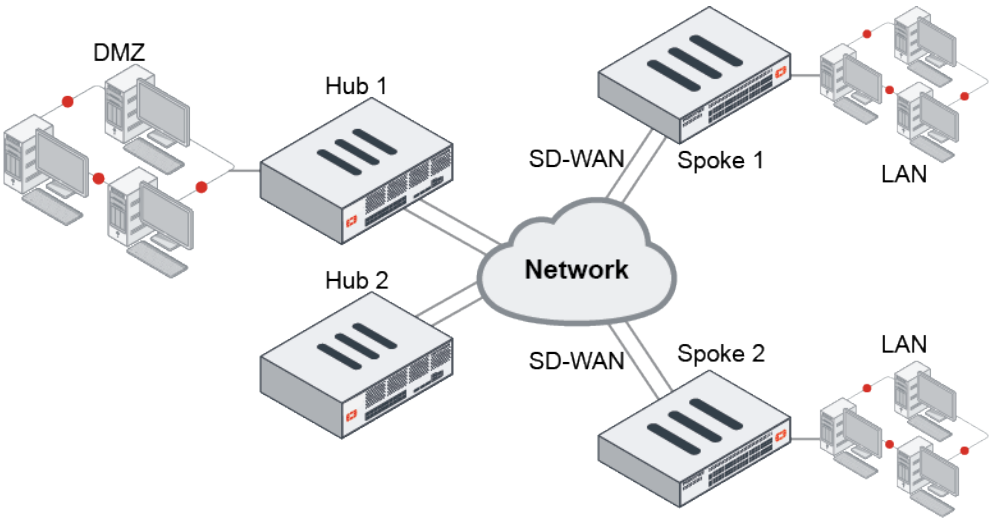
1. Configure Spoke 1:

```
config system sdwan
    set status enable
    config zone
        edit "virtual-wan-link"
        next
        edit "sdwanzone_v4"
        next
    end
    config members
        edit 1
            set interface "t1"
            set zone "sdwanzone_v4"
        next
        edit 4
            set interface "t21"
            set zone "sdwanzone_v4"
        next
        edit 2
            set interface "t2"
            set zone "sdwanzone_v4"
        next
    end
    config health-check
        edit "h1"
            set server "10.34.1.1"
            set interval 1000
            set failtime 10
            set members 1 2
            config sla
                edit 1
                    set packetloss-threshold 40
                next
            end
        next
    end
    config duplication
        edit 1
            set srcaddr "all"
            set dstaddr "all"
            set srcintf "port1"
            set dstintf "sdwanzone_v4"
            set service "ALL"
            set packet-duplication force
            set packet-de-duplication enable
        next
    end
end
```

2. Configure Spoke 2 with similar settings.

Duplicate packets based on SD-WAN rules

SD-WAN duplication rules can specify SD-WAN service rules to trigger packet duplication. This allows the duplication to occur based on an SD-WAN rule instead of the source, destination, and service parameters in the duplication rule.



1. Packets can be forced to duplicate to all members of the same SD-WAN zone. See Duplicate packets on other zone members on page 811 for details.

   For example, in Spoke 1 set `packet-duplication` to `force` so that when a client sends a packet to the server, it is duplicated to all members of the same zone as long as its health check is alive. If a members health check is dead, then the member is removed from the SD-WAN duplication zone.
2. Packets can be duplicated to other members of the SD-WAN zone on-demand only when the condition of the link is not good enough.

   Set `packet-duplication` to `on-demand`. If `sla-match-service` is disabled, when all the SLAs of the member exceed threshold (sla_map=0), the packet is duplicated. But when the SLAs are within threshold (sla_map!=0), the packet is not duplicated.

   If `sla-match-service` is enabled, then only the SLA health checks and targets used in the service rule need to exceed threshold in order to trigger packet duplication.
3. Packets can be duplicated to all members of the same SD-WAN zone when the traffic matches one or more regular SD-WAN service rules.

The following example shows the third type of packet duplication.

In this example, SD-WAN is configured with three members: vpn1, vpn2, and vpn3. Service rule 1 controls all traffic from 10.100.20.0/24 to 172.16.100.0/24 using member 1.

To send a duplicate of the traffic that matches service rule 1 using member 2, members 1 and 2 are added to the same SD-WAN zone, and a duplication rule is configured with service-id set to 1.

To send a duplicate of the traffic that matches service rule 1 using member 2:

```
config system sdwan
    set status enable
    config zone
        edit "virtual-wan-link"
        next
        edit "zone2"
```

```
        next
    end
    config members
        edit 1
            set interface "vpn1"
        next
        edit 2
            set interface "vpn2"
        next
        edit 3
            set interface "vpn3"
            set zone "zone2"
        next
    end
    config service
        edit 1
            set dst "172.16.100.0"
            set src "10.100.20.0"
            set priority-members 1
        next
    end
    config duplication
        edit 1
            set service-id 1
            set packet-duplication force
        next
    end
end
```

Speed tests run from the hub to the spokes in dial-up IPsec tunnels

In a hub and spoke SD-WAN topology that uses dial-up VPN overlays, QoS can be applied on individual tunnels based on the measured bandwidth between the hub and spokes. The FortiGate can use the built in speed test to dynamically populate the egress bandwidth to individual dial-up tunnels from the hub.

SD-WAN members on a spoke can switch routes when the speed test is running from the hub to the spoke. The speed test results can be cached for reuse when a tunnel comes back after going down.

CLI commands

Allow upload speed tests to be run from the hub to spokes on demand for dial-up IPsec tunnel:

```
config system speed-test-schedule
    edit <interface>
        set dynamic-server {enable | disable}
    next
end
```

`<interface>`	The dial-up IPsec tunnel interface on the hub.
`dynamic-server {enable | disable}`	Enable/disable the dynamic speed test server (default = disable).

To limit the maximum and minimum bandwidth used in the speed test, enable `set update-inbandwidth` and `set update-outbandwidth`. See Scheduled interface speedtest on page 713 for more information.

```
config system global
   set speedtest-server {enable | disable}
end
```

`speedtest-server {enable | disable}`	Enable/disable the speed test server on the spoke (default = disable). This setting must be enabled on spoke FortiGates. This enables iPerf in server mode, which listens on the default iPerf TCP port 5201.

Allow an SD-WAN member on the spoke to switch routes when it is on speed test from the hub to spokes:

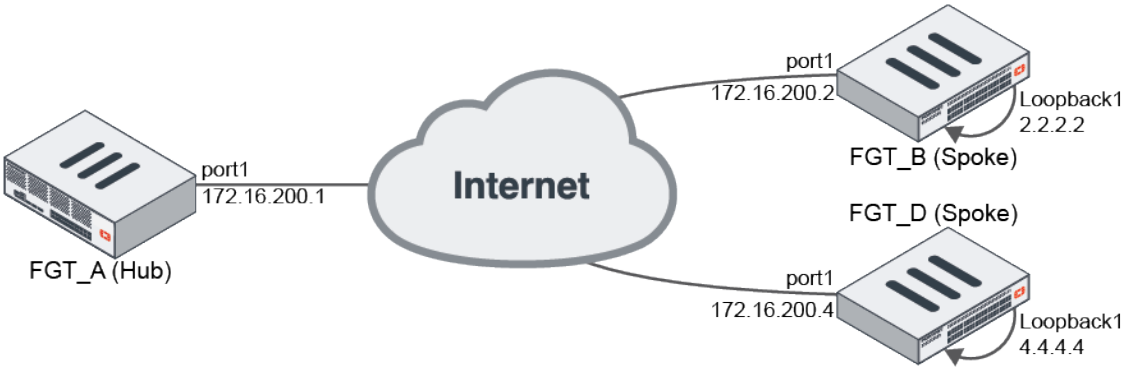
```
config system sdwan
    set speedtest-bypass-routing {enable | disable}
    config neighbor
        edit <bgp neighbor>
            set mode speedtest
        next
    end
end
```

`speedtest-bypass-routing {enable | disable}`	Enable/disable bypass routing when doing a speed test on an SD-WAN member (default = disable).
`set mode speedtest`	Use the speed test to select the neighbor.

Manually run uploading speed test on the physical interfaces of each tunnel of an dial-up IPsec interface:

```
execute speed-test-dynamic <interface> <tunnel_name> <'y'/'n'> <max-out> <min-out>
```

`<interface>`	IPsec phase1 interface name.
`<tunnel_name>`	The tunnel name, or `all` for all tunnels.
`<'y'/'n'>`	Apply the result to the tunnels' shaper or not.
`<max-out>`	The maximum speed used in a speed test, in kbps.
`<min-out>`	The minimum speed used in a speed test, in kbps.



Manually run a non-blocking uploading speed test:

```
diagnose netlink interface speed-test-tunnel <interface> <tunnel_name>
```

Debug and test commands:

`diagnose debug application speedtest <int>`	Enable debug of the speed test module in the forticron daemon.
`diagnose debug application speedtestd <int>`	Enable debug of the speed test server daemon.
`diagnose test application forticron 9`	List the scheduled speed tests.
`diagnose test application forticron 10`	Show the cached speed test results.
`diagnose test application forticron 11`	Write the cached speed test results to disk.
`diagnose test application forticron 12`	Load the speed test results from disk.
`diagnose test application forticron 99`	Cancel all pending speed tests.

Example

In this example, the hub is configured as a VPN dial-up server and both of the spokes are connected to the hub. It is assumed that the VPN configuration is already done, with a dynamic gateway type and kernel device creation (`net-device`) disabled. Only one SD-WAN interface is used, so there is only one VPN overlay member in the SD-WAN zone. Multiple WAN interfaces and VPN overlays could be used.

The VPN interfaces and IP addresses are:

FortiGate	Interface	IP Address
FGT_A (Hub)	hub-phase1	10.10.100.254
FGT_B (Spoke)	spoke11-p1	10.10.100.2
FGT_D (Spoke)	spoke21-p1	10.10.100.3

A recurring speed test is configured that runs on the hub over the dial-up interfaces. The speed tests are performed over the underlay interface from the hub to the spoke. Each spoke is configured to operate as a speed test server and to allow the speed test to run on its underlay interface. The spokes establish BGP peering with the hub over the VPN interface, and advertises its loopback network to the hub. The specific configuration is only shown for FGT_B.

When the speed test is running, routing through the VPN overlay can be bypassed, and route maps are used to filter the routes that are advertised to peers. The spoke's route map does not advertise any routes to the peer, forcing the hub to use others paths to reach the spoke's network.

When no speed tests are running, the spoke's route map allows its network to be advertised on the hub.

When the speed test is complete, the measured egress bandwidth is dynamically applied to the VPN tunnel on the hub, and the result is cached for future use, in case the tunnel is disconnected and reconnected again.

To configure the hub FortiGate (FGT_A):

1. Configure a shaping profile:

```
config firewall shaping-profile
    edit "profile_1"
        config shaping-entries
            edit 1
                set class-id 2
                set priority low
                set guaranteed-bandwidth-percentage 10
                set maximum-bandwidth-percentage 10
            next
        end
        set default-class-id 2
    next
end
```

   Three classes are used in the profile for low, medium, and high priority traffic. Each class is assigned a guaranteed and maximum bandwidth as a percentage of the measured bandwidth from the speed test.

2. Use the shaping profile in the interface:

```
config system interface
    edit "hub-phase1"
        set egress-shaping-profile "profile_1"
    next
end
```

3. Configure a schedule to use for the speed tests:

```
config firewall schedule recurring
    edit "speedtest_recurring"
        set start 01:00
        set end 23:00
        set day monday tuesday wednesday thursday friday saturday
    next
end
```

4. Configure the speed test schedule:

```
config system speed-test-schedule
    edit "hub-phase1"
        set schedules "speedtest_recurring"
        set dynamic-server enable
    next
end
```

To configure the spoke FortiGates (FGT_B and FGT_D):

1. Enable the speed test daemon:

```
config system global
    set speedtest-server enable
end
```

2. Allow speed tests on the interface:

```
config system interface
    edit "port1"
        append allowaccess speed-test
    next
end
```

3. Configure SD-WAN with bypass routing enabled for speed tests on member *spoke11-p1*:

```
config system sdwan
    set speedtest-bypass-routing enable
    config members
        edit 1
            set interface "spoke11-p1"
        next
    end
    config neighbor
        edit "10.10.100.254"
            set member 1
            set mode speedtest
        next
    end
end
```

4. Configure BGP routing:

```
config router route-map
    edit "No_Speed-Test"
        config rule
            edit 1
                set action permit
            next
        end
    next
    edit "Start_Speed-Test"
        config rule
            edit 1
                set action deny
            next
        end
    next
end

config router bgp
    set as 65412
    config neighbor
        edit "10.10.100.254"
            set remote-as 65412
            set route-map-out "Start_Speed-Test"
            set route-map-out-preferable "No_Speed-Test"
```

```
            next
        end
        config network
            edit 1
                set prefix 2.2.2.2 255.255.255.255
            next
            edit 2
                set prefix 10.1.100.0 255.255.255.0
            next
        end
    end
```

To manually run the speed test:

```
# execute speed-test-dynamic hub-phase1 all y 1000 100
Start testing the speed of each tunnel of hub-phase1
[6400d9] hub-phase1_0: physical_intf=port1, local_ip=172.16.200.1, server_ip=172.16.200.2
Wait for test 6400d9 to finish...
Speed-test result for test ID 6400d9:
    Completed
    measured upload bandwidth is 1002 kbps
    measured time Sun Jun 20 15:56:34 2021

The tested out-bandwidth is more than the set maximum accepted value 1000. Will update the
tunnel's shaper by the set update-outbandwidth-maximum.
Apply shaping profile 'profile_1' with bandwidth 1000 to tunnel hub-phase1_0 of interface
hub-phase1
[6400e0] hub-phase1_1: physical_intf=port1, local_ip=172.16.200.1, server_ip=172.16.200.4
Wait for test 6400e0 to finish...
Speed-test result for test ID 6400e0:
    Completed
    measured upload bandwidth is 1002 kbps
    measured time Sun Jun 20 15:56:39 2021

The tested out-bandwidth is more than the set maximum accepted value 1000. Will update the
tunnel's shaper by the set update-outbandwidth-maximum.
Apply shaping profile 'profile_1' with bandwidth 1000 to tunnel hub-phase1_1 of interface
hub-phase1
```

```
# diagnose netlink interface speed-test-tunnel hub-phase1 all
send speed test request for tunnel 'hub-phase1_0' of 'hub-phase1': 172.16.200.1 ->
172.16.200.2
send speed test request for tunnel 'hub-phase1_1' of 'hub-phase1': 172.16.200.1 ->
172.16.200.4
```

Results

1. Before the speed test starts, FGT_A can receive the route from FGT_B by BGP:

   ```
   # get router info routing-table bgp
   Routing table for VRF=0
   B       2.2.2.2/32 [200/0] via 10.10.100.2 (recursive via 172.16.200.2, hub-phase1),
   00:00:10
   B       10.1.100.0/24 [200/0] via 10.10.100.2 (recursive via 172.16.200.2, hub-phase1),
   00:00:10
   ```

2. At the scheduled time, the speed test starts for the hub-phase1 interface from hub to spoke:

```
# diagnose test application forticron 9
Speed test schedules:
    Interface     Server     Update    Up/Down-limit (kbps)                Days
H:M     TOS     Schedule
-------------------------------------------------------------------------------------
----------------------------------
    hub-phase1    dynamic                                                 1111111
14:41    0x00    speedtest_recurring
Active schedules:
        64002f: hub-phase1(port1) 172.16.200.2     hub-phase1_1
        64002e: hub-phase1(port1) 172.16.200.4     hub-phase1_0
```

The `diagnose debug application speedtest -1` command can be used on both the hub and spokes to check the speed test execution.

3. While the speed test is running, FGT_A does not receive the route from FGT_B by BGP:

```
#  get router info routing-table bgp
Routing table for VRF=0
```

4. Speed tests results can be dynamically applied to the dial-up tunnel for egress traffic shaping:

```
# diagnose vpn tunnel list
------------------------------------------------------
name=hub-phase1_0 ver=2 serial=c 172.16.200.1:0->172.16.200.4:0 tun_id=172.16.200.4 dst_
mtu=1500 dpd-link=on remote_location=0.0.0.0 weight=1
...
egress traffic control:
        bandwidth=737210(kbps) lock_hit=0 default_class=2 n_active_class=3
        class-id=2      allocated-bandwidth=73720(kbps)         guaranteed-
bandwidth=73720(kbps)
                        max-bandwidth=73720(kbps)       current-bandwidth=0(kbps)
                        priority=low    forwarded_bytes=52
                        dropped_packets=0       dropped_bytes=0
        class-id=3      allocated-bandwidth=221163(kbps)        guaranteed-
bandwidth=221162(kbps)
                        max-bandwidth=294883(kbps)      current-bandwidth=0(kbps)
                        priority=medium         forwarded_bytes=0
                        dropped_packets=0       dropped_bytes=0
        class-id=4      allocated-bandwidth=442325(kbps)        guaranteed-
bandwidth=147441(kbps)
                        max-bandwidth=442325(kbps)      current-bandwidth=0(kbps)
                        priority=high   forwarded_bytes=0
                        dropped_packets=0       dropped_bytes=0
------------------------------------------------------
name=hub-phase1_1 ver=2 serial=d 172.16.200.1:0->172.16.200.2:0 tun_id=172.16.200.2 dst_
mtu=1500 dpd-link=on remote_location=0.0.0.0 weight=1
...
egress traffic control:
        bandwidth=726813(kbps) lock_hit=0 default_class=2 n_active_class=3
        class-id=2      allocated-bandwidth=72681(kbps)         guaranteed-
bandwidth=72681(kbps)
                        max-bandwidth=72681(kbps)       current-bandwidth=0(kbps)
                        priority=low    forwarded_bytes=123
                        dropped_packets=0       dropped_bytes=0
        class-id=3      allocated-bandwidth=218044(kbps)        guaranteed-
bandwidth=218043(kbps)
                        max-bandwidth=290725(kbps)      current-bandwidth=0(kbps)
```

```
                        priority=medium         forwarded_bytes=0
                        dropped_packets=0       dropped_bytes=0
        class-id=4      allocated-bandwidth=436087(kbps)        guaranteed-
bandwidth=145362(kbps)
                        max-bandwidth=436087(kbps)      current-bandwidth=0(kbps)
                        priority=high   forwarded_bytes=0
                        dropped_packets=0       dropped_bytes=0
```

5. Speed test results can be cached, indexed, and written to disk:

```
# diagnose test application forticron 10
Speed test results:
1: vdom=root, phase1intf=hub-phase1, peer-id='spoke11-p1', bandwidth=737210, last_
log=1624226603
2: vdom=root, phase1intf=hub-phase1, peer-id='spoke21-p1', bandwidth=726813, last_
log=1624226614

# diagnose test application forticron 11
Write 2 logs to disk.

# diagnose test application forticron 12
load 2 results.
```

Disable then reenable the IPsec VPN tunnel and the cached speed test results can be applied to the tunnel again:

```
# diagnose vpn tunnel list
------------------------------------------------------
name=hub-phase1_0 ver=2 serial=c 172.16.200.1:0->172.16.200.4:0 tun_id=172.16.200.4 dst_
mtu=1500 dpd-link=on remote_location=0.0.0.0 weight=1
...
egress traffic control:
        bandwidth=737210(kbps) lock_hit=0 default_class=2 n_active_class=3
------------------------------------------------------
name=hub-phase1_1 ver=2 serial=d 172.16.200.1:0->172.16.200.2:0 tun_id=172.16.200.2 dst_
mtu=1500 dpd-link=on remote_location=0.0.0.0 weight=1
...
egress traffic control:
        bandwidth=726813(kbps) lock_hit=0 default_class=2 n_active_class=3
```

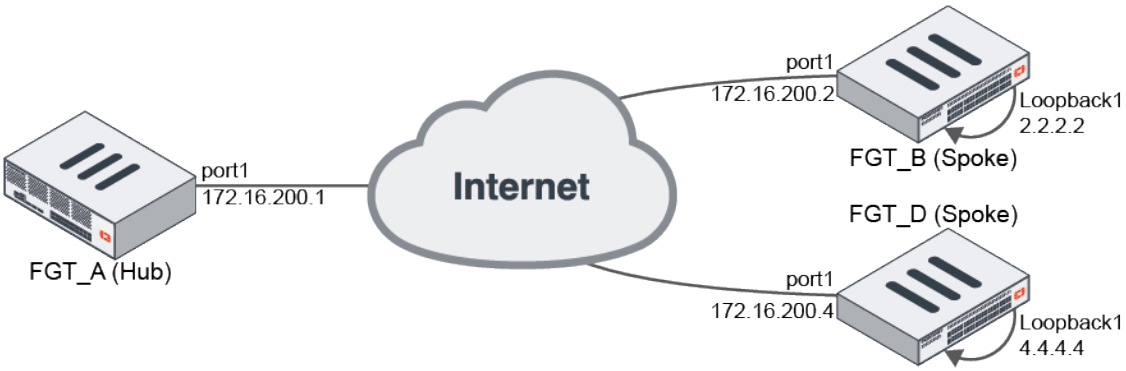
Interface based QoS on individual child tunnels based on speed test results

In a hub and spoke SD-WAN topology that uses dial-up VPN overlays, QoS can be applied on individual tunnels based on the measured bandwidth between the hub and spokes. The FortiGate can use the built in speed test to dynamically populate the egress bandwidth to individual dial-up tunnels from the hub.

A bandwidth limit, derived from the speed test, and a traffic shaping profile can be applied on the dial-up IPsec tunnel interface on the hub. A class ID and percentage based QoS settings can be applied to individual child tunnels using a traffic shaping policy and profile.

CLI commands

If the interface is an IPsec dial-up server, then egress shaping profile type can only be set to `policing`; it cannot be set to `queuing`:



```
config firewall shaping-profile
    edit <profile-name>
```

```
        set type policing
    next
end
```

The outbandwidth value is dynamically obtained from the speed test results for each individual child tunnel, and should not be set manually:

```
config system interface
    edit <dialup-server-phase1-name>
        set egress-shaping-profile <profile-name>
        set outbandwidth <bandwidth>
    next
end
```

Example

In this example, the hub is configured as a VPN dial-up server and both of the spokes are connected to the hub. It is assumed that the VPN configuration is already done, with a dynamic gateway type and kernel device creation (`net-device`) disabled. Only one SD-WAN interface is used, so there is only one VPN overlay member in the SD-WAN zone. Multiple WAN interfaces and VPN overlays could be used.

The VPN interfaces and IP addresses are:

FortiGate	Interface	IP Address
FGT_A (Hub)	hub-phase1	10.10.100.254
FGT_B (Spoke)	spoke11-p1	10.10.100.2
FGT_D (Spoke)	spoke21-p1	10.10.100.3

The hub VPN has two child tunnels, one to each spoke.

The speed test configuration is shown in Speed tests run from the hub to the spokes in dial-up IPsec tunnels on page 815. This example shows applying a shaping profile to the hub's tunnel interface in order to apply interface based traffic shaping to the child tunnels.

A traffic shaping policy is used to match and assign traffic to the classes in the shaping profile.

To configure the hub FortiGate (FGT_A) and check the results:

1. Configure the hub FortiGate (FGT_A) as in Speed tests run from the hub to the spokes in dial-up IPsec tunnels on page 815.

2. Configure the shaping profile:

```
config firewall shaping-profile
    edit "profile_1"
        config shaping-entries
            edit 1
                set class-id 2
                set priority low
                set guaranteed-bandwidth-percentage 10
                set maximum-bandwidth-percentage 10
            next
            edit 2
                set class-id 3
                set priority medium
                set guaranteed-bandwidth-percentage 30
                set maximum-bandwidth-percentage 40
            next
            edit 3
                set class-id 4
                set priority high
                set guaranteed-bandwidth-percentage 20
                set maximum-bandwidth-percentage 60
            next
        end
        set default-class-id 2
    next
end
```

3. Configure a traffic shaping policy:

```
config firewall shaping-policy
    edit 2
        set service "ALL"
        set schedule "always"
        set dstintf "hub-phase1"
        set class-id 3
        set srcaddr "all"
        set dstaddr "all"
    next
end
```

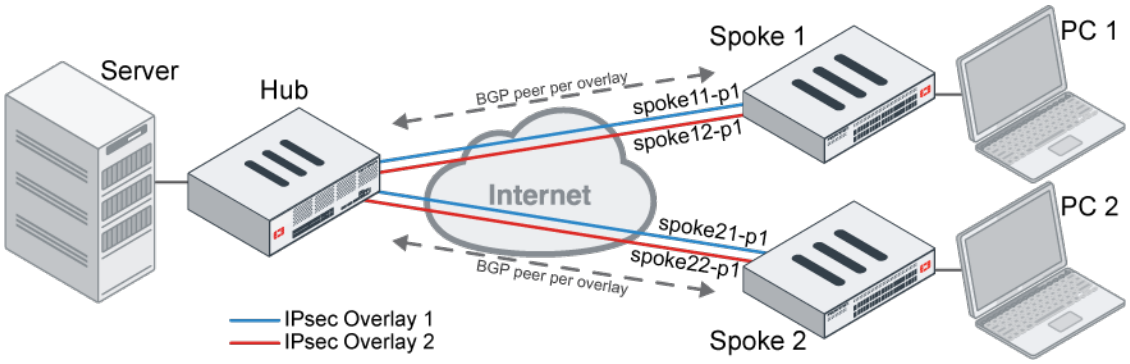
In this example, all traffic through the hub-phase1 interface is put into class ID 3. Class IDs an be assigned based on your traffic requirements.

4. At the schedules time, the speed test will start for the hub-phase1 interface from the hub to the spokes. The speed test results can then be dynamically applied on individual child tunnels as egress traffic shaping, and the class ID percentage based QoS settings is applicable on them as templates.

```
# diagnose vpn tunnel list
------------------------------------------------------
name=hub-phase1_0 ver=2 serial=c 172.16.200.1:0->172.16.200.4:0 tun_id=172.16.200.4 dst_
mtu=1500 dpd-link=on remote_location=0.0.0.0 weight=1
...
egress traffic control:
        bandwidth=737210(kbps) lock_hit=0 default_class=2 n_active_class=3
        class-id=2      allocated-bandwidth=73720(kbps)         guaranteed-
bandwidth=73720(kbps)
                        max-bandwidth=73720(kbps)       current-bandwidth=0(kbps)
```

```
                        priority=low    forwarded_bytes=52
                        dropped_packets=0       dropped_bytes=0
        class-id=3      allocated-bandwidth=221163(kbps)        guaranteed-
bandwidth=221162(kbps)
                        max-bandwidth=294883(kbps)      current-bandwidth=0(kbps)
                        priority=medium         forwarded_bytes=0
                        dropped_packets=0       dropped_bytes=0
        class-id=4      allocated-bandwidth=442325(kbps)        guaranteed-
bandwidth=147441(kbps)
                        max-bandwidth=442325(kbps)      current-bandwidth=0(kbps)
                        priority=high   forwarded_bytes=0
                        dropped_packets=0       dropped_bytes=0
----------------------------------------------------
name=hub-phase1_1 ver=2 serial=d 172.16.200.1:0->172.16.200.2:0 tun_id=172.16.200.2 dst_
mtu=1500 dpd-link=on remote_location=0.0.0.0 weight=1
...
egress traffic control:
        bandwidth=726813(kbps) lock_hit=0 default_class=2 n_active_class=3
        class-id=2      allocated-bandwidth=72681(kbps)         guaranteed-
bandwidth=72681(kbps)
                        max-bandwidth=72681(kbps)       current-bandwidth=0(kbps)
                        priority=low    forwarded_bytes=123
                        dropped_packets=0       dropped_bytes=0
        class-id=3      allocated-bandwidth=218044(kbps)        guaranteed-
bandwidth=218043(kbps)
                        max-bandwidth=290725(kbps)      current-bandwidth=0(kbps)
                        priority=medium         forwarded_bytes=0
                        dropped_packets=0       dropped_bytes=0
        class-id=4      allocated-bandwidth=436087(kbps)        guaranteed-
bandwidth=145362(kbps)
                        max-bandwidth=436087(kbps)      current-bandwidth=0(kbps)
                        priority=high   forwarded_bytes=0
                        dropped_packets=0       dropped_bytes=0
```

The guaranteed and maximum bandwidths equal 10% of the speed test result, as expected.



SD-WAN in large scale deployments

Phase 2 selectors can be used to inject IKE routes on the ADVPN shortcut tunnel. When configuration method (`mode-cfg`) is enabled in IPsec phase 1 configuration, enabling `mode-cfg-allow-client-selector` allows custom phase 2 selectors to be configured. By also enabling the addition of a route to the peer destination selector (`add-route`) in the phase 1 configuration, IKE routes based on the phase 2 selectors can be injected. This means that routes do not need to be reflected on the hub to propagate them between spokes, avoiding possible BGP daemon process load issues and improving network scalability in a large-scale ADVPN network.

Route map rules can apply priorities to BGP routes. On the hub, priorities can be set in a route map's rules, and the route map can be applied on BGP routes. This allows the hub to mark the preferred path learned from the spokes with a priority value (lower priority is preferred), instead of using multiple SD-WAN policy routes on the hub. When a preferred outbound route map (`route-map-out-preferable`) is also configured in an SD-WAN neighbor on the spoke, deploying SD-WAN rules on the hub to steer traffic from the hub to a spoke is unnecessary.

SD-WAN members' local cost can be exchanged on the ADVPN shortcut tunnel so that spokes can use the remote cost as tiebreak to select a preferred shortcut. If multiple shortcuts originate from the same member to different members on

the same remote spoke, then the remote cost on the shortcuts is used as the tiebreak to decide which shortcut is preferred.

In this example, SD-WAN is configured on an ADVPN network with a BGP neighbor per overlay.

Instead of reflecting BGP routes with the route-reflector on the hub, when the shortcuts are triggered, IKE routes on the shortcuts are directly injected based on the configured phase 2 selectors to allow routes to be exchanged between spokes.

Routes between the hub and the spokes are exchanged by BGP, and the spokes use the default route to send spoke-to-spoke traffic to the hub and trigger the shortcuts.

Instead of configuring SD-WAN rules on the hub, different priorities are configured on the BGP routes by matching different BGP communities to steer traffic from the hub to the spokes.

To configure Spoke 1:

1. Configure phase 1:

```
config vpn ipsec phase1-interface
    edit "spoke11-p1"
        ...
        set ike-version 2
        set net-device enable
        set add-route enable
        set mode-cfg enable
        set auto-discovery-receiver enable
        set mode-cfg-allow-client-selector enable
        set link-cost 11
        ...
    next
    edit "spoke12-p1"
       ...
        set ike-version 2
        set net-device enable
        set add-route enable
        set mode-cfg enable
        set auto-discovery-receiver enable
        set mode-cfg-allow-client-selector enable
        set link-cost 21
    next
end
```

2. Configure phase 2:

```
config vpn ipsec phase2-interface
    edit "spoke11-p2"
        ...
        set src-name "LAN_Net"
        set dst-name "all"
    next
    edit "spoke12-p2"
        ...
        set src-name "LAN_Net"
        set dst-name "all"
    next
end
```

3. Configure an address group:

   Spoke 1 uses LAN subnet 10.1-3.100.0/24.

```
config firewall addrgrp
    edit "LAN_Net"
        set member "10.1.100.0" "10.2.100.0" "10.3.100.0"
    next
end
```

4. Configure route maps:
   - If overlay 1 to the hub is in SLA, attach "65000:1" to the BGP routes advertised to the hub over overlay 1.
   - If overlay 2 to the hub is in SLA, attach "65000:2" to the BGP routes advertised to the hub over overlay 2.
   - If any overlay to the hub is out of SLA, attach "65000:9999" to the BGP routes advertised to the hub over any overlay.

```
config router route-map
    edit "HUB_CARRIER1"
        config rule
            edit 1
                set set-community "65000:1"
                ...
            next
        end
        ...
    next
    edit "HUB_CARRIER2"
        config rule
            edit 1
                set set-community "65000:2"
                ...
            next
        end
        ...
    next
    edit "HUB_BAD"
        config rule
            edit 1
                set set-community "65000:9999"
                ...
            next
        end
        ...
```

```
    next
end
```

5. Configure BGP and SD-WAN members and neighbors:

```
config router bgp
    set as 65412
    config neighbor
        edit "10.10.15.253"
            set remote-as 65412
            set route-map-out "HUB_BAD"
            set route-map-out-preferable "HUB_CARRIER1"
            ...
        next
        edit "10.10.16.253"
            set remote-as 65412
            set route-map-out "HUB_BAD"
            set route-map-out-preferable "HUB_CARRIER2"
            ...
        next
    end
end
```

```
config system sdwan
    config members
        edit 1
            set interface "spoke11-p1"
            set cost 10
        next
        edit 2
            set interface "spoke12-p1"
            set cost 20
        next
    end
    config neighbor
        edit "10.10.15.253"
            set member 1
            set health-check "1"
            set sla-id 1
        next
        edit "10.10.16.253"
            set member 2
            set health-check "11"
            set sla-id 1
        next
    end
end
```

To configure Spoke 2:

1. Configure phase 1:

```
config vpn ipsec phase1-interface
    edit "spoke21-p1"
        ...
        set ike-version 2
        set net-device enable
```

```
            set add-route enable
            set mode-cfg enable
            set auto-discovery-receiver enable
            set mode-cfg-allow-client-selector enable
            set link-cost 101
            ...
        next
        edit "spoke22-p1"
           ...
            set ike-version 2
            set net-device enable
            set add-route enable
            set mode-cfg enable
            set auto-discovery-receiver enable
            set mode-cfg-allow-client-selector enable
            set link-cost 201
        next
    end
```

2. Configure phase 2:

```
config vpn ipsec phase2-interface
    edit "spoke21-p2"
        ...
        set src-name "LAN_Net"
        set dst-name "all"
    next
    edit "spoke22-p2"
        ...
        set src-name "LAN_Net"
        set dst-name "all"
    next
end
```

3. Configure an address group:

   Spoke 2 uses LAN subnet 192.168.5-7.0/24.

```
config firewall addrgrp
    edit "LAN_Net"
        set member "192.168.5.0" "192.168.6.0" "192.168.7.0"
    next
end
```

4. Configure route maps:
   - If overlay 1 to the hub is in SLA, attach "65000:1" to the BGP routes advertised to the hub over overlay 1.
   - If overlay 2 to the hub is in SLA, attach "65000:2" to the BGP routes advertised to the hub over overlay 2.
   - If any overlay to the hub is out of SLA, attach "65000:9999" to the BGP routes advertised to the hub over any overlay.

```
config router route-map
    edit "HUB_CARRIER1"
        config rule
            edit 1
                set set-community "65000:1"
                ...
            next
        end
```

```
        ...
    next
    edit "HUB_CARRIER2"
        config rule
            edit 1
                set set-community "65000:2"
                ...
            next
        end
        ...
    next
    edit "HUB_BAD"
        config rule
            edit 1
                set set-community "65000:9999"
                ...
            next
        end
        ...
    next
end
```

5. Configure BGP and SD-WAN members and neighbors:

```
config router bgp
    set as 65412
    config neighbor
        edit "10.10.15.253"
            set remote-as 65412
            set route-map-out "HUB_BAD"
            set route-map-out-preferable "HUB_CARRIER1"
            ...
        next
        edit "10.10.16.253"
            set remote-as 65412
            set route-map-out "HUB_BAD"
            set route-map-out-preferable "HUB_CARRIER2"
            ...
        next
    end
end
```

```
config system sdwan
    config members
        edit 1
            set interface "spoke21-p1"
            set cost 10
        next
        edit 2
            set interface "spoke22-p1"
            set cost 20
        next
    end
    config neighbor
        edit "10.10.15.253"
            set member 1
            set health-check "1"
```

```
            set sla-id 1
        next
        edit "10.10.16.253"
            set member 2
            set health-check "11"
            set sla-id 1
        next
    end
end
```

To configure the hub:

1. Configure the route maps:
   - Set the priority to 100 for routes with community 65000:1, indicating that they are in SLA for overlay 1.
   - Set the priority to 200 for routes with community 65000:2, indicating that they are in SLA for overlay 2.
   - Set the priority to 9999 for routes with community 65000:9999, indicating that they are out of SLA for any overlay.

```
config router route-map
     edit "Set_Pri"
        config rule
            edit 1
                set match-community "comm_65000:1"
                set set-priority 100
            next
            edit 2
                set match-community "comm_65000:2"
                set set-priority 200
            next
            edit 3
                set match-community "comm_65000:9999"
                set set-priority 9999
            next
        end
    next
end
```

2. Configure BGP:

```
config router bgp
    set as 65412
    config neighbor-group
        edit "advpn"
            set remote-as 65412
            set route-map-in "Set_Pri"
            ...
        next
        edit "advpn2"
            set remote-as 65412
            set route-map-in "Set_Pri"
            ...
        next
    end
    config neighbor-range
        edit 1
            set prefix 10.10.15.0 255.255.255.0
```

```
            set neighbor-group "advpn"
        next
        edit 2
            set prefix 10.10.16.0 255.255.255.0
            set neighbor-group "advpn2"
        next
    end
end
```

To test the configuration:

1. Check the routing tables on the spokes:

   Spoke 1:

```
spoke-1 (root) # get router info routing-table all
B*      0.0.0.0/0 [200/0] via 10.10.15.253 (recursive is directly connected, spoke11-
p1), 00:01:17, [1/0]          // default route to hub
                          [200/0] via 10.10.16.253 (recursive is directly connected,
spoke12-p1), 00:01:17, [1/0]
B       9.0.0.0/24 [200/0] via 10.10.15.253 (recursive is directly connected, spoke11-
p1), 00:01:17, [1/0]         // route to the server behind hub
                           [200/0] via 10.10.16.253 (recursive is directly connected,
spoke12-p1), 00:01:17, [1/0]
C       10.1.100.0/24 is directly connected, port2             // route to PC 1
C       10.10.15.0/24 is directly connected, spoke11-p1        // overlay 1
C       10.10.15.1/32 is directly connected, spoke11-p1
C       10.10.16.0/24 is directly connected, spoke12-p1        // overlay 2
C       10.10.16.1/32 is directly connected, spoke12-p1
```

   Spoke 2:

```
spoke-2 (root) # get router info routing-table all
B*      0.0.0.0/0 [200/0] via 10.10.15.253 (recursive is directly connected, spoke21-
p1), 00:46:14, [1/0]          // default route to hub
                          [200/0] via 10.10.16.253 (recursive is directly connected,
spoke22-p1), 00:46:14, [1/0]
B       9.0.0.0/24 [200/0] via 10.10.15.253 (recursive is directly connected, spoke21-
p1), 00:46:18, [1/0]         // route to the server behind hub
                           [200/0] via 10.10.16.253 (recursive is directly connected,
spoke22-p1), 00:46:18, [1/0]
C       10.10.15.0/24 is directly connected, spoke21-p1        // overlay 1
C       10.10.15.2/32 is directly connected, spoke21-p1
C       10.10.16.0/24 is directly connected, spoke22-p1        // overlay 2
C       10.10.16.2/32 is directly connected, spoke22-p1
C       192.168.5.0/24 is directly connected, port2            // route to PC 2
```

2. Send traffic from PC 1 to PC 2 and trigger the shortcut:

   The IKE routes on the shortcut are directly injected based on the phase 2 selectors, and spoke-to-spoke traffic then goes directly through the shortcut instead of going through the hub.

   Spoke 1:

```
spoke-1 (root) # get router info routing-table static
S       192.168.5.0/24 [15/0] via spoke11-p1_0 tunnel 172.16.200.4 vrf 0, [1/0]
S       192.168.6.0/24 [15/0] via spoke11-p1_0 tunnel 172.16.200.4 vrf 0, [1/0]
S       192.168.7.0/24 [15/0] via spoke11-p1_0 tunnel 172.16.200.4 vrf 0, [1/0]
```

```
spoke-1 (root) # diagnose sniffer packet any 'host 192.168.5.44' 4
interfaces=[any]
filters=[host 192.168.5.44]
1.446306 port2 in 10.1.100.22 -> 192.168.5.44: icmp: echo request
1.446327 spoke11-p1_0 out 10.1.100.22 -> 192.168.5.44: icmp: echo request
1.446521 spoke11-p1_0 in 192.168.5.44 -> 10.1.100.22: icmp: echo reply
1.446536 port2 out 192.168.5.44 -> 10.1.100.22: icmp: echo reply
```

Spoke 2:

```
spoke-2 (root) # get router info routing-table static
S       10.1.100.0/24 [15/0] via spoke21-p1_0 tunnel 10.10.15.1 vrf 0, [1/0]
S       10.2.100.0/24 [15/0] via spoke21-p1_0 tunnel 10.10.15.1 vrf 0, [1/0]
S       10.3.100.0/24 [15/0] via spoke21-p1_0 tunnel 10.10.15.1 vrf 0, [1/0]
```

3. Confirm that the overlays are in SLA on the spokes:

   Spoke 1:

```
spoke-1 (root) # diagnose sys sdwan  neighbor
Neighbor(10.10.15.253): member(1)role(standalone)
        Health-check(1:1)  sla-pass selected alive
Neighbor(10.10.16.253): member(2)role(standalone)
        Health-check(11:1)  sla-pass selected alive
```

   Spoke 2:

```
spoke-2 (root) # diagnose sys sdwan neighbor
Neighbor(10.10.15.253): member(1)role(standalone)
        Health-check(1:1)  sla-pass selected alive
Neighbor(10.10.16.253): member(2)role(standalone)
        Health-check(11:1)  sla-pass selected alive
```

4. On the hub, check that the routes received from the spokes have the expected priorities:

```
hub (root) # diagnose ip route list | grep proto=11
tab=254 vf=0 scope=0 type=1 proto=11 prio=100 0.0.0.0/0.0.0.0/0->10.1.100.0/24
pref=0.0.0.0 gwy=10.10.15.1 dev=101(hub-phase1)
tab=254 vf=0 scope=0 type=1 proto=11 prio=200 0.0.0.0/0.0.0.0/0->10.1.100.0/24
pref=0.0.0.0 gwy=10.10.16.1 dev=102(hub2-phase1)
tab=254 vf=0 scope=0 type=1 proto=11 prio=100 0.0.0.0/0.0.0.0/0->192.168.5.0/24
pref=0.0.0.0 gwy=10.10.15.2 dev=101(hub-phase1)
tab=254 vf=0 scope=0 type=1 proto=11 prio=200 0.0.0.0/0.0.0.0/0->192.168.5.0/24
pref=0.0.0.0 gwy=10.10.16.2 dev=102(hub2-phase1)
```

   The priority set by the hub's route map is based on the community string received from the spoke. The route with a lower priority value is selected, so traffic to Spoke 1 goes out on the hub-phase1 tunnel:

```
hub (root) # diagnose sniffer packet any 'host 9.0.0.2' 4
interfaces=[any]
filters=[host 9.0.0.2]
2.735456 R190 in 9.0.0.2 -> 10.1.100.22: icmp: echo request
2.735508 hub-phase1 out 9.0.0.2 -> 10.1.100.22: icmp: echo request
2.735813 hub-phase1 in 10.1.100.22 -> 9.0.0.2: icmp: echo reply
2.735854 R190 out 10.1.100.22 -> 9.0.0.2: icmp: echo reply
```

5. If overlay 1 goes out of SLA, the priorities of the routes on the hub are updated and traffic from the hub to Spoke 1 goes through overlay 2:

   Spoke 1:

```
spoke-1 (root) # diagnose sys sdwan  neighbor
Neighbor(10.10.15.253): member(1)role(standalone)
        Health-check(1:1)  sla-fail alive
Neighbor(10.10.16.253): member(2)role(standalone)
        Health-check(11:1)  sla-pass selected alive
```

Spoke 2:

```
spoke-2 (root) # diagnose sys sdwan neighbor
Neighbor(10.10.15.253): member(1)role(standalone)
        Health-check(1:1)  sla-fail alive
Neighbor(10.10.16.253): member(2)role(standalone)
        Health-check(11:1)  sla-pass selected alive
```

Hub:

```
hub (root) # diagnose ip route list | grep proto=11
tab=254 vf=0 scope=0 type=1 proto=11 prio=200 0.0.0.0/0.0.0.0/0->10.1.100.0/24
pref=0.0.0.0 gwy=10.10.16.1 dev=102(hub2-phase1)
tab=254 vf=0 scope=0 type=1 proto=11 prio=9999 0.0.0.0/0.0.0.0/0->10.1.100.0/24
pref=0.0.0.0 gwy=10.10.15.1 dev=101(hub-phase1)
tab=254 vf=0 scope=0 type=1 proto=11 prio=200 0.0.0.0/0.0.0.0/0->192.168.5.0/24
pref=0.0.0.0 gwy=10.10.16.2 dev=102(hub2-phase1)
tab=254 vf=0 scope=0 type=1 proto=11 prio=9999 0.0.0.0/0.0.0.0/0->192.168.5.0/24
pref=0.0.0.0 gwy=10.10.15.2 dev=101(hub-phase1)
```

```
hub (root) # diagnose sniffer packet any 'host 9.0.0.2' 4
interfaces=[any]
filters=[host 9.0.0.2]
3.550181 R190 in 9.0.0.2 -> 10.1.100.22: icmp: echo request
3.550234 hub2-phase1 out 9.0.0.2 -> 10.1.100.22: icmp: echo request
3.550713 hub2-phase1 in 10.1.100.22 -> 9.0.0.2: icmp: echo reply
3.550735 R190 out 10.1.100.22 -> 9.0.0.2: icmp: echo reply
```

6. Verify the service diagnostics on Spoke 1:

```
# diagnose sys sdwan service

Service(1): Address Mode(IPV4) flags=0x200 use-shortcut-sla
 Tie break: cfg
  Gen(4), TOS(0x0/0x0), Protocol(0: 1->65535), Mode(sla), sla-compare-order
  Members(2):
    1: Seq_num(1 spoke11-p1), alive, sla(0x1), gid(0), cfg_order(0), local cost(10),
selected
    2: Seq_num(2 spoke12-p1), alive, sla(0x1), gid(0), cfg_order(1), local cost(20),
selected
  Src address(1):
        10.1.100.0-10.1.100.255

  Dst address(1):
        0.0.0.0-255.255.255.255
```

7. Verify the service diagnostics on Spoke 2:

```
# diagnose sys sdwan service

Service(1): Address Mode(IPV4) flags=0x200 use-shortcut-sla
 Tie break: cfg
  Gen(2), TOS(0x0/0x0), Protocol(0: 1->65535), Mode(sla), sla-compare-order
```

```
  Members(2):
    1: Seq_num(1 spoke21-p1), alive, sla(0x1), gid(0), cfg_order(0), local cost(10),
selected
    2: Seq_num(2 spoke22-p1), alive, sla(0x1), gid(0), cfg_order(1), local cost(20),
selected
  Src address(1):
        192.168.5.0-192.168.5.255

  Dst address(1):
        0.0.0.0-255.255.255.255
```

8. Trigger shortcuts between Spoke 1 and Spoke 2:
   - Shortcuts spoke11-p1_1 and spoke11-p1_0 originate from spoke11-p1.
   - spoke11-p1_1 corresponds to spoke21-p1_0 on Spoke 2.
   - spoke11-p1_0 corresponds to spoke22-p1_0 on Spoke 2.

   Spoke 1:

```
# diagnose sys sdwan service

Service(1): Address Mode(IPV4) flags=0x200 use-shortcut-sla
 Tie break: cfg
  Gen(11), TOS(0x0/0x0), Protocol(0: 1->65535), Mode(sla), sla-compare-order
  Member sub interface(4):
    3: seq_num(1), interface(spoke11-p1):
       1: spoke11-p1_0(80)
       2: spoke11-p1_1(81)
  Members(4):
    1: Seq_num(1 spoke11-p1_1), alive, sla(0x1), gid(0), remote cost(101), cfg_order(0),
local cost(10), selected
    2: Seq_num(1 spoke11-p1_0), alive, sla(0x1), gid(0), remote cost(201), cfg_order(0),
local cost(10), selected
    3: Seq_num(1 spoke11-p1), alive, sla(0x1), gid(0), cfg_order(0), local cost(10),
selected
    4: Seq_num(2 spoke12-p1), alive, sla(0x1), gid(0), cfg_order(1), local cost(20),
selected
  Src address(1):
        10.1.100.0-10.1.100.255

  Dst address(1):
        0.0.0.0-255.255.255.255
```

   Spoke 2:

```
# diagnose sys sdwan service

Service(1): Address Mode(IPV4) flags=0x200 use-shortcut-sla
 Tie break: cfg
  Gen(15), TOS(0x0/0x0), Protocol(0: 1->65535), Mode(sla), sla-compare-order
  Member sub interface(4):
    2: seq_num(1), interface(spoke21-p1):
       1: spoke21-p1_0(75)
    4: seq_num(2), interface(spoke22-p1):
       1: spoke22-p1_0(74)
  Members(4):
    1: Seq_num(1 spoke21-p1_0), alive, sla(0x1), gid(0), remote cost(11), cfg_order(0),
local cost(10), selected
```

```
    2: Seq_num(1 spoke21-p1), alive, sla(0x1), gid(0), cfg_order(0), local cost(10),
selected
    3: Seq_num(2 spoke22-p1_0), alive, sla(0x1), gid(0), remote cost(11), cfg_order(1),
local cost(20), selected
    4: Seq_num(2 spoke22-p1), alive, sla(0x1), gid(0), cfg_order(1), local cost(20),
selected
  Src address(1):
        192.168.5.0-192.168.5.255

  Dst address(1):
        0.0.0.0-255.255.255.255
```

The spoke11-p1_1 shortcut on Spoke 1 is preferred over spoke11-p1_0 due to the lower remote link cost of 101 when they have the same local SD-WAN member cost of 10.

9. Verify the policy route list on Spoke 1:

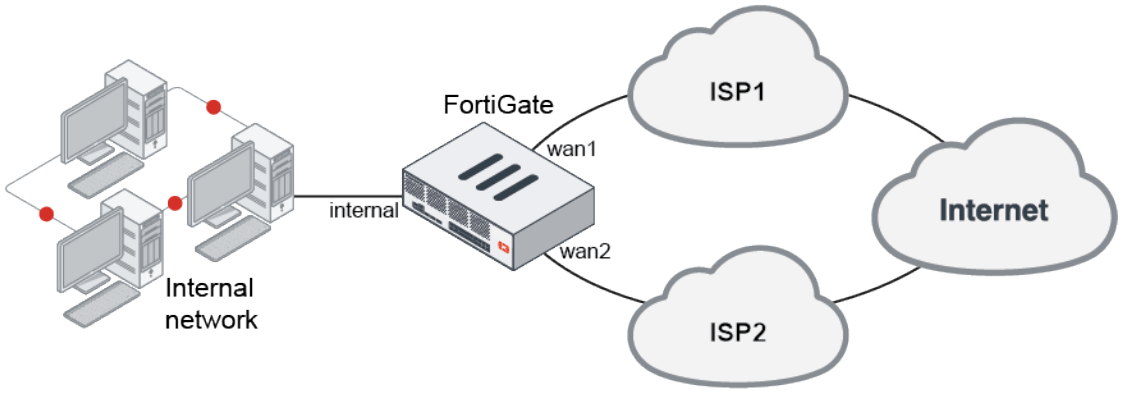
```
# diagnose firewall proute list
list route policy info(vf=root):

id=2131755009(0x7f100001) vwl_service=1(1) vwl_mbr_seq=1 1 1 2 dscp_tag=0xfc 0xfc
flags=0x0 tos=0x00 tos_mask=0x00 protocol=0 sport=0-65535 iif=0(any) dport=1-65535 path
(4) oif=81(spoke11-p1_1) oif=80(spoke11-p1_0) oif=54(spoke11-p1) oif=55(spoke12-p1)
source(1): 10.1.100.0-10.1.100.255
destination(1): 0.0.0.0-255.255.255.255
hit_count=176 last_used=2022-07-12 11:56:08
```

Advanced configuration

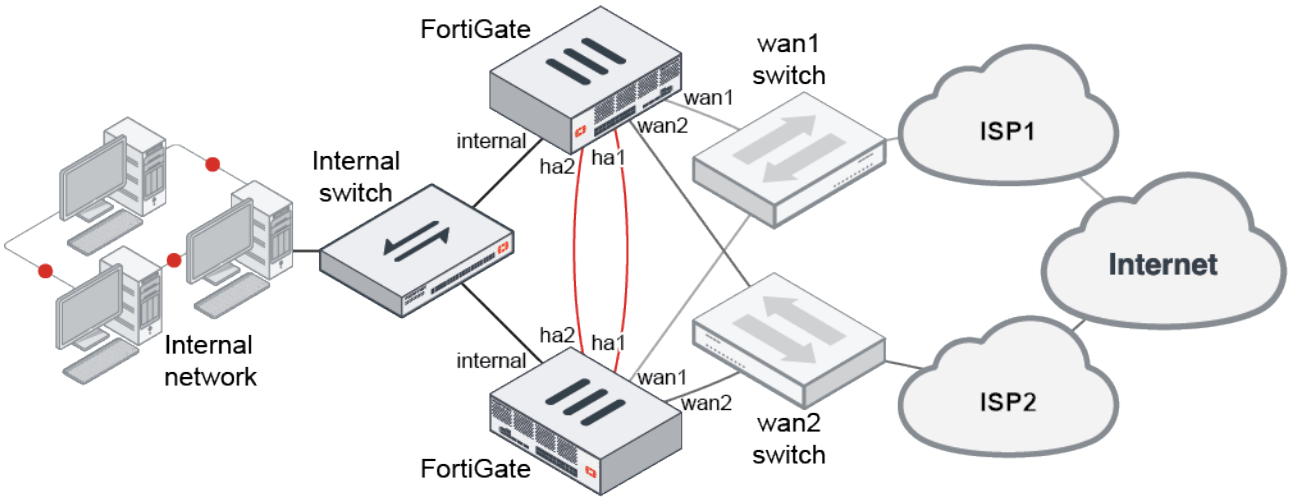
The following topics provide instructions on SD-WAN advanced configuration:

- SD-WAN with FGCP HA on page 836
- Configuring SD-WAN in an HA cluster using internal hardware switches on page 843
- SD-WAN configuration portability on page 847
- SD-WAN segmentation over a single overlay on page 853
- Matching BGP extended community route targets in route maps on page 868
- Copying the DSCP value from the session original direction to its reply direction on page 873



See also Packet distribution for aggregate static IPsec tunnels in SD-WAN on page 1734.

SD-WAN with FGCP HA



This example shows how to convert a standalone FortiGate SD-WAN solution to a FGCP HA cluster with full-mesh WAN set up. This configuration allows you to load balance your internet traffic between multiple ISP links. It also provides redundancy for your internet connection if your primary ISP in unavailable, or if one of the FortiGates in the HA cluster fails.

This example assumes that a standalone FortiGate has already been configured for SD-WAN by following the SD-WAN quick start on page 632.

Standalone FortiGate:

FGCP HA cluster:

The following devices are required to convert the topology to HA:

- A second FortiGate that is the same model running the same firmware version.
- Two switches for connecting each FortiGate's WAN interface to the corresponding ISP modem.

Before you begin:

- Ensure that the licenses and subscriptions on both HA members match.
- Ensure that there are one or more ports reserved for HA heartbeat.
- Ensure you have physical access to both HA members.

Enabling HA and re-cabling the WAN interfaces will cause network interruptions. This procedure should be performed during a maintenance window.

Configuring the standalone FortiGate for HA

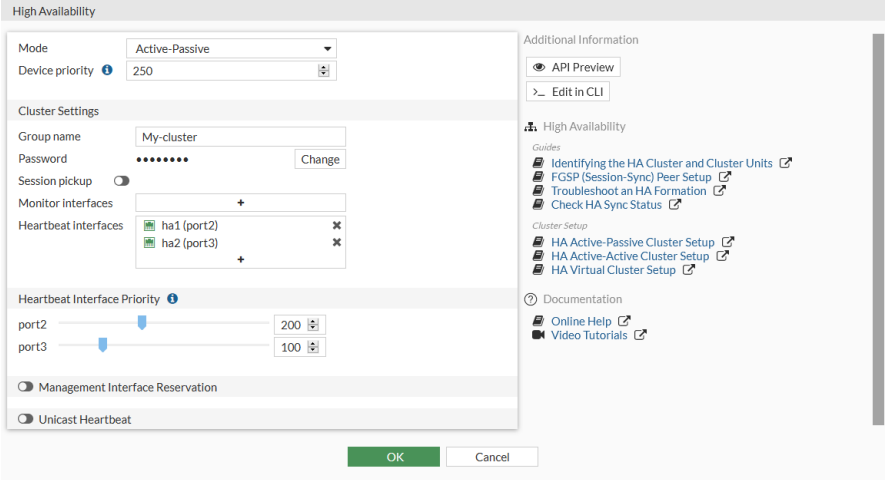
After running the following commands, the FortiGate negotiates to establish an HA cluster. You might temporarily lose connectivity with the FortiGate as FGCP negotiations take place and the MAC addresses of the FortiGate interfaces are changed to HA virtual MAC addresses.

This configurations sets the HA mode to active-passive.

The ha1 and ha2 interfaces are configured as the heartbeat interfaces, with priorities set to 200 and 100 respectively. Setting different priorities for the heartbeat interfaces is a best practice, but is not required.

If you have more than one cluster on the same network, each cluster should have a different group ID. Changing the group ID changes the cluster interface's virtual MAC addresses. If the group IP causes a MAC address conflict on your network, select a different group ID.

Enabling override and increasing the device priority means that this FortiGate always becomes the primary unit.



To configure the standalone FortiGate for HA in the GUI:

1. Go to *System* > *Settings* and change the *Host name* so that the FortiGate can be easily identified as the primary unit.
2. Go to *System* > *HA* and configure the following options:

Mode	Active-Passive
Device priority	250
Group name	My-cluster
Password	<password>
Heartbeat interfaces	ha1 and ha2
Heartbeat Interface Priority	**port2** (ha1): 200 **port3** (ha2): 100

Override and the group ID can only be configured from the CLI.

3. Click *OK*.
   Connectivity with the FortiGate will temporarily be lost.

To configure the standalone FortiGate for HA in the CLI:

1. Change the host name so that the FortiGate can be easily identified:

```
config system global
    set hostname primary_FG
end
```

2. Configure HA:

```
config system ha
    set mode a-p
    set group-id 100
    set group-name My-cluster
    set password <password>
    set priority 250
    set override enable
    set hbdev ha1 200 ha2 100
end
```

If HA mode does not start after running the above steps, ensure that none of the FortiGate's interfaces use DHCP or PPPoE addressing.

Configuring the secondary FortiGate for HA

The secondary FortiGate must be the same model and running the same firmware version as the primary FortiGate. The HA settings are the same as the for the primary unit, except the secondary device has a lower priority and override is not enabled.

It is best practice to reset the FortiGate to factory default settings prior to configuring HA. This reduces the chance of synchronization problems.

```
# execute factoryreset
This operation will reset the system to factory default!
Do you want to continue? (y/n) y
```

This is unnecessary if the device is new from the factory.

To configure the secondary FortiGate for HA in the GUI:

1. Go to *System* > *Settings* and change the *Host name* so that the FortiGate can be easily identified as the backup unit.
2. Go to *System* > *HA* and configure the options the same as for the primary FortiGate, except with a lower priority:

Mode	Active-Passive
Device priority	128
Group name	My-cluster
Password	<password>
Heartbeat interfaces	ha1 and ha2
Heartbeat Interface Priority	**port2** (ha1): 200 **port3** (ha2): 100

3. Click *OK*.

To configure the secondary FortiGate for HA in the CLI:

1. Change the host name so that the secondary FortiGate can be easily identified:

```
config system global
    set hostname secondary_FG
end
```

2. Configure HA:

```
config system ha
    set mode a-p
    set group-id 100
    set group-name My-cluster
    set password <password>
    set priority 128
    set hbdev ha1 200 ha2 100
end
```

Connecting the heartbeat interfaces between the FortiGates

To connect and check the heartbeat interfaces:

1. Connect the heartbeat interfaces ha1 and ha2 between the primary and secondary FortiGate.
   a. An HA primary device is selected. Because the primary FortiGate has a higher priority and override enabled, it assumes the role of HA primary.

b. The secondary FortiGate synchronizes its configuration from the primary device.

2. Verify that the checksums match between the primary and secondary FortiGates:

```
# diagnose sys ha checksum cluster

================== FG5H0XXXXXXXXX0 ==================

is_manage_primary()=1, is_root_primary()=1
debugzone
global: 2b e9 81 38 c2 9d 4f db b7 0e 1f 49 42 c6 1e fb
root: af a6 48 c5 c2 9a 8b 81 a5 53 fb 27 e9 ae 01 6a
all: 89 1f 63 77 48 8a 30 ee 57 06 ca eb 71 e6 8e ad

checksum
global: 2b e9 81 38 c2 9d 4f db b7 0e 1f 49 42 c6 1e fb
root: af a6 48 c5 c2 9a 8b 81 a5 53 fb 27 e9 ae 01 6a
all: 89 1f 63 77 48 8a 30 ee 57 06 ca eb 71 e6 8e ad

================== FG5H0XXXXXXXXX1 ==================

is_manage_primary()=0, is_root_primary()=0
debugzone
global: 2b e9 81 38 c2 9d 4f db b7 0e 1f 49 42 c6 1e fb
root: af a6 48 c5 c2 9a 8b 81 a5 53 fb 27 e9 ae 01 6a
all: 89 1f 63 77 48 8a 30 ee 57 06 ca eb 71 e6 8e ad

checksum
global: 2b e9 81 38 c2 9d 4f db b7 0e 1f 49 42 c6 1e fb
root: af a6 48 c5 c2 9a 8b 81 a5 53 fb 27 e9 ae 01 6a
all: 89 1f 63 77 48 8a 30 ee 57 06 ca eb 71 e6 8e ad
```

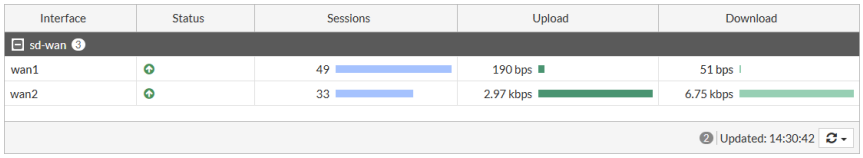
If all of the cluster members have identical checksums, then their configurations are synchronized. If the checksums are not the same, wait for a few minutes, then repeat the command. Some parts of the configuration might take a significant amount of time to synchronize (tens of minutes).

Connecting other traffic interfaces

After the device configurations are synchronized, you can connect the rest of the traffic interfaces. Making these connections will disrupt traffic as cables are disconnected and reconnected.

Switches must be used between the cluster and the ISPs, and between the cluster and the internal network, as shown in the topology diagram.

Checking cluster operations



The *HA Status* dashboard widget shows the synchronization status. Hover over the host names of each FortiGate in the widget to verify that they are synchronized and have the same checksum.

To view more information about the cluster status, including the number of sessions passing through the cluster members, go to *System* > *HA*.

See Check HA synchronization status on page 2366 for more information.

Results

1. Browse the internet on a computer in the internal network.
2. Go to *Network* > *SD-WAN* and select the *SD-WAN Zones* tab to see the bandwidth, volume, and sessions for traffic on the SD-WAN interfaces. See Results on page 637 for details.
3. Go to *Dashboard* > *Network*, and expand the *SD-WAN* widget to see information about each interface, such as the number of sessions and the bit rate.

Testing HA failover

All traffic should currently be flowing through the primary FortiGate. If it becomes unavailable, traffic fails over to the secondary FortiGate. When the primary FortiGate rejoins the cluster, the secondary FortiGate continues to operate as the primary FortiGate.

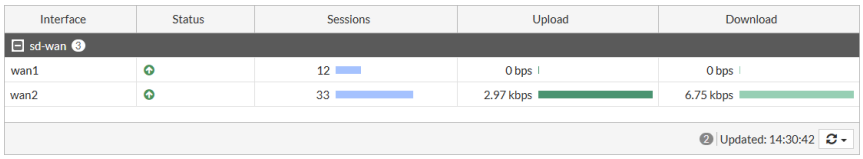
To test this, ping a reliable IP address from a computer in the internal network, and then power off the primary FortiGate.

There will be a momentary pause in the ping results until traffic diverts to the backup FortiGate, allowing the ping traffic to continue:

```
64 bytes from 184.25.76.114: icmp_seq=69 ttl=52 time=8.719 ms\
64 bytes from 184.25.76.114: icmp_seq=70 ttl=52 time=8.822 ms\
64 bytes from 184.25.76.114: icmp_seq=74 ttl=52 time=8.901 ms\
Request timeout for icmp_seq 75\
64 bytes from 184.25.76.114: icmp_seq=76 ttl=52 time=8.860 ms\
64 bytes from 184.25.76.114: icmp_seq=77 ttl=52 time=9.174 ms\
64 bytes from 184.25.76.114: icmp_seq=83 ttl=52 time=8.639 ms}
```

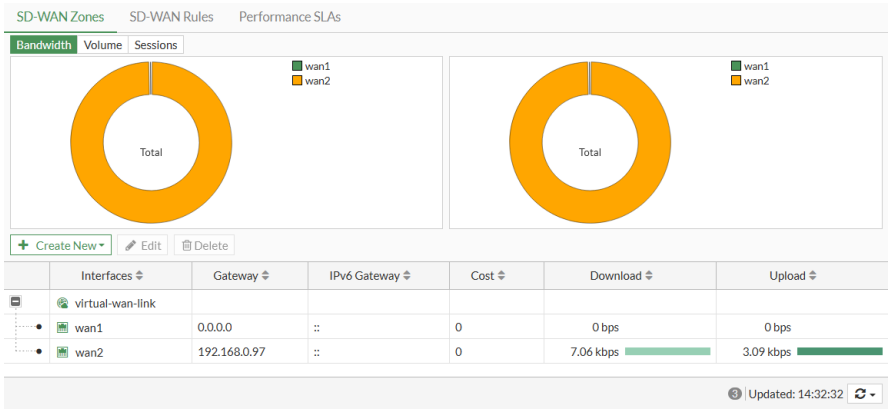
If you are using port monitoring, you can also unplug the primary FortiGate's internet facing interface to test failover.

After the secondary FortiGate becomes the primary, you can log into the cluster using the same IP address as before the fail over. If the primary FortiGate is powered off, you will be logged into the backup FortiGate. Check the host name to verify what device you have logged into. The FortiGate continues to operate in HA mode, and if you restart the primary FortiGate, it will rejoin the cluster and act as the backup FortiGate. Traffic is not disrupted when the restarted FortiGate rejoins the cluster.



You can also use the CLI to force an HA failover. See Force HA failover for testing and demonstrations on page 2392 for information.

Testing ISP failover



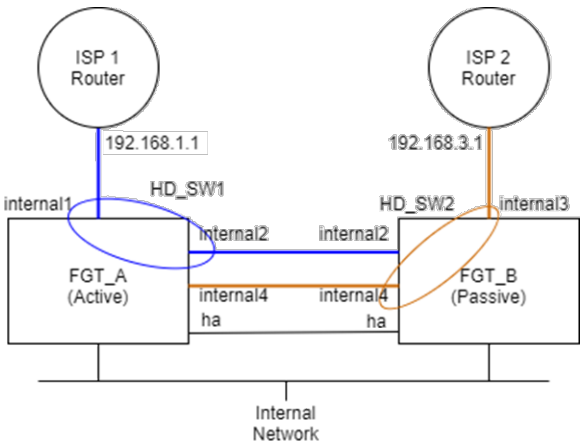
To test a failover of the redundant internet configuration, you need to simulate a failed internet connection to one of the ports. You can do this by disconnecting power from the wan1 switch, or by disconnecting the wan1 interfaces of both FortiGates from ISP1.

After disconnecting, verify that users still have internet access

- Go to *Dashboard* > *Network*, and expand the *SD-WAN* widget. The *Upload* and *Download* columns for wan1 show that traffic is not going through that interface.

- Go to *Network* > *SD-WAN* and select the *SD-WAN Zones* tab. The *Bandwidth*, *Volume*, and *Sessions* tabs show that traffic is entirely diverted to wan2.

Users on the network should not notice the wan1 failure. If you are using the wan1 gateway IP address to connect to the administrator dashboard, it will appear as though you are still connecting through wan1.



After verifying a successful failover, reestablish the connection to ISP1.

Configuring SD-WAN in an HA cluster using internal hardware switches

In this SD-WAN configuration, two FortiGates in an active-passive (A-P) HA pair are used to provide hardware redundancy. Instead of using external switches to provide a mesh network connection to the ISP routers, the FortiGates use their built-in hardware switches to connect to the ISP routers.

Only FortiGate models that have hardware switches can be used for this solution. Ports in a software switch are not in a forwarding state when a FortiGate is acting as a secondary device in a A-P cluster.

In this topology:

- Two hardware switches are created, HD_SW1 and HD_SW2.
- HD_SW1 is used to connect to ISP 1 Router and includes the internal1 and internal2 ports.
- HD_SW2 is used to connect to ISP 2 Router and includes the internal3 and internal4 ports.
- Another interface on each device is used as the HA heartbeat interface, connecting the two FortiGates in HA.

The FortiGates create two hardware switches to connect to ISP 1 and ISP2. When FGT_A is the primary device, it reaches ISP 1 on internal1 in HD_SW1 and ISP 2 on internal4 in HD_SW2. When FGT_B is the primary device, it reaches ISP 1 on internal2 in HD_SW1 and ISP 2 on internal3 on HD_SW2.

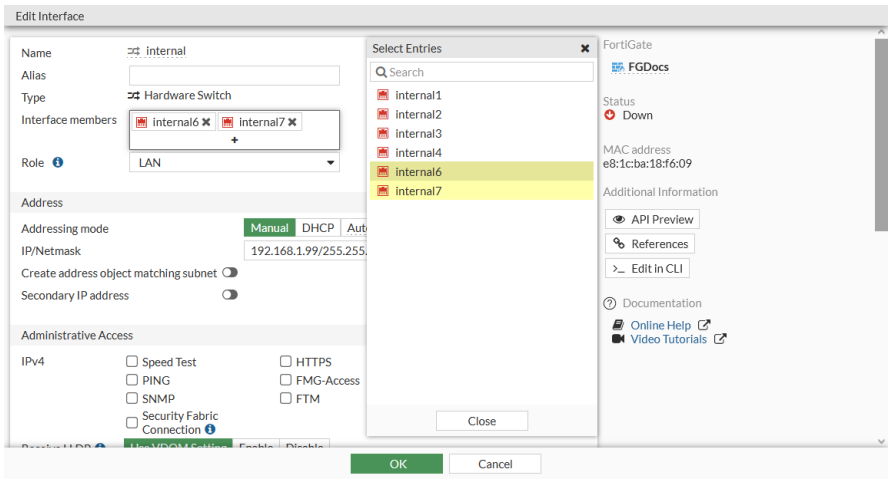
HA failover

This is not a standard HA configuration with external switches. In the case of a device failure, one of the ISPs will no longer be available because the switch that is connected to it will be down.

For example, If FGT_A loses power, HA failover will occur and FGT_B will become the primary unit. Its connection to internal2 on HD_SW1 will also be down, so it will be unable to connect to ISP 1. Its SD-WAN SLAs will be broken, and traffic will only be routed through ISP 2.

A link on a hardware switch cannot be monitored in HA monitor, so it is impossible to perform link failure when a port in either of the hardware switches fails. Performing a link failure is unnecessary in this configuration though, because any link failure on the hardware switch will be experienced by both cluster members. SD-WAN SLA health checks should be used to monitor the health of each ISP.

Failure on a hardware switch or ISP router



If a hardware switch or switch interface is down, or the ISP router is down, the SD-WAN can detect the broken SLA and continue routing to the other ISP.

For example, if FGT_A is the primary unit, and ISP 2 Router becomes unreachable, the SLA health checks on SD-WAN will detect the broken SLA and cause traffic to stop routing to ISP 2.

Configuration

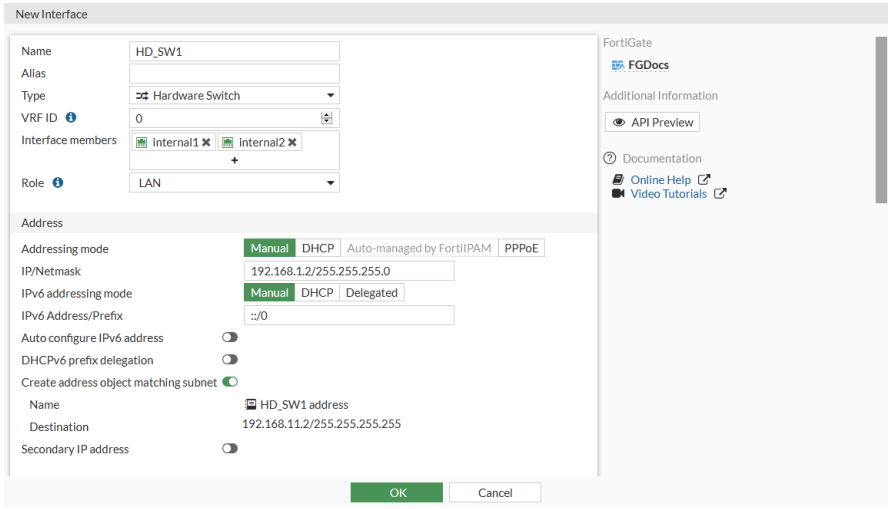
To configure the HA A-P cluster with internal hardware switches:

1. Configure two FortiGates with internal switches in an A-P HA cluster (follow the steps in HA active-passive cluster setup on page 2354), starting by connecting the heartbeat interface.
2. When the HA cluster is up, connect to the primary FortiGate's GUI.
3. Remove the existing interface members from the default hardware switch:
   a. Go to *Network* > *Interfaces*.
   b. In the *LAN* section, double-click the *internal* interface to edit it.
   c. In *Interface Members*, remove all of the interfaces

d. Click *OK*.

4. Configure the hardware switch interfaces for the two ISPs:

a. Go to *Network* > *Interfaces* and click *Create New* > *Interface*.

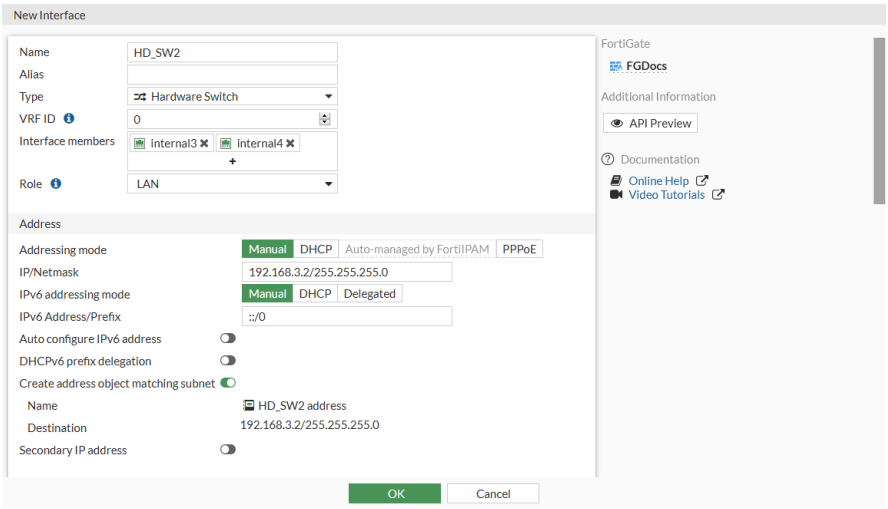


b. Enter a name (*HD_SW1*).

c. Set *Type* to *Hardware Switch*.

d. In *Interface Members*, add two interfaces (*internal1* and *internal2*).

e. Set *IP/Netmask* to 192.168.1.2/24.



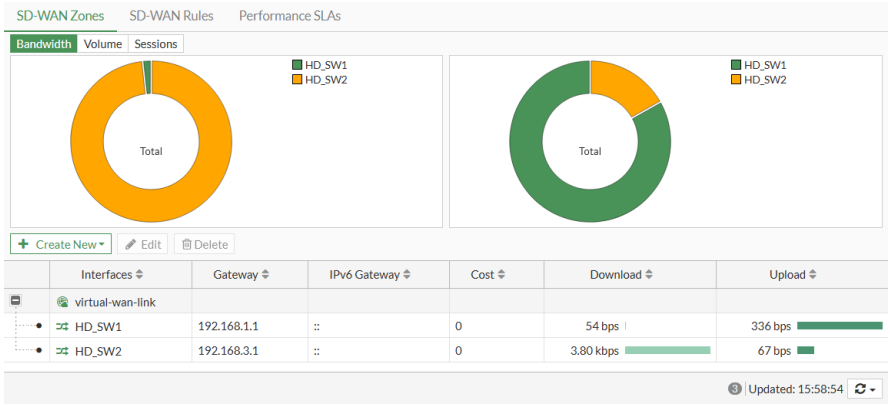
f. Configure the remaining settings as needed.

g. Click *OK*.

h. Repeat these steps to create a second hardware switch interface (*HD_SW2*) with two interface members

(*internal3* and *internal4*) and *IP/Netmask* set to *192.168.3.2/24*.

To connect the devices as shown in the topology:



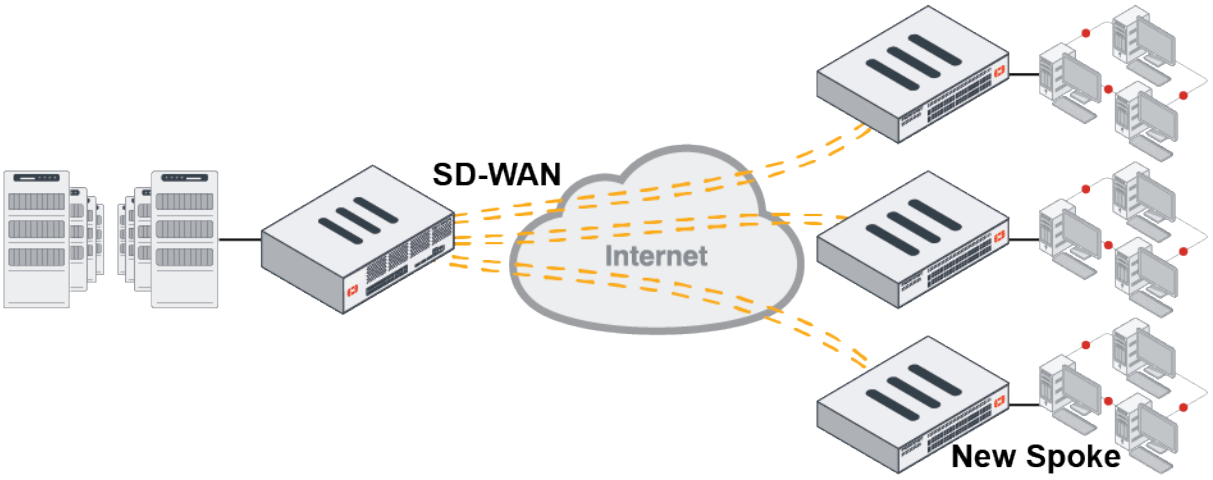
1. Connect the incoming interface to the internal switch on both FortiGates.
2. On FGT_A, connect internal1 of HD_SW1 to ISP 1 Router.
3. On FGT_B, connect internal3 of HD_SW2 to ISP 2 Router.
4. For HD_SW1, connect FGT_A internal2 directly to FGT_B internal2.
5. For HD_SW2, connect FGT_A internal4 directly to FGT_B internal4.

To configure SD-WAN:

The primary FortiGate makes all the SD-WAN decisions.

---

1. On the primary FortiGate, go to *Network* > *SD-WAN*, select the *SD-WAN Zones* tab, and click *Create New* > *SD-WAN Member*.
2. In the *Interface* dropdown, select *HD_SW1*.
3. Leave *SD-WAN Zone* set to *virtual-wan-link*.
4. Enter the *Gateway* address *192.168.1.1*.
5. Click *OK*.
6. Repeat these steps to add the second interface (*HD_SW2*) with the gateway *192.168.3.1*.
7. Click *Apply*.



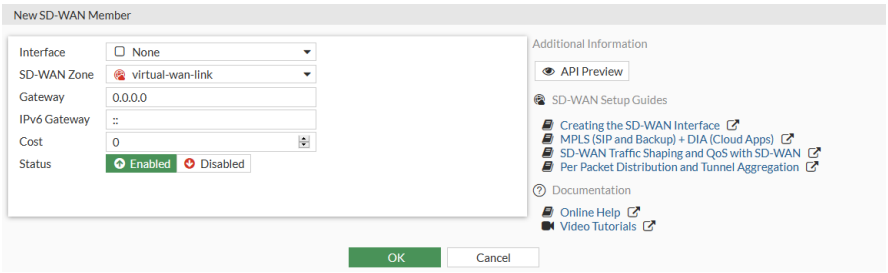
8. Create a health check:
   a. Go to *Network* > *SD-WAN*, select the *Performance SLA* tab, and click *Create New*.
   b. Set *Name* to *GW_HC*.
   c. Set *Protocol* to *Ping* and *Servers* to *8.8.8.8*.
   d. Set *Participants* to *All SD-WAN Members*.
   e. Enable *SLA Target* and leave the default values.
   f. Click *OK*.
9. Create SD-WAN rules as needed. The SLA health check can be used to determine when the ISP connections are in or out of SLA, and to failover accordingly.

SD-WAN configuration portability

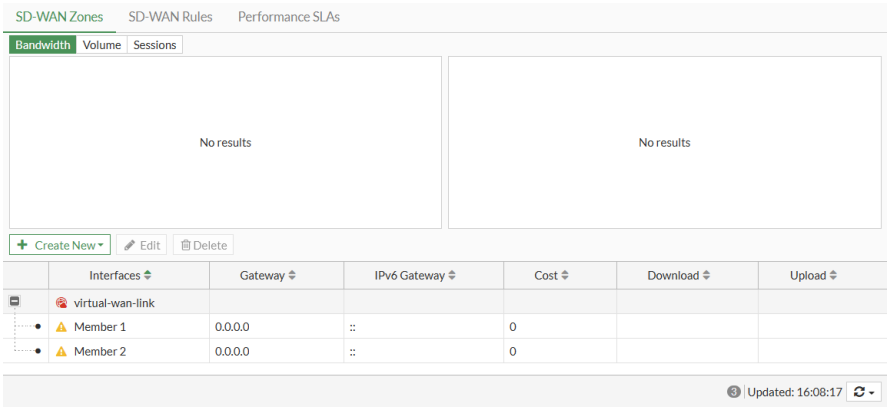
When configuring SD-WAN, adding interfaces to members is optional.

This allows the SD-WAN to be configured without associating any interfaces to SD-WAN members. It also allows a configuration to be copied directly from one device to another, without requiring the devices to have interfaces with the same names.

After the configuration is created, add interfaces to the members make it functional.



Example 1



In this example, we create a template with two SD-WAN members configured without assigned interfaces that are used in a performance SLA and SD-WAN rule. The template can be used to configure new devices, as in Example 2 on page 851. Interfaces are then assigned to the members, and the configuration becomes active.

To create the SD-WAN members in the GUI:

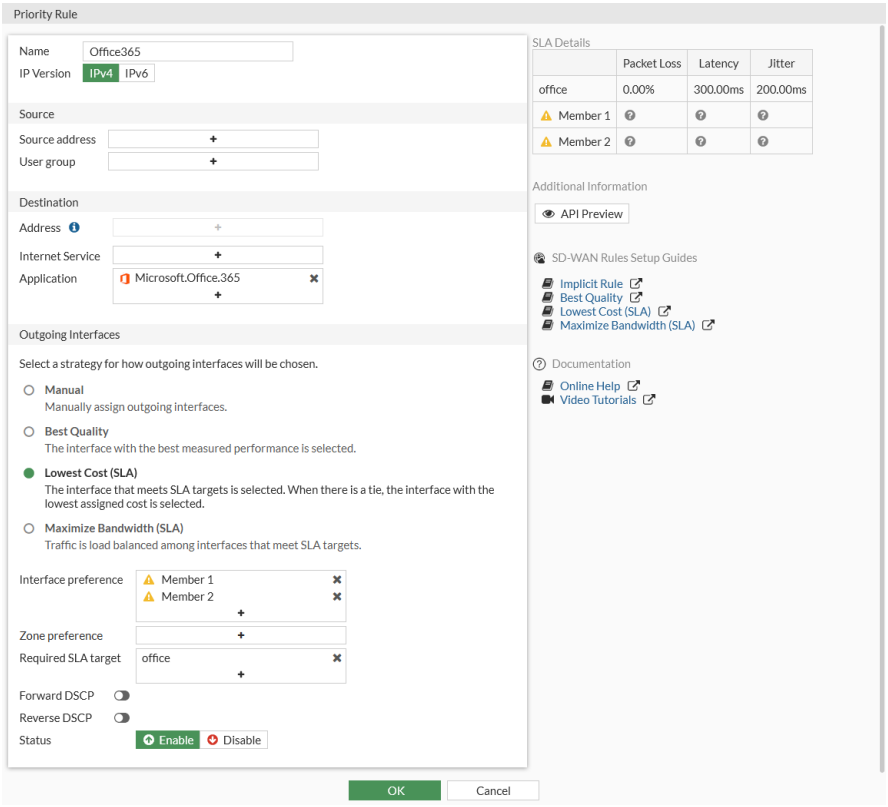
1. Go to *Network* > *SD-WAN*, select the *SD-WAN Zones* tab, and click *Create New* > *SD-WAN Member*.
2. Leave all the settings set to their default values and click *OK*.

3. Repeat the above steps to create a second member.
   The empty members are listed on the *SD-WAN Zones* tab.

   The members are disabled until interfaces are configured, but can still be used in performance SLAs and SD-WAN rules.

To create a performance SLA in the GUI:

1. Go to *Network* > *SD-WAN* and select the *Performance SLAs* tab.
2. Click *Create New*.

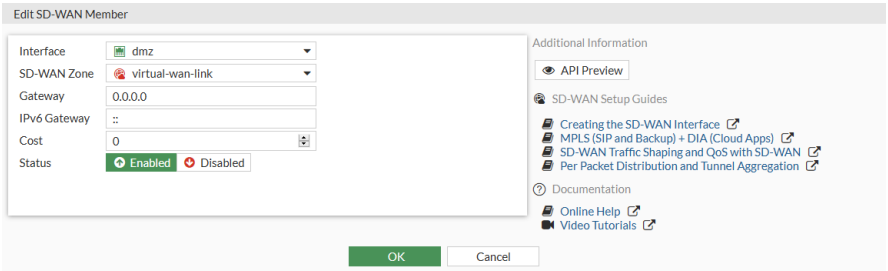


3. Configure the performance SLA, specifying the empty members as participants.

4. Click *OK*.

To create an SD-WAN rule in the GUI:

1. Go to *Network* > *SD-WAN*, select the *SD-WAN Rules* tab, and click *Create New*.
2. Configure the rule, adding both members to the *Interface preference* field:



3. Click *OK*.

To assign interfaces to the SD-WAN members in the GUI:

1. Go to *Network* > *SD-WAN* and select the *SD-WAN Zones* tab.
2. Edit the first member

3. Set *Interface* to an actual interface.

4. Click *OK*.
5. Repeat the above steps to assign an interface to the second member.

To configure the SD-WAN in the CLI:

1. Create SD-WAN members:

```
config system sdwan
    set status enable
    config members
        edit 1
        next
        edit 2
        next
    end
end
```

2. Create a health check (performance SLA):

```
config system sdwan
    config health-check
        edit "office"
            set server "office365.com"
            set protocol http
            set sla-fail-log-period 300
            set sla-pass-log-period 300
            set members 2 1
            config sla
                edit 1
                    set latency-threshold 300
                    set jitter-threshold 200
                next
                edit 2
                    set link-cost-factor latency
                    set latency-threshold 20
                next
            end
        next
    end
end
```

3. Create a service (rule):

```
config system sdwan
    config service
        edit 3
            set name "Office365"
```

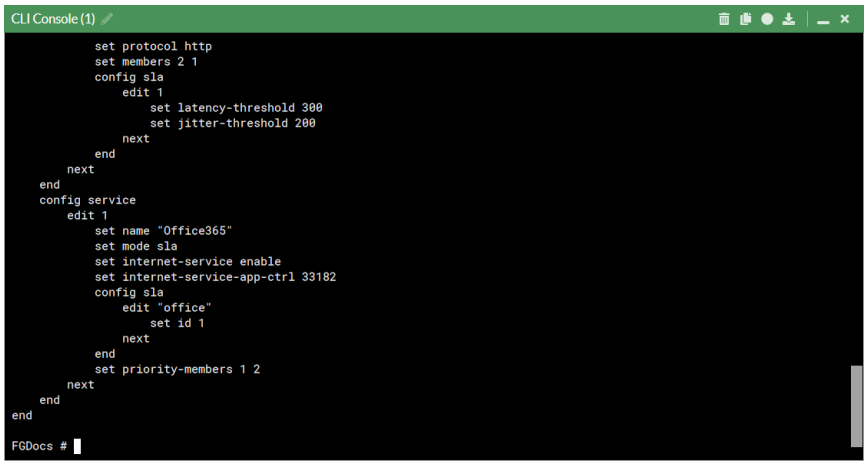
```
                set mode sla
                set internet-service enable
                set internet-service-app-ctrl 33182
                config sla
                    edit "office"
                        set id 2
                    next
                end
                set priority-members 1 2
            next
        end
    end
```

The SD-WAN configuration can now be used in as a template for new spokes, as in Example 2 on page 851.

To assign interfaces to the SD-WAN members in the CLI:

```
config system sdwan
    config members
        edit 1
            set interface "_OCVPN4-0.0"
        next
        edit 2
            set interface "_OCVPN4-0.1"
        next
    end
end
```

If no SD-WAN zone is specified, members are added to the default *virtual-wan-link* zone.



Example 2

In this example, the configuration from Example 1 is copied onto a new FortiGate.

Using the CLI console and the GUI

To copy the SD-WAN configuration from the original FortiGate:

1. Optionally, change the console screen paging setting. See Screen paging on page 40 for details.
2. Open the CLI console.
3. If necessary, click *Clear console* to empty the console.
4. Enter the following command:
   `show system sdwan`
5. Either click *Download* and open the file in a text editor, or click *Copy to clipboard* and paste the content into a text editor.

6. Edit the CLI configuration as necessary. For example, the first line that shows the `show` command should be deleted, and the default health checks can be removed.
7. If required, save the CLI configuration as a text file.

To paste the SD-WAN configuration onto a new FortiGate:

1. Copy the SD-WAN configuration from the text editor.
2. On the new FortiGate, open the CLI console.
3. Press *Ctrl* + *v* to paste the CLI commands.
4. In necessary, press *Enter* to apply the last `end` command.
   The SD-WAN configuration is copied to the new FortiGate.
   If the interfaces do not exist, the SD-WAN members are created without interfaces, and are disabled until interfaces are configured.

To assign interfaces to the SD-WAN members:

1. Go to *Network* > *SD-WAN* and select the *SD-WAN Zones* tab.
2. Edit the first member
3. Set *Interface* to an actual interface.
4. Click *OK*.
5. Repeat the above steps to assign an interface to the second member.

Using a terminal emulator

The following instructions use PuTTy. The steps may vary in other terminal emulators.

To copy the SD-WAN configuration from the original FortiGate:

1. Connect to the FortiGate. See Connecting to the CLI on page 32 for details.
2. Enter the following command:
   ```
   show system sdwan
   ```
3. Select the output, press *Ctrl* + *c* to copy it, and then paste it into a text editor.
4. Edit the CLI configuration as necessary. For example, the default health checks can be removed.
5. If required, save the CLI configuration as a text file.

To paste the SD-WAN configuration onto a new FortiGate:

1. Connect to the new FortiGate. See Connecting to the CLI on page 32 for details.
2. Copy the SD-WAN configuration from the text editor.
3. Right-click to paste the SD-WAN configuration.
4. In necessary, press *Enter* to apply the last `end` command.
   The SD-WAN configuration is copied to the new FortiGate.
   If the interfaces do not exist, the SD-WAN members are created without interfaces, and are disabled until interfaces are configured.

To assign interfaces to the SD-WAN members in the CLI:

```
config system sdwan
    config members
        edit 1
            set interface "_OCVPN4-0.0"
        next
        edit 2
            set interface "_OCVPN4-0.1"
        next
    end
end
```

If no SD-WAN zone is specified, members are added to the default *virtual-wan-link* zone.

SD-WAN segmentation over a single overlay

SD-WAN, VPN, and BGP configurations support L3 VPN segmentation over a single overlay. In these configurations, a hub and spoke SD-WAN deployment requires that branch sites, or spokes, are able to accommodate multiple companies or departments, and each company's subnet is separated by a different VRF. A subnet on one VRF cannot communicate with a subnet on another VRF between different branches, but can communicate with the same VRF.

SD-WAN options

VRF-aware SD-WAN health checks

SD-WAN on the originating spoke can tag the health check probes with the correct VRF when transmitting to a multi-VRF tunnel. The hub can then forward the probes to the correct health check server in the same VRF as the hub.

```
config system sdwan
   config health-check
       edit <name>
           set vrf <vrf id>
           set source <address>
       next
   end
end
```

`vrf <vrf id>`	Virtual Routing Forwarding ID.
`source <address>`	Source IP address used in the health-check packet to the server.

Overlay stickiness

When a hub has multiple overlays, traffic received on one overlay should egress on the same overlay when possible. The `service-sla-tie-break` option ensures overlay stickiness. In SD-WAN service rules, options are available to ensure that traffic received in a zone stays in that zone.

```
config system sdwan
    config zone
        edit <name>
            set service-sla-tie-break input-device
        next
    end
    config service
        edit <id>
            set input-zone <zone>
            set tie-break input-device
        next
    end
end
```

`service-sla-tie-break input-device`	Members that meet the SLA are selected by matching the input device.
`input-zone <zone>`	Source input-zone name.
`tie-break input-device`	Members that meet the SLA are selected by matching the input device.

IPsec options

Configurable rate limit for shortcut offers sent by the hub

By default, the hub sends a shortcut offer to a spoke every five seconds. If the hub continues to send offers that keep failing, and there are a large number of spokes, this can cause a high load on the hub. This setting makes the interval between shortcut offers configurable.

```
config vpn ipsec phase1-interface
    edit <name>
        set auto-discovery-offer-interval <interval>
    next
end
```

`auto-discovery-offer-interval <interval>`	Interval between shortcut offer messages, in seconds (1 - 300, default = 5).

Segmentation over a single overlay

Segmentation requires that VRF info is encapsulated within the IPsec VPN tunnel. This setting enables multi-VRF IPSEC tunnels.

```
config vpn ipsec phase1-interface
    edit <name>
        set encapsulation vpn-id-ipip
    next
end
```

`encapsulation vpn-id-ipip`	VPN ID with IPIP encapsulation.

VPN configuration for BGP

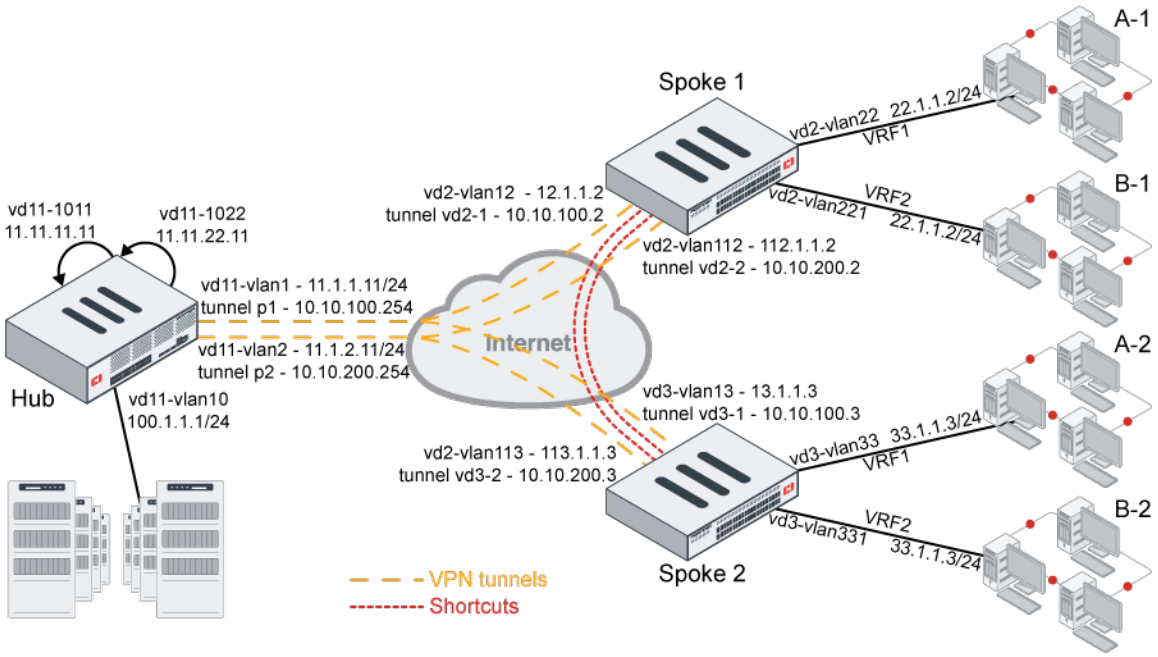
The role of a VRF can be specified, along with other VRF details. Up to 252 VRFs can be configured per VDOM for any device.

```
config router bgp
    config vrf
        edit <vrf>
            set role {standalone | ce | pe}
            set rd <string>
            set export-rt <route_target>
            set import-rt <route_target>
            set import-route-map <route_map>
            config leak-target
                edit <vrf>
                    set route-map <route-map>
                    set interface <interface>
                next
            end
        next
    end
end
```

`role {standalone | ce | pe}`	VRF role: standalone, customer edge (CE), or provider edge (PE).
`rd <string>`	Route Distinguisher: AA|AA:NN. This option is only available when the role is CE.
`export-rt <route_target>`	List of export route target. This option is only available when the role is CE.
`import-rt <route_target>`	List of import route target. This option is only available when the role is CE.
`import-route-map <route_map>`	Import route map. This option is only available when the role is CE.
`route-map <route-map>`	Route map of VRF leaking.
`interface <interface>`	Interface that is used to leak routes to the target VRF.

In FortiOS 7.0, `config vrf` was `config vrf-leak`, and `config leak-target` was `config target`.

Display BGP routes by VRF and neighbor



```
# diagnose ip router bgp set-filter vrf <vrf>
# diagnose ip router bgp set-filter neighbor <neighbor address>
# diagnose ip router bgp set-filter reset
# execute router clear bgp vpnv4 unicast soft {in | out}
# get router info filter show
# get router info filter vrf {vrf | all}
```

Examples

In example 1, multiple companies (or departments of a company) share the ADVPN. Company A and company B each have two branches in two different locations. Company A's branches (A-1 and A-2) can talk to each other using the VPN shortcut, but not to company B's branches (B-1 and B-2). Likewise, company B's branches can talk to each other using the VPN shortcut, but not to company A's branches. Traffic can share the tunnels and shortcuts, but cannot be mixed up.

Example 2 shows that performance SLA health checks can be sent from a spoke's VRF to the loopback on the hub that is in the same VRF.

Example 3 shows that when traffic is ingress on the hub on one overlay, it will preferably egress on the same overlay.

Example 1

In this example, two spokes each have two tunnels to the hub.

- Each spoke has two VRFs behind it that can use the same IP address or subnets.
- The computers in VRF1 behind spoke 1 can talk to the computers in VRF1 behind spoke 2, but not to any of the computers in the VRF2s behind either spoke.
- The computers in VRF2 behind spoke 1 can talk to the computers in VRF2 behind spoke 2, but not to any of the computers in the VRF1s behind either spoke.

To configure the hub:

```
config router bgp
    set as 65505
    set router-id 11.11.11.11
    set ibgp-multipath enable
    set additional-path enable
    set additional-path-vpnv4 enable
    set cluster-id 11.12.13.14
    set additional-path-select 3
    config neighbor-group
        edit "gr1"
            set capability-graceful-restart enable
            set capability-default-originate enable
            set next-hop-self-rr enable
            set soft-reconfiguration-vpnv4 enable
            set remote-as 65505
            set additional-path both
            set additional-path-vpnv4 both
            set adv-additional-path 3
            set route-reflector-client enable
            set route-reflector-client-vpnv4 enable
        next
        edit "gr2"
            set capability-graceful-restart enable
            set capability-default-originate enable
            set next-hop-self-rr enable
            set soft-reconfiguration-vpnv4 enable
            set remote-as 65505
            set additional-path both
            set additional-path-vpnv4 both
            set adv-additional-path 3
            set route-reflector-client enable
            set route-reflector-client-vpnv4 enable
        next
    end
    config neighbor-range
        edit 1
            set prefix 10.10.100.0 255.255.255.0
            set neighbor-group "gr1"
        next
        edit 2
            set prefix 10.10.200.0 255.255.255.0

no_ofld_reason:  disabled-by-policy
```

Example 2

In this example, SLA health checks are sent from a spoke's VRF to the loopback on the hub that is in the same VRF.

To configure the health check:

```
config system sdwan
    config health-check
        edit "1"
            set server "11.11.22.11"
            set vrf 1
            set source 22.1.1.2
            set members 1 2
            config sla
                edit 1
                    set latency-threshold 200
                    set jitter-threshold 50
                next
            end
        next
    end
end
```

To check the health check status:

```
# diagnose sys sdwan health-check status  1
Health Check(1):
Seq(1 vd2-1): state(alive), packet-loss(0.000%) latency(0.023), jitter(0.002), mos(4.404),
bandwidth-up(0), bandwidth-dw(0), bandwidth-bi(0) sla_map=0x1
Seq(2 vd2-2): state(alive), packet-loss(0.000%) latency(0.022), jitter(0.002), mos(4.404),
bandwidth-up(0), bandwidth-dw(0), bandwidth-bi(0) sla_map=0x1
```

Example 3

In this example, when traffic from spoke 1 arrives at the hub on tunnel 1, it will egress the hub on tunnel 1 to go to other spokes. If traffic arrives on tunnel 2, it will egress on tunnel 2, and not tunnel 1.

To configure SD-WAN on the hub:

```
config system sdwan
    set status enable
    config zone
        edit "virtual-wan-link"
            set service-sla-tie-break input-device
        next
    end
    config members
        edit 1
            set interface "p1"
        next
        edit 2
            set interface "p2"
        next
    end
    config health-check
        edit "1"
            set server "22.1.1.2"
            set members 1 2
            config sla
```

```
                edit 1
                next
            end
        next
    end
    config service
        edit 1
            set mode sla
            set dst "all"
            config sla
                edit "1"
                    set id 1
                next
            end
            set priority-members 1 2
            set tie-break input-device
        next
    end
end
```

To verify that traffic stays in the same overlay on ingress and egress on the hub:

1. Confirm that the SD-WAN service rule has `Tie break` set to `input-device` so that, when SLAs are met on all of the members, traffic prefers to egress on the same member as the input device:

```
# diagnose sys sdwan service

Service(1): Address Mode(IPV4) flags=0x200 use-shortcut-sla
 Tie break: input-device
  Gen(1), TOS(0x0/0x0), Protocol(0: 1->65535), Mode(sla), sla-compare-order
  Members(2):
    1: Seq_num(1 p1), alive, sla(0x1), gid(0), cfg_order(0), local cost(0), selected
    2: Seq_num(2 p2), alive, sla(0x1), gid(0), cfg_order(1), local cost(0), selected
  Dst address(1):
        0.0.0.0-255.255.255.255
```

2. Use `diagnose sniffer packet` commands to verify that traffic ingress and egress are on the same overlay.

Matching BGP extended community route targets in route maps

BGP extended community route targets can be matched in route maps. This can be applied in a scenario where the BGP route reflector receives routes from many VRFs, and instead of reflecting all routes from all VRFs, users only want to reflect routes based on a specific extended community route target.

To configure the extended community list:

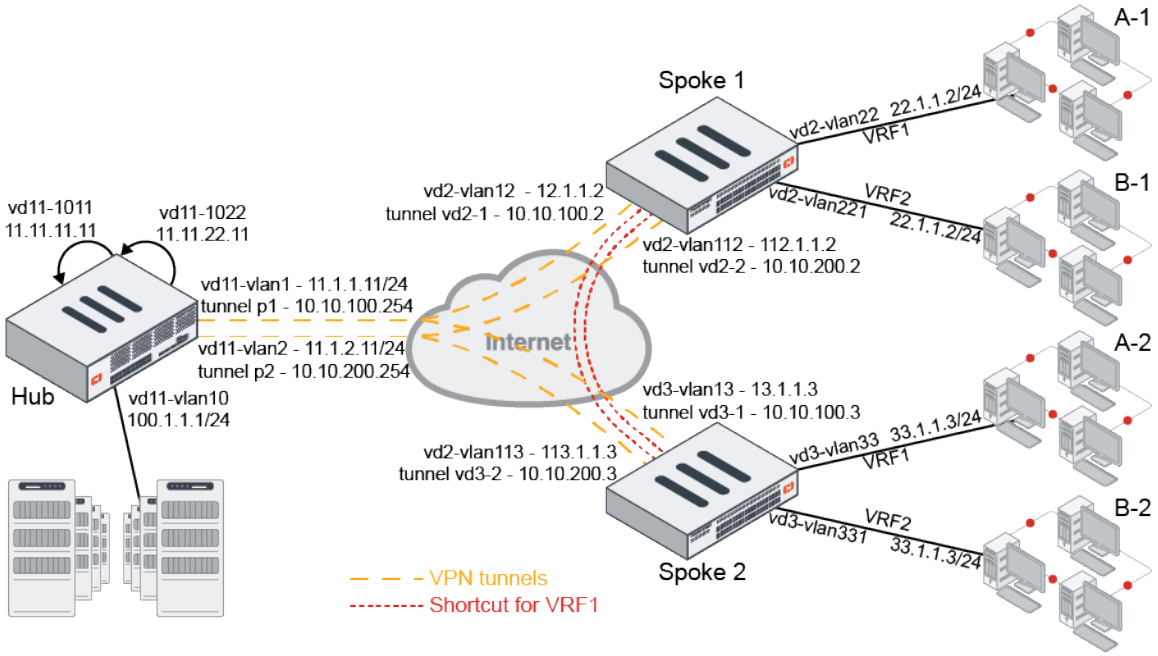
```
config router extcommunity-list
    edit <name>
        set type {standard | expanded}
        config rule
            edit <id>
                set action {deny | permit}
                set type {rt | soo}
                set match <extended_community_specifications>
```

```
                set regexp <ordered_list_of_attributes>
            next
        end
    next
end
```

`type {standard | expanded}`	Set the extended community list type (standard or expanded).
`action {deny | permit}`	Deny or permit route-based operations based on the route's extended community attribute.
`type {rt | soo}`	Set the extended community type: • rt: route target • soo: site of origin
`match <extended_community_specifications>`	Set the extended community specifications for matching a reserved extended community (community number in AA:NN format; use quotation marks complex expressions, `"123:234 345:456"`).
`regexp <ordered_list_of_attributes>`	Set the ordered list of extended community attributes as a regular expression.

To configure the BGP extended community list in the route map:

```
config router route-map
    edit <name>
        config rule
            edit <id>
                set match-extcommunity <list>
                set match-extcommunity-exact {enable | disable}
            next
        end
    next
end
```



`match-extcommunity <list>`	Set the BGP extended community list to match to.
`match-extcommunity-exact {enable | disable}`	Enable/disable exact matching of extended communities.

Example

In this example, multiple companies (or departments of a company) share the same hub and spoke VPN infrastructure. Company A and company B each have two branches in two different locations. The goal is for company A's branches (A-1 and A-2) to be able to communicate only with each other over VPN but not with company B's branches. Likewise, company B's branches (B-1 and B-2) can only communicate with each other over VPN but not with company A's. This is accomplished by placing each branch VLAN into their respective VRFs (VRF1 and VRF2), and encapsulating the VRF information within the VPN tunnel. The hub forms BGP peering with its neighbors, spoke 1 and spoke 2, over each IPsec overlay. The hub's BGP route reflector reflects the routes to the corresponding VRFs, allowing each spoke to form ADVPN shortcuts with the other spoke for each VRF.

However, in this scenario, we want A-1 and A-2 to use an ADVPN shortcut, but we do not want B-1 and B-2 to use ADVPN. A route map is configured on the hub to match the desired extended community route target number where only

this route target is permitted, and others are denied. This allows the hub's BGP route reflector to only reflect routes associated with VRF1, allowing the spokes to form an ADVPN shortcut for VRF1. Routes associated with VRF2 are not reflected, and each spoke must route traffic through the hub to reach VRF2 on the other spoke.

Configure the topology by following the instructions of Example 1 in SD-WAN segmentation over a single overlay on page 853. Note that when checking the spoke 1 routes in example 1, there is a VRF2 route:

```
Spoke 1 # get router info routing-table bgp
…
Routing table for VRF=2
B V     33.1.1.0/24 [200/0] via 10.10.100.3 [2] (recursive via vd2-1 tunnel 11.1.1.11),
00:00:20, [1/0]
                    [200/0] via 10.10.200.3 [2] (recursive via vd2-2 tunnel 11.1.2.11),
00:00:20, [1/0]
```

The following procedure applies a route map on the hub's BGP configurations to limit route reflection to only routes matching the external community target of 1:1. This external community target corresponds to BGP paths for VRF1 learned from spoke 1 and spoke 2. The external community target of 2:1 corresponds to BGP paths for VRF2. By not explicitly permitting this target (2:1) in the community list and denying everything other than the permitted target (1:1) in the route map, the VRF2 BGP paths are essentially omitted from being reflected to the spokes.

To configure BGP filtering for an extended community route target on the hub:

1. Identify the external community target of VRF1 to be permitted:

```
# get router info bgp network 33.1.1.0/24
VRF 0 BGP routing table entry for 33.1.1.0/24
Paths: (2 available, best #2, table Default-IP-Routing-Table)
  Advertised to non peer-group peers:
   11.1.1.1
  Advertised to peer-groups:
  gr1 gr2
…
VRF 1 BGP routing table entry for 33.1.1.0/24
```

```

    0.0.0.0 from 10.10.200.3 (3.3.3.3)
      Origin IGP metric 0, localpref 100, valid, internal, best
      Extended Community: RT:1:1
      Receive Path ID: 1
      Advertised Path ID: 2
       Last update: Wed Aug 17 10:31:02 2022
VRF 2 BGP routing table entry for 33.1.1.0/24
Paths: (2 available, best #2, table Default-IP-Routing-Table)
  Not advertised to any peer
  Original VRF 0 external duplicated
  Local, (Received from a RR-client)
    0.0.0.0 from 10.10.100.3 (3.3.3.3)
      Origin IGP metric 0, localpref 100, valid, internal, best
      Extended Community: RT:2:1
      Receive Path ID: 1
      Advertised Path ID: 1
       Last update: Wed Aug 17 10:31:02 2022
  Original VRF 0 external duplicated
  Local, (Received from a RR-client)
    0.0.0.0 from 10.10.200.3 (3.3.3.3)
      Origin IGP metric 0, localpref 100, valid, internal, best
      Extended Community: RT:2:1
      Receive Path ID: 1
      Advertised Path ID: 2
       Last update: Wed Aug 17 10:31:02 2022
```

2. Configure the extended community list:

```
config router extcommunity-list
    edit "extcomm1"
        config rule
            edit 1
                set action permit
                set match "1:1"
                set type rt
            next
        end
    next
end
```

3. Apply the extended community list to the route map:

```
config router route-map
    edit "rmp11"
        config rule
```

```
            edit 1
                set match-extcommunity "extcomm1"
            next
            edit 2
                set action deny
            next
        end
    next
end
```

4. Update the related BGP neighbor group settings:

```
config router bgp
    config neighbor-group
        edit "gr1"
            set route-map-out-vpnv4 "rmp11"
        next
        edit "gr2"
            set route-map-out-vpnv4 "rmp11"
        next
    end
end
```

5. Refresh the routes:

```
# execute router clear bgp all vpnv4 unicast out
```

6. Check the spoke 1 routes. Since the extended community route target is applied, the VFR2 route does not appear in the BGP routing table:

```
# get router info routing-table bgp
Routing table for VRF=0
B*      0.0.0.0/0 [200/0] via 10.10.100.254 (recursive via vd2-1 tunnel 11.1.1.11),
03:47:50, [1/0]
                  [200/0] via 10.10.200.254 (recursive via vd2-2 tunnel 11.1.2.11),
03:47:50, [1/0]
B       1.1.1.1/32 [200/0] via 11.1.1.1 [2] (recursive via 12.1.1.1, vd2-vlan12),

03:47:50, [1/0]
```

Copying the DSCP value from the session original direction to its reply direction

In an SD-WAN scenario when DSCP tags are used to mark traffic from the spoke to the hub, it is sometimes desirable for the hub to mark the reply traffic with the same DSSP tags. The `diffserv-copy` setting in firewall policy configurations allows the DSCP tag to be copied to the reply direction.

```
config firewall policy
    edit <id>
        set diffserv-copy {enable | disable}
    next
end
```

Example

The use cases in this example are for a hub and spoke SD-WAN deployment. Traffic from the spoke (either real traffic or SLA health check probes) can be marked with a certain DSCP tag when leaving the spoke. QoS may be applied by an upstream device based on the DSCP tag. When the traffic arrives on the hub, the hub may also want to mark the reply traffic to the spoke with the same DSCP tag. This would allow QoS to be applied to the traffic in the reply direction as well, which is traffic in the hub to spoke direction associated with the same session in the spoke to hub direction.

While this topology simplifies the SD-WAN deployment into a single hub and spoke, this feature applies to the following configurations:

- Multiple spokes (branch sites)
- One or more hubs (data center sites)
- Multiple overlays connecting spokes to hubs
- SD-WAN configured on spokes to pick the best overlay

Use case 1: typical forwarding traffic

Traffic originates from the spoke and is destined for a server behind the hub. The spoke marks the traffic with a DSCP tag of 101010. This is done by enabling `diffserv-foward` on the spoke firewall policy. It can also be accomplished by enabling `dscp-forward` in an SD-WAN rule.

The hub allows the traffic in through a firewall policy. By enabling `diffserv-copy` on the firewall policy, it will mark the reply traffic on the corresponding sessions with the same DSCP tag in which it came.

To configure the FortiGates:

1. Configure the firewall policy on the spoke (FortiGate A):

```
config firewall policy
    edit 1
        set srcintf "port1"
        set dstintf "virtual-wan-link"
        set action accept
        set srcaddr "all"
        set dstaddr "all"
        set srcaddr6 "all6"
        set dstaddr6 "all6"
        set schedule "always"
        set service "ALL"
        set logtraffic all
        set nat enable
        set diffserv-forward enable
        set diffservcode-forward 101010
    next
end
```

2. Configure the firewall policy on the hub (FortiGate B):

```
config firewall policy
    edit 3
        set srcintf "virtual-wan-link"
        set dstintf "wan1"
        set action accept
        set srcaddr "all"
        set dstaddr "all"
        set srcaddr6 "all"
        set dstaddr6 "all"
        set schedule "always"
        set service "ALL"
        set logtraffic all
        set auto-asic-offload disable
        set nat enable
        set diffserv-copy enable
    next
end
```

To test the configuration:

1. Generate some forwarding traffic.
2. Verify that the session's `tos` value from the original direction is applied to the reply direction:

```
# diagnose sys session filter policy 3
# diagnose sys session filter dst 172.16.200.55
# diagnose sys session list

session info: proto=1 proto_state=00 duration=35 expire=59 timeout=0 flags=00000000
socktype=0 sockport=0 av_idx=0 use=3
origin-shaper=
reply-shaper=
per_ip_shaper=
class_id=0 ha_id=0 policy_dir=0 tunnel=/ vlan_cos=0/255
```

```
state=log may_dirty f00
statistic(bytes/packets/allow_err): org=3024/36/1 reply=3024/36/1 tuples=2
tx speed(Bps/kbps): 82/0 rx speed(Bps/kbps): 82/0
orgin->sink: org pre->post, reply pre->post dev=20->17/17->20 gwy=172.16.200.55/10.2.2.1
hook=post dir=org act=snat 10.2.2.1:25290->172.16.200.55:8(172.16.200.2:25290)
hook=pre dir=reply act=dnat 172.16.200.55:25290->172.16.200.2:0(10.2.2.1:25290)
misc=0 policy_id=3 pol_uuid_idx=1097 auth_info=0 chk_client_info=0 vd=3
serial=0000a018 tos=6a/6a app_list=0 app=0 url_cat=0
rpdb_link_id=00000000 ngfwid=n/a
npu_state=0x4000001 no_offload
no_ofld_reason:  disabled-by-policy
total session 1
```

Use case 2: local-in traffic destined to a loopback interface

SLA health checks from the spoke are destined for a loopback interface on the hub. The health check is marked with a DSCP tag of 000001 by the spoke. When the hub receives the probes to its loopback, it will mark the replies with the same DSCP tags in which it came.

To configure the FortiGates:

1. Configure the health check on the spoke (FortiGate A):

```
config system sdwan
    config health-check
        edit "ping"
            set server "1.1.1.1"
            set diffservcode 000001
        set members 0
    next
end
```

2. Configure the loopback interface on the hub (FortiGate B):

```
config system interface
    edit "loopback"
        set vdom "vdom1"
        set ip 1.1.1.1 255.255.255.255
        set allowaccess ping https ssh  http telnet
        set type loopback
        set role lan
        set snmp-index 35
    next
end
```

3. Configure the firewall policy on the hub:

```
config firewall policy
    edit 1
        set srcintf "virtual-wan-link"
        set dstintf "loopback"
        set action accept
        set srcaddr "all"
        set dstaddr "all"
        set srcaddr6 "all"
        set dstaddr6 "all"
        set schedule "always"
```

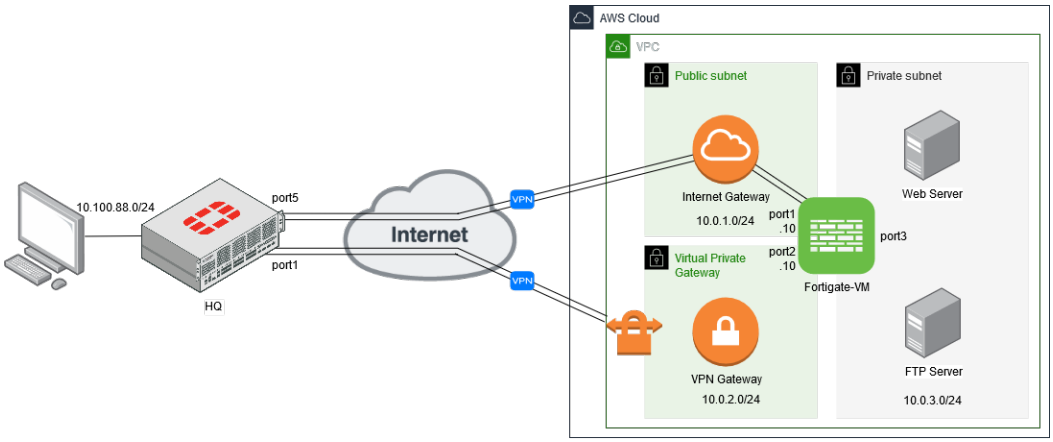
```
        set service "ALL"
        set logtraffic all
        set auto-asic-offload disable
        set nat enable
        set diffserv-copy enable
    next
end
```

To test the configuration:

1. Generate some local-in traffic.
2. Verify that the session's `tos` value from the original direction is applied to the reply direction:

```
# diagnose sys session list

session info: proto=1 proto_state=00 duration=1 expire=59 timeout=0 flags=00000000
socktype=0 sockport=0 av_idx=0 use=3
origin-shaper=
reply-shaper=
per_ip_shaper=
class_id=0 ha_id=0 policy_dir=0 tunnel=/ vlan_cos=0/0
state=log local may_dirty
statistic(bytes/packets/allow_err): org=80/2/1 reply=80/2/1 tuples=2
tx speed(Bps/kbps): 0/0 rx speed(Bps/kbps): 0/0
orgin->sink: org pre->in, reply out->post dev=20->42/42->20 gwy=1.1.1.1/0.0.0.0
hook=pre dir=org act=noop 10.2.2.1:15->1.1.1.1:8(0.0.0.0:0)
hook=post dir=reply act=noop 1.1.1.1:15->10.2.2.1:0(0.0.0.0:0)
misc=0 policy_id=1 pol_uuid_idx=0 auth_info=0 chk_client_info=0 vd=3
serial=0001a846 tos=41/41 app_list=0 app=0 url_cat=0
rpdb_link_id=00000000 ngfwid=n/a
npu_state=0x000001 no_offload
no_ofld_reason:  local disabled-by-policy
total session 1
```



Capture packets can also be used verify that the DSCP value from the original direction is applied to the reply direction.

SD-WAN cloud on-ramp

In this example, you configure a connection to a new cloud deployment that has some remote servers. SD-WAN is used to steer traffic through the required overlay tunnel.

The on-premise FortiGate has two internet connections, each with a single VPN connection. The two VPN gateways are configured on the cloud for redundancy, one terminating at the FortiGate-VM, and the other at the native AWS VPN Gateway.

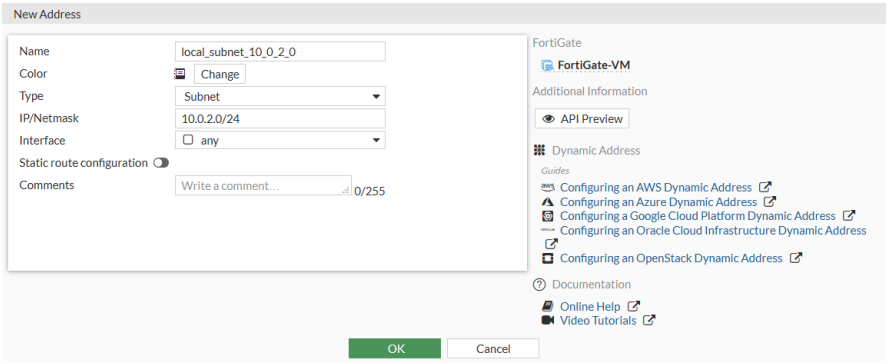
This example uses AWS as the Infrastructure as a Service (IaaS) provider, but the same configuration can also apply to other services. A full mesh VPN setup is not shown, but can be added later if required.

To connect to the servers that are behind the cloud FortiGate-VM, virtual IP addresses (VIPs) are configured on port2 to map to the servers:

- VPN traffic terminating on port1 is routed to the VIP on port2 to access the web servers.
- VPN traffic terminating on the VPN gateway accesses the VIPs on port2 directly.

There are four major steps to configure this setup:

1. Configuring the VPN overlay between the HQ FortiGate and cloud FortiGate-VM on page 877
2. Configuring the VPN overlay between the HQ FortiGate and AWS native VPN gateway on page 882
3. Configuring the VIP to access the remote servers on page 885
4. Configuring the SD-WAN to steer traffic between the overlays on page 888

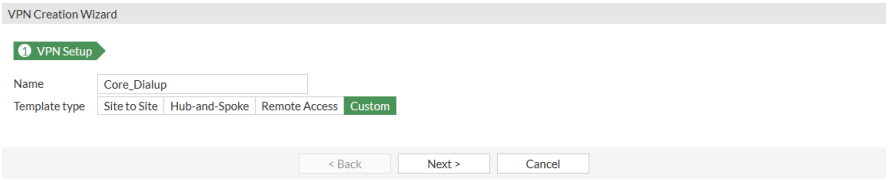


After the configuration is complete, verify the traffic to ensure that the configuration is working as expected, see Verifying the traffic on page 892.

Configuring the VPN overlay between the HQ FortiGate and cloud FortiGate-VM

Configure the cloud FortiGate-VM

To create an address for the VPN gateway:

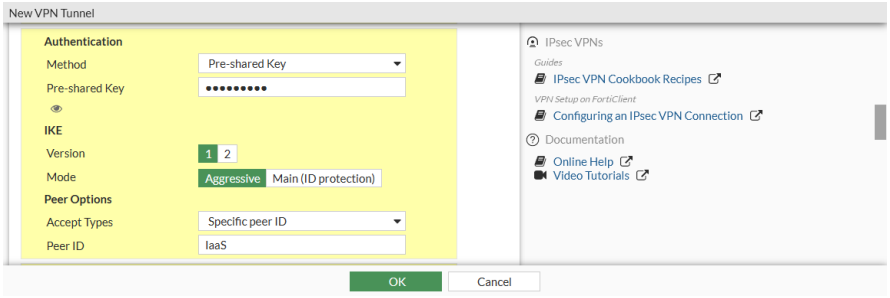


1. Go to *Policy & Objects* > *Addresses* and click *Create New* > *Address*.
2. Set *Name* to *local_subnet_10_0_2_0*.
3. Set *IP/Netmask* to *10.0.2.0/24*.

4. Click *OK*.

To configure a custom IPsec VPN:

1. Go to *VPN* > *IPsec Wizard*.
2. Set *Name* to *Core_Dialup*.
3. Set *Template type* to *Custom*.



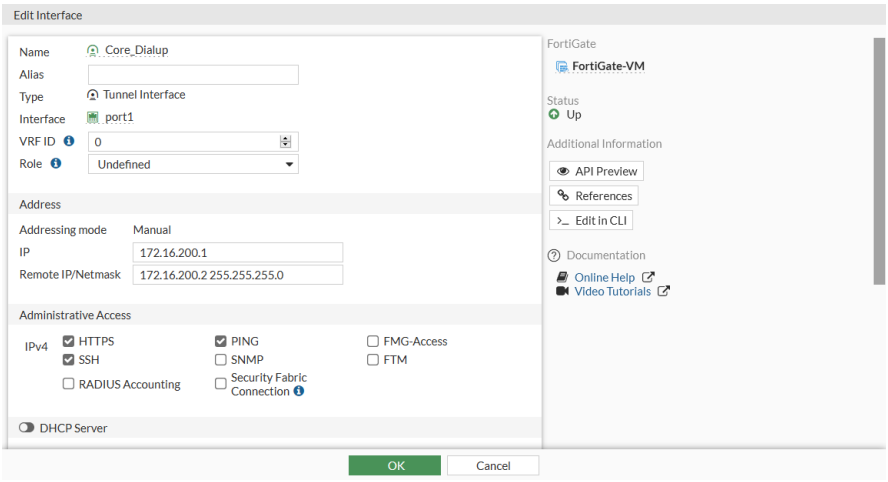
4. Click *Next*.
5. Configure *Network* settings:

Remote Gateway	Dialup User
Interface	port1
NAT Traversal	Enable

6. Configure *Authentication* settings:

Method	Pre-shared Key
Pre-shared Key	Enter the pre-shared key.
Version	1
Mode	Aggressive This setting allows the peer ID to be specified.
Accept Types	Specific peer ID
Peer ID	IaaS The other end of the tunnel needs to have its local ID set to IaaS.

7. Leave the default *Phase 1 Proposal* settings and disable *XAUTH*.

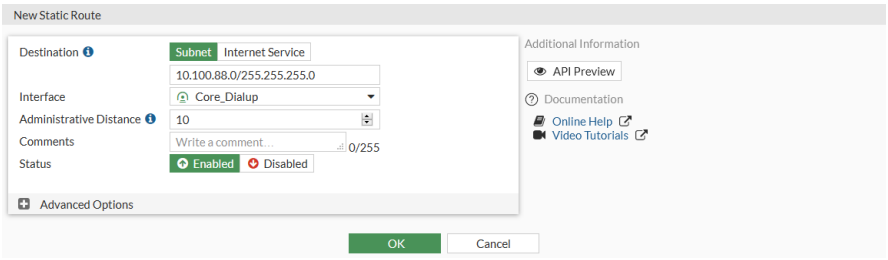


8. Configure the *Phase 2 Selector* settings:

Name	Ent_Core
Local Address	Named Address - *local_subnet_10_0_2_0*
Remote Address	Named Address - *all* This setting allows traffic originating from both the remote subnet 10.100.88.0 and the health checks from the VPN interface on the remote FortiGate. For increased security, each subnet can be specified individually.

9. Click *OK*.

To configure remote and local tunnel IP addresses:

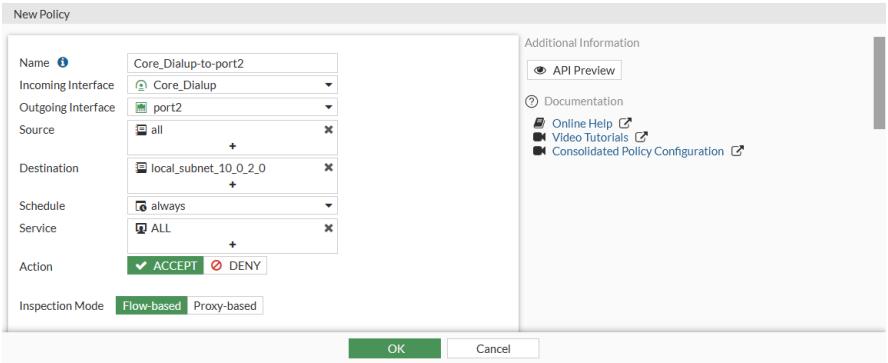


1. Go to *Network* > *Interfaces* and edit the *Core_Dialup* interface under *port1*.
2. Set *IP* to *172.16.200.1*.
3. Set *Remote IP/Netmask* to *172.16.200.2 255.255.255.0*. This is where remote health check traffic will come from.
4. Enable *Administrative access* for *HTTPS*, *PING*, and *SSH*.

5. Click *OK*.

To configure a route to the remote subnet through the tunnel:

1. Go to *Network* > *Static Routes* and click *Create New*.
2. Set *Destination* to *Subnet* and enter the IP address and netmask: *10.100.88.0/255.255.255.0*.
3. Set *Interface* to *Core_Dialup*.



4. Click *OK*.

To configure a firewall policy to allow traffic from the tunnel to port2:

1. Go to *Policy & Objects* > *Firewall Policy* and click *Create New*.
2. Configure the following:

Name	Core_Dialup-to-port2
Incoming Interface	Core_Dialup
Outgoing Interface	port2
Source	all
Destination	local_subnet_10_0_2_0
Schedule	always
Service	ALL
Action	ACCEPT

3. Configure the remaining settings as required.
4. Click *OK*.

Configure the HQ FortiGate

To create an address for the VPN gateway:

1. Go to *Policy & Objects* > *Addresses* and click *Create New* > *Address*.
2. Set *Name* to *remote_subnet_10_0_2_0*.
3. Set *IP/Netmask* to *10.0.2.0/24*.
4. Click *OK*.

To configure a custom IPsec VPN:

1. Go to *VPN* > *IPsec Wizard*.
2. Set *Name* to *FGT_AWS_Tun*.
3. Set *Template type* to *Custom*.
4. Click *Next*.
5. Configure *Network* settings:

Remote Gateway	Static IP Address
IP Address	100.21.29.17
Interface	port5
NAT Traversal	Enable

6. Configure *Authentication* settings:

Method	Pre-shared Key
Pre-shared Key	Enter the pre-shared key.
Version	1
Mode	Aggressive This setting allows the peer ID to be specified.
Accept Types	Any peer ID

7. Leave the default *Phase 1 Proposal* settings, except set *Local ID* to *IaaS*.
8. Disable *XAUTH*.
9. Configure the *Phase 2 Selector* settings:

Name	FGT_AWS_Tun
Local Address	Named Address - *all* This setting allows traffic originating from both the local subnet 10.100.88.0 and the health checks from the VPN interface. For increased security, each subnet can be specified individually.
Remote Address	Named Address - *remote_subnet_10_0_2_0*

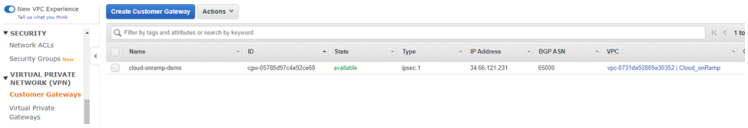
10. Click *OK*.

To configure local and remote tunnel IP addresses:

1. Go to *Network* > *Interfaces* and edit the *FGT_AWS_Tun* interface under *port5*.
2. Set *IP* to *172.16.200.2*.
3. Set *Remote IP/Netmask* to *172.16.200.1 255.255.255.0*.
4. Enable *Administrative access* for *HTTPS*, *PING*, and *SSH*.
5. Click *OK*.

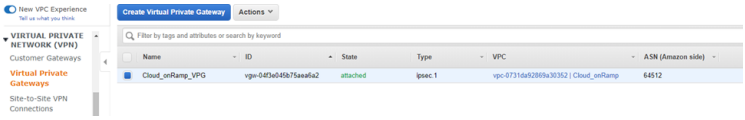
Routing is defined when creating the SD-WAN interface. The firewall policy is created after the SD-WAN interface is defined.

Configuring the VPN overlay between the HQ FortiGate and AWS native VPN gateway



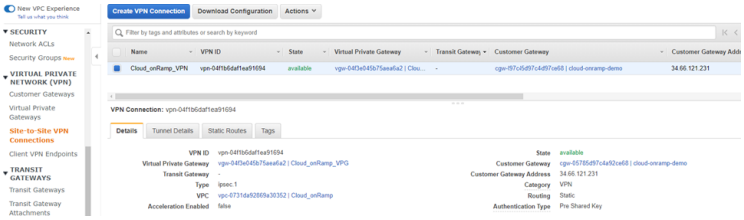
This example uses static routing. It is assumed that the AWS VPN Gateway is already configured, and that proper routing is applied on the corresponding subnet.

Verify the AWS configuration

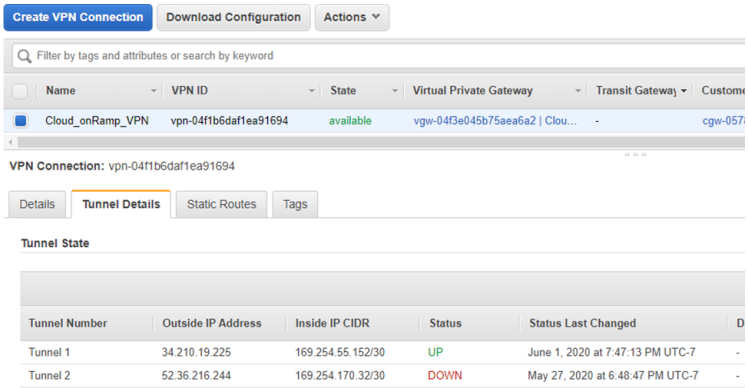


See Creating routing tables and associate subnets in the AWS Administration Guide for configuration details.

To check the AWS configuration:

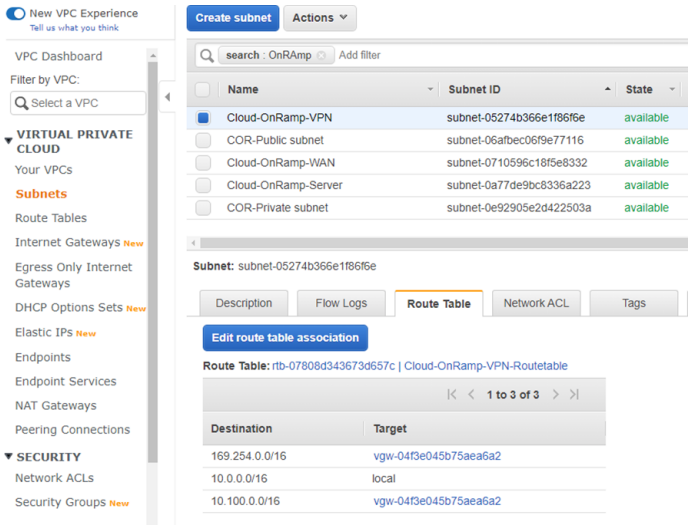


1. Go to *Virtual Private Network (VPN)* > *Customer Gateways* to confirm that the customer gateway defines the FortiGate IP address as its Gateway IP address, in this case *34.66.121.231*.

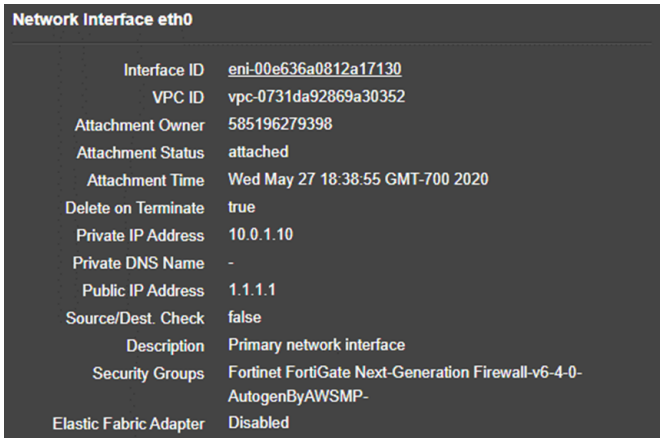


2. Go to *Virtual Private Network (VPN)* > *Virtual Private Gateways* to confirm that a virtual private gateway (VPG) has been created. In this case it is attached to the *Cloud_onRamp* VPC that contains the FortiGate and servers.

3. Go to *Virtual Private Network (VPN)* > *Site-to-Site VPN Connections* to confirm that site-to-site VPN connections have been created and attached to the customer gateway and virtual private gateway.
If *Routing Options* is *Static*, the IP prefix of the remote subnet on the HQ FortiGate (10.100.88.0) is entered here.



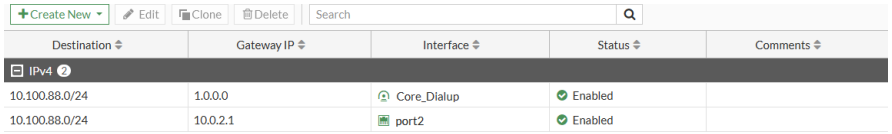
AWS site-to-site VPN always creates two VPN tunnels for redundancy. In this example, only Tunnel 1 is used.



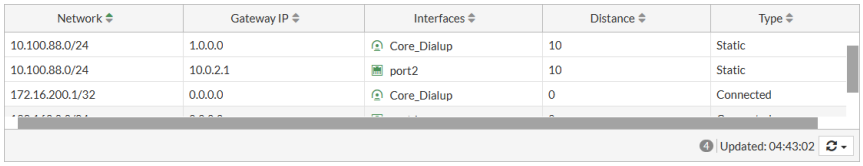
4. Click *Download Configuration* to download the FortiGate's tunnel configurations. The configuration can be referred to when configuring the FortiGate VPN.

5. The new VPG is attached to your VPC, but to successfully route traffic to the VPG, proper routing must be defined. Go to *Virtual Private Cloud* > *Subnets*, select the *Cloud-OnRamp-VPN*, and select the *Route Table* tab to verify that there are at least two routes to send traffic over the VPG.

   - *169.254.0.0/24* defines the tunnel IP address. Health check traffic originating from the FortiGate will come from this IP range.
   - *10.100.0.0/16* defines the remote subnet from the HQ FortiGate.
   - Both routes point to the just created VPG *vgw-04xxxx*.
6. On the cloud FortiGate-VM EC2 instances, ensure that port1 and port2 both have *Source/Dest. Check* set to *false*. This allows the FortiGate to accept and route traffic to and from a different network.
   If you launched the instance from the AWS marketplace, this setting defaults to *true*.



Configure routing to the VPG on the cloud FortiGate-VM



To configure routing to the VPG on the cloud FortiGate-VM:

1. Go to *Network* > *Static Routes* and click *Create New*.
2. Set *Destination* to *Subnet* and enter the IP address and netmask: *10.100.88.0/255.255.255.0*.
3. Set *Gateway Address* to *Specify* and enter *10.0.2.1*.

4. Set *Interface* to *port2*.
   The new route must have the same *Administrative Distance* as the route that was created for traffic through the *Core_Dialup* tunnel to ensure that both routes are added to the routing table (see To configure a route to the remote subnet through the tunnel).
   The *Gateway Address* is arbitrarily set to 10.0.2.1. The VPG does not have an IP address, but the address defined here allows the FortiGate to route traffic out of port2, while AWS routes the traffic based on its routing table.
5. Click *OK*.
6. Go to *Network* > *Static Routes* to view the configured static routes:

7. If *Optimal* dashboards is selected, go to *Dashboard* > *Network* and expand the Routing widget to view the routing table.
   If *Comprehensive* dashboards is selected, go to *Dashboard* > *Routing Monitor* and select *Static & Dynamic* in the widget toolbar to view the routing table:

Configure IPsec VPN on the HQ FortiGate

To configure a custom IPsec VPN:

1. Go to *VPN* > *IPsec Wizard*.
2. Set *Name* to *AWS_VPG*.
3. Set *Template type* to *Custom*.
4. Click *Next*.
5. Configure *Network* settings:

Remote Gateway	Static IP Address
IP Address	34.210.19.225 This address is taken from the downloaded AWS configuration file.
Interface	port1
NAT Traversal	Enable

6. Configure *Authentication* settings:

Method	Pre-shared Key
Pre-shared Key	Enter the pre-shared key.
Version	1
Mode	Main

7. Configure the *Phase 1 Proposal* settings using information from the downloaded AWS configuration file.

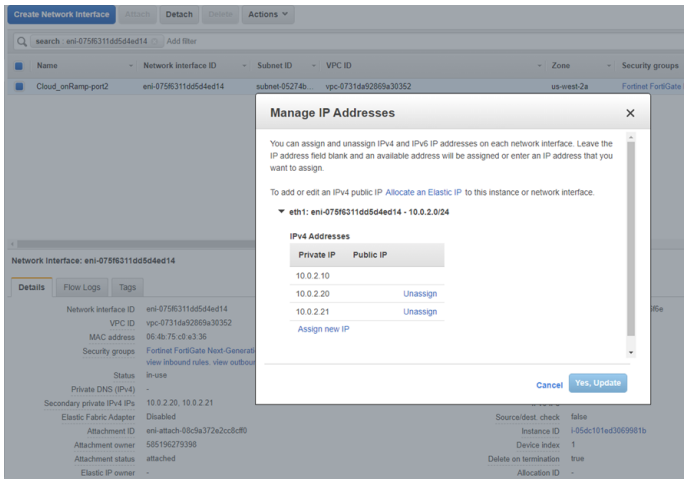
8. Disable *XAUTH*.
9. Configure the *Phase 2 Selector* settings:

Name	AWS_VPG
Local Address	Named Address - *all* This setting allows traffic originating from both the local subnet 10.100.88.0 and the health checks from the VPN interface. For increased security, each subnet can be specified individually.
Remote Address	Named Address - *remote_subnet_10_0_2_0*

10. Click *OK*.

To configure local and remote tunnel IP addresses:

1. Go to *Network* > *Interfaces* and edit the *AWS_VPG* interface under *port1*.
2. Set *IP* to *169.254.55.154*.
3. Set *Remote IP/Netmask* to *169.254.55.153 255.255.255.0*.
4. Enable *Administrative access* for *HTTPS* and *PING*.
5. Click *OK*.



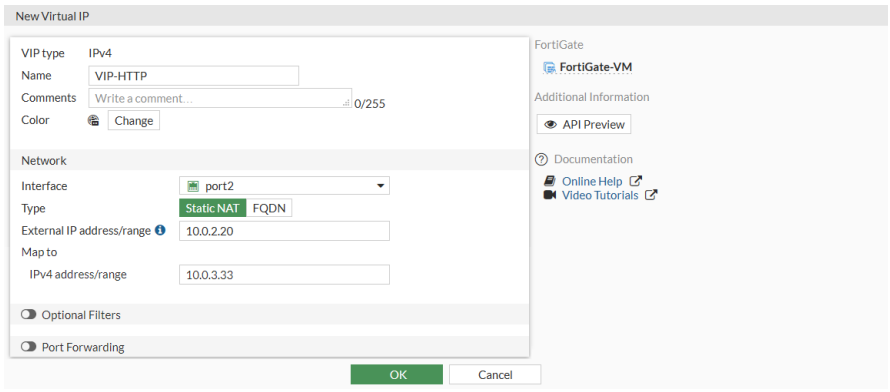
Routing is defined when creating the SD-WAN interface. The firewall policy is created after the SD-WAN interface is defined.

Configuring the VIP to access the remote servers

VIPs, interface IP addresses, and policies are created on the cloud FortiGate-VM to allow access to the remote servers.

To configure additional private IPs on AWS for the FortiGate VIP:

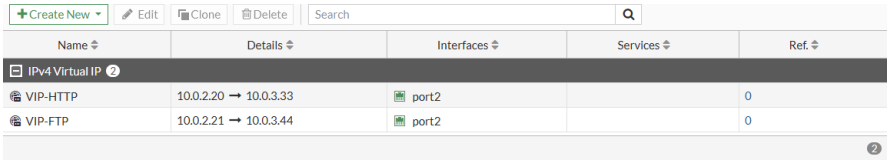
1. On the FortiGate EC2 instance, edit the *Elastic Network Interface* that corresponds to *port2*. In this example, Network Interface *eth1*.
2. Go to *Actions* > *Manage IP Addresses*.
3. Add two private IP address in the 10.0.2.0/24 subnet.
   These address will be used in the VIPs on the FortiGate. This ensures that traffic to these IP addresses is routed to the FortiGate by AWS.



4. Click *Yes, Update*.

To configure VIPs on the cloud FortiGate-VM:

1. Go to *Policy & Objects* > *Virtual IPs* and click *Create New* > *Virtual IP*.
2. Configure the following:



Name	VIP-HTTP
Interface	port2
External IP address/range	10.0.2.20
Map to IPv4 address/range	10.0.3.33

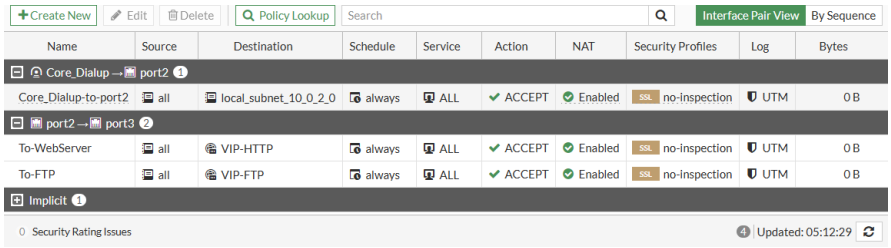
3. Click *OK*.

4. Create a second VIP for the FTP server with the following settings:

Name	VIP-FTP
Interface	port2
External IP address/range	10.0.2.21
Map to IPv4 address/range	10.0.3.44

To configure firewall policies to allow traffic from port2 to port3:

1. Go to *Policy & Objects* > *Firewall Policy* and click *Create New*.
2. Configure the following:



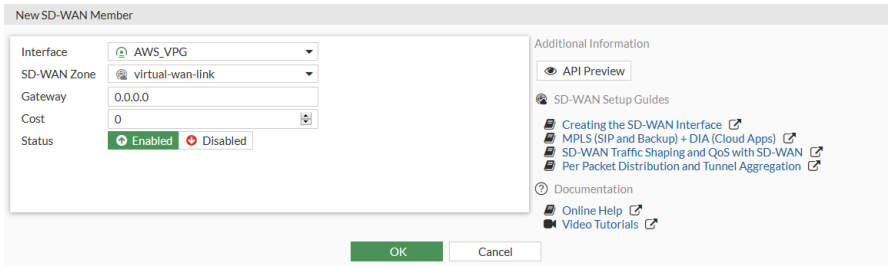
Name	To-WebServer
Incoming Interface	port2
Outgoing Interface	port3
Source	all
Destination	VIP-HTTP
Schedule	always
Service	ALL
Action	ACCEPT
NAT	Enabled

3. Configure the remaining settings as required.
4. Click *OK*.
5. Create a second policy for the FTP VIP with the following settings:

Name	To-FTP
Incoming Interface	port2
Outgoing Interface	port3
Source	all
Destination	VIP-FTP
Schedule	always
Service	ALL
Action	ACCEPT

NAT	Enabled

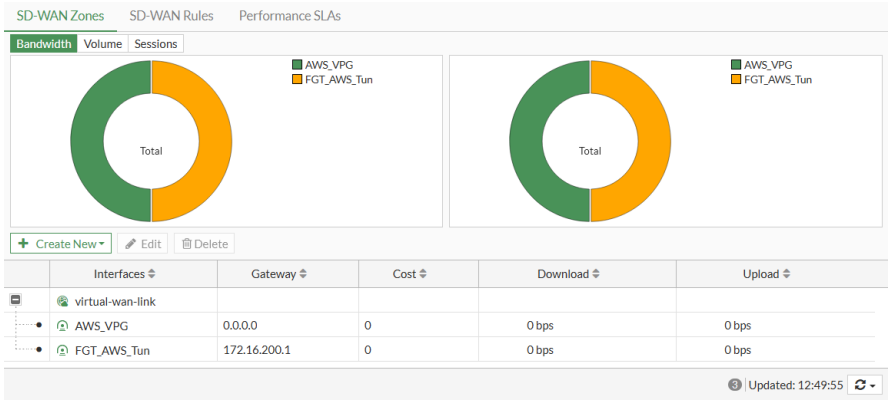
6. Click *OK*.



Configuring the SD-WAN to steer traffic between the overlays

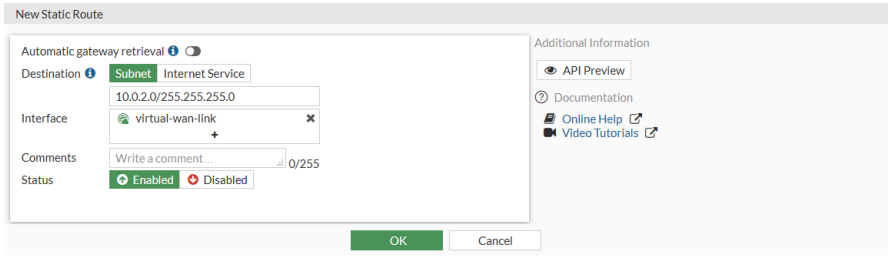
Configure the HQ FortiGate to use two overlay tunnels for SD-WAN, steering HTTPS and HTTP traffic through the FGT_AWS_Tun tunnel, and SSH and FTP throguh the AWS_VPG tunnel.

1. Add SD-WAN member interfaces
2. Configure a route to the remote network
3. Configure firewall policies
4. Configure a health check
5. Configure SD-WAN rules



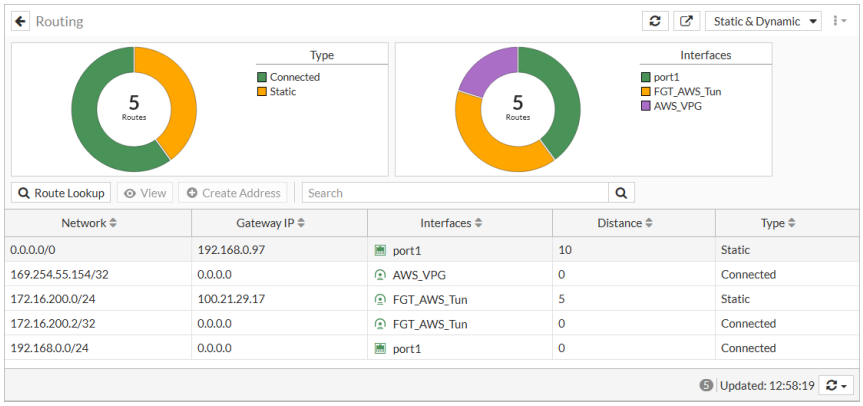
To add SD-WAN member interfaces:

1. Go to *Network* > *SD-WAN*, select the *SD-WAN Zones* tab, and click *Create New* > *SD-WAN Member*.
2. Set *Interface* to *AWS_VPG* then click *OK*.



3. Click *Create New* > *SD-WAN Member* again.
4. Set *Interface* to *FGT_AWS_Tun*.
5. Set *Gateway* to *172.16.200.1*.

6. Click *OK*.



To configure a route to the remote network 10.0.2.0/24:

1. Go to *Network* > *Static Routes* and click *Create New*.
2. Set *Destination* to *Subnet* and enter the IP address and netmask: *10.0.2.0/255.255.255.0*.
3. Set *Interface* to *virtual-wan-link*.

4. Click *OK*.

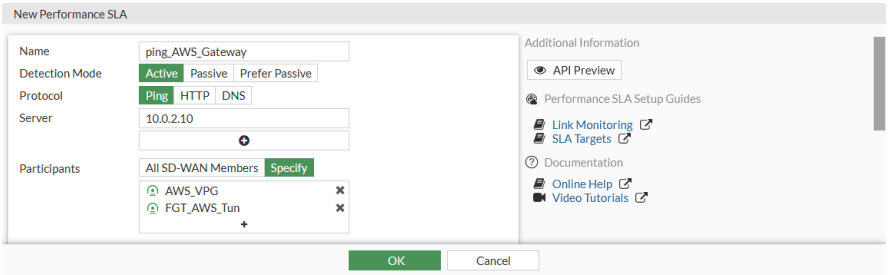
   Individual routes to each tunnel are automatically added to the routing table with the same distance:

To configure firewall policies to allow traffic from the internal subnet to SD-WAN:

1. Go to *Policy & Objects* > *Firewall Policy* and click *Create New*.
2. Configure the following:

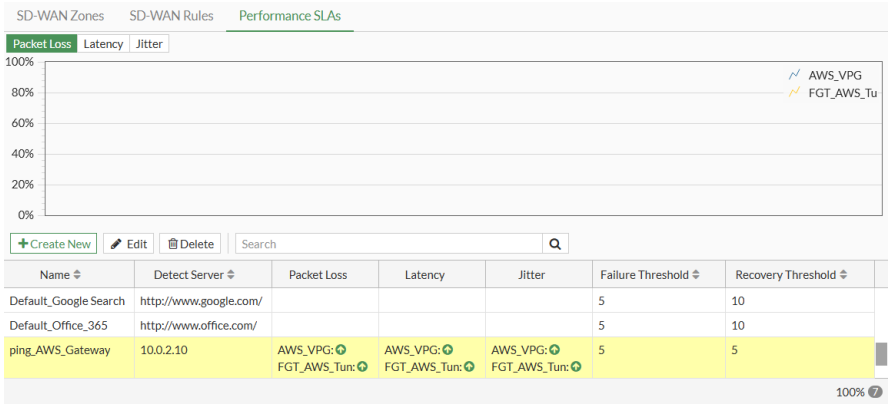
Name	ISFW-to-IaaS

Incoming Interface	port3
Outgoing Interface	virtual-wan-link
Source	all
Destination	all
Schedule	always
Service	ALL
Action	ACCEPT
NAT	Enabled



3. Configure the remaining settings as required.
4. Click *OK*.
   Once the firewall policies are configured, the VPN tunnels should come up when there is traffic.

To configure a health check to monitor the status of the tunnels:



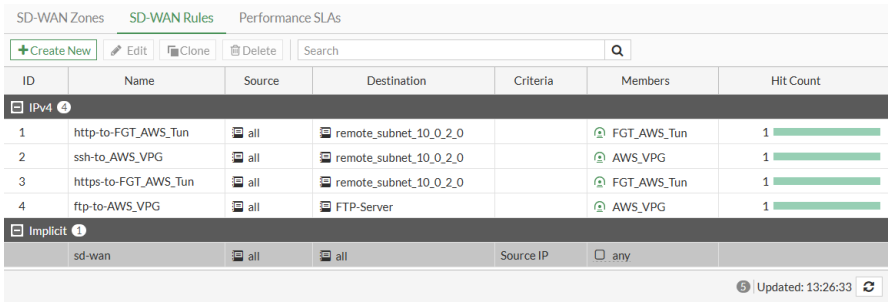
As you are accessing the servers on the 10.0.2.0/24 subnet, it is preferable to use the FortiGate port2 interface as the ping server for detection. This ensures that, if the gateway is not reachable in either tunnel, its routes are brought down and traffic continues on the other tunnel.

1. Go to *Network* > *SD-WAN*, select the *Performance SLAs* tab, and click *Create New*.
2. Configure the following:

Name	ping_AWS_Gateway
Protocol	Ping
Server	10.0.2.10
Participants	Specify Add AWS_VPG and FGT_AWS_Tun as participants.

3. Click *OK*.

Health check probes originate from the VPN interface's IP address. This is why the phase2 selectors are configured with *Local Address* set to *all*.



To configure SD-WAN rules to steer traffic:

HTTPS and HTTP traffic is steered to the FGT_AWS_Tun tunnel, and SSH and FTP traffic is steered to the AWS_VPG tunnel. The Manual algorithm is used in this example.

1. Go to *Network* > *SD-WAN*, select the *SD-WAN Rules* tab, and click *Create New*.
2. Configure the following:

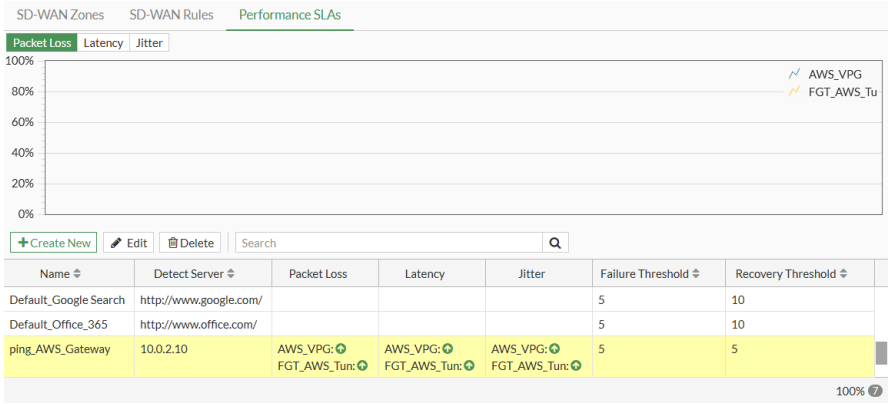
Name	http-to-FGT_AWS_Tun
Source Address	all
Address	remote_subnet_10_0_2_0
Protocol	TCP
Port range	80 - 80
Outgoing Interfaces	Manual
Interface preference	FGT_AWS_Tun

3. Click *OK*.
4. Create other SD-WAN rules as required:

Verifying the traffic

To verify that pings are sent across the IPsec VPN tunnels

- On the HQ FortiGate, run the following CLI command:



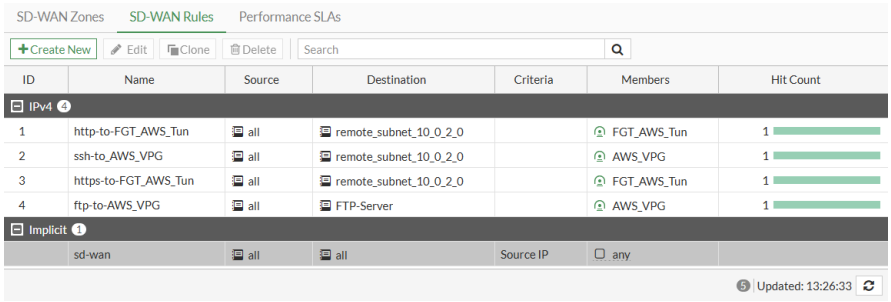
```
# diagnose sniffer packet any 'host 10.0.2.10' 4 0 1 interfaces=[any]
Using Original Sniffing Mode
interfaces=[any]
filters=[host 10.0.2.10]
pcap_snapshot: snaplen raised from 0 to 262144
2021-06-05 11:35:14.822600 AWS_VPG out 169.254.55.154 -> 10.0.2.10: icmp: echo request
2021-06-05 11:35:14.822789 FGT_AWS_Tun out 172.16.200.2 -> 10.0.2.10: icmp: echo request
2021-06-05 11:35:14.877862 FGT_AWS_Tun in 10.0.2.10 -> 172.16.200.2: icmp: echo reply
2021-06-05 11:35:14.878887 AWS_VPG in 10.0.2.10 -> 169.254.55.154: icmp: echo reply
```

- On the cloud FortiGate-VM, run the following CLI command:

```
# diagnose sniffer packet any 'host 10.0.2.10' 4 0 1 interfaces=[any]
Using Original Sniffing Mode
interfaces=[any]
filters=[host 10.0.2.10]
pcap_snapshot: snaplen raised from 0 to 262144
2021-06-05 11:37:57.176329 port2 in 169.254.55.154 -> 10.0.2.10: icmp: echo request
2021-06-05 11:37:57.176363 port2 out 10.0.2.10 -> 169.254.55.154: icmp: echo reply
2021-06-05 11:37:57.176505 Core_Dialup in 172.16.200.2 -> 10.0.2.10: icmp: echo request
2021-06-05 11:37:57.176514 Core_Dialup out 10.0.2.10 -> 172.16.200.2: icmp: echo reply
```

To verify the SLA health checks on the HQ FortiGate:

1. Go to *Network* > *SD-WAN*, select the *Performance SLAs* tab, select *Packet Loss*, and click the *ping_AWS_Gateway* SLA:



2. Run the following CLI command:

```
# diagnose sys sdwan health-check
…
Seq(1 AWS_VPG): state(alive), packet-loss(0.000%) latency(56.221), jitter(0.290) sla_
map=0x0
Seq(2 FGT_AWS_Tun): state(alive), packet-loss(0.000%) latency(55.039), jitter(0.223)
sla_map=0x0
```

To verify service rules:

1. Go to *Network* > *SD-WAN* and select the *SD-WAN Rules* tab:

2. Run the following CLI command:

```
# diagnose sys sdwan service

Service(1): Address Mode(IPV4) flags=0x0
  Gen(1), TOS(0x0/0x0), Protocol(6: 80->80), Mode(manual)
  Members:
    1: Seq_num(2 FGT_AWS_Tun), alive, selected
  Src address:
        0.0.0.0-255.255.255.255
  Dst address:
        10.0.2.0-10.0.2.255

Service(2): Address Mode(IPV4) flags=0x0
  Gen(1), TOS(0x0/0x0), Protocol(6: 22->22), Mode(manual)

```

To verify that sessions are going to the correct tunnel:

1. Run the following CLI command to verify that HTTPS and HTTP traffic destined for the Web server at 10.0.2.20 uses FGT_AWS_Tun:

```
# diagnose sys session filter dst 10.0.2.20
# diagnose sys session list

session info: proto=6 proto_state=11 duration=2 expire=3597 timeout=3600 flags=00000000

```

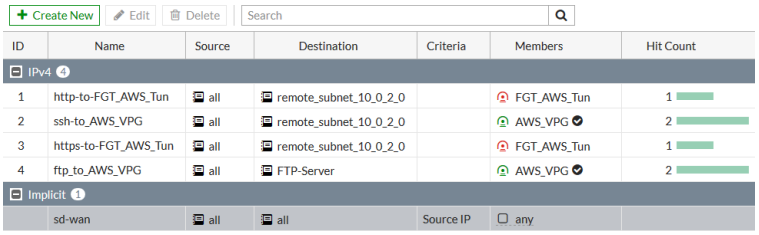
To simulate an issue on an overlay VPN tunnel:

On the cloud FortiGate-VM, disable the firewall policy allowing Core_Dialup to port2.

1. Health-checks through the FGT_AWS_Tun tunnel fail:
   a. Go to *Network* > *SD-WAN*, select the *Performance SLAs* tab, select *Packet Loss*, and click the *ping_AWS_Gateway* SLA:



Name	Detect Server	Packet Loss	Latency	Jitter	Failure Threshold	Recovery Threshold
Default_AWS	http://aws.amazon.com/				5	10
Default_DNS	208.91.112.53 208.91.112.52 (System DNS)				5	10
Default_FortiGuard	http://fortiguard.com/				5	10
Default_Gmail	gmail.com				5	10
Default_Google Search	http://www.google.com/				5	10
Default_Office_365	http://www.office.com/				5	10
ping_AWS_Gateway	10.0.2.10	AWS_VPG: 0.00% FGT_AWS_Tun:	AWS_VPG: 54.98ms FGT_AWS_Tun:	AWS_VPG: 0.41ms FGT_AWS_Tun:	5	5

b. Run the following CLI command:

```
# diagnose sys sdwan health-check
…
Seq(1 AWS_VPG): state(alive), packet-loss(0.000%) latency(52.746), jitter(0.713) sla_
map=0x0
Seq(2 FGT_AWS_Tun): state(dead), packet-loss(19.000%) sla_map=0x0
```

2. Service rules show that the member is down:

a. Go to *Network* > *SD-WAN* and select the *SD-WAN Rules* tab:

ID	Name	Source	Destination	Criteria	Members	Hit Count
IPv4 4						
1	http-to-FGT_AWS_Tun	all	remote_subnet_10_0_2_0		FGT_AWS_Tun	1
2	ssh-to_AWS_VPG	all	remote_subnet_10_0_2_0		AWS_VPG	2
3	https-to-FGT_AWS_Tun	all	remote_subnet_10_0_2_0		FGT_AWS_Tun	1
4	ftp_to_AWS_VPG	all	FTP-Server		AWS_VPG	2
Implicit 1						
	sd-wan	all	all	Source IP	any	

b. Run the following CLI command:

```
# diagnose sys sdwan service

Service(1): Address Mode(IPV4) flags=0x0
  Gen(2), TOS(0x0/0x0), Protocol(6: 80->80), Mode(manual)
  Members:
    1: Seq_num(2 FGT_AWS_Tun), dead
  Src address:
        0.0.0.0-255.255.255.255
  Dst address:
        10.0.2.0-10.0.2.255

Service(2): Address Mode(IPV4) flags=0x0
  Gen(1), TOS(0x0/0x0), Protocol(6: 22->22), Mode(manual)
  Members:
    1: Seq_num(1 AWS_VPG), alive, selected
  Src address:
        0.0.0.0-255.255.255.255
  Dst address:
        10.0.2.0-10.0.2.255
```

```
Service(3): Address Mode(IPV4) flags=0x0

```

3. Sessions are redirected to the working tunnel:
   a. Run the following CLI command:

```
# diagnose sys session list

session info: proto=6 proto_state=11 duration=3 expire=3596 timeout=3600
flags=00000000 socktype=0 sockport=0 av_idx=0 use=4
origin-shaper=
reply-shaper=
per_ip_shaper=
class_id=0 ha_id=0 policy_dir=0 tunnel=AWS_VPG/ vlan_cos=0/255
state=log may_dirty ndr npu f00 csf_syncd_log app_valid
statistic(bytes/packets/allow_err): org=504/4/1 reply=620/3/1 tuples=3
tx speed(Bps/kbps): 150/1 rx speed(Bps/kbps): 184/1
orgin->sink: org pre->post, reply pre->post dev=0->17/17->0
gwy=169.254.55.153/0.0.0.0
hook=post dir=org act=snat 10.100.88.101:56373->10.0.2.20:80(169.254.55.154:56373)
hook=pre dir=reply act=dnat 10.0.2.20:80->169.254.55.154:56373(10.100.88.101:56373)

total session 2
```

4. Routes to the *FGT_AWS_Tun* tunnel are removed:
   a. If *Optimal* dashboards is selected, go to *Dashboard* > *Network* and expand the Routing widget to view the routing table.
   If *Comprehensive* dashboards is selected, go to *Dashboard* > *Routing Monitor* and select *Static & Dynamic* in the widget toolbar to view the routing table:

Network	Gateway IP	Interfaces	Distance	IP Version	Type
IPv4 40					
0.0.0.0/0	10.100.64.254	Internet_A (port1)	1	IPv4	Static
0.0.0.0/0	10.100.65.254	Internet_B (port5)	1	IPv4	Static
10.0.2.0/24	169.254.55.153	AWS_VPG	1	IPv4	Static
10.0.10.0/24	0.0.0.0	VPN_A_Tunnel (Branch-HQ-A)	0	IPv4	Connected
10.0.10.1/32	0.0.0.0	VPN_A_Tunnel (Branch-HQ-A)	0	IPv4	Connected

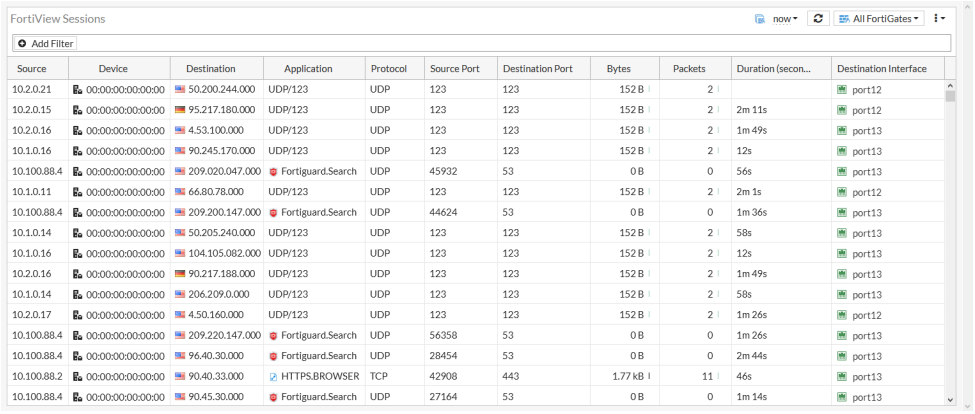
   b. Run the following CLI command:

```
# get router info routing-table all
Codes: K - kernel, C - connected, S - static, R - RIP, B - BGP
       O - OSPF, IA - OSPF inter area
       N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
       E1 - OSPF external type 1, E2 - OSPF external type 2
       i - IS-IS, L1 - IS-IS level-1, L2 - IS-IS level-2, ia - IS-IS inter area
       * - candidate default

Routing table for VRF=0
S*      0.0.0.0/0 [1/0] via 10.100.64.254, port1
                  [1/0] via 10.100.65.254, port5
S       10.0.2.0/24 [1/0] via 169.254.55.153, AWS_VPG
C       10.0.10.0/24 is directly connected, Branch-HQ-A
C       10.0.10.1/32 is directly connected, Branch-HQ-A
…
```

Troubleshooting SD-WAN

The following topics provide instructions on SD-WAN troubleshooting:



- Tracking SD-WAN sessions on page 899
- Understanding SD-WAN related logs on page 899
- SD-WAN related diagnose commands on page 902
- SD-WAN bandwidth monitoring service on page 906
- Using SNMP to monitor health check on page 909

Tracking SD-WAN sessions

You can check the destination interface in *Dashboard* > *FortiView Sessions* in order to see which port the traffic is being forwarded to.

The example below demonstrates a source-based load-balance between two SD-WAN members:

- If the source IP address is an *even* number, it will go to *port13*.
- If the source IP address is an *odd* number, it will go to *port12*.

Source	Device	Destination	Application	Protocol	Source Port	Destination Port	Bytes	Packets	Duration (secon...	Destination Interface
10.2.0.21	00:00:00:00:00:00	50.200.244.000	UDP/123	UDP	123	123	152 B	2		port12
10.2.0.15	00:00:00:00:00:00	95.217.180.000	UDP/123	UDP	123	123	152 B	2	2m 11s	port12
10.2.0.16	00:00:00:00:00:00	4.53.100.000	UDP/123	UDP	123	123	152 B	2	1m 49s	port13
10.1.0.16	00:00:00:00:00:00	90.245.170.000	UDP/123	UDP	123	123	152 B	2	12s	port13
10.100.88.4	00:00:00:00:00:00	209.020.047.000	Fortiguard.Search	UDP	45932	53	0 B	0	56s	port13
10.1.0.11	00:00:00:00:00:00	66.80.78.000	UDP/123	UDP	123	123	152 B	2	2m 1s	port12
10.100.88.4	00:00:00:00:00:00	209.200.147.000	Fortiguard.Search	UDP	44624	53	0 B	0	1m 36s	port13
10.1.0.14	00:00:00:00:00:00	50.205.240.000	UDP/123	UDP	123	123	152 B	2	58s	port13

Understanding SD-WAN related logs

This topic lists the SD-WAN related logs and explains when the logs will be triggered.

Health-check detects a failure:

- When health-check detects a failure, it will record a log:

```
1: date=2021-04-20 time=17:06:31 eventtime=1618963591590008160 tz="-0700"
logid="0100022921" type="event" subtype="system" level="critical" vd="root"
logdesc="Routing information changed" name="test" interface="R150" status="down"
msg="Static route on interface R150 may be removed by health-check test. Route:
(10.100.1.2->10.100.2.22 ping-down)"
```

- When health-check detects a recovery, it will record a log:

```
2: date=2021-04-20 time=17:11:46 eventtime=1618963906950174240 tz="-0700"
logid="0100022921" type="event" subtype="system" level="critical" vd="root"
logdesc="Routing information changed" name="test" interface="R150" status="up"
msg="Static route on interface R150 may be added by health-check test. Route:
(10.100.1.2->10.100.2.22 ping-up)"
```

Health-check has an SLA target and detects SLA qualification changes:

- When health-check has an SLA target and detects SLA changes, and changes to fail:

```
1: date=2021-04-20 time=21:32:33 eventtime=1618979553388763760 tz="-0700"
logid="0113022923" type="event" subtype="sdwan" level="notice" vd="root" logdesc="SDWAN
status" eventtype="Health Check" healthcheck="test" slatargetid=1 oldvalue="2"
newvalue="1" msg="Number of pass member changed."
```

```
2: date=2021-04-20 time=21:32:33 eventtime=1618979553388751880 tz="-0700"
logid="0113022923" type="event" subtype="sdwan" level="notice" vd="root" logdesc="SDWAN
status" eventtype="Health Check" healthcheck="test" slatargetid=1 member="1" msg="Member
status changed. Member out-of-sla."
```

- When health-check has an SLA target and detects SLA changes, and changes to pass:

```
1: date=2021-04-20 time=21:38:49 eventtime=1618979929908765200 tz="-0700"
logid="0113022923" type="event" subtype="sdwan" level="notice" vd="root" logdesc="SDWAN
status" eventtype="Health Check" healthcheck="test" slatargetid=1 oldvalue="1"
newvalue="2" msg="Number of pass member changed."
```

```
2: date=2021-04-20 time=21:38:49 eventtime=1618979929908754060 tz="-0700"
logid="0113022923" type="event" subtype="sdwan" level="information" vd="root"
logdesc="SDWAN status" eventtype="Health Check" healthcheck="test" slatargetid=1
member="1" msg="Member status changed. Member in sla."
```

SD-WAN calculates a link's session/bandwidth over/under its ratio and stops/resumes traffic:

- When SD-WAN calculates a link's session/bandwidth over its configured ratio and stops forwarding traffic:

```
1: date=2021-04-20 time=21:55:14 eventtime=1618980914728863220 tz="-0700"
logid="0113022924" type="event" subtype="sdwan" level="notice" vd="root" logdesc="SDWAN
volume status" eventtype="Volume" interface="R160" member="2" msg="Member enters into
conservative status with limited ablity to receive new sessions for too much traffic."
```

- When SD-WAN calculates a link's session/bandwidth according to its ratio and resumes forwarding traffic:

```
2: date=2021-04-20 time=22:12:52 eventtime=1618981972698753360 tz="-0700"
logid="0113022924" type="event" subtype="sdwan" level="notice" vd="root" logdesc="SDWAN
volume status" eventtype="Volume" interface="R160" member="2" msg="Member resume normal
status to receive new sessions for internal adjustment"
```

The SLA mode service rule's SLA qualified member changes:

- When the SLA mode service rule's SLA qualified member changes. In this example R150 fails the SLA check, but is still alive:

```
1: date=2021-04-20 time=22:40:46 eventtime=1618983646428803040 tz="-0700"
logid="0113022923" type="event" subtype="sdwan" level="notice" vd="root" logdesc="SDWAN
status" eventtype="Service" serviceid=1 service="test" seq="2,1" msg="Service
prioritized by SLA will be redirected in sequence order."
```

- When the SLA mode service rule's SLA qualified member changes. In this example R150 changes from fail to pass:

```
2: date=2021-04-20 time=22:41:51 eventtime=1618983711678827920 tz="-0700"
logid="0113022923" type="event" subtype="sdwan" level="notice" vd="root" logdesc="SDWAN
status" eventtype="Service" serviceid=1 service="test" seq="1,2" msg="Service
prioritized by SLA will be redirected in sequence order."
```

The priority mode service rule member's link status changes:

- When priority mode service rule member's link status changes. In this example R150 changes to better than R160, and both are still alive:

```
1: date=2021-04-20 time=22:56:55 eventtime=1618984615708804760 tz="-0700"
logid="0113022923" type="event" subtype="sdwan" level="notice" vd="root" logdesc="SDWAN
status" eventtype="Service" serviceid=1 service="test" metric="packet-loss" seq="2,1"
msg="Service prioritized by performance metric will be redirected in sequence order."
```

- When priority mode service rule member's link status changes. In this example R160 changes to better than R150, and both are still alive:

```
2: date=2021-04-20 time=22:56:58 eventtime=1618984618278852140 tz="-0700"
logid="0113022923" type="event" subtype="sdwan" level="notice" vd="root" logdesc="SDWAN
status" eventtype="Service" serviceid=1 service="test" metric="packet-loss" seq="1,2"
msg="Service prioritized by performance metric will be redirected in sequence order."
```

SD-WAN member is used in service and it fails the health-check:

- When SD-WAN member fails the health-check, it will stop forwarding traffic:

```
1: date=2021-04-20 time=23:04:32 eventtime=1618985072898756700 tz="-0700"
logid="0113022923" type="event" subtype="sdwan" level="notice" vd="root" logdesc="SDWAN
status" eventtype="Service" interface="R150" member="1" serviceid=1 service="test"
gateway=10.100.1.1 msg="Member link is unreachable or miss threshold. Stop forwarding
traffic. "
```

- When SD-WAN member passes the health-check again, it will resume forwarding logs:

```
2: date=2021-04-20 time=23:06:08 eventtime=1618985168018789600 tz="-0700"
logid="0113022923" type="event" subtype="sdwan" level="notice" vd="root" logdesc="SDWAN
status" eventtype="Service" interface="R150" member="1" serviceid=1 service="test"
gateway=10.100.1.1 msg="Member link is available. Start forwarding traffic. "
```

Load-balance mode service rule's SLA qualified member changes:

- When load-balance mode service rule's SLA qualified member changes. In this example R150 changes to not meet SLA:

```
1: date=2021-04-20 time=23:10:24 eventtime=1618985425048820800 tz="-0700"
logid="0113022923" type="event" subtype="sdwan" level="notice" vd="root" logdesc="SDWAN
status" eventtype="Service" serviceid=1 service="test" member="2(R160)" msg="Service
will be load balanced among members with available routing."
```

- When load-balance mode service rule's SLA qualified member changes. In this example R150 changes to meet SLA:

```
2: date=2021-04-20 time=23:11:34 eventtime=1618985494478807100 tz="-0700"
logid="0113022923" type="event" subtype="sdwan" level="notice" vd="root" logdesc="SDWAN
status" eventtype="Service" serviceid=1 service="test" member="2(R160),1(R150)"
msg="Service will be load balanced among members with available routing."
```

SLA link status logs, generated with interval sla-fail-log-period or sla-pass-log-period:

- When SLA fails, SLA link status logs will be generated with interval sla-fail-log-period:

```
1: date=2021-04-20 time=23:18:10 eventtime=1618985890469018260 tz="-0700"
logid="0113022925" type="event" subtype="sdwan" level="notice" vd="root" logdesc="SDWAN
SLA information" eventtype="SLA" healthcheck="test" slatargetid=1 interface="R150"
status="up" latency="0.061" jitter="0.004" packetloss="2.000%"
inbandwidthavailable="0kbps" outbandwidthavailable="200.00Mbps"
bibandwidthavailable="200.00Mbps" inbandwidthused="1kbps" outbandwidthused="1kbps"
bibandwidthused="2kbps" slamap="0x0" metric="packetloss" msg="Health Check SLA status.
SLA failed due to being over the performance metric threshold."
```

- When SLA passes, SLA link status logs will be generated with interval sla-pass-log-period:

```
2: date=2021-04-20 time=23:18:12 eventtime=1618985892509027220 tz="-0700"
logid="0113022925" type="event" subtype="sdwan" level="information" vd="root"
logdesc="SDWAN SLA information" eventtype="SLA" healthcheck="test" slatargetid=1
interface="R150" status="up" latency="0.060" jitter="0.003" packetloss="0.000%"
inbandwidthavailable="0kbps" outbandwidthavailable="200.00Mbps"
bibandwidthavailable="200.00Mbps" inbandwidthused="1kbps" outbandwidthused="1kbps"
bibandwidthused="2kbps" slamap="0x1" msg="Health Check SLA status."
```

SD-WAN related diagnose commands

This topic lists the SD-WAN related diagnose commands and related output.

To check SD-WAN health-check status:

```
FGT # diagnose sys sdwan health-check
Health Check(server):
Seq(1 R150): state(alive), packet-loss(0.000%) latency(0.110), jitter(0.024) sla_map=0x0
Seq(2 R160): state(alive), packet-loss(0.000%) latency(0.068), jitter(0.009) sla_map=0x0

FGT # diagnose sys sdwan health-check
Health Check(ping):
Seq(1 R150): state(alive), packet-loss(0.000%) latency(0.100), jitter(0.017) sla_map=0x0
Seq(2 R160): state(dead), packet-loss(100.000%) sla_map=0x0

FGT # diagnose sys sdwan health-check google
Health Check(google):
Seq(1 R150): state(alive), packet-loss(0.000%) latency(0.081), jitter(0.019) sla_map=0x0
Seq(2 R160): state(alive), packet-loss(0.000%) latency(0.060), jitter(0.004) sla_map=0x0
```

To check SD-WAN member status:

- When SD-WAN load-balance mode is *source-ip-based*/*source-dest-ip-based*.

```
FGT # diagnose sys sdwan member
Member(1): interface: R150, gateway: 10.100.1.1 2000:10:100:1::1, priority: 0 1024,
weight: 0
Member(2): interface: R160, gateway: 10.100.1.5 2000:10:100:1::5, priority: 0 1024,
weight: 0
```

- When SD-WAN load-balance mode is *weight-based*.

```
FGT # diagnose sys sdwan member
Member(1): interface: R150, gateway: 10.100.1.1 2000:10:100:1::1, priority: 0 1024,
weight: 33
  Session count: 15
Member(2): interface: R160, gateway: 10.100.1.5 2000:10:100:1::5, priority: 0 1024,
weight: 66
  Session count: 1
```

- When SD-WAN load-balance mode is *measured-volume-based*.
  - Both members are under volume and still have room:

```
FGT # diagnose sys sdwan member
Member(1): interface: R150, gateway: 10.100.1.1 2000:10:100:1::1, priority: 0 1024,
```

```
weight: 33
  Config volume ratio: 33, last reading: 218067B, volume room 33MB
Member(2): interface: R160, gateway: 10.100.1.5 2000:10:100:1::5, priority: 0 1024,
weight: 66
  Config volume ratio: 66, last reading: 202317B, volume room 66MB
```

- Some members are overloaded and some still have room:

```
FGT # diagnose sys sdwan member
Member(1): interface: R150, gateway: 10.100.1.1 2000:10:100:1::1, priority: 0 1024,
weight: 0
  Config volume ratio: 33, last reading: 1287767633B, overload volume 517MB
Member(2): interface: R160, gateway: 10.100.1.5 2000:10:100:1::5, priority: 0 1024,
weight: 63
  Config volume ratio: 66, last reading: 1686997898B, volume room 63MB
```

- When SD-WAN load balance mode is *usage-based*/*spillover*.
  - When no spillover occurs:

```
FGT # diagnose sys sdwan member
Member(1): interface: R150, gateway: 10.100.1.1 2000:10:100:1::1, priority: 0 1024,
weight: 255
  Egress-spillover-threshold: 400kbit/s, ingress-spillover-threshold: 300kbit/s
  Egress-overbps=0, ingress-overbps=0
Member(2): interface: R160, gateway: 10.100.1.5 2000:10:100:1::5, priority: 0 1024,
weight: 254
  Egress-spillover-threshold: 0kbit/s, ingress-spillover-threshold: 0kbit/s
  Egress-overbps=0, ingress-overbps=0
```

  - When member has reached limit and spillover occurs:

```
FGT # diagnose sys sdwan member
Member(1): interface: R150, gateway: 10.100.1.1 2000:10:100:1::1, priority: 0 1024,
weight: 255
  Egress-spillover-threshold: 400kbit/s, ingress-spillover-threshold: 300kbit/s
  Egress-overbps=1, ingress-overbps=0
Member(2): interface: R160, gateway: 10.100.1.5 2000:10:100:1::5, priority: 0 1024,
weight: 254
  Egress-spillover-threshold: 0kbit/s, ingress-spillover-threshold: 0kbit/s
  Egress-overbps=0, ingress-overbps=0
```

  - You can also use the `diagnose netlink dstmac list` command to check if you are over the limit.

```
FGT # diagnose netlink dstmac list R150
dev=R150 mac=00:00:00:00:00:00 vwl rx_tcp_mss=0 tx_tcp_mss=0 egress_overspill_
threshold=50000 egress_bytes=100982 egress_over_bps=1 ingress_overspill_
threshold=37500 ingress_bytes=40 ingress_over_bps=0 sampler_rate=0 vwl_zone_id=1
intf_qua=0
```

To check SD-WAN service rules status:

- *Manual mode* service rules.

```
FGT # diagnose sys sdwan service
Service(1): Address Mode(IPV4) flags=0x200
  Gen(1), TOS(0x0/0x0), Protocol(0: 1->65535), Mode(manual)
  Members(2):
    1: Seq_num(1 R150), alive, selected
    2: Seq_num(2 R160), alive, selected
```

```
  Dst address(1):
        10.100.21.0-10.100.21.255
```

- *Auto mode* service rules.

```
FGT # diagnose sys sdwan service
Service(1): Address Mode(IPV4) flags=0x200
  Gen(1), TOS(0x0/0x0), Protocol(0: 1->65535), Mode(auto), link-cost-factor(latency),
link-cost-threshold(10), heath-check(ping)
  Members(2):
    1: Seq_num(2 R160), alive, latency: 0.066, selected
    2: Seq_num(1 R150), alive, latency: 0.093
  Dst address(1):
        10.100.21.0-10.100.21.255
```

- *Priority mode* service rules.

```
FGT # diagnose sys sdwan service
Service(1): Address Mode(IPV4) flags=0x200
  Gen(1), TOS(0x0/0x0), Protocol(0: 1->65535), Mode(priority), link-cost-factor
(latency), link-cost-threshold(10), heath-check(ping)
  Members(2):
    1: Seq_num(2 R160), alive, latency: 0.059, selected
    2: Seq_num(1 R150), alive, latency: 0.077, selected
  Dst address(1):
        10.100.21.0-10.100.21.255
```

- *Load-balance* mode service rules.

```
FGT # diagnose sys sdwan service
Service(1): Address Mode(IPV4) flags=0x200
  Gen(1), TOS(0x0/0x0), Protocol(0: 1->65535), Mode(load-balance hash-mode=round-robin)
  Members(2):
    1: Seq_num(1 R150), alive, sla(0x1), gid(2), num of pass(1), selected
    2: Seq_num(2 R160), alive, sla(0x1), gid(2), num of pass(1), selected
  Dst address(1):
        10.100.21.0-10.100.21.255
```

- *SLA mode* service rules.

```
FGT # diagnose sys sdwan service
Service(1): Address Mode(IPV4) flags=0x200
  Gen(1), TOS(0x0/0x0), Protocol(0: 1->65535), Mode(sla), sla-compare-order
  Members(2):
    1: Seq_num(1 R150), alive, sla(0x1), gid(0), cfg_order(0), cost(0), selected
    2: Seq_num(2 R160), alive, sla(0x1), gid(0), cfg_order(1), cost(0), selected
  Dst address(1):
        10.100.21.0-10.100.21.255
```

To check interface logs from the past 15 minutes:

```

YouTube(31077 4294838537): 209.85.200.132 6 443 Thu Apr 22 10:02:03 2021
```

To check the dynamic tunnel status:

```
# diagnose sys link-monitor interface <name> <name>_0
```

For example:

```
# diagnose sys link-monitor interface vd2-2
Interface(vd2-2): state(up, since Tue Jun 15 12:31:28 2021), bandwidth(up:1299bps,
down:0bps), session count(IPv4:2, IPv6:0), tx(2409919 bytes), rx(5292290 bytes), latency
(0.03), jitter(0.00), packet-loss(0.00).

# diagnose sys link-monitor interface vd2-2 vd2-2_0
Interface(vd2-2_0): state(up, since Tue Jun 15 15:21:52 2021), bandwidth(up:640bps,
down:0bps), session count(IPv4:0, IPv6:0), tx(102242 bytes), rx(16388 bytes), latency(0.03),
jitter(0.00), packet-loss(0.00).
```

To check BGP learned routes and determine if they are used in SD-WAN service:

```
FGT # get router info bgp network 10.100.11.0/24
VRF 0 BGP routing table entry for 10.100.11.0/24
Paths: (2 available, best #2, table Default-IP-Routing-Table)
  Advertised to non peer-group peers:
   10.100.1.1
  Original VRF 0
  20 10
    10.100.1.1 from 10.100.1.1 (5.5.5.5)
      Origin incomplete metric 0, route tag 15, localpref 100, valid, external, best
      Community: 30:5
      Advertised Path ID: 2
       Last update: Thu Apr 22 10:27:27 2021

  Original VRF 0
  20 10
    10.100.1.5 from 10.100.1.5 (6.6.6.6)
      Origin incomplete metric 0, route tag 15, localpref 100, valid, external, best
      Community: 30:5
      Advertised Path ID: 1
       Last update: Thu Apr 22 10:25:50 2021
```

```
FGT # diagnose sys sdwan route-tag-list
Route-tag: 15, address: v4(1), v6(0)Last write/now: 6543391 6566007
        service(1), last read route-tag 15 at 6543420
Prefix(24): Address list(1):
        10.100.11.0-10.100.11.255 oif: 50 48
```

```
FGT # diagnose firewall proute list
list route policy info(vf=root):

```

SD-WAN bandwidth monitoring service

The bandwidth measuring tool is used to detect true upload and download speeds. Bandwidth tests can be run on demand or automated using a script to measure upload and download speeds up to 1 Gbps of throughput. This can be useful when configuring SD-WAN SLA and rules to balance SD-WAN traffic.

The speed test tool requires a valid SD-WAN Bandwidth Monitoring Service license.

The speed test tool is compatible with iperf3.6 with SSL support. It can test the upload bandwidth to the FortiGate Cloud speed test service. It can initiate the server connection and send download requests to the server. The tool can be run up to 10 times a day .

FortiGate downloads the speed test server list. The list expires after 24 hours. One of the speed test servers is selected, based on user input. The speed test runs, testing upload and download speeds. The test results are shown in the command terminal.

To download the speed test server list:

```
# execute speed-test-server download
Download completed.
```

To check the speed test server list:

```
# execute speed-test-server list
AWS_West valid
        Host: 34.210.67.183 5204 fortinet

        Host: 35.197.18.234 5207 fortinet
```

To run the speed test:

You can run the speed test without specifying a server. The system will automatically choose one server from the list and run the speed test.

```
# execute speed-test auto
The license is valid to run speed test.
Speed test quota for 2/1 is 9
current vdom=root
Run in uploading mode.
Connecting to host 35.230.2.124, port 5206
[ 16] local 172.16.78.185 port 2475 connected to 35.230.2.124 port 5206

speed test Done.
```

To add a script to run a speed test automatically once every 24 hours:

```
config system auto-script
    edit "speedtest"
        set interval 86400
        set repeat 0
        set start auto
        set script "
execute speed-test-server download
execute speed-test"
    next
end
```

To view the results of the speed test script:

```
execute auto-script result speedtest
```

Using SNMP to monitor health check

You can monitor SD-WAN health check related statistics using SNMP. The MIB file can be downloaded by going to *System* > *SNMP* and clicking *Download FortiGate MIB File*.

The following OIDs can be monitored:

Name	OID	Description
fgVWLHealthCheckLinkNumber	.1.3.6.1.4.1.12356.101.4.9.1	The number of health check links in fgVWLHealthCheckLinkTable
fgVWLHealthCheckLinkTable	.1.3.6.1.4.1.12356.101.4.9.2	SD-WAN health check statistics table. This table has a dependent expansion relationship with fgVdTable.Only health checks with a configured member link are present in this table.

Name	OID	Description
fgVWLHealthCheckLinkTableEntry	.1.3.6.1.4.1.12356.101.4.9.2.1	SD-WAN health check statistics on a virtual domain.
fgVWLHealthCheckLinkID	.1.3.6.1.4.1.12356.101.4.9.2.1.1	SD-WAN health check link ID. Only health checks with configured member link are present in this table. Virtual-wan-link health check link IDs are only unique within a virtual domain.
fgVWLHealthCheckLinkName	.1.3.6.1.4.1.12356.101.4.9.2.1.2	Health check name.
fgVWLHealthCheckLinkSeq	.1.3.6.1.4.1.12356.101.4.9.2.1.3	SD-WAN member link sequence.
fgVWLHealthCheckLinkState	.1.3.6.1.4.1.12356.101.4.9.2.1.4	Health check state on a specific member link.
fgVWLHealthCheckLinkLatency	.1.3.6.1.4.1.12356.101.4.9.2.1.5	The average latency of a health check on a specific member link within last 30 probes, in float number.
fgVWLHealthCheckLinkJitter	.1.3.6.1.4.1.12356.101.4.9.2.1.6	The average jitter of a health check on a specific member link within last 30 probes, in float number.
fgVWLHealthCheckLinkPacketSend	.1.3.6.1.4.1.12356.101.4.9.2.1.7	The total number of packets sent by a health check on a specific member link.
fgVWLHealthCheckLinkPacketRecv	.1.3.6.1.4.1.12356.101.4.9.2.1.8	The total number of packets received by a health check on a specific member link.
fgVWLHealthCheckLinkPacketLoss	.1.3.6.1.4.1.12356.101.4.9.2.1.9	The packet loss percentage of a health check on a specific member link within last 30 probes, in float number.
fgVWLHealthCheckLinkVdom	.1.3.6.1.4.1.12356.101.4.9.2.1.10	The VDOM that the link monitor entry exists in. This name corresponds to the fgVdEntName used in fgVdTable.
fgVWLHealthCheckLinkBandwidthIn	.1.3.6.1.4.1.12356.101.4.9.2.1.11	The available bandwidth of incoming traffic detected by a health check on a specific member link, in Mbps,

Name	OID	Description
fgVWLHealthCheckLinkBandwidthOut	.1.3.6.1.4.1.12356.101.4.9.2.1.12	The available bandwidth of outgoing traffic detected by a health check on a specific member link, in Mbps.
fgVWLHealthCheckLinkBandwidthBi	.1.3.6.1.4.1.12356.101.4.9.2.1.13	The available bandwidth of bi-direction traffic detected by a health check on a specific member link, in Mbps.
fgVWLHealthCheckLinkIfName	.1.3.6.1.4.1.12356.101.4.9.2.1.14	SD-WAN member interface name.

Example

This example shows a SD-WAN health check configuration and its collected statistics.

To configure the SD-WAN health check:

```
config system sdwan
    set status enable
    config zone
        edit "virtual-wan-link"
        next
    end
    config members
        edit 1
            set interface "port1"
            set gateway 192.168.2.1
        next
        edit 2
            set interface "MPLS"
            set zone "SD-Zone2"
            set cost 20
        next
        edit 3
            set interface "port2"
        next
    end
    config health-check
        edit "pingserver"
            set server "8.8.8.8"
            set sla-fail-log-period 10
            set sla-pass-log-period 20
            set members 2 1 3
            config sla
                edit 1
                    set link-cost-factor jitter packet-loss
                    set packetloss-threshold 2
                next
            end
        next
```

```
    end
end
```

The collected statistics:

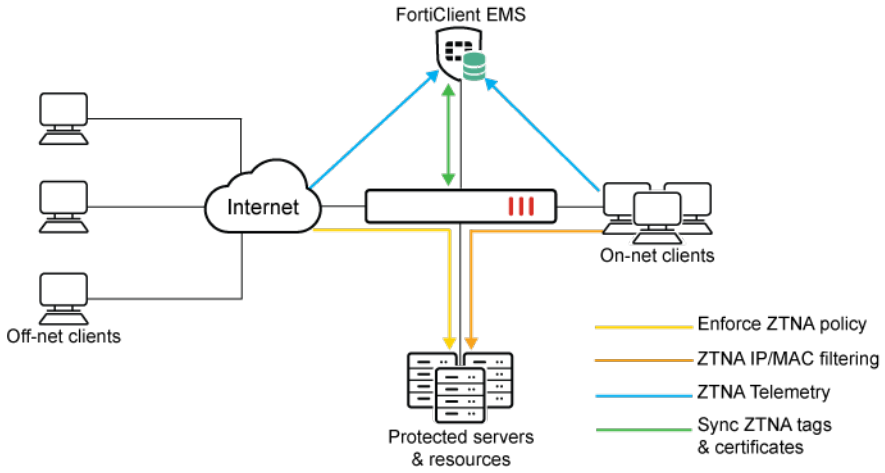
fgVWLHealthCheckLinkID	.1.3.6.1.4.1.12356.101.4.9.2.1.1	1	2	3
fgVWLHealthCheckLinkName	.1.3.6.1.4.1.12356.101.4.9.2.1.2	pingserver	pingserver	pingserver
fgVWLHealthCheckLinkSeq	.1.3.6.1.4.1.12356.101.4.9.2.1.3	2	1	3
fgVWLHealthCheckLinkState	.1.3.6.1.4.1.12356.101.4.9.2.1.4	0	0	0
fgVWLHealthCheckLinkLatency	.1.3.6.1.4.1.12356.101.4.9.2.1.5	39.302	43.124	44.348
fgVWLHealthCheckLinkJitter	.1.3.6.1.4.1.12356.101.4.9.2.1.6	4.346	3.951	5.05
fgVWLHealthCheckLinkPacketSend	.1.3.6.1.4.1.12356.101.4.9.2.1.7	3657689	3657689	3657689
fgVWLHealthCheckLinkPacketRecv	.1.3.6.1.4.1.12356.101.4.9.2.1.8	3196258	3220258	3219466
fgVWLHealthCheckLinkPacketLoss	.1.3.6.1.4.1.12356.101.4.9.2.1.9	0	0	0
fgVWLHealthCheckLinkVdom	.1.3.6.1.4.1.12356.101.4.9.2.1.10	root	root	root
fgVWLHealthCheckLinkBandwidthIn	.1.3.6.1.4.1.12356.101.4.9.2.1.11	9999963	9999937	9999999
fgVWLHealthCheckLinkBandwidthOut	.1.3.6.1.4.1.12356.101.4.9.2.1.12	9999981	9999953	9999998
fgVWLHealthCheckLinkBandwidthBi	.1.3.6.1.4.1.12356.101.4.9.2.1.13	19999944	19999890	19999997
fgVWLHealthCheckLinkIfName	.1.3.6.1.4.1.12356.101.4.9.2.1.14	MPLS	port1	port2

Zero Trust Network Access

This section includes information about ZTNA related new features:

- Zero Trust Network Access introduction on page 913
  - Basic ZTNA configuration on page 915
  - Establish device identity and trust context with FortiClient EMS on page 927
    - ZTNA scalability support for concurrent endpoints on page 932
  - SSL certificate based authentication on page 934
  - Full versus simple ZTNA policies NEW on page 936
- ZTNA advanced configurations on page 943
- ZTNA configuration examples on page 952
- ZTNA troubleshooting and debugging commands on page 1022
- ZTNA troubleshooting scenarios on page 1027

Zero Trust Network Access introduction



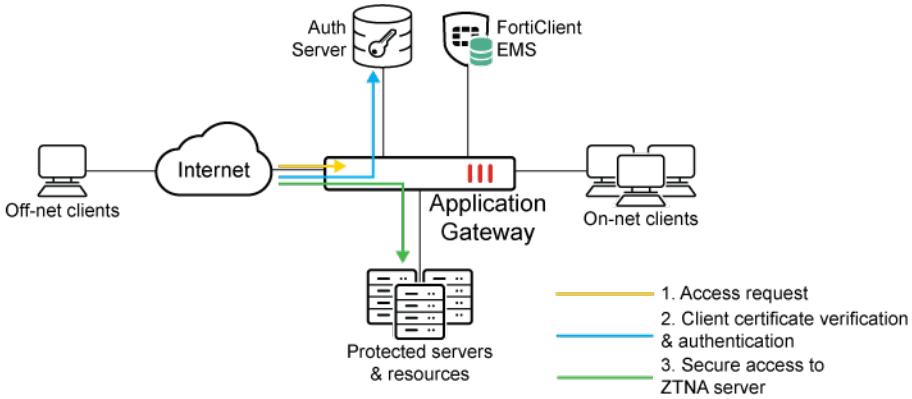
Zero Trust Network Access (ZTNA) is an access control method that uses client device identification, authentication, and Zero Trust tags to provide role-based application access. It gives administrators the flexibility to manage network access for On-net local users and Off-net remote users. Access to applications is granted only after device verification, authenticating the user's identity, authorizing the user, and then performing context based posture checks using Zero Trust tags.

Traditionally, a user and a device have different sets of rules for on-net access and off-net VPN access to company resources. With a distributed workforce and access that spans company networks, data centers, and cloud, managing the rules can become complex. User experience is also affected when multiple VPNs are needed to get to various resources. ZTNA can improve this experience.

ZTNA application gateway and IP/MAC based access control

- ZTNA application gateway allows users to securely access resources through an SSL encrypted access proxy. This simplifies remote access by eliminating the use of VPNs.
- IP/MAC based access control combines IP/MAC with uses ZTNA tags for identification and security posture check to implement role-based zero trust access.

ZTNA telemetry, tags, and policy enforcement



When On-net and Off-net FortiClient endpoints register to FortiClient EMS, device information, log on user information, and security posture are all shared over ZTNA telemetry with the EMS server. Clients also make a certificate signing request to obtain a client certificate from the EMS that is acting as the ZTNA Certificate Authority (CA).

Based on the client information, EMS applies matching Zero Trust tagging rules to tag the clients. These tags, and the client certificate information, are synchronized with the FortiGate in real-time. This allows the FortiGate to verify the client's identity using the client certificate, and grant access based on the ZTNA tags applied in the ZTNA policy.

For more information, see Establish device identity and trust context with FortiClient EMS on page 927.

Application gateway

The FortiGate application gateway can proxy HTTP, SSH, RDP, SMB, FTP, and other TCP traffic over secure connections with the client. This enables seamless access from the client to the protected servers, without needing to form IPsec or SSL VPN tunnels.

HTTPS access proxy

The FortiGate HTTPS access proxy works as a reverse proxy for the HTTP server. When a client connects to a webpage hosted by the protected server, the address resolves to the FortiGate's access proxy VIP. The FortiGate proxies the

connection and takes steps to authenticate the user. It prompts the user for their certificate on the browser, and verifies this against the ZTNA endpoint record that is synchronized from the EMS. If an authentication scheme, such as SAML authentication, is configured, the client is redirected to a captive portal for sign-on. If this passes, traffic is allowed based on ZTNA policies, and the FortiGate returns the webpage to the client.

For example configurations, see ZTNA HTTPS access proxy example on page 953, ZTNA HTTPS access proxy with basic authentication example on page 963, and ZTNA application gateway with SAML authentication example on page 983.

TCP forwarding access proxy (TFAP)

The TCP forwarding access proxy works as a special type of HTTPS reverse proxy. Instead of proxying traffic to a web server, TCP traffic is tunneled between the client and the access proxy over HTTPS, and forwarded to the protected resource. The FortiClient on the remote endpoint intercepts traffic destined for the protected resources and routes them to the FortiGate proxy gateway. An HTTPS connection is made to the FortiGate's access proxy VIP, where the client certificate is verified and access is granted based on the ZTNA policies. TCP traffic is forwarded from the FortiGate to the protected resource, and an end to end connection is established. To reduce overhead, you can disable access proxy encryption on the client, as some TCP protocols, like RDP, are already secure. The TCP forwarding access proxy supports UTM scanning and deep inspection for HTTP, HTTPS, SMTP, SMTPS, IMAP, IMAPS, POP3, POP3S, SMB, and CIFS.

For an example configuration, see ZTNA TCP forwarding access proxy example on page 970.

SSH access proxy

The SSH access proxy provides some benefits to proxying SSH connections over TFAP, including allowing SSH deep inspection, performing optional SSH host-key validation, and allowing one time user authentication to authenticate the ZTNA SSH access proxy connection and SSH server connection.

For an example configuration, see ZTNA SSH access proxy example on page 976.

Basic ZTNA configuration components

The basic components that are require to configure ZTNA application gateway on the FortiGate are:

1. FortiClient EMS fabric connector and ZTNA tags.
2. FortiClient EMS running version 7.0.0 or later or FortiClient EMS Cloud.
3. FortiClient running 7.0.0 or later.
4. ZTNA server
5. ZTNA policy
6. (Optional) User authentication
7. (Optional) HA configurations

For configuration details, see Basic ZTNA configuration on page 915.

Basic ZTNA configuration

To deploy a ZTNA application gateway, configure the following components on the FortiGate:

1. Configure a FortiClient EMS connector on page 916
2. Configure a ZTNA server on page 918
3. Configure a ZTNA policy on page 921
4. Optional authentication on page 924
5. Optional HA configurations on page 926

To configure ZTNA in the GUI, go to *System* > *Feature Visibility* and enable *Zero Trust Network Access*.

Desktop models that are below 100-series have ZTNA settings disabled by default. To configure ZTNA, enable the following:

```
config system global
    set proxy-and-explicit-proxy enable
end
```

Configure a FortiClient EMS connector

To add an on-premise FortiClient EMS server in the GUI:

1. Go to *Security Fabric* > *Fabric Connectors* and double-click the *FortiClient EMS* card.
2. Set the *Status* to *Enabled*.
3. Enter a name for the connector and the IP address or FQDN of the EMS.
4. Click *OK*.
5. A window appears to verify the EMS server certificate. Click *Accept*.
   See FortiClient EMS for more information.

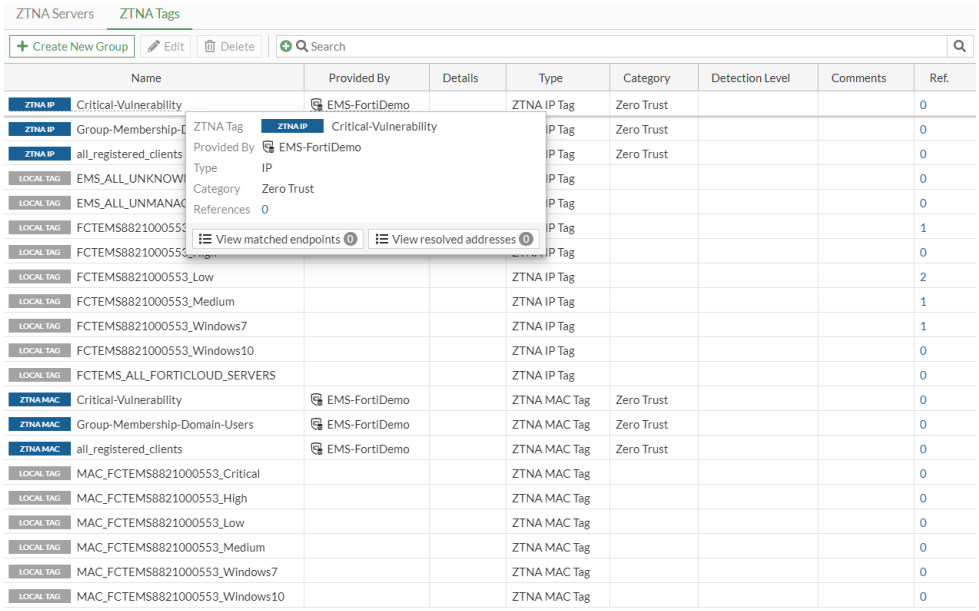
To add an on-premise FortiClient EMS server in the CLI:

```
config endpoint-control fctems
    edit <name>
        set server <server IP or domain>
    next
end
```

To add FortiClient EMS Cloud in the GUI:

1. Go to *Security Fabric* > *Fabric Connectors* and double-click the *FortiClient EMS* card.
2. Set the *Status* to *Enabled*.
3. Set the *Type* to *FortiClient EMS Cloud*.
4. Enter a name for the connector.
5. Click *OK*. A window appears to verify the EMS server certificate.
6. Click *Accept*.
   See FortiClient EMS for more information.

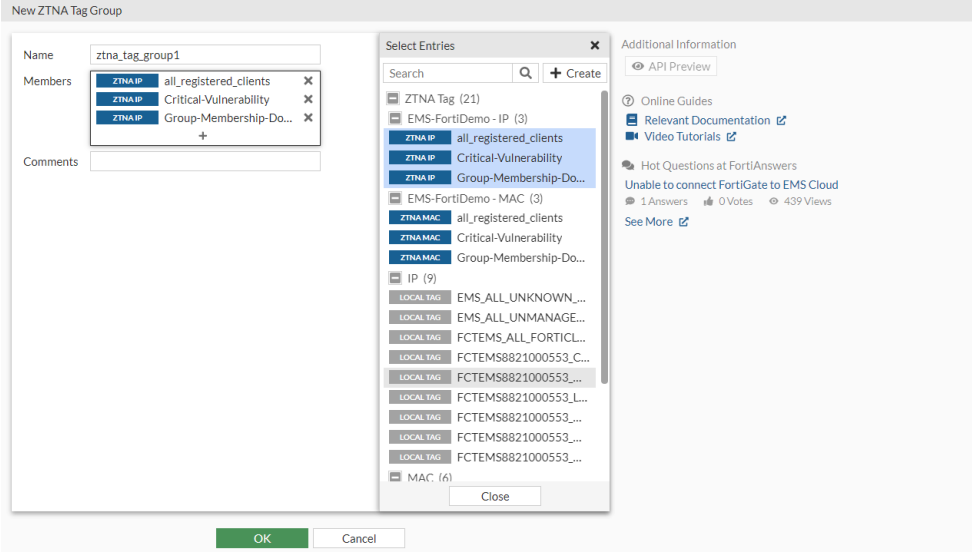
To add FortiClient EMS Cloud in the CLI:



```
config endpoint-control fctems
    edit <name>
        set fortinetone-cloud-authentication enable
        set certificate <string>
    next
end
```

ZTNA tags

After the FortiGate connects to the FortiClient EMS, it automatically synchronizes ZTNA tags. ZTNA tags are generated from tagging rules configured on the FortiClient EMS. These tagging rules are based on various posture checks that can be applied on the endpoints. See Endpoint Posture Check Reference.



To view the synchronized ZTNA tags in the GUI:

1. Go to *Policy & Objects* > *ZTNA* and select the *ZTNA Tags* tab.
2. Hover the cursor over a tag name to view more information about the tag, such as its resolved addresses.

To create a ZTNA tag group in the GUI:

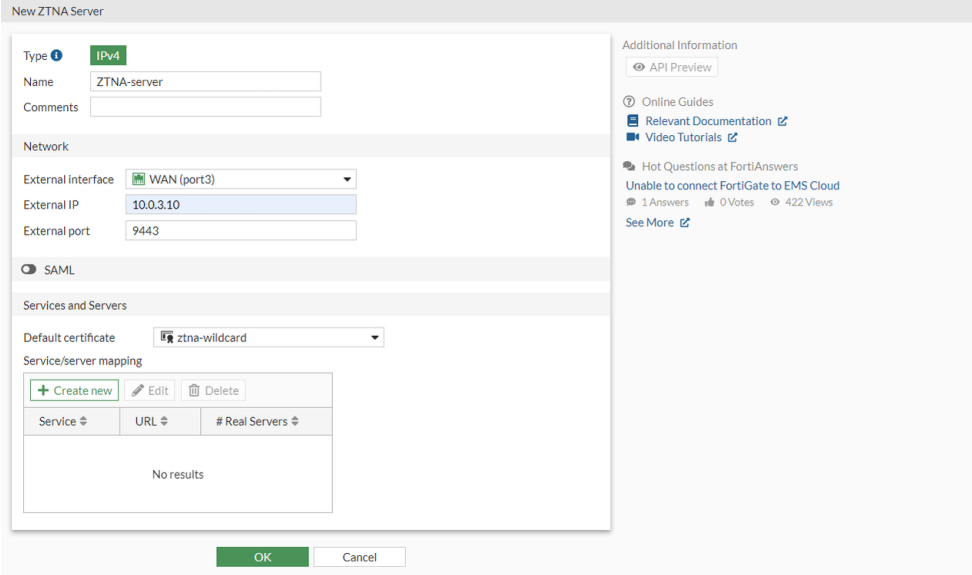
1. Go to *Policy & Objects* > *ZTNA* and select the *ZTNA Tags* tab.
2. Click *Create New Group*.
3. Enter a name for the group and select the group members.

4. Click *OK*.

To view the synchronized ZTNA tags in the CLI:

```
# diagnose firewall dynamic address
# diagnose firewall dynamic list
```

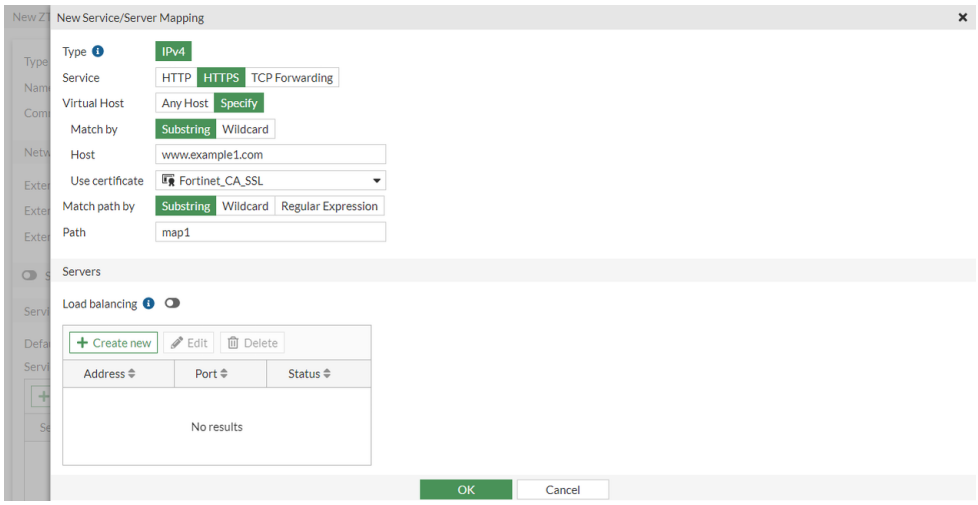
To create a ZTNA tag group in the CLI:



```
config firewall addrgrp
    edit <group name>
        set category ztna-ems-tag
        set member <members>
    next
end
```

Configure a ZTNA server

To configure a ZTNA server, define the access proxy VIP and the real servers that clients will connect to. The access proxy VIP is the FortiGate ZTNA gateway that clients make HTTPS connections to. The service/server mappings define the virtual host matching rules and the real server mappings of the HTTPS requests.



To create a ZTNA server for HTTPS access proxy in the GUI:

1. Go to *Policy & Objects* > *ZTNA* and select the *ZTNA Servers* tab.
2. Click *Create New*.
3. Enter a name for the server.
4. Select an external interface, enter the external IP address, and select the external port that the clients will connect to.
5. Select the *Default certificate*. Clients will be presented with this certificate when they connect to the access proxy VIP.

6. Add server mapping:
   a. In the *Service/server mapping* table, click *Create New*.
   b. Set *Service* to *HTTPS*.
   c. Set *Virtual Host* to *Any Host* or *Specify*.
      - *Any Host*: Any request that resolves to the access proxy VIP will be mapped to your real servers. For example, if both www.example1.com and www.example2.com resolve to the VIP, then both requests are mapped to your real servers.
      - *Specify*: Enter the name or IP address of the host that the request must match. For example, if www.example1.com is entered as the host, then only requests to www.example1.com will match.
   d. Configure the path as needed.

      The path can be matched by substring, wildcard, or regular expression. For example, if the virtual host is specified as www.example1.com, and the path substring is map1, then www.example1/map1 will be matched.

   e. If multiple servers will be configured, enable *Load balancing* and select an algorithm.
   f. Add a server:

i. In the *Servers* table, click *Create New*.
ii. Enter the server IP address and port number.
iii. Set the server status.
iv. Click *OK*.
v. Add more servers as needed.

g. Click *OK*.
h. Add more server mappings as needed.

7. Click *OK*.

To create a ZTNA server and access proxy VIP in the CLI:

1. Configure an access proxy VIP:

```
config firewall vip
    edit <name>
        set type access-proxy
        set extip <external IP>
        set extintf <external interface>
        set server-type {https | ssh}
        set extport <external port>
        set ssl-certificate <certificate>
    next
end
```

2. If the virtual host is specified, configure the virtual host:

```
config firewall access-proxy-virtual-host
    edit <auto generated when configured from GUI>
        set ssl-certificate <certificate>
        set host <host name or IP>
        set host-type {sub-string | wildcard}
    next
end
```

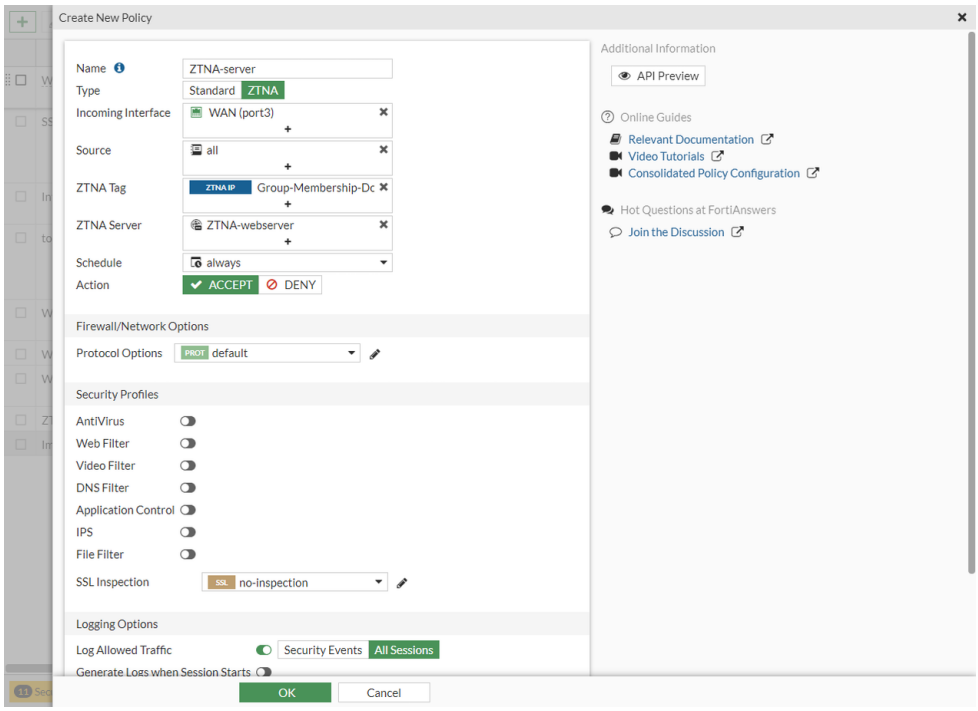
3. Configure the server and path mapping:

```
config firewall access-proxy
    edit <name>
        set vip <vip name>
        set client-cert {enable | disable}
        set empty-cert-action {accept | block}
        set log-blocked-traffic {enable | disable}
        config api-gateway
            edit 1
                set url-map <mapped path>
                set service {http | https | tcp-forwarding | samlsp}
                set virtual-host <name of virtual-host if specified>
                set url-map-type {sub-string | wildcard | regex}
                config realservers
                    edit 1
                        set addr-type ip
                        set ip <ip of real server>
                        set port <port>
                        set status {active | standby | disable}
                        set health-check {enable | disable}
```

```
                        set translate-host {enable | disable}
                    next
                end
                set ldb-method static
                set persistence none
                set ssl-dh-bits 2048
                set ssl-algorithm high
                set ssl-min-version tls-1.1
                set ssl-max-version tls-1.3
            next
        end
    next
end
```

Configure a ZTNA policy

A ZTNA policy is used to enforce zero trust role based access control by using ZTNA tags or tag groups to verify a device's security posture. A ZTNA policy can also utilize security profiles to protect this traffic.



In earlier versions, ZTNA rules were special proxy policies that controlled access to the ZTNA servers, and they could be configured from the *Policy & Objects* > *ZTNA* > *ZTNA Rules* tab. However, on this version and above, these special proxy policies are now configured from *Policy & Objects* > *Proxy Policy* page.

There are two ways to configure ZTNA rules in the GUI by using a full or simple ZTNA policy:

- Full ZTNA policy: The legacy method for configuring access-proxy policies.
- Simple ZTNA policy: A simplified method for configuring a ZTNA policy using firewall policies. This method covers most functionalities of a Full ZTNA policy, except it cannot control access based on destination interface or real server's destination address.

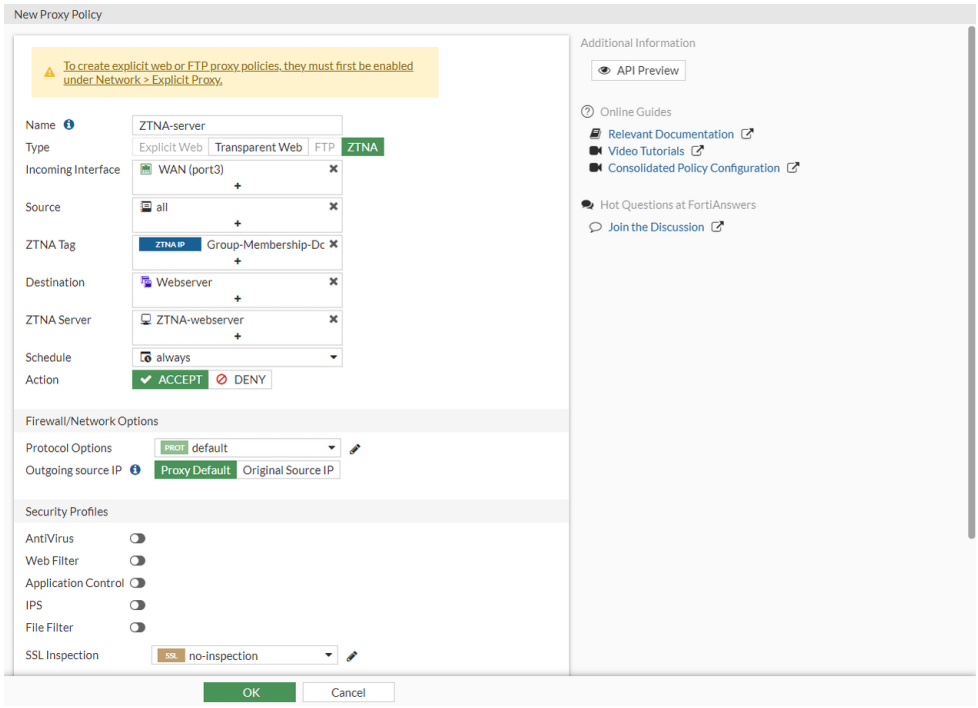
To configure a simple ZTNA policy in the GUI:

1. Go to *Policy & Objects* > *Firewall Policy*.
2. Click *Create New*.
3. Enter a name for the ZTNA policy.
4. Set *Type* to *ZTNA*.
5. Select an *Incoming Interface* and *Source*.
6. Add the ZTNA tags or tag groups that are allowed access. If multiple tags are included, the matching method is set to *Any* by default.
7. Select the *ZTNA Server*.
8. Select the *Action*.

9. Configure the remaining options as needed.
10. Click OK.

To configure a simple ZTNA policy in the CLI:

```
config firewall policy
    edit 1
        set name <ZTNA policy name>
        set srcintf <interface>
        set dstintf "any"
        set action accept
        set srcaddr "all"
        set dstaddr <access proxy vip>
        set ztna-ems-tag <ZTNA tags>
        set schedule "always"
        set nat enable
    next
end
```



The `dstintf` command cannot be modified.

To configure a full ZTNA policy in the GUI:

1. Go to *System* > *Feature Visibility*.
2. Under *Security Features*, enabled *Explicit Proxy*.
3. Click *Apply*.
4. Go to *Policy & Objects* > *Proxy Policy*.

5. Click *Create New*.
6. Enter a name for the rule.
7. Select an *Incoming Interface* and *Source*.
8. Add the ZTNA tags or tag groups that are allowed access. If multiple tags are included, the matching method is set to *Any* by default.
9. Select the *Destination*.
10. Select the *ZTNA Server*.
11. Select the *Action*.

12. Configure the remaining options as needed.
13. Click *OK*.

To configure a full ZTNA policy in the CLI:

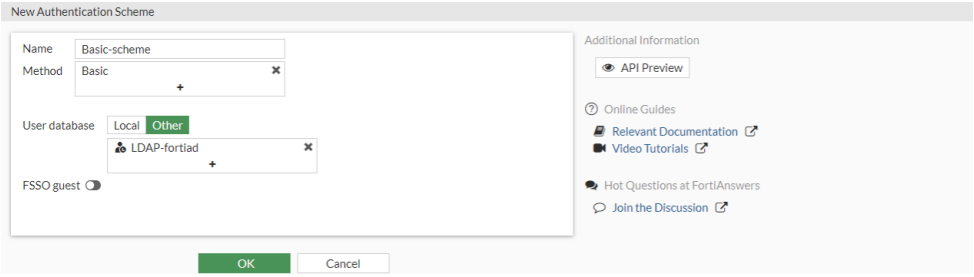
```
config firewall proxy-policy
    edit 1
        set name <ZTNA policy name>
        set proxy access-proxy
        set access-proxy <access proxy>
        set srcintf <interface>
        set srcaddr "all"
        set transparent {enable | disable}
        set dstaddr "all"
        set ztna-ems-tag <ZTNA tag(s)>
        set ztna-tags-match-logic {or | and}
        set action accept
        set schedule "always"
        set logtraffic all
        set poolname <ip_pool>
        set utm-status enable
```

```
        set ssl-ssh-profile <inspection profile>
    next
end
```

The `transparent` and `poolname` settings cannot be enabled at the same time. Use one setting at a time when configuring ZTNA policies.

Optional authentication

To configure authentication to the access proxy, you must configure an authentication scheme and authentication rule in the GUI or CLI. They are used to authenticate proxy-based policies, similar to configuring authentication for explicit and transparent proxy.



The authentication scheme defines the method of authentication that is applied. For ZTNA, basic HTTP and SAML methods are supported. Each method has additional settings to define the data source to check against. For example, with basic HTTP authentication, a user database can reference an LDAP server, RADIUS server, local database, or other supported authentication servers that the user is authenticated against.

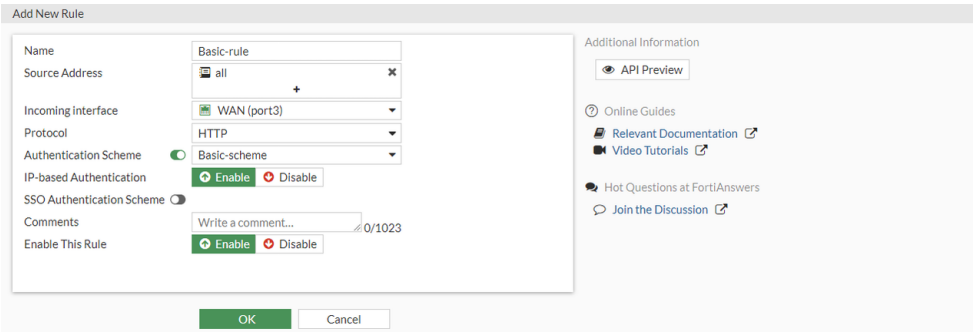
The authentication rule defines the proxy sources and destinations that require authentication, and which authentication scheme to apply. For ZTNA, active authentication method is supported. The active authentication method references a scheme where users are actively prompted for authentication, like with basic authentication.

After the authentication rule triggers the method to authenticate the user, a successful authentication returns the groups that the user belongs to. In the ZTNA policy you can define a user or user group as the allowed source. Only users that match that user or group are allowed through the proxy policy.

To configure a basic authentication scheme in the GUI:

1. Go to *Policy & Objects* > *Authentication Rules*.
2. Click *Create New* > *Authentication Scheme*.
3. Enter a name for the scheme.
4. Set the *Method* as *Basic*.
5. Select the *User database* as required.

6. Click *OK*.



To configure a basic authentication scheme in the CLI:

```
config authentication scheme
    edit <name>
        set method basic
```

```
        set user-database <auth server>
    next
end
```

To configure an authentication rule in the GUI:

1. Go to *Policy & Objects* > *Authentication Rules*.
2. Click *Create New* > *Authentication Rule*.
3. Enter a name for the rule.
4. Select the *Source Address*.
5. Select the *Incoming interface*.
6. Select the *Authentication Scheme*.

7. Click *OK*.

To configure an authentication rule in the CLI:

```
config authentication rule
    edit <name>
        set status enable
        set protocol http
        set srcintf <interface>
        set srcaddr <address>
        set dstaddr <address>
        set ip-based enable
        set active-auth-method <active auth scheme>
    next
end
```

To apply a user group to a full ZTNA policy in the GUI:

1. Go to *Policy & Objects* > *Proxy Policy*.
2. Edit an existing rule, or click *Create New* to create a new rule.
3. Click in the *Source* field, select the *User* tab, and select the users and user groups that will be allowed access.
4. Configure the remaining settings as required.
5. Click *OK*.

To apply a user group to a full ZTNA policy in the CLI:

```
config firewall proxy-policy
    edit <policy ID>
```

```
        set name <ZTNA policy name>
        set proxy access-proxy
        set access-proxy <access proxy>
        set srcintf <interface>
        set srcaddr "all"
        set dstaddr "all"
        set ztna-ems-tag <ZTNA tags>
        set ztna-tags-match-logic {or | and}
        set action accept
        set schedule "always"
        set logtraffic all
        set groups <user group>
        set utm-status enable
        set ssl-ssh-profile <inspection profile>
    next
end
```

The authentication rule and scheme defines the method used to authenticate users. With basic HTTP authentication, a sign in prompt is shown after the client certificate prompt. After the authentication passes, the returned groups that the user is a member of are checked against the user groups that are defined in the ZTNA policy. If a group matches, then the user is allowed access after passing a posture check.

For basic setup information, see ZTNA HTTPS access proxy with basic authentication example on page 963.

For advanced setup information, see ZTNA application gateway with SAML authentication example on page 983 and ZTNA application gateway with SAML and MFA using FortiAuthenticator example on page 987.

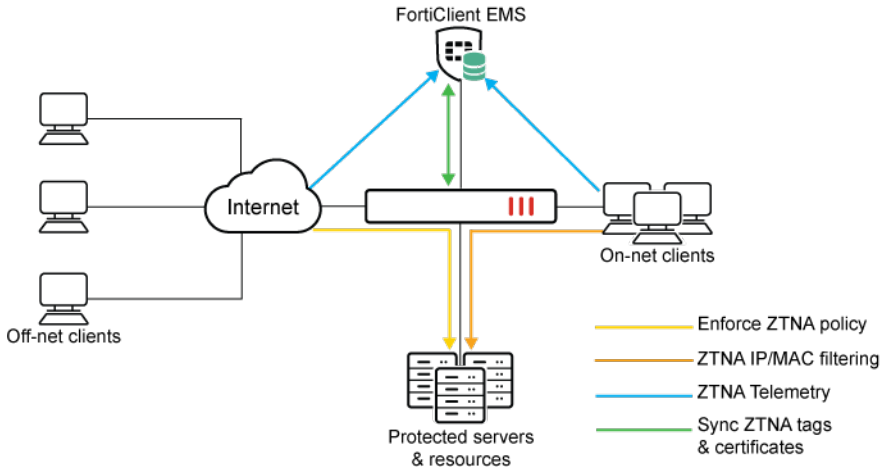
Optional HA configurations

User information and TLS sessions are synchronized between HA members for ZTNA proxy sessions. When a failover occurs, the new primary unit will continue allowing sessions from the logged in users without asking for the client certificate and re-authentication again.

There are no special configurations for HA. Refer to HA active-passive cluster setup on page 2354 and HA active-active cluster setup on page 2356 to configure your HA cluster.

HTTP access proxy vs TCP forwarding access proxy

In an HTTP access proxy connection, there is no configurations needed on the client endpoint. Users can simply access the HTTP website on a browser by entering its URL. For TCP forwarding access proxy, a ZTNA rule must be configured on the FortiClient endpoint. This rule instructs the FortiClient to listen to traffic to the destination address and port, and redirects the traffic to the FortiGate access proxy over HTTPS.



When deciding between using HTTP access proxy or TFAP for accessing web applications, consider the following.

- Use HTTP access proxy when the protected web application address can be resolved by the remote users publicly.
- Use TFAP when the protected application address can only be resolved on the internal network. TCP forwarding rules allow the FortiClient to intercept the request to the destination address and forward them to the application gateway.

For more information, see ZTNA TCP forwarding access proxy example on page 970.

Establish device identity and trust context with FortiClient EMS

How device identity is established through client certificates, and how device trust context is established between FortiClient, FortiClient EMS, and the FortiGate, are integral to ZTNA.

Device roles

FortiClient

FortiClient endpoints provide the following information to FortiClient EMS when they register to the EMS:

- Device information (network details, operating system, model, and others)
- Logged on user information
- Security posture (On-net/Off-net, antivirus software, vulnerability status, and others)

It also requests and obtains a client device certificate from the EMS ZTNA Certificate Authority (CA) when it registers to FortiClient EMS. The client uses this certificate to identify itself to the FortiGate.

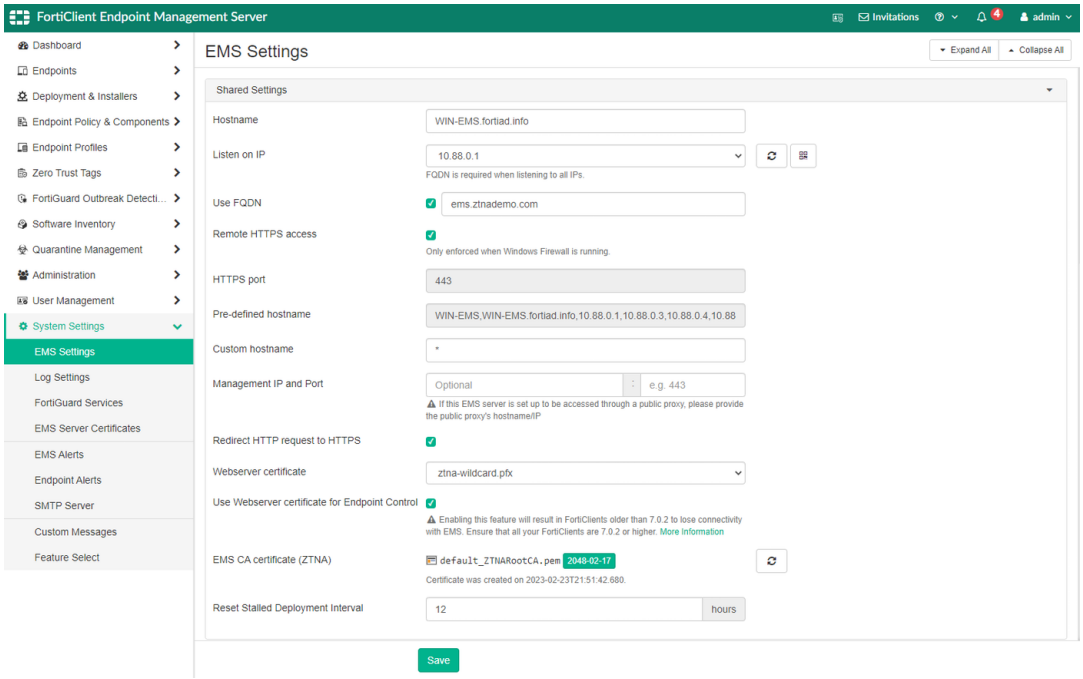
FortiClient EMS

FortiClient EMS issues and signs the client certificate with the FortiClient UID, certificate serial number, and EMS serial number. The certificate is then synchronized to the FortiGate. EMS also shares its EMS ZTNA CA certificate with the FortiGate, so that the FortiGate can use it to authenticate the clients.

FortiClient EMS uses zero trust tagging rules to tag endpoints based on the information that it has on each endpoint. The tags are also shared with the FortiGate. See Endpoint Posture Check Reference for a list of the endpoint posture checks that EMS can perform.

Each ZTNA tag creates two firewall addresses in all VDOMs on a FortiGate. One firewall address is the IP address, and the other firewall address is the MAC address. Because each FortiGate model has a global limit and a per-VDOM limit for the maximum number of supported firewall addresses, the FortiGate model determines the maximum number of ZTNA tags allowable by that unit, which is the maximum number of firewall address divided by two. For each FortiGate model's limit, see the Maximum Values table.

FortiGate

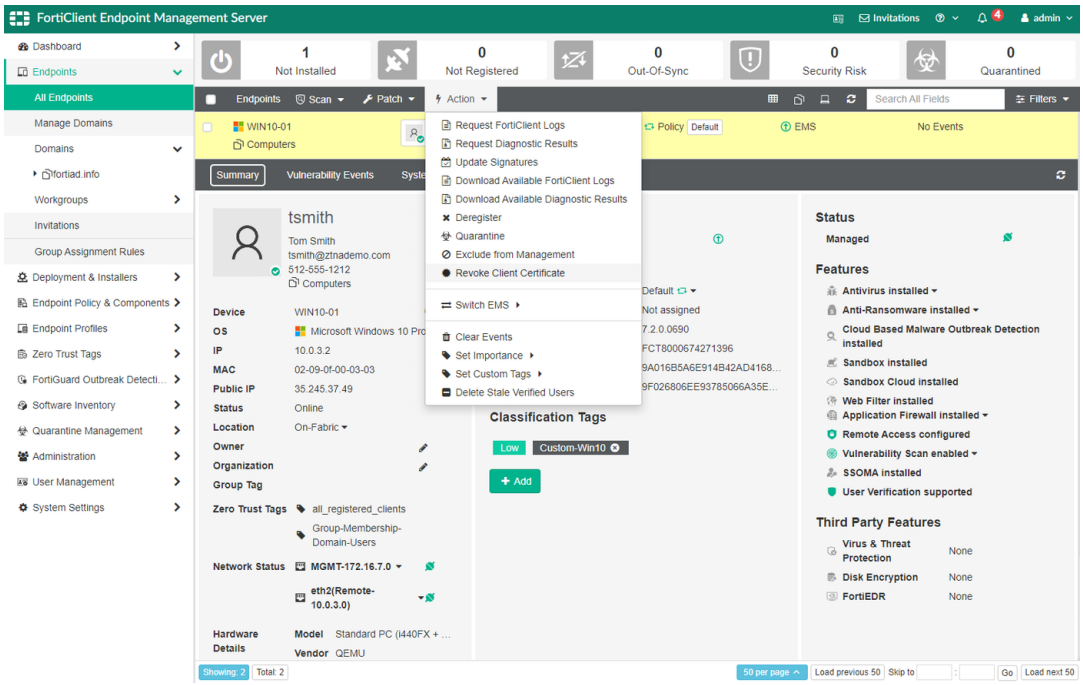


The FortiGate maintains a continuous connection to the EMS server to synchronize endpoint device information, including primarily:

- FortiClient UID
- Client certificate SN
- EMS SN
- Device credentials (user/domain)
- Network details (IP and MAC address and routing to the FortiGate)

When a device's information changes, such as when a client moves from on-net to off-net, or their security posture changes, EMS is updated with the new device information and then updates the FortiGate. The FortiGate's WAD daemon can use this information when processing ZTNA traffic. If an endpoint's security posture change causes it to no longer match the ZTNA policy criteria on an existing session, then the session is terminated.

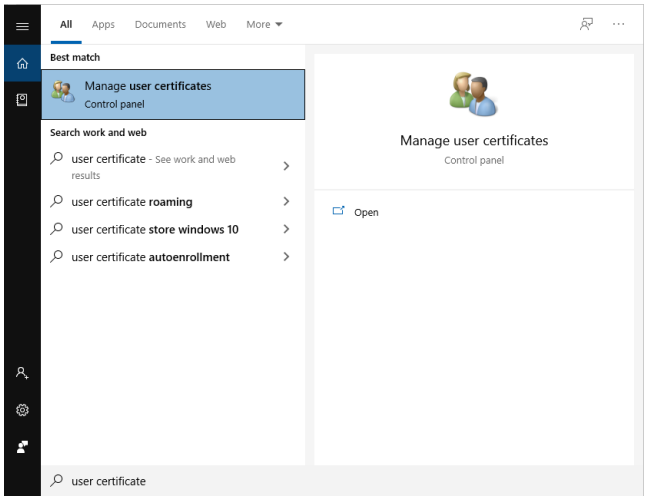
Certificate management on FortiClient EMS



FortiClient EMS has a *default_ZTNARootCA* certificate generated by default that the ZTNA CA uses to sign CSRs from the FortiClient endpoints. Clicking the refresh button revokes and updates the root CA, forcing updates to the FortiGate and FortiClient endpoints by generating new certificates for each client.

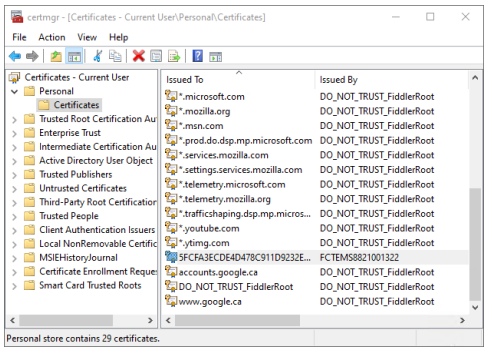
Do not confuse the EMS CA certificate (ZTNA) with the SSL certificate. The latter is the server certificate that is used by EMS for HTTPS access and fabric connectivity to the EMS server.

EMS can also manage individual client certificates. To revoke the current client certificate that is used by the endpoint: go to *Endpoint* > *All Endpoints*, select the client, and click *Action* > *Revoke Client Certificate*.



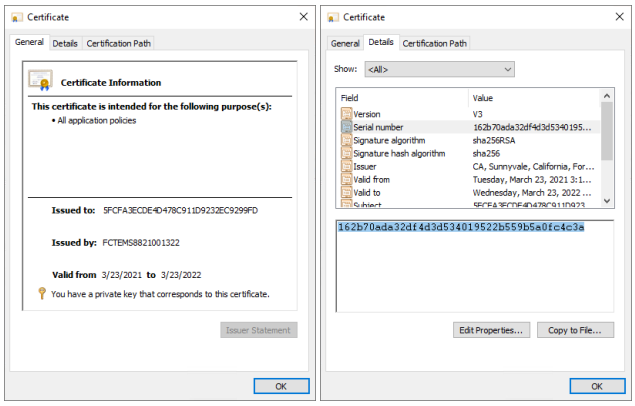
Locating and viewing the client certificate on an endpoint

In Windows, FortiClient automatically installs certificates into the certificate store. The certificate information in the store, such as certificate UID and SN, should match the information on EMS and the FortiGate.

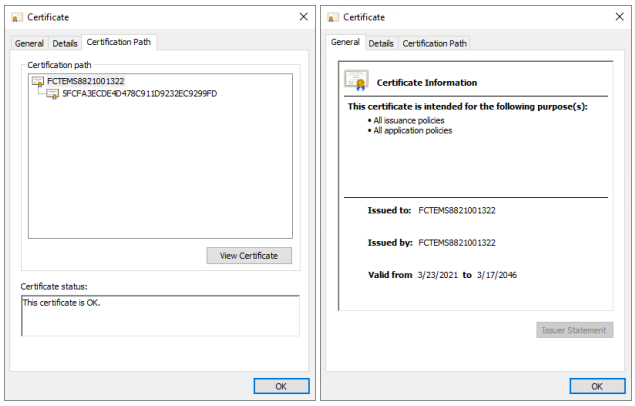


To locate certificates on other operating systems, consult the vendor documentation.

To locate the client certificate and EMS ZTNA CA certificate on a Windows PC:



1. In the Windows search box, enter *user certificate* and click *Manage user certificates* from the results.



2. In the certificate manager, go to *Certificates - Current User* > *Personal* > *Certificates* and find the certificate that is issued by the FortiClient EMS.

3. Right-click on it and select Properties.
4. The *General* tab shows the client certificate UID and the issue and expiry dates. The *Details* tab show the certificate SN.

5. Go to the *Certificate Path* tab to see the full certificate chain.
6. Select the root CA and click *View Certificate* to view the details about the EMS ZTNA CA certificate.

Verifying that the client information is synchronized to the FortiGate

The following diagnose commands help to verify the presence of matching endpoint record, and information such as the client UID, client certificate SN, and EMS certificate SN on the FortiGate. If any of the information is missing or incomplete, client certificate authentication might fail because the corresponding endpoint entry is not found. More in-depth diagnosis would be needed to determine the reason for the missing records.

Command	Description
`# diagnose endpoint record list <ip>`	Show the endpoint record list. Optionally, filter by the endpoint IP address.
`# diagnose wad dev query-by uid <uid> <ems sn> <ems tenant id>`	Query from WAD diagnose command by UID.
`# diagnose wad dev query-by ipv4 <ip>`	Query from WAD diagnose command by IP address.
`# diagnose test application fcnacd 7` `# diagnose test application fcnacd 8`	Check the FortiClient NAC daemon ZTNA and route cache.
`#diagnose test application fcnacd 5`	Force a sync with the FortiClient EMS server.

To check the endpoint record list for IP address 10.0.3.2:

```
# diagnose endpoint record list 10.0.3.2
Record #1:
                IP Address = 10.0.3.2
                MAC Address = 02:09:0f:00:03:03
                MAC list =
                VDOM =  (-1)
                EMS serial number: FCTEMS8822001975
                EMS tenant id: 00000000000000000000000000000000
                Client cert SN: 2B8D4FF0E71FE7E064288FE1B4F87E25232092D0
                Public IP address: 34.23.223.220
                Quarantined: no
                Online status: online
                Registration status: registered
                On-net status: on-net
                Gateway Interface:
                FortiClient version: 7.2.0
                AVDB version: 1.0
                FortiClient app signature version: 23.544
                FortiClient vulnerability scan engine version: 2.34
                FortiClient UID: 9A016B5A6E914B42AD4168C066EB04CA
                …
                Number of Routes: (0)
online records: 1; offline records: 0; quarantined records: 0; out-of-sync records: 0
```

To check the tags that are processed by the WAD daemon for a particular device:

```
# diagnose wad dev query-by uid 9A016B5A6E914B42AD4168C066EB04CA FCTEMS8822001975

ZTNA scalability support for concurrent endpoints

ZTNA scalability supports up to 50 thousand concurrent endpoints. Communication between FortiOS and FortiClient EMS has efficient queries that request incremental updates. Retrieved device information can be written to the FortiClient NAC daemon cache.

FortiOS can receive tag information from the EMS common tags API. This feature requires FortiClient EMS 7.0.3 or later.

The APIs `api/v1/report/fct/uid_tags` and `api/v1/report/fct/tags` replace the API `api/v1/report/fct/host_tags`.

To use the common tags API capability:

1. Enable the common tags API when connecting the EMS:

```
config endpoint-control fctems
    edit "local.ems"
        set server "10.6.30.213"
        set capabilities fabric-auth silent-approval websocket websocket-malware push-
ca-certs common-tags-api
    next
end
```

2. The FortiGate uses the new APIs to obtain device information from the EMS:

```
[ec_ems_context_submit_work:414] Call submitted successfully.
    obj-id: 11, desc: REST API to get updates of tag endpoints., entry:
api/v1/report/fct/tags.
[ec_ems_context_submit_work:414] Call submitted successfully.
    obj-id: 12, desc: REST API to get updates of tags associated with FCT UID., entry:
api/v1/report/fct/uid_tags.
[ec_ez_worker_process:334] Processing call for obj-id: 11, entry:
"api/v1/report/fct/tags"
[dynamic_addr_ha_act:215] called (EMS SN N/A).
[dynamic_addr_ha_act:215] called (EMS SN N/A).
[ec_ez_worker_process:441] Call completed successfully.
    obj-id: 11, desc: "REST API to get updates of tag endpoints.", entry:
"api/v1/report/fct/tags".
[ec_ez_worker_process:334] Processing call for obj-id: 12, entry:
"api/v1/report/fct/uid_tags"
[ec_record_sync_tags_info_store:1419] Received 1 tags for
3D86DF70B85E16CBAD67908A897B4494 with sn FCTEMS8888888888
[ec_record_sync_tags_info_store:1419] Received 1 tags for
DA12930442F13F84D2441F03FCB6A10E with sn FCTEMS8888888888
[ec_record_sync_tags_info_store:1419] Received 1 tags for
25C59C275F257F4C5FBC7F6F5F56788E with sn FCTEMS8888888888
[ec_ez_worker_process:441] Call completed successfully.
    obj-id: 12, desc: "REST API to get updates of tags associated with FCT UID.", entry:
"api/v1/report/fct/uid_tags".
[ec_ems_context_submit_work:414] Call submitted successfully.
    obj-id: 7, desc: REST API to get updates about system info., entry:
api/v1/report/fct/sysinfo.
[ec_ems_context_submit_work:414] Call submitted successfully.
    obj-id: 11, desc: REST API to get updates of tag endpoints., entry:
api/v1/report/fct/tags.
[ec_ez_worker_process:334] Processing call for obj-id: 11, entry:
"api/v1/report/fct/tags"
[ec_ez_worker_process:441] Call completed successfully.
    obj-id: 11, desc: "REST API to get updates of tag endpoints.", entry:
"api/v1/report/fct/tags".
(......)
```

3. Confirm that the device information from the EMS is written to the FortiClient NAC daemon cache:

```
# diagnose endpoint record list
    ...
          Avatar source: OS
            Phone number:
            Number of Routes: (1)
```

```
                    Gateway Route #0:
                            - IP:10.1.91.6, MAC: 4f:8d:c2:73:dd:fe, Indirect: no
                            - Interface:port2, VFID:1, SN: FG5H1E5999999999
online records: 37174; offline records: 0; quarantined records: 0; out-of-sync records:
0
```

4. Use the tags that are pulled from the EMS in a firewall address:

```
config firewall address
    edit "FCTEMS8888888888_ZT_AD_MGMT"
        set type dynamic
        set sub-type ems-tag
        set obj-tag "ZT_AD_MGMT"
        set tag-type "zero_trust"
    next
end
```

5. Check the tags' resolved IP and MAC addresses:

```
# diagnose firewall fqdn getinfo-ip FCTEMS8888888888_ZT_AD_MGMT
getinfo FCTEMS8888888888_ZT_AD_MGMT id:114 generation:106 count:187 data_len:6160 flag 0

# diagnose firewall fqdn getinfo-mac MAC_FCTEMS8888888888_ZT_AD_MGMT
getinfo MAC_FCTEMS8888888888_ZT_AD_MGMT id:163 generation:105 count:371 data_len:2226
flag 0

# diagnose firewall dynamic address  FCTEMS8888888888_ZT_AD_MGMT
CMDB name: FCTEMS8888888888_ZT_AD_MGMT
TAG name: ZT_AD_MGMT
FCTEMS8888888888_ZT_AD_MGMT: ID(114)
        ADDR(10.1.10.4)
(......)
        ADDR(10.1.99.195)
Total IP dynamic range blocks: 190.
Total IP dynamic addresses: 281.

# diagnose firewall dynamic address MAC_FCTEMS8888888888_ZT_AD_MGMT
CMDB name: MAC_FCTEMS8888888888_ZT_AD_MGMT
TAG name: ZT_AD_MGMT
MAC_FCTEMS8888888888_ZT_AD_MGMT: ID(163)
        MAC(52:f1:9d:06:1c:db)
        MAC(4b:77:2b:db:82:15)
        MAC(df:6e:9e:d9:04:1e)
Total MAC dynamic addresses: 393.
```

SSL certificate based authentication

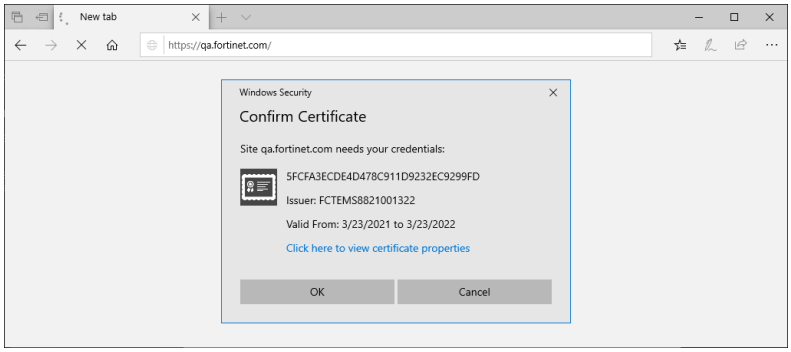
A client certificate is obtained when an endpoint registers to EMS. FortiClient automatically submits a CSR request and the FortiClient EMS signs and returns the client certificate. This certificate is stored in the operating system's certificate store for subsequent connections. The endpoint information is synchronized between the FortiGate and FortiClient EMS. When an endpoint disconnects or is unregistered from EMS, its certificate is removed from the certificate store and revoked on EMS. The endpoint obtains a certificate again when it reconnected the EMS.

By default, client certificate authentication is enabled on the access proxy, so when the HTTPS request is received the FortiGate's WAD process challenges the client to identify itself with its certificate. The FortiGate makes a decision based on the following possibilities:

1. If the client responds with the correct certificate that the client UID and certificate SN can be extracted from:
   - If the client UID and certificate SN match the record on the FortiGate, the client is allowed to continue with the ZTNA proxy rule processing.
   - If the client UID and certificate SN do not match the record on the FortiGate, the client is blocked from further ZTNA proxy rule processing.
2. If the client cancels and responds with an empty client certificate:
   - If `empty-cert-action` is set to `accept`, the client is allowed to continue with ZTNA proxy rule processing.
   - If `empty-cert-action` is set to `block`, the client is blocked from further ZTNA proxy rule processing.

To configure the client certificate actions:

```
config firewall access-proxy
    edit <name>
        set client-cert {enable | disable}
        set empty-cert-action {accept | block | accept-unmanageable}
    next
end
```



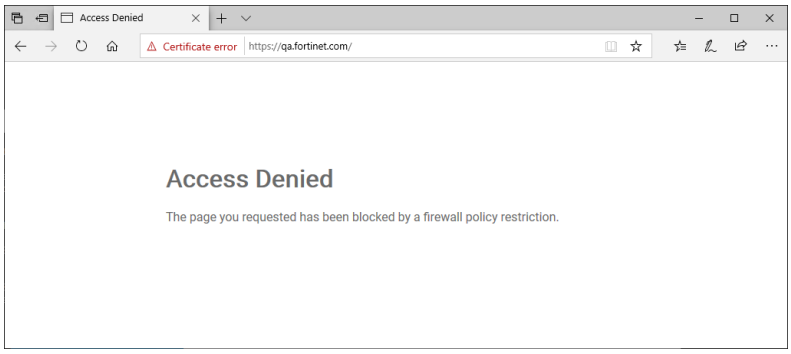
Example

In this example, a client connects to *qa.fortinet.com* and is prompted for a client certificate.

- `client-cert` is set to `enable`, and `empty-cert-action` is set to `block`.
- The ZTNA server is configured, and a ZTNA policy is set to allow this client.
- The domain resolves to the FortiGate access proxy VIP.

Scenario 1:

When prompted for the client certificate, the client clicks *OK* and provides a valid certificate that is verified by the FortiGate.



Result:

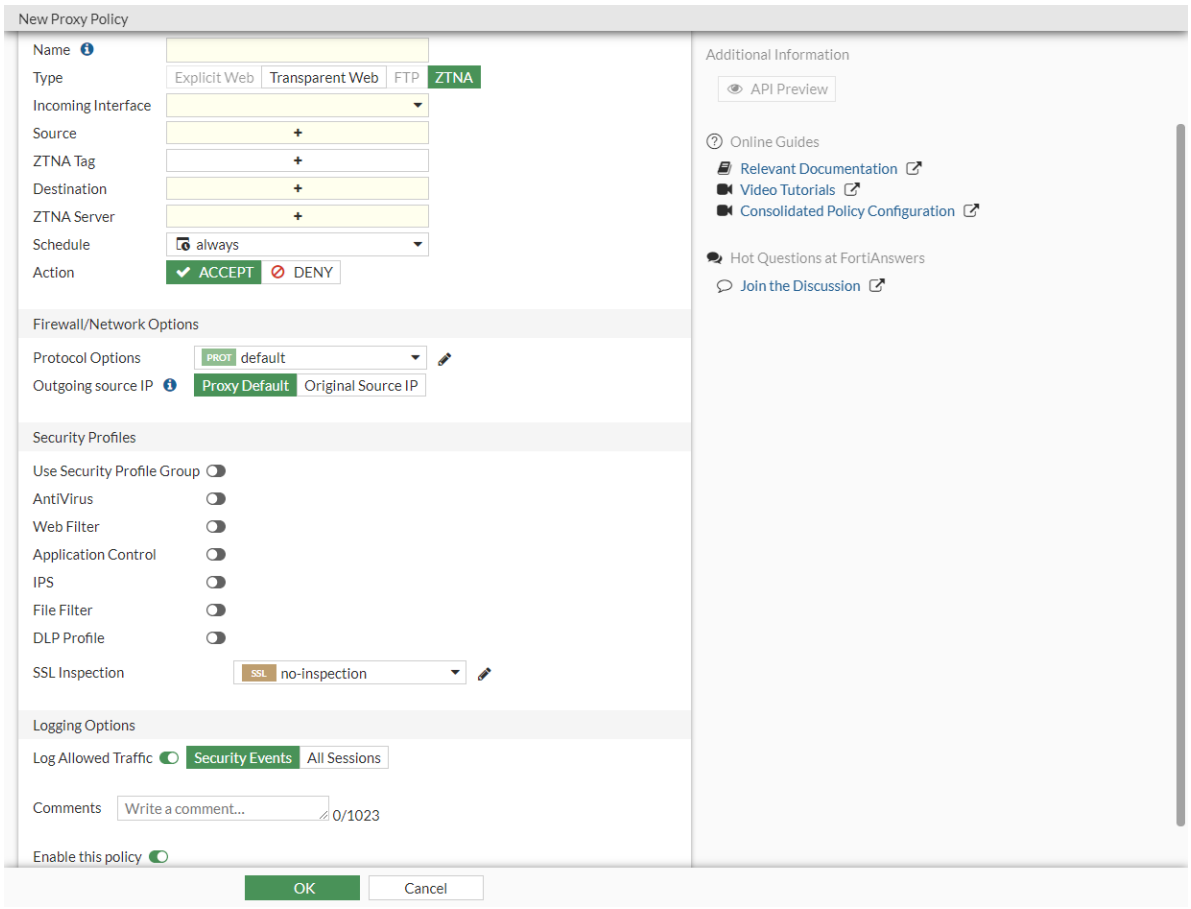
The client passes SSL certificate authentication and is allowed to access the website.

Scenario 2:

When prompted for the client certificate, the client clicks *Cancel*, resulting in an empty certificate response to the access proxy.

Result:

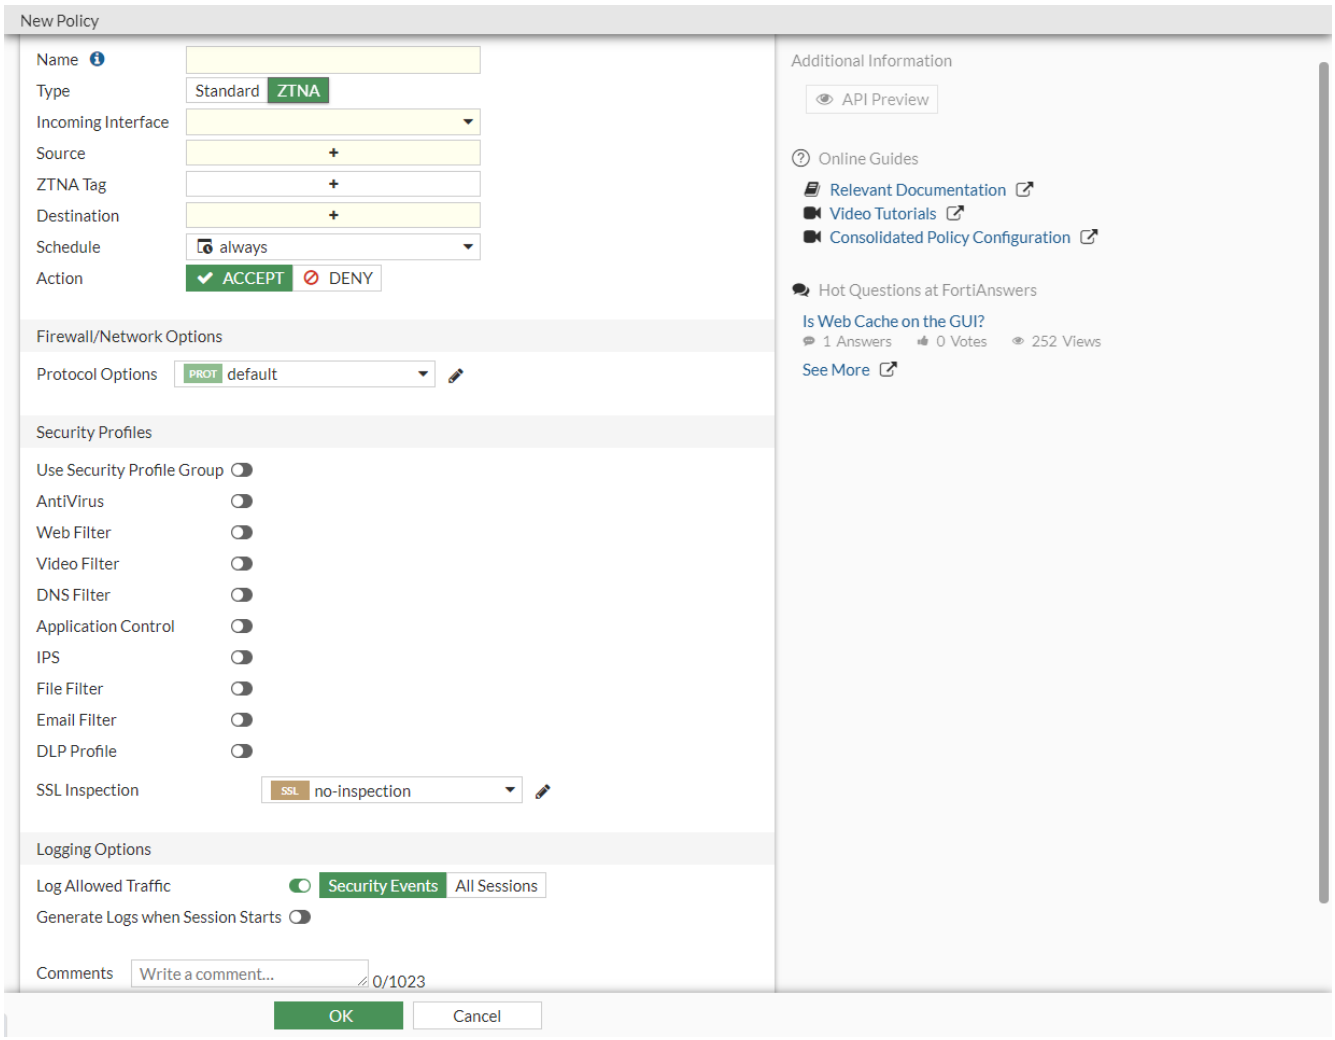
Because the certificate response is empty and `empty-cert-action` is set to `block`, the WAD daemon blocks the connection.



Currently, the Microsoft Edge, Google Chrome, and Safari browsers are supported by ZTNA.

Full versus simple ZTNA policies - NEW

There are two ways to configure ZTNA rules in the GUI by using a full or simple ZTNA policy.



Full ZTNA policy

In a full ZTNA policy, the CLI configuration remains the same as previous versions. In the GUI, the *Policy & Objects* > *ZTNA* > *ZTNA Rules* tab has been removed. Administrators can configure ZTNA policies from the *Policy & Objects* > *Proxy Policy* page, and by setting the *Type* to *ZTNA*.

Simple ZTNA policy

In a simple ZTNA policy, a regular firewall policy is used for policy management. When creating a new firewall policy, administrators can configure a ZTNA policy by setting the *Type* to *ZTNA*.

A simple ZTNA policy cannot control access based on the destination interface or the real server's destination address. See the Examples section for detailed configurations.

Authentication for ZTNA policies

Authentication remains largely the same between both ZTNA policy configuration modes. You can specify user groups under *Source* to define the groups in which the access control applies to. However, the underlying authentication schemes and rules must still be in place to direct the traffic to the ZTNA application gateway.

Authentication for regular firewall policies

Authentication for regular firewall policies is traditionally handled by authd, which does not require an authentication scheme and rules to be configured in order to function. This enhancement allows authentication for regular firewall policies to be handled by WAD so that the authentication scheme and rules are used to determine the type of

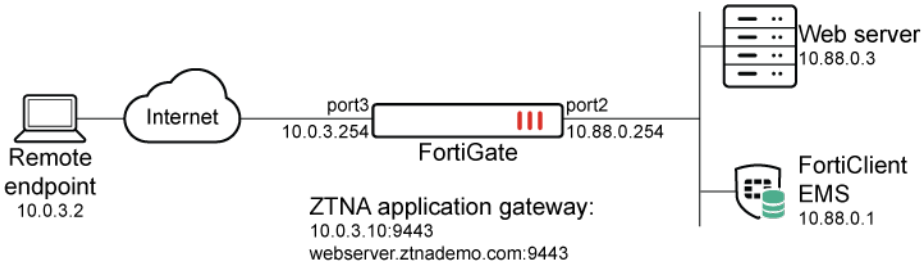
authentication and the traffic that requires authentication. This option is disabled by default, but can be enabled as follows:

```
config firewall auth-portal
    set proxy-auth {enable | disable}
end
```

Redirecting a simple ZTNA policy to a full ZTNA policy

An option is added so that after matching a simple ZTNA policy, the traffic can be redirected for a full ZTNA policy match. This setting can only be configured from the CLI, and it is disabled by default.

```
config firewall policy
    edit <id>
        set ztna-policy-redirect {enable | disable}
    next
end
```



For example, a client has both tag A and tag B. In the simple ZTNA policy, the client matches a policy that requires tag A for a posture check. If they are using the `ztna-policy-redirect` option, then it will also require a full ZTNA policy match.

If a full ZTNA policy allows either tag A or tag B or all traffic in general, then the traffic is allowed. Otherwise, if a full ZTNA policy explicitly denies one of the tags, the traffic will be denied.

If no full ZTNA policy is matched, then the traffic is implicitly denied.

Examples

The following examples demonstrate how to configure a ZTNA policy using the full and simple ZTNA policy modes.

It is assumed that the following settings are already configured:

- EMS connection and EMS tags (Malicious-File-Detected and FortiAD.Info)
- ZTNA server configuration (ZTNA-webserver)
- Authentication scheme and rule

Configuring a full ZTNA policy

To configure a full ZTNA policy in the GUI:

1. Go to *Policy & Objects* > *Proxy Policy* and click *Create New*.
2. Configure the following settings:

Name	*ZTNA-webserver*
Type	*ZTNA*
Incoming Interface	*port3*
Source	*all*
Destination	*Webserver1* (10.88.0.3/32)
ZTNA Server	*ZTNA-webserver*
Schedule	*always*
Action	*ACCEPT*

3. Click *OK*.

To configure a full ZTNA policy in the CLI:

```
config firewall proxy-policy
    edit 1
        set name "ZTNA-webserver"
        set proxy access-proxy
        set access-proxy "ZTNA-webserver"
        set srcintf "port3"
        set srcaddr "all"
        set dstaddr "Webserver1"
        set action accept
        set schedule "always"
    next
end
```

When traffic is allowed, the ZTNA logs show traffic passing through policy 1 on a policy called `ZTNA-webserver`, which is a proxy policy.

To verify the traffic logs:

```
# execute log filter category traffic
# execute log filter field subtype ztna
# execute log display
9 logs found.
9 logs returned.
1: date=2023-03-06 time=20:16:11 eventtime=1678162572109525759 tz="-0800" logid="0005000024"
type="traffic" subtype="ztna" level="notice" vd="root" srcip=10.0.3.2 srcport=28597

```

Configuring a simple ZTNA policy

To configure a simple ZTNA policy in the GUI:

1. Go to *Policy & Objects* > *Firewall Policy* and click *Create New*.
2. Configure the following settings:

Name	*ZTNA-webserver-fp*
Type	*ZTNA*
Incoming Interface	*port3*
Source	*all*
Destination	*ZTNA-webserver*
Schedule	*always*
Action	*ACCEPT*

3. Click *OK*.

To configure a simple ZTNA policy in the CLI:

```
config firewall policy
    edit 9
        set name "ZTNA-webserver-fp"
        set srcintf "port3"
        set dstintf "any"
        set action accept
        set srcaddr "all"
        set dstaddr "ZTNA-webserver"
        set schedule "always"
        set service "ALL"
    next
end
```

When traffic is allowed, the ZTNA logs show traffic passing through policy 9 on a policy called `ZTNA-webserver-fp`, which is a firewall policy.

To verify the traffic logs:

```
# execute log filter category traffic
# execute log filter field subtype ztna
# execute log display
14 logs found.
10 logs returned.

1: date=2023-03-06 time=23:01:55 eventtime=1678172515724776640 tz="-0800" logid="0005000024"
type="traffic" subtype="ztna" level="notice" vd="root" srcip=10.0.3.2 srcport=31687
srcintf="port3" srcintfrole="wan" dstcountry="Reserved" srccountry="Reserved"
dstip=10.88.0.3 dstport=9443 dstintf="port2" dstintfrole="dmz" sessionid=28076
srcuuid="b458a65a-f759-51ea-d7df-ef2e750026d1" service="tcp/9443" proxyapptype="http"

1d28-687edafe9439" policyname="ZTNA-webserver-fp" duration=75 gatewayid=1 vip="ZTNA-
```

```
webserver" accessproxy="ZTNA-webserver" clientdevicemanageable="manageable" wanin=3445
rcvdbyte=3445 wanout=1189 lanin=2358 sentbyte=2358 lanout=4759 appcat="unscanned"
```

Configuring a ZTNA simple policy with ZTNA tags and authentication

In this example, a simple ZTNA policy uses the FortiAD.Info tag for a posture check and authentication against a pre-configured Active Directory server where the user tsmith resides. The authentication scheme and rule have already been configured as follows:

```
config authentication scheme
    edit "ZTNA-Auth-scheme"
        set method basic
        set user-database "LDAP-fortiad"
    next
end
```

```
config authentication rule
    edit "ZTNA-Auth-rule"
        set srcintf "port3"
        set srcaddr "all"
        set active-auth-method "ZTNA-Auth-scheme"
    next
end
```

To append ZTNA tag and authentication settings to the simple ZTNA policy:

1. Go to *Policy & Objects* > *Firewall Policy* and edit the *ZTNA-webserver-fp* policy.
2. For the *Source* field, click the + and add the user group named *LDAP-Remote-Allowed-Group*.
3. For the *ZTNA Tag* field, click the + and add the *FortiAD.Info tag*.
4. Click *OK*.

To verify the configuration:

1. Connect to the web server from a client.
2. After selecting the client certificate, the browser will prompt for a username and password. Enter the username (tsmith) and their password.

   Upon a successful authentication, the user will be able to access the web server.
3. On the FortiGate, verify that the logs for the allowed traffic show the user tsmith and the tag EMS1_ZTNA_FortiAD.Info:

```
# execute log filter field subtype ztna
# execute log display
18 logs found.
10 logs returned.
1: date=2023-03-06 time=23:25:23 eventtime=1678173923745891128 tz="-0800"
logid="0005000024" type="traffic" subtype="ztna" level="notice" vd="root" srcip=10.0.3.2
srcport=32017 srcintf="port3" srcintfrole="wan" dstcountry="Reserved"
srccountry="Reserved" dstip=10.88.0.3 dstport=9443 dstintf="port2" dstintfrole="dmz"
sessionid=29615 srcuuid="b458a65a-f759-51ea-d7df-ef2e750026d1" service="tcp/9443"
proxyapptype="http" proto=6 action="accept" policyid=9 policytype="proxy-policy"
poluuid="1f1d5036-bcaa-51ed-1d28-687edafe9439" policyname="ZTNA-webserver-fp"
duration=106 user="tsmith" group="LDAP-Remote-Allowed-Group" authserver="LDAP-fortiad"
gatewayid=1 vip="ZTNA-webserver" accessproxy="ZTNA-webserver"
```

```
clientdeviceid="9A016B5A6E914B42AD4168C066EB04CA" clientdevicemanageable="manageable"
clientdevicetags="MAC_EMS1_ZTNA_all_registered_clients/EMS1_ZTNA_all_registered_

fctuid="9A016B5A6E914B42AD4168C066EB04CA" appcat="unscanned"
```

ZTNA advanced configurations

This section includes the following ZTNA advanced configurations:

- Access control of unmanageable and unknown devices on page 943
- HTTP2 connection coalescing and concurrent multiplexing for ZTNA on page 950

Access control of unmanageable and unknown devices

The ZTNA application gateway can determine whether a client device that does not have FortiClient installed is a mobile device that is considered unmanageable, or is not a mobile device that is considered unknown. The ZTNA application gateway tags the device as either `EMS_ALL_UNMANAGEABLE_CLIENTS` or `EMS_ALL_UNKNOWN_CLIENTS` respectively. The FortiGate WAD process achieves this by either matching device TLS fingerprints against a library or learning information from the HTTP User-Agent header if the `set user-agent-detect` setting is enabled.

Configuring the ZTNA access proxy and proxy policy

The `EMS_ALL_UNMANAGEABLE_CLIENTS` and `EMS_ALL_UNKNOWN_CLIENTS` tags allow for ZTNA access control of unmanageable and unknown devices using a proxy policy. The `accept-unmanageable` option for the `empty-cert-action` setting allows unmanageable clients to continue ZTNA proxy rule processing.

```
config firewall access-proxy
    edit <name>
        set client-cert enable
        set user-agent-detect {enable | disable}
        set empty-cert-action {accept | block | accept-unmanageable}
     next
end
```

`user-agent-detect {enable | disable}`	Enable/disable detecting the device type by HTTP User-Agent if no client certificate is provided (default = enable).
`empty-cert-action {accept | block | accept-unmanageable}`	Set the action for an empty client certificate: • `accept`: accept the SSL handshake if the client certificate is empty. • `block`: block the SSL handshake if the client certificate is empty. • `accept-unmanageable`: accept the SSL handshake only if the end point is unmanageable.

The `user-agent-detect` and `empty-cert-action` settings can only be configured in the CLI.

```
config firewall proxy-policy
    edit <id>
        set ztna-ems-tag {EMS_ALL_UNMANAGEABLE_CLIENTS | EMS_ALL_UNKNOWN_CLIENTS}
```

```
    next
end
```

`ztna-ems-tag {EMS_ALL_ UNMANAGEABLE_CLIENTS | EMS_ALL_UNKNOWN_ CLIENTS}`	Set the EMS tag names: • `EMS_ALL_UNMANAGEABLE_CLIENTS`: match any device that is unmanageable. • `EMS_ALL_UNKNOWN_CLIENTS`: match any device that is not recognized.

Consider the following use cases.

- Case 1: if a client device sends a TLS client hello in a mobile pattern, then WAD will try to match its TLS fingerprint with a WAD original library and mark it with an `EMS_ALL_UNMANAGEABLE_CLIENTS` tag.
- Case 2: if WAD cannot match the TLS fingerprint with an original library but `user-agent-detect` is enabled (under `config firewall access-proxy`), WAD will try to learn the device type from client request's User-Agent header. If it matches a mobile device, then it is still marked with an `EMS_ALL_UNMANAGEABLE_CLIENTS` tag.
- Case 3: if WAD cannot match the TLS fingerprint with an existing original or temporary library, or cannot learn it from User-Agent header, or `user-agent-detect` is disabled, then it will mark the device as `EMS_ALL_UNKNOWN_ CLIENTS`.

In the access proxy settings, if `empty-cert-action` is set to `accept-unmanageable`, then only case 1 and 2 would go through the proxy policy. Case 3 would be denied, and a replacement message page would appear.

To configure ZTNA policy access control of unmanageable devices:

1. Configure the client certificate actions:

```
config firewall access-proxy
    edit "zt1"
        set vip "zt1"
        set client-cert enable
        set user-agent-detect enable
        set auth-portal disable
        set empty-cert-action accept
        set log-blocked-traffic disable
        set add-vhost-domain-to-dnsdb disable
        set decrypted-traffic-mirror ''
    next
end
```

2. Configure the proxy policy with the ZTNA EMS tag to control device access:

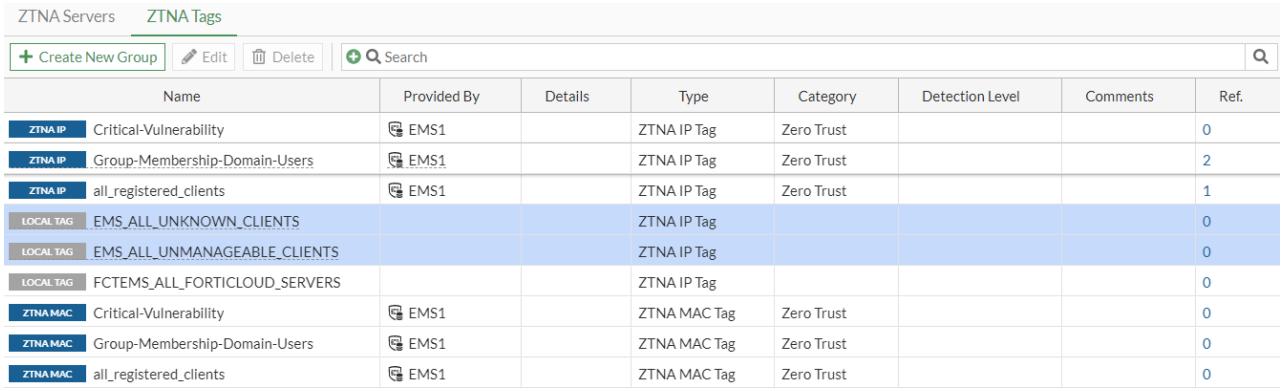
```
config firewall proxy-policy
    edit 1
        set proxy access-proxy
        set access-proxy "zt1"
        set srcintf "port2" "ag2"
        set srcaddr "all"
        set dstaddr "all"
        set ztna-ems-tag "EMS_ALL_UNMANAGEABLE_CLIENTS"
    next
end
```

Configuring dynamic address local tags

Like other ZTNA tags,`EMS_ALL_UNMANAGEABLE_CLIENTS` and `EMS_ALL_UNKNOWN_CLIENTS` are dynamic addresses on the FortiGate. The following diagnostic commands can be used to view local tag information:

- `diagnose firewall dynamic address`: a list of unmanageable and unknown clients' IP addresses associated with the `EMS_ALL_MANAGEABLE_CLIENTS` and `EMS_ALL_UNKNOWN_CLIENTS` dynamic addresses, respectively, is displayed.
- `diagnose user-device-store device memory list`: when device detection is enabled on a FortiGate interface that has a layer 2 connection to unmanageable and unknown device clients, then a client's device information is displayed.

To verify the list of dynamic firewall addresses in the CLI:



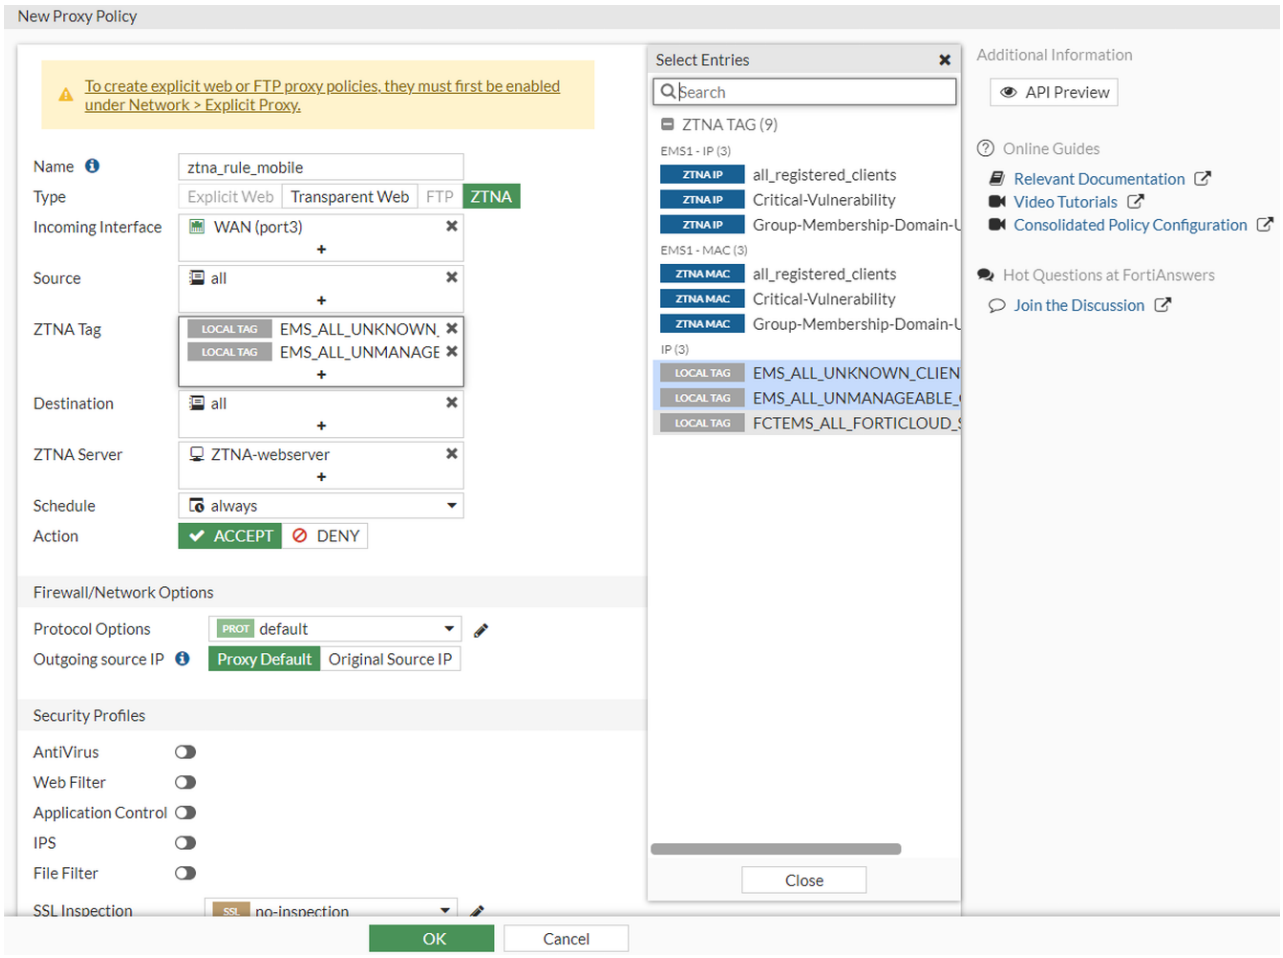
```
(vdom1) # diagnose firewall dynamic address
List all dynamic addresses:
IP dynamic addresses in VDOM vdom1(vfid: 1):
...
CMDB name: EMS_ALL_UNMANAGEABLE_CLIENTS
EMS_ALL_UNMANAGEABLE_CLIENTS: ID(101)
        ADDR(10.1.100.22)
Total IP dynamic range blocks: 1.
Total IP dynamic addresses: 1.
CMDB name: EMS_ALL_UNKNOWN_CLIENTS
EMS_ALL_UNKNOWN_CLIENTS: ID(154)
Total IP dynamic range blocks: 0.
Total IP dynamic addresses: 0.
...
```

To verify the client device information in the CLI:

```
(vdom1) # diagnose user-device-store device memory list
Record #1:
         ...
        device_info
                ...
                'is_online' = 'true'
                'is_ems_registered' = 'false'
                'active_start_time' = '1668811449'
                'is_fortiguard_src' = 'false'
                'tags' = 'EMS_ALL_UNMANAGEABLE_CLIENTS'
                ...
        interface_info
        ...
```

To view the local tag information in the GUI:

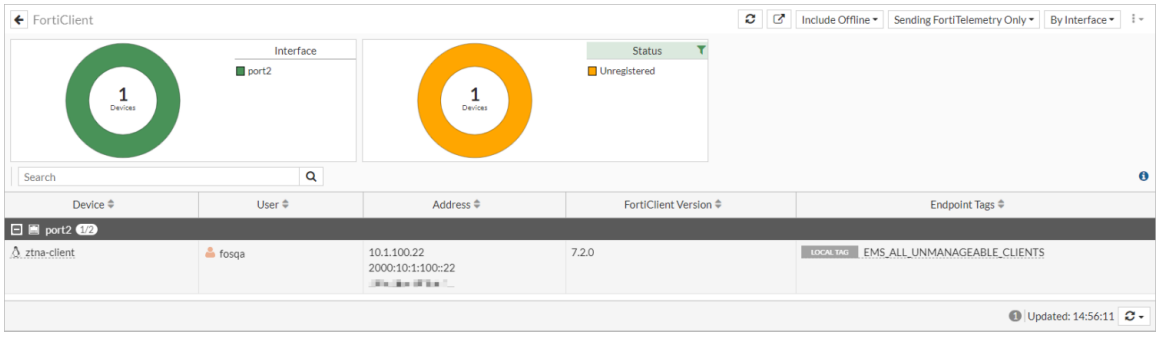
1. Go to *Policy & Objects* > *ZTNA* and select the *ZTNA Tags* tab.



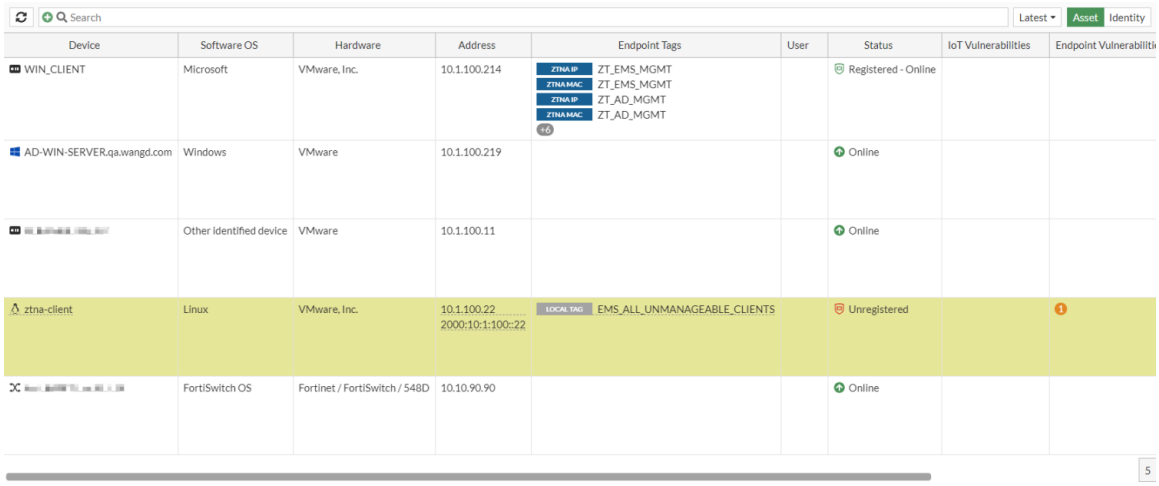
Name	Provided By	Details	Type	Category	Detection Level	Comments	Ref.
ZTNA IP Critical-Vulnerability	EMS1		ZTNA IP Tag	Zero Trust			0
ZTNA IP Group-Membership-Domain-Users	EMS1		ZTNA IP Tag	Zero Trust			2
ZTNA IP all_registered_clients	EMS1		ZTNA IP Tag	Zero Trust			1
LOCAL TAG EMS_ALL_UNKNOWN_CLIENTS			ZTNA IP Tag				0
LOCAL TAG EMS_ALL_UNMANAGEABLE_CLIENTS			ZTNA IP Tag				0
LOCAL TAG FCTEMS_ALL_FORTICLOUD_SERVERS			ZTNA IP Tag				0
ZTNA MAC Critical-Vulnerability	EMS1		ZTNA MAC Tag	Zero Trust			0
ZTNA MAC Group-Membership-Domain-Users	EMS1		ZTNA MAC Tag	Zero Trust			0
ZTNA MAC all_registered_clients	EMS1		ZTNA MAC Tag	Zero Trust			0

2. Hover over a tag to view the tooltip, which displays matched endpoints and resolved addresses.

To apply a local tag in a full ZTNA policy:



1. Go to *Policy & Objects* > *Proxy Policy*.
2. Click *Create New*, or select and edit an existing entry.
3. In the *ZTNA Tag* field, click the + to add tags. The local tags appear in the *IP* section.



4. Configure the other settings as needed.
5. Click *OK*.

Local tag information is also available in the following GUI widgets and pages:

- *Dashboard* > *FortiClient* widget

- *Security Fabric > Asset Identity Center* page

Viewing ZTNA traffic logs

ZTNA traffic logs include the following fields related to unmanageable and unknown devices.

- Client connection status with EMS server with possible values of unknown, offline, or online:
  - CLI = `emsconnection`
  - GUI = *EMS Connection*
- Device manageability status with possible values of unknown, manageable, or unmanageable:
  - CLI = `clientdevicemanageable`
  - GUI = *Client Device Manageable*

The device manageability status can have one of the following values:

- Unknown: traffic from a client with an unknown TLS fingerprint and where the user agent information is not available for learning.
- Manageable: traffic from a non-mobile device (platform or operating system), with a known TLS fingerprint, or where the user agent information is available for learning.
- Unmanageable: traffic from a mobile device with a known mobile TLS fingerprint or user agent information is available for learning.

To view the ZTNA traffic logs in the CLI:

```
(vdom1)# execute log filter category 0
(vdom1)# execute log filter field subtype ztna
(vdom1)# execute log display

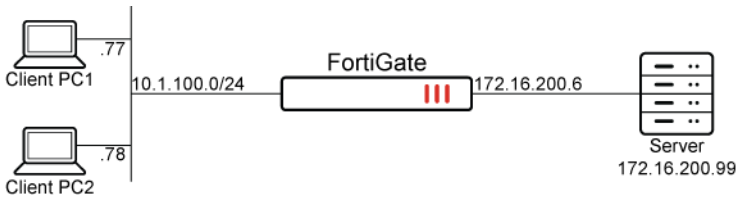
To view the ZTNA traffic logs in the GUI:

1. Go to *Log & Report* > *ZTNA Traffic*.
2. Select an entry and click *Details*.
3. Check the *Client Device Manageable* and *EMS Connection* fields.

HTTP2 connection coalescing and concurrent multiplexing for ZTNA

HTTP2 connection coalescing and concurrent multiplexing allows multiple HTTP2 requests to share the same TLS connection when the destination IP is the same, and the host names are compatible in the certificate. In ZTNA scenarios, the FortiGate application gateway may accept multiple HTTP2 requests to the same ZTNA server destined to different virtual hosts on the same real server. These HTTP2 requests can share the same TLS connection between the FortiGate and the real server so that the handshake does not need to be performed multiple times for multiple connections.

In order for the FortiGate to match the SNI (Server Name Indication), this SNI value must appear under the SAN extension on the server certificate. Configuring the SNI value under the CN alone will not work.



To configure the ZTNA access proxy:

```
config firewall access-proxy
    edit <name>
        set http-supported-max-version {http1 | http2}
        set svr-pool-multiplex {enable | disable}
        set svr-pool-ttl <integer>
        set svr-pool-server-max-request <integer>
    next
end
```

`http-supported-max-version {http1 | http2}`	Set the maximum supported HTTP version: • http1: support HTTP 1.1 and HTTP1. • http2: support HTTP2, HTTP 1.1, and HTTP1 (default).
`svr-pool-multiplex {enable | disable}`	Enable/disable server pool multiplexing. When enabled, share the connected server in HTTP, HTTPS, and web portal API gateway.
`svr-pool-ttl <integer>`	Set the time-to-live in the server pool for idle connections to servers (in seconds, 0 - 2147483647, default = 15).
`svr-pool-server-max-request <integer>`	Set the maximum number of requests that servers in server pool handle before disconnecting (0 - 2147483647, default = 0).

Example

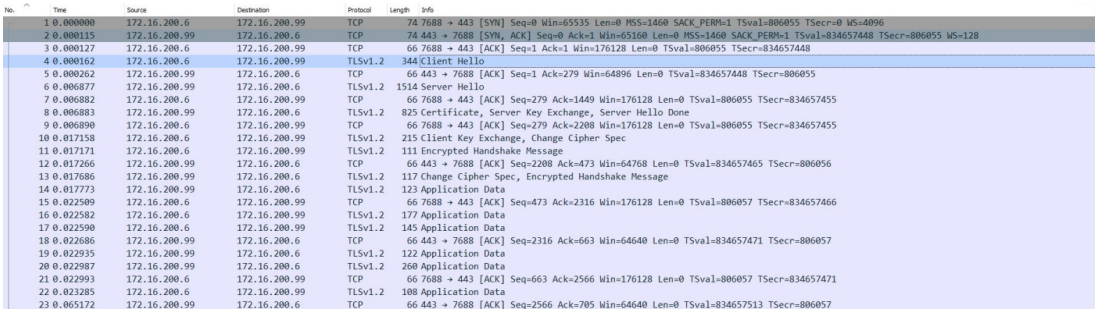
In this example, multiple clients submit requests in HTTP2. The requests hit the VIP address, and then FortiGate opens a session between itself (172.16.200.6) and the server (172.16.200.99). The coalescing occurs in this session as the multiple streams share the same TLS session to connect to the same destination server.

To configure connection coalescing and concurrent multiplexing with ZTNA:

1. Configure the VIP:

```
config firewall vip
    edit "vip-ztna"
        set type access-proxy
        set extip 10.1.100.223
        set extintf "port2"
        set server-type https
        set extport 443
        set ssl-certificate "Fortinet_SSL"
    next
end
```

2. Configure the ZTNA server and path mapping:



```
config firewall access-proxy
    edit "ztna"
        set vip "vip-ztna"
        set client-cert disable
        set svr-pool-multiplex enable
        set http-supported-max-version http2
        config api-gateway
            edit 1
                set url-map "/a"
                set virtual-host "a.ftnt.com"
                config realservers
                    edit 1
                        set ip 172.16.200.99
                    next
                end
            next
            edit 2
                set url-map "/b"
                set virtual-host "b.ftnt.com"
                config realservers
                    edit 1
                        set ip 172.16.200.99
                    next
                end
            next
        end
    next
end
```

3. Configure the ZTNA policy:

```
config firewall proxy-policy
    edit 3
        set proxy access-proxy
        set access-proxy "ztna"
        set srcintf "port2"
        set srcaddr "all"
        set dstaddr "all"
        set action accept
        set schedule "always"
        set logtraffic all
```

```
        set utm-status enable
        set ssl-ssh-profile "deep-inspection-clone"
        set av-profile "av"
    next
end
```

4. Get the clients to access a.ftnt.com and b.ftnt.com. The clients share access with the same real server and certificate (CN=*.ftnt.com). The FortiGate shares the first TLS connection with second TLS connection.
5. Verify the sniffer packet capture on the FortiGate server side. There is one client hello.

No.	Time	Source	Destination	Protocol	Length	Info

22	0.023285	172.16.200.6	172.16.200.99	TLSv1.2	108	Application Data
23	0.065172	172.16.200.99	172.16.200.6	TCP	66	443 → 7688 [ACK] Seq=2566 Ack=705 Win=64640 Len=0 TSval=834657513 TSecr=806057

6. Disable server pool multiplexing:

```
config firewall access-proxy
    edit "ztna"
        set vip "vip-ztna"
        set svr-pool-multiplex disable
    next
end
```

7. Verify the sniffer packet capture. This time, the FortiGate does not coalesce the TLS connection, so there are two client hellos.

No.	Time	Source	Destination	Protocol	Length	Info

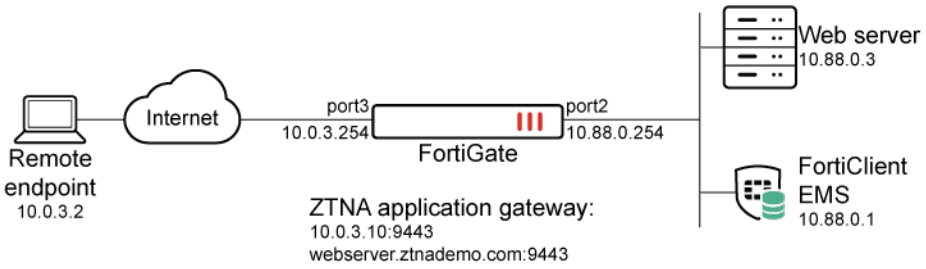
ZTNA configuration examples



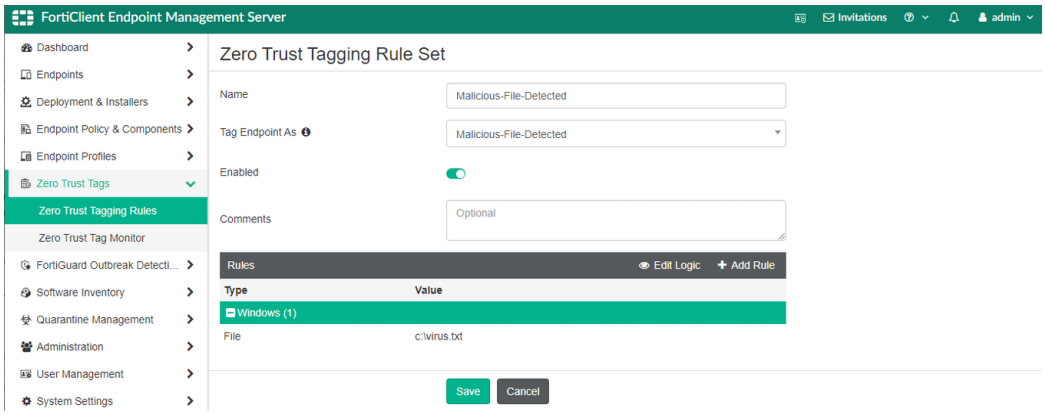
This section includes the following ZTNA configuration examples:

- ZTNA HTTPS access proxy example on page 953
- ZTNA HTTPS access proxy with basic authentication example on page 963
- ZTNA TCP forwarding access proxy example on page 970
- ZTNA SSH access proxy example on page 976
- ZTNA application gateway with SAML authentication example on page 983
- ZTNA application gateway with SAML and MFA using FortiAuthenticator example on page 987
- ZTNA IP MAC based access control example on page 1003
- ZTNA IPv6 examples on page 1010

- ZTNA Zero Trust application gateway example on page 1016
- ZTNA access proxy with KDC to access shared drives on page 1017

ZTNA HTTPS access proxy example

In this example, an HTTPS access proxy is configured to demonstrate its function as a reverse proxy on behalf of the web server it is protecting. It verifies user identity, device identity, and trust context, before granting access to the protected source.

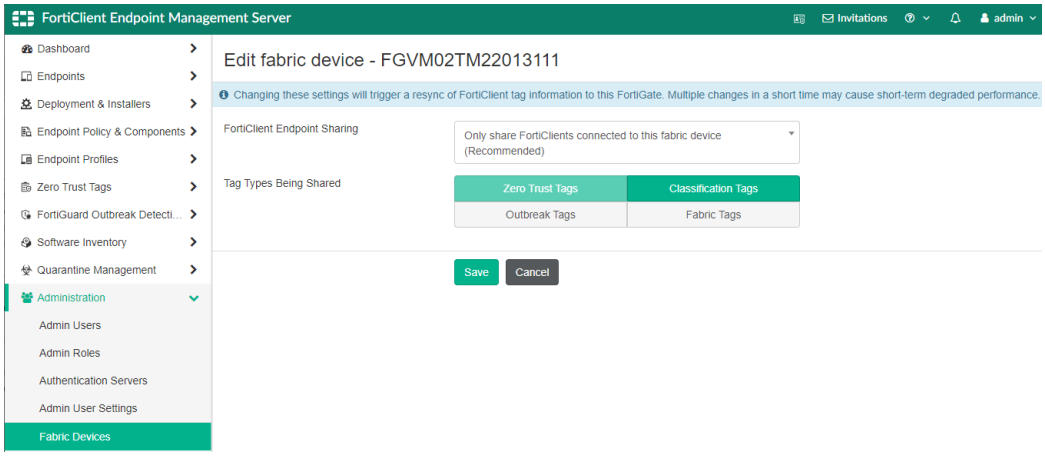


This example shows access control that allows or denies traffic based on ZTNA tags. Traffic is allowed when the FortiClient endpoint is tagged as *Low Importance* using Classification tags, and denied when the endpoint is tagged with *Malicious-File-Detected*.

This example assumes that the FortiGate EMS fabric connector is already successfully connected.

To configure ZTNA in the GUI, go to *System* > *Feature Visibility* and enable *Zero Trust Network Access*.

To configure a Zero Trust tagging rule on the FortiClient EMS:

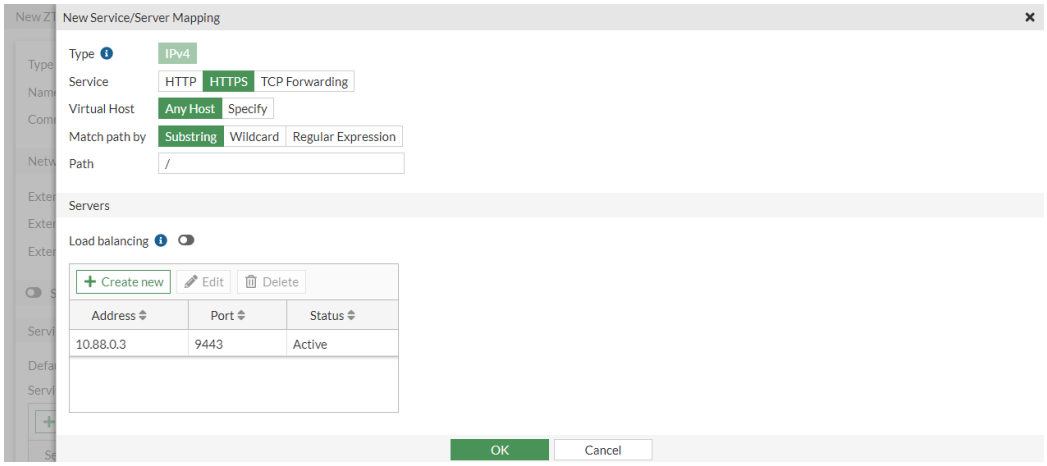


1. Log in to the FortiClient EMS.
2. Go to *Zero Trust Tags* > *Zero Trust Tagging Rules*, and click *Add*.
3. In the *Name* field, enter *Malicious-File-Detected*.
4. In the *Tag Endpoint As* dropdown list, select *Malicious-File-Detected*.
   EMS uses this tag to dynamically group together endpoints that satisfy the rule, as well as any other rules that are configured to use this tag.
5. Click *Add Rule* then configure the rule:
   a. For *OS*, select *Windows*.
   b. From the *Rule Type* dropdown list, select *File* and click the + button.
   c. Enter a file name, such as *C:\virus.txt*.
   d. Click *Save*.

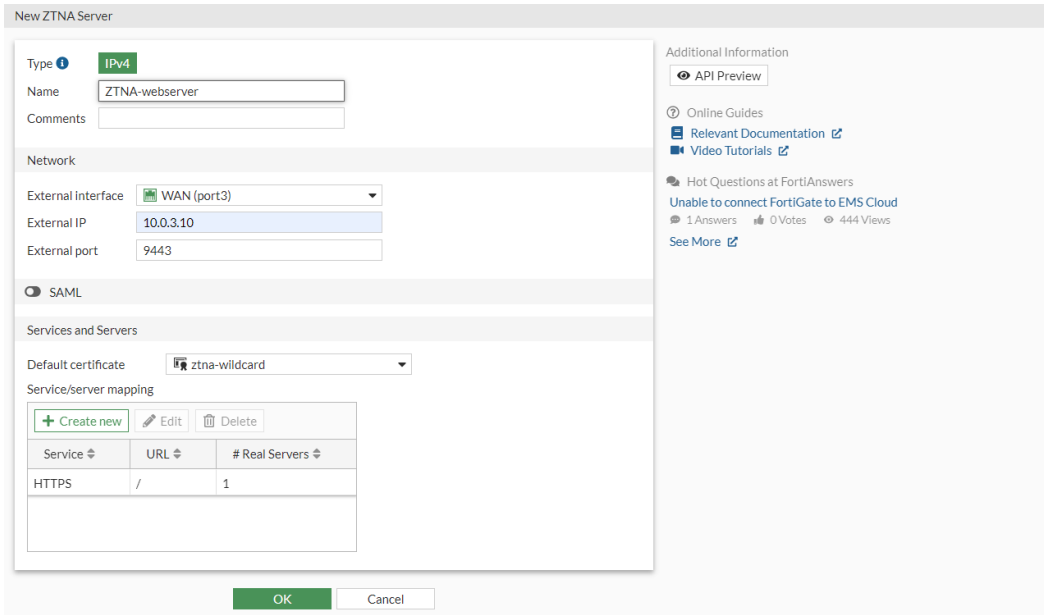
6. Click *Save*.

To configure FortiClient EMS to share classification tags:

1. Go to *Administration* > *Fabric Devices*.
2. Select the FortiGate device.
3. Click *Edit*.
4. Under *Tag Types Being Shared*, add *Classification Tags*.



5. Click *Save*.

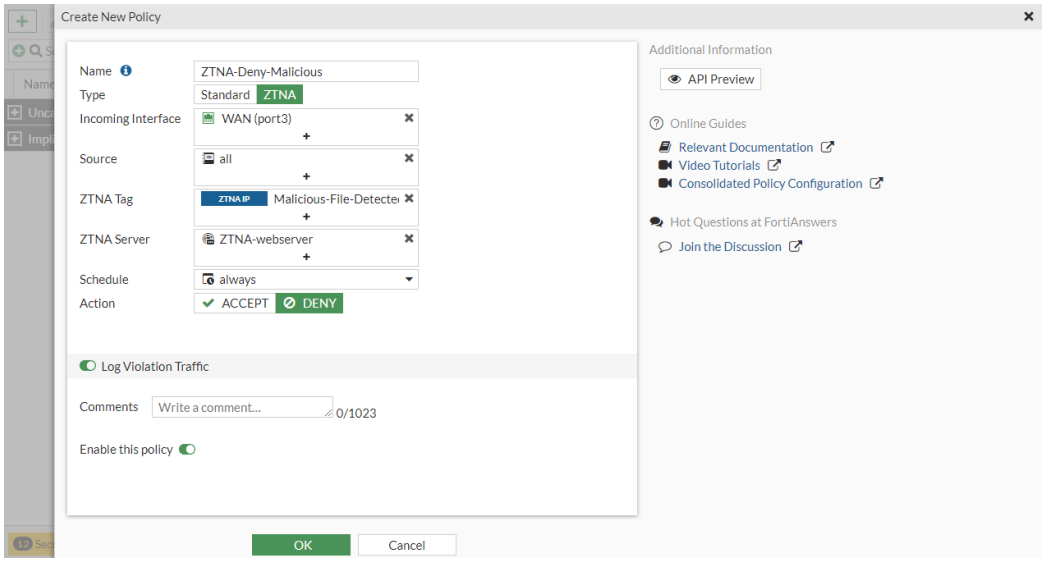


To configure a ZTNA server for HTTPS access proxy in the GUI:

1. Go to *Policy & Objects* > *ZTNA* and select the *ZTNA Servers* tab.
2. Click *Create New*.
3. Set *Name* to *ZTNA-webserver*.
4. Configure the network settings:
   a. Set *External interface* to *port3*.
   b. Set *External IP* to *10.0.3.10*.
   c. Set *External port* to *9443*.
5. Select the *Default certificate*. Clients will be presented with this certificate when they connect to the access proxy VIP.
6. Add server mapping:

a. In the *Service/server mapping* table, click *Create New*.
b. Set *Service* to *HTTPS*.
c. Set *Virtual Host* to *Any Host*.
d. Configure the path as needed. For example, to map to *webserver.ztnademo.com/fortigate*, enter */fortigate*.
e. Add a server:
   i. In the *Servers* table, click *Create New*.
   ii. Set *IP* to *10.88.0.3*.
   iii. Set *Port* to *9443*.
   iv. Click *OK*.

f. Click *OK*.



7. Click *OK*.

To configure simple ZTNA policies to allow and deny traffic based on ZTNA tags in the GUI:

1. Go to *Policy & Objects* > *Firewall Policy*.
2. Create a rule to deny traffic:

a. Click *Create New*.
b. Set *Name* to *ZTNA-Deny-malicious*.
c. Set *Type* to *ZTNA*.
d. Set *Incoming Interface* to *port3*.
e. Set *Source* to *all*.
f. Add the ZTNA tag *Malicious-File-Detected*.
   This tag is dynamically retrieved from EMS when you first created the Zero Trust Tagging Rule.
g. Select the ZTNA server *ZTNA-webserver*.
h. Set *Action* to *DENY*.
i. Enable *Log Violation Traffic*.

j. Click *OK*.

3. Create a rule to allow traffic:
   a. Click *Create New*.
   b. Set *Name* to *ZTNA-Allow-Simple*.
   c. Set *Type* to *ZTNA*.
   d. Set *Incoming Interface* to *port3*.
   e. Set *Source* to *all*. This can also be set to specific IP addresses to only allow those addresses to connect to this HTTPS access proxy.
   f. Add the *Class* tag *Low*.
   g. Select the ZTNA server *ZTNA-webserver*.
   h. Configure the remaining options as needed.
   i. Click *OK*.
4. On the firewall policy list, make sure that the deny rule (*ZTNA-Deny-malicious*) is above the allow rule (*ZTNA-Allow-Simple*).

To configure HTTPS access in the CLI:

1. Configure the access proxy VIP:

```
config firewall vip
    edit "ZTNA-webserver"
        set type access-proxy
        set extip 10.0.3.10
        set extintf "port3"
        set server-type https
        set extport 9443
        set ssl-certificate "ztna-wildcard"
    next
end
```

2. Configure the server and path mapping:

```
config firewall access-proxy
    edit "ZTNA-webserver"
        set vip "ZTNA-webserver"
        set client-cert enable
        set log-blocked-traffic enable
        config api-gateway
            edit 1
                config realservers
                    edit 1
                        set ip 10.88.0.3
                        set port 9443
                    next
                end
            next
        end
    next
end
```

3. Configure ZTNA policies:

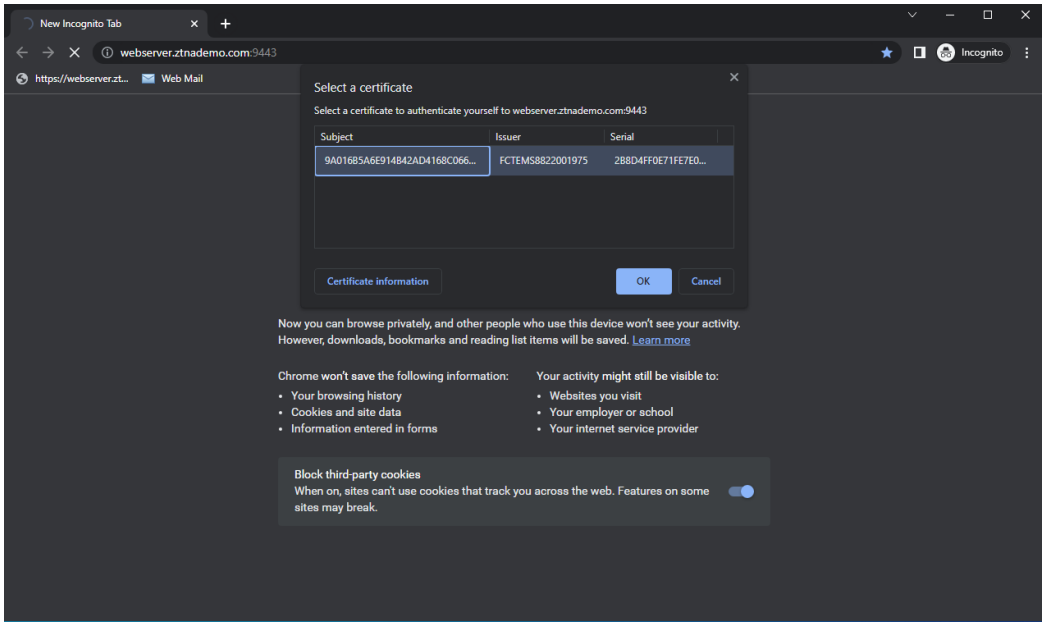
```
config firewall policy
     edit 9
        set name "ZTNA-Deny-Malicious"
        set srcintf "port3"
        set dstintf "any"
        set srcaddr "all"
        set dstaddr "ZTNA-webserver"
        set ztna-ems-tag "EMS1_ZTNA_Malicious-File-Detected"
        set schedule "always"
        set logtraffic all
    next
    edit 10
        set name "ZTNA-Allow-Simple"
        set srcintf "port3"
        set dstintf "any"
        set action accept
        set srcaddr "all"
        set dstaddr "ZTNA-webserver"
        set ztna-ems-tag "EMS1_CLASS_Low"
        set schedule "always"
        set logtraffic all
```

```
        set nat enable
    next
end
```

For configuration examples using full ZTNA policy, see Configure a ZTNA policy on page 921.

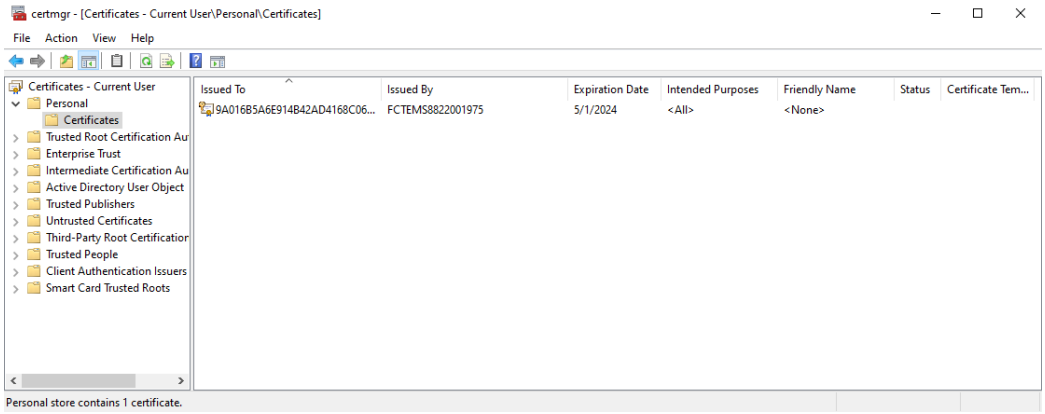
Testing the remote access to the HTTPS access proxy

After FortiClient EMS and FortiGate are configured, the HTTPS access proxy remote connection can be tested.

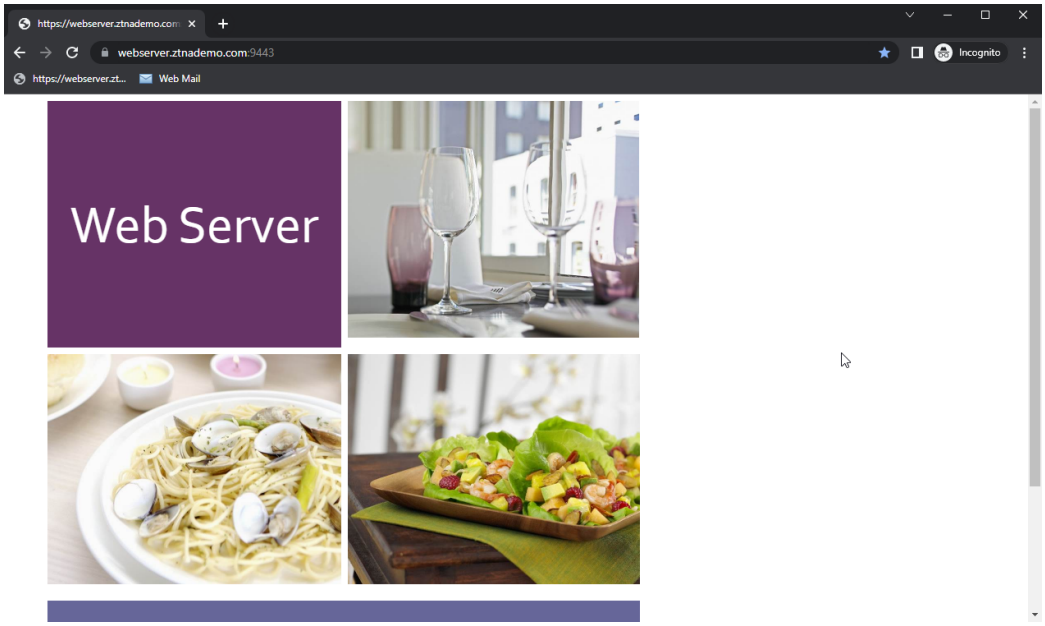


Access allowed:

1. On the remote Windows PC, open FortiClient.
2. On the *Zero Trust Telemetry* tab, make sure that you are connected to the EMS server.

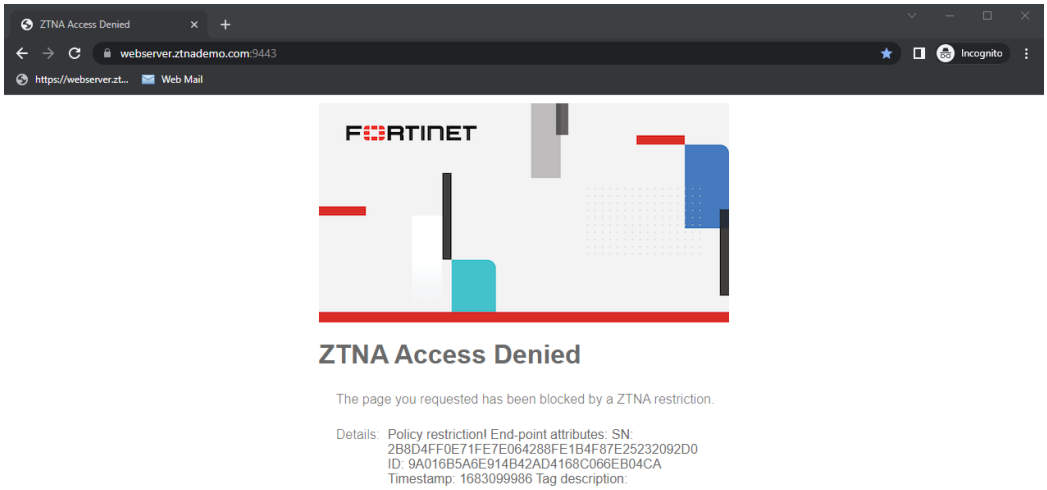


It is not necessary to configure a *ZTNA Destination* on the FortiClient for the HTTPS access proxy use case. In fact, configuring a *ZTNA Destination* rule for the website may interfere with its operation.



3. Open a browser and enter the address of the server and the access port. When entering the FQDN, make sure that the DNS can resolve the address to the IP address of the FortiGate. In this example, webserver.ztnademo.com resolves to 10.0.3.10.
4. The browser prompts for the client certificate to use. Select the EMS signed certificate, then click *OK*.

The certificate is in the *User Configuration* store, under *Personal* > *Certificates*. The details show the SN of the certificate, which matches the record on the FortiClient EMS and the FortiGate.



5. The client is verified by the FortiGate to authenticate your identity.
6. The FortiGate matches your security posture by verifying your ZTNA tag and matching the corresponding ZTNA rule, and you are allowed access to the web server.

Access denied:

1. On the remote Windows PC, trigger the Zero Trust Tagging Rule by creating the file in C:\virus.txt.
2. Open a browser and enter the address http://webserver.ztnademo.com:9443.
3. The client is verified by the FortiGate to authenticate your identity.
4. FortiGate checks your security posture. Because EMS has tagged the PC with the *Malicious-File-Detected* tag, it matches the *ZTNA-Deny-malicious* rule.

5. You are denied access to the web server.

Logs and debugs

Access allowed:

```
# diagnose endpoint record list
Record #1:
                IP Address = 10.0.3.2

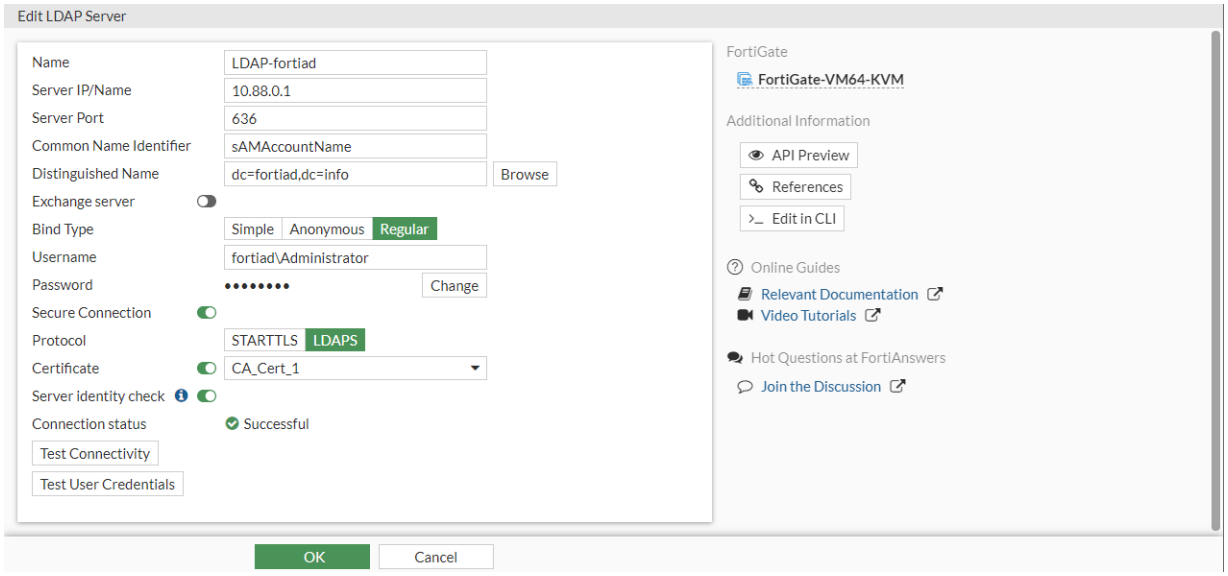
ZTNA HTTPS access proxy with basic authentication example

This example expands on the previous example (ZTNA HTTPS access proxy example on page 953), adding LDAP authentication to the ZTNA rule. Users are allowed based on passing the client certificate authentication check, user authentication, and security posture check.

Users that are in the AD security group *ALLOWED-VPN* are allowed access to the access proxy. Users that are not part of this security group are not allowed access.

This example assumes that the FortiGate EMS fabric connector is already successfully connected.

LDAP/Active Directory Users and Groups:



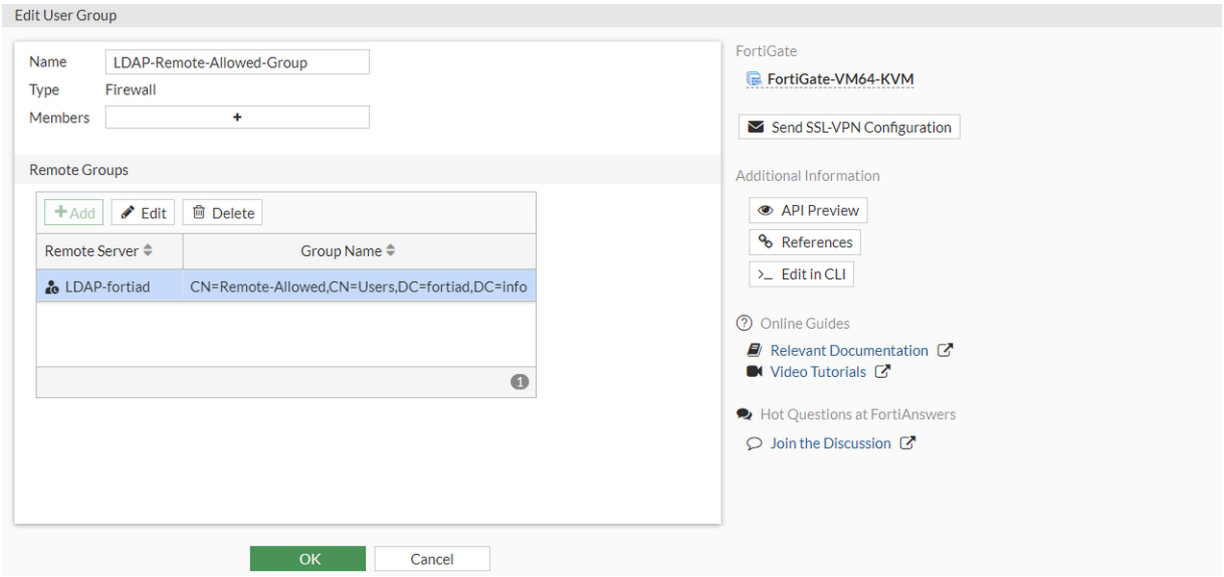
- Domain: fortiad.info
- Users (Groups):
  - tsmith (Domain Users, Remote-Allowed)
  - lhansen (Domain Users)

To configure a secure connection to the LDAP server in the GUI:

1. Go to *User & Authentication* > *LDAP Servers* and click *Create New*.
2. Configure the following settings:

Name	LDAP-fortiad
Server IP/Name	10.88.0.1
Server Port	636
Common Name Identifier	sAMAccountName

Distinguished Name	dc=fortiad,dc=info
Exchange server	Disabled
Bind Type	Regular Enter the *Username* and *Password* for LDAP binding and lookup.
Secure Connection	Enabled • Set *Protocol* to *LDAPS* • Enable *Certificate* and select the CA certificate to validate the server certificate.
Server identity check	Optionally, enable to verify the domain name or IP address against the server certificate.



3. Click *Test Connectivity* to verify the connection to the server.
4. Click *OK*.

To configure a secure connection to the LDAP server in the CLI:

```
config user ldap
    edit "LDAP-fortiad"
        set server "10.88.0.1"
        set cnid "sAMAccountName"
        set dn "dc=fortiad,dc=info"
        set type regular
        set username "fortiad\\Administrator"
        set password <password>
        set secure ldaps
        set ca-cert "CA_Cert_1"
        set port 636
    next
end
```

To configure a remote user group from the LDAP server in the GUI:

1. Go to *User & Authentication* > *User Groups* and click *Create New*.
2. Set the name to *LDAP-Remote-Allowed-Group*.
3. Set *Type* to *Firewall*.
4. In the *Remote Groups* table click *Add*:
   a. Set *Remote Server* to *LDAP-fortiad*.
   b. Locate the *Remote-Allowed* group, right-click on it, and click *Add Selected*.
   c. Click *OK*.

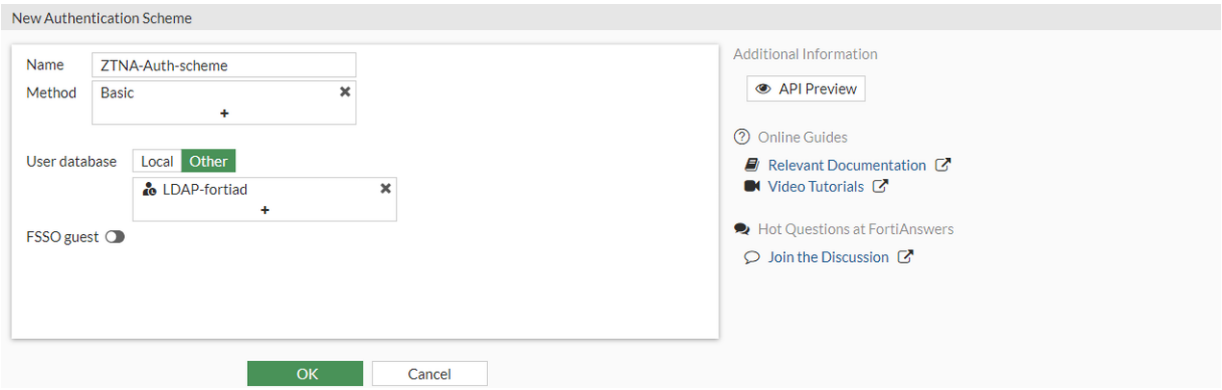
5. Click *OK*.

To configure a remote user group from the LDAP server in the CLI:

```
config user group
    edit "LDAP-Remote-Allowed-Group"
        set member "LDAP-fortiad"
        config match
            edit 1
                set server-name "LDAP-fortiad"
                set group-name "CN=Remote-Allowed,CN=Users,DC=fortiad,DC=info"
            next
        end
    next
end
```

Authentication scheme and rules

After the LDAP server and user group have been configured, an authentication scheme and rule must be configured.



To configure authentication schemes and rules in the GUI, go to *System* > *Feature Visibility* and enable *Explicit Proxy*.

Authentication scheme

The authentication scheme defines the method of authentication that is applied. In this example, basic HTTP authentication is used so that users are prompted for a username and password the first time that they connect to a website through the HTTPS access proxy.

To configure an authentication scheme in the GUI:

1. Go to *Policy & Objects* > *Authentication Rules* and click *Create New* > *Authentication Scheme*.
2. Set the name to *ZTNA-Auth-scheme*.
3. Set *Method* to *Basic*.
4. Set *User database* to *Other* and select *LDAP-fortiad* as the LDAP server.

5. Click *OK*.

To configure an authentication scheme in the CLI:

```
config authentication scheme
    edit "ZTNA-Auth-scheme"
        set method basic
        set user-database "LDAP-fortiad"
    next
end
```

Authentication rule

The authentication rule defines the proxy sources and destination that require authentication, and what authentication scheme is applied. In this example, active authentication through the basic HTTP prompt is used and applied to all sources.

To configure an authentication rule in the GUI:

1. Go to *Policy & Objects* > *Authentication Rules* and click *Create New* > *Authentication Rule*.
2. Set the name to *ZTNA-Auth-rule*.
3. Set *Source Address* to *all*.
4. Set *Protocol* to *HTTP*.
5. Enable *Authentication Scheme* and select *ZTNA-Auth-scheme*.
6. Click *OK*.

To configure an authentication rule in the CLI:

```
config authentication rule
    edit "ZTNA-Auth-rule"
        set srcaddr "all"
        set active-auth-method "ZTNA-Auth-scheme"
    next
end
```

Applying the user group to a ZTNA policy

A user or user group must be applied to the ZTNA policy that you need to control user access to. The authenticated user from the authentication scheme and rule must match the user or user group in the ZTNA policy.

In this example, the user group is applied to the two simple ZTNA policies that were configured in ZTNA HTTPS access proxy example on page 953.

To apply a user group to the simple ZTNA policies in the GUI:

1. Go to *Policy & Objects* > *Firewall Policy*.
2. Edit the *ZTNA-Deny-malicious* rule.
3. Click in the *Source* field, select the *User* tab, select the *LDAP-Remote-Allowed-Group* group, then click *Close*.
4. Click *OK*.
5. Edit the *ZTNA-Allow-Simple* rule.
6. Click in the *Source* field, select the *User* tab, select the *LDAP-Remote-ALlowed-Group* group, then click *Close*.
7. Click *OK*.

To apply a user group to the simple ZTNA policies in the CLI:

```
config firewall policy
     edit 9
        set name "ZTNA-Deny-Malicious"
        set srcintf "port3"
        set dstintf "any"
        set srcaddr "all"
        set dstaddr "ZTNA-webserver"
        set ztna-ems-tag "EMS1_ZTNA_Malicious-File-Detected"
        set schedule "always"
        set logtraffic all
        set groups "LDAP-Remote-Allowed-Group"
    next
    edit 10
        set name "ZTNA-Allow-Simple"
        set srcintf "port3"
        set dstintf "any"
        set action accept
        set srcaddr "all"
        set dstaddr "ZTNA-webserver"
        set ztna-ems-tag "EMS1_CLASS_Low"
        set schedule "always"
        set logtraffic all
        set nat enable
```

```
        set groups "LDAP-Remote-Allowed-Group"
    next
end
```

For configuration examples using full ZTNA policy, see Configure a ZTNA policy on page 921.

Testing remote access to the HTTPS access proxy with user authentication

Scenario 1: access allowed - user tsmith

1. On a remote Windows PC, open the FortiClient app, select the *Zero Trust Telemetry* tab, and confirm that you are connected to the EMS server.

   It is not necessary to configure a *ZTNA Destination* on the FortiClient for the HTTPS access proxy use case. In fact, configuring a *ZTNA Destination* rule for the website may interfere with its operation.

2. In a browser, enter the address of the server and the access port.

   If entering an FQDN, make sure that DNS can resolve the address to the IP address of the FortiGate. In this example, *webserver.ztnademo.com* resolves to 10.0.3.10.

3. When the browser asks for the client certificate to use, select the EMS signed certificate, then click *OK*.

   The client certificate is verified by the FortiGate to authenticate your identity.

4. When prompted, enter the username *tsmith* and the password, and click *Sign in*.

   As *tsmith* is a member of the *Remote-Allowed-Group* group in Active Directory, it will match the *LDAP-Remote-Allowed-Group* user group. After the user authentication passes, the FortiGate performs a posture check on the ZTNA group. When that passes, you are allowed access to the website.

Verifying the results

```
#  diagnose firewall auth list

10.0.3.2, tsmith
        type: fw, id: 0, duration: 12, idled: 12
        expire: 288, allow-idle: 300
        packets: in 0 out 0, bytes: in 0 out 0
        group_id: 3
        group_name: LDAP-Remote-Allowed-Group
```

```
# diagnose test app fcnacd 7
Entry #1:

sentbyte=2876 lanout=337447 fctuid="9A016B5A6E914B42AD4168C066EB04CA" appcat="unscanned"
```

Scenario 2: access denied – user lhansen

1. If scenario 1 has just been tested, log in to the FortiGate and deauthenticate the user:
   a. Go to *Dashboard* > *Assets & Identities* and expand the *Firewall Users* widget.
   b. Right-click on the user *tsmith* and select deauthenticate.
2. On a remote Windows PC, open the FortiClient app, select the *Zero Trust Telemetry* tab, and confirm that you are connected to the EMS server.
3. In a browser, enter the address *webserver.ztnademo.com*.
4. When the browser asks for the client certificate to use, select the EMS signed certificate, then click *OK*. This option might not appear if you have already selected the certificate when testing scenario 1.

   The client certificate is verified by the FortiGate to authenticate your identity.
5. When prompted, enter the username *lhansen* and the password, and click *Sign in*.

   As *lhansen* is not a member of the *Remote-Allowed* group in Active Directory, it will not match the *LDAP-Remote-Allowed-Group* user group. Because no other policies are matched, this user is implicitly denied

Verifying the results

Go to *Dashboard* > *Assets & Identities*, expand the *Firewall Users* widget, and confirm that user *lhansen* is listed, but no applicable user group is returned.

```
# execute log display

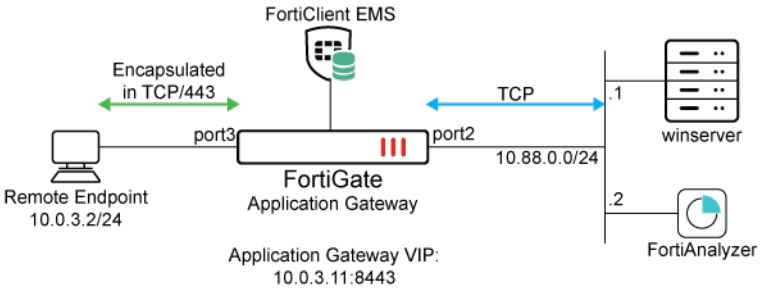
ZTNA TCP forwarding access proxy example

In this example, a TCP forwarding access proxy (TFAP) is configured to demonstrate an HTTPS reverse proxy that forwards TCP traffic to the designated resource. The access proxy tunnels TCP traffic between the client and the FortiGate over HTTPS, and forwards the TCP traffic to the protected resource. It verifies user identity, device identity, and trust context, before granting access to the protected source.

TCP forwarding access proxy supports communication between the client and the access proxy without SSL/TLS encryption. The connection still begins with a TLS handshake. The client uses the HTTP 101 response to switch protocols and remove the HTTPS stack. Further end to end communication between the client and server are encapsulated in the specified TCP port, but not encrypted by the access proxy. This improves performance by reducing the overhead of encrypting an already secured underlying protocol, such as RDP, SSH, or FTPS. Users should still enable the encryption option for end to end protocols that are insecure.



In this example, RDP (Remote Desktop Protocol) and SMB (Server Message Block) protocol access are configured to one server, and SSH access to the other server. Encryption is disabled for RDP and SSH, and enabled for SMB.

FortiClient (Windows) must be running 7.0.3 or later to detect SMB.

You cannot use ZTNA connection rules and TCP forwarding on a Windows 7 endpoint.

This example assumes that the FortiGate EMS fabric connector is already successfully connected.

To configure the ZTNA server for TCP access proxy in the GUI:

1. Go to *Policy & Objects* > *ZTNA* and select the *ZTNA Servers* tab.
2. Click *Create New*.
3. Set *Name* to *ZTNA-tcp-server*.
4. Configure the network settings:
   a. Set *External interface* to *port3*.
   b. Set *External IP* to *10.0.3.11*.
   c. Set *External port* to *8443*.
5. Select the *Default certificate*. Clients will be presented with this certificate when they connect to the access proxy VIP.
6. Add server mapping:
   a. In the *Service/server mapping* table, click *Create New*.
   b. Set *Service* to *TCP Forwarding*.
   c. Add a server:
      i. In the *Servers* table, click *Create New*.
      ii. Create a new address for the FortiAnalyzer server at 10.88.0.2 and use it as the address.
      iii. Set *Port* to *22*.
      iv. Click *OK*.
   d. Add another server:
      i. In the *Servers* table, click *Create New*.
      ii. Create a new address for the winserver at 10.88.0.1 and use it as the address.
      iii. Set *Port* to *445, 3389* to correspond to SMB and RDP.
      iv. Click *OK*.
   e. Click *OK*.
7. Click *OK*.

To configure a simple ZTNA policy to allow traffic to the TCP access proxy in the GUI:

1. Go to *Policy & Objects* > *Firewall Policy*, and click *Create New*.
2. Set *Name* to *ZTNA_remote*.
3. Set *Type* to *ZTNA*.
4. Set *Incoming Interface* to *port3*.
5. Set *Source* to *all*.
6. Select the ZTNA server *ZTNA-tcp-server*.
7. Configure the remaining options as needed.
8. Click *OK*.

To configure the access proxy VIP in the CLI:

```
config firewall vip
    edit "ZTNA-tcp-server"
        set type access-proxy
```

```
        set extip 10.0.3.11
        set extintf "port3"
        set server-type https
        set extport 8443
        set ssl-certificate "Fortinet_SSL"
    next
end
```

To configure the server addresses in the CLI:

```
config firewall address
    edit "FAZ"
        set subnet 10.88.0.2 255.255.255.255
    next
    edit "winserver"
        set subnet 10.88.0.1 255.255.255.255
    next
end
```

To configure access proxy server mappings in the CLI:

```
config firewall access-proxy
    edit "ZTNA-tcp-server"
        set vip "ZTNA-tcp-server"
        config api-gateway
            edit 1
                set url-map "/tcp"
                set service tcp-forwarding
                config realservers
                    edit 1
                        set address "FAZ"
                        set mappedport 22
                    next
                    edit 2
                        set address "winserver"
                        set mappedport 445 3389
                    next
                end
            next
        end
    next
end
```

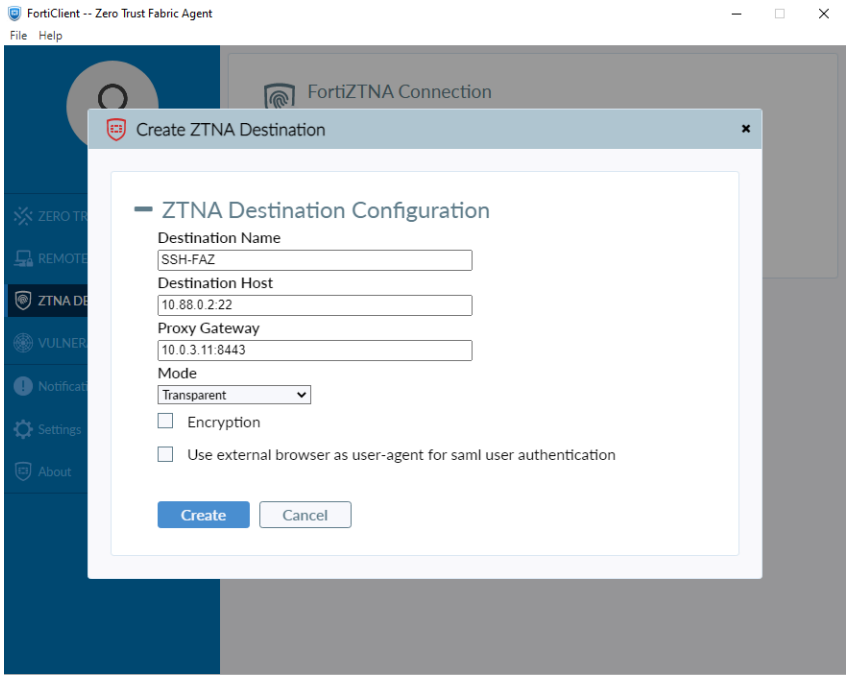
The mapped port (`mappedport`) restricts the mapping to the specified port or port range. If `mappedport` is not specified, then any port will be matched.

To configure a ZTNA rule (proxy policy) in the CLI:

```
config firewall policy
    edit 11
        set name "ZTNA_remote"
        set srcintf "port3"
        set dstintf "any"
        set action accept
        set srcaddr "all"
        set dstaddr "ZTNA-tcp-server"
```

```
        set schedule "always"
        set logtraffic all
        set nat enable
    next
end
```

For configuration examples using full ZTNA policy, see Configure a ZTNA policy on page 921.

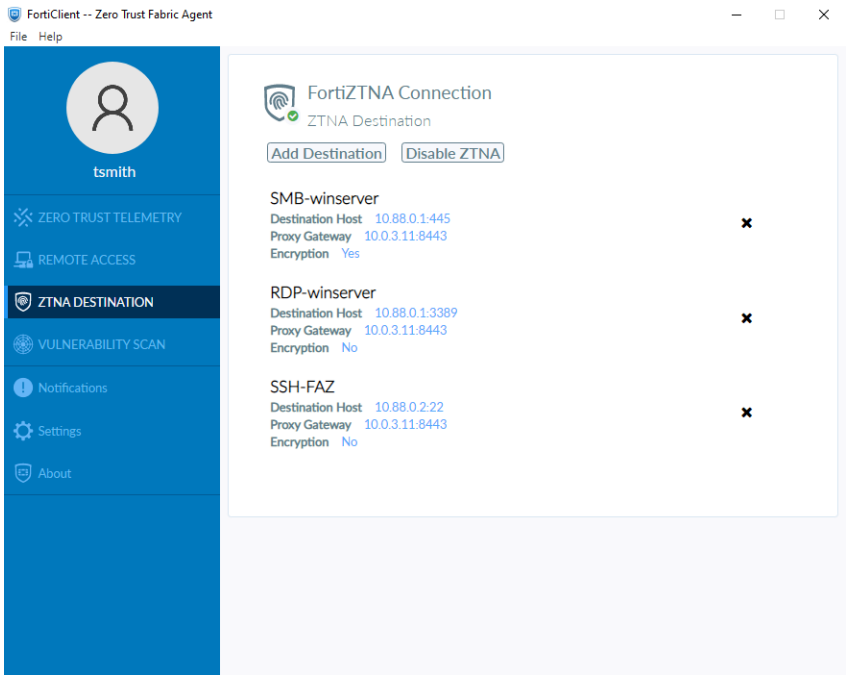


Test the connection to the access proxy

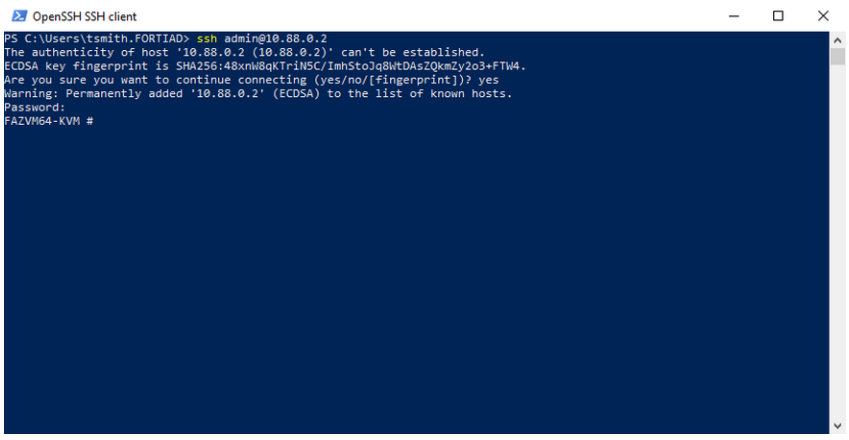
Before connecting, users must have a ZTNA connection rule in FortiClient.

ZTNA TCP forwarding rules can be provisioned from the EMS server. See Provisioning ZTNA TCP forwarding rules via EMS for details.

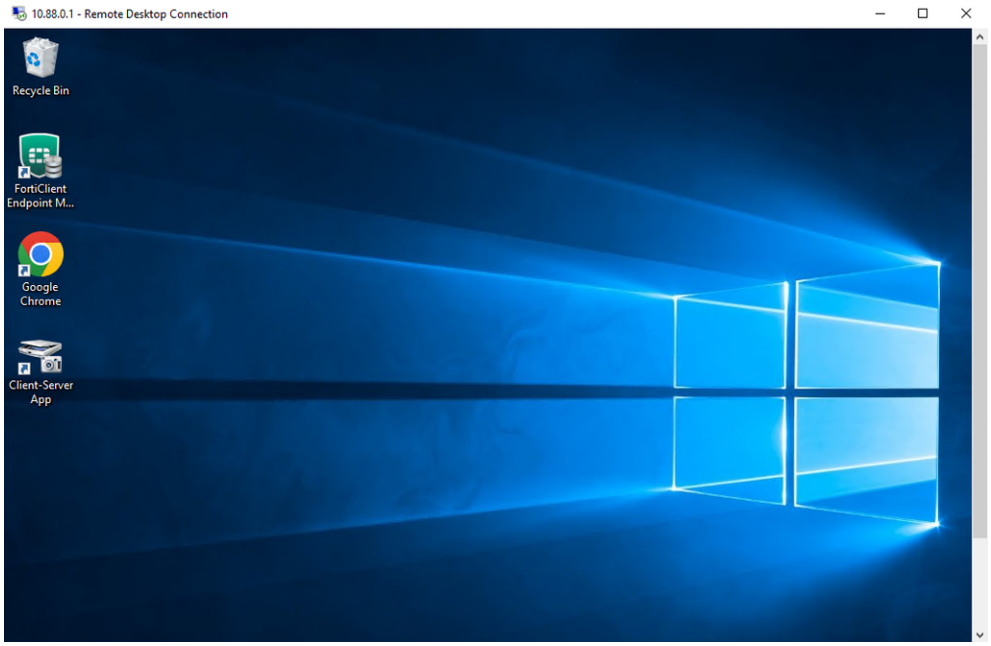
To create a ZTNA Destination in FortiClient:



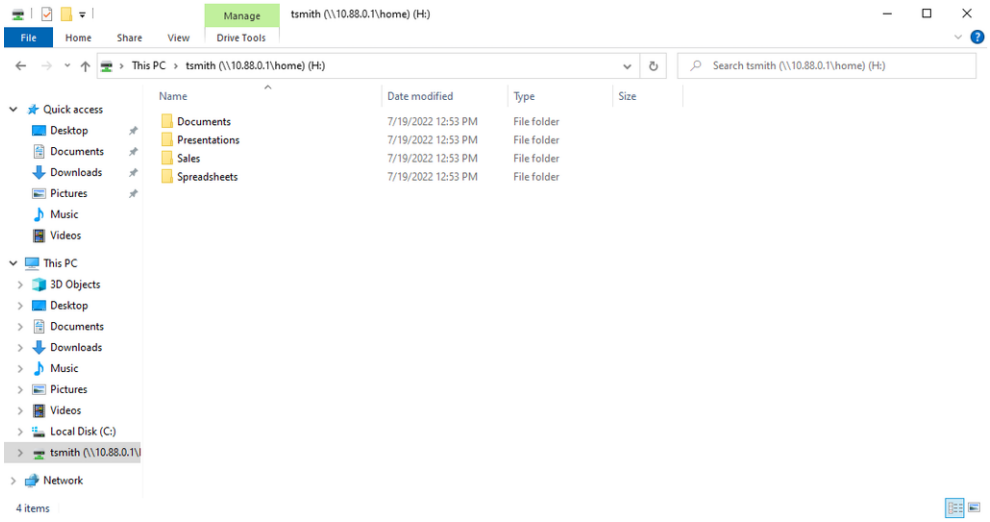
1. On the *ZTNA Destination* tab, click *Add Destination*.
2. Set *Destination Name* to *SSH-FAZ*.
3. Set *Destination Host* to *10.88.0.2:22*. This is the real IP address and port of the server.
4. Set *Proxy Gateway* to *10.0.3.11:8443*. This is the access proxy address and port that are configured on the FortiGate.
5. Leave *Encryption* disabled. This option determines whether or not the Client to FortiGate access proxy connection is encrypted in HTTPS.



6. Click *Create*.
7. Create a second rule with the following settings:



- *Rule Name*: *RDP-winserver*
- *Destination Host*: *10.88.0.1:3389*
- *Proxy Gateway*: *10.0.3.11:8443*
- *Encryption*: Disabled



8. Create a third rule with the following settings:
   - *Rule Name*: *SMB-winserver*
   - *Destination Host*: *10.88.0.1:445*
   - *Proxy Gateway*: *10.0.3.11:8443*
   - *Encryption*: Enabled

After creating the ZTNA connection rules, you can SSH, RDP, and SMB directly to the server IP address and port.

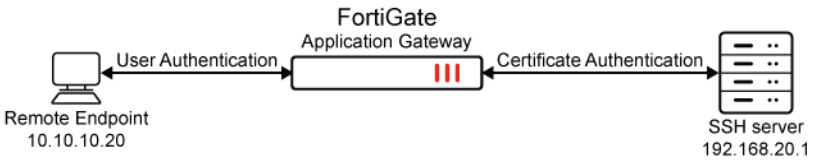
ZTNA SSH access proxy example

ZTNA can be configured with SSH access proxy to provide a seamless SSH connection to the server.

Advantages of using an SSH access proxy instead of a TCP forwarding access proxy include:

- Establishing device trust context with user identity and device identity checks.
- Applying SSH deep inspection to the traffic through the SSH related profile.
- Performing optional SSH host-key validation of the server.
- Using one-time user authentication to authenticate the ZTNA SSH access proxy connection and the SSH server connection.



Perform SSH host-key validation of the server

To act as a reverse proxy for the SSH server, the FortiGate must perform SSH host-key validation to verify the identity of the SSH server. The FortiGate does this by storing the public key of the SSH server in its SSH host-key configurations. When a connection is made to the SSH server, if the public key matches one that is used by the server, then the connection is established. If there is no match, then the connection fails.

One-time user authentication

SSH access proxy allows user authentication to occur between the client and the access proxy, while using the same user credentials to authenticate with the SSH server. The following illustrates how this works:

1. The remote endpoint registers to FortiClient EMS and receives the client certificate.
2. The remote endpoint tries to connect to the SSH access proxy. It must use the same username that is later used for access proxy authentication.
3. The FortiGate challenges the endpoint with device identity validation.
4. The remote endpoint provides the EMS issued certificate for device identification.
5. The FortiGate challenges the endpoint with user authentication. For example, this could be done with basic or SAML authentication.
6. The users enters their credentials on the remote endpoint.
7. The FortiGate authenticates the user and collects the username.
8. Using the FortiGate's CA or the customer's CA certificate, the FortiGate signs an SSH certificate and embeds the username in its principal.
9. The FortiGate attempts to connect to the SSH server using the certificate authentication.
10. The SSH server verifies the authenticity of the certificate, and matches the username principal against its authorized_keys file.
11. If the username matches a record in the file, then the SSH connection is established. If no match is found, then the SSH connection fails.

Example

In this example, an SSH connection is established using SSH access proxy with host-key validation and one-time authentication.

- The SSH server is a Linux based server that uses sshd to provide remote access
- For SSH host-key validation, the public key of the SSH server has been imported into the FortiGate.
- For one-time authentication using certificate authentication:
  - The SSH server must allow certificate authentication.
  - The SSH server must have the proper entry in its authorized_keys file that contains the user principal and the FortiGate CA's public key.
  - The entry is present in the user directory corresponding to the user that is trying to log in.

To pre-configure the Linux SSH server:

1. Retrieve the public key used for host-key validation:
   a. Locate the public key files in the SSH server:

   ```
   $ ls -la /etc/ssh/*.pub
   -rw-r--r-- 1 root root 186 Mar 29  2020 /etc/ssh/ssh_host_ecdsa_key.pub
   -rw-r--r-- 1 root root 106 Mar 29  2020 /etc/ssh/ssh_host_ed25519_key.pub
   -rw-r--r-- 1 root root 406 Mar 29  2020 /etc/ssh/ssh_host_rsa_key.pub2
   ```

   b. Choose the public key file based on the hash type (in this case, ECDSA), and show it's content:

   ```
   $ cat /etc/ssh/ssh_host_ecdsa_key.pub
   ecdsa-sha2-nistp256 AAAAE2*********IpEik=
   ```

   This key will be used when configuring the FortiGate.
2. Retrieve the FortiGate CA's public key from the FortiGate:

```
# show full firewall ssh local-ca Fortinet_SSH_CA
config firewall ssh local-ca
    edit "Fortinet_SSH_CA"
        set password ENC <hidden password>
        set private-key "-----BEGIN OPENSSH PRIVATE KEY-----
<hidden private key>
-----END OPENSSH PRIVATE KEY-----"
        set public-key "ssh-rsa AAAAB3**********JLXlxj3″
        set source built-in
    next
end
```

3. On the Linux server, enable the SSH service to use the authorized_keys file:
   a. Locate and edit the */etc/ssh/sshd_config* file.
   b. Ensure that the *AuthorizedKeysFile* line is uncommented, for example:

   ```
   AuthorizedKeysFile      .ssh/authorized_keys .ssh/authorized_keys2
   ```

4. Allow remote SSH log in with certificate authentication and principal name:
   a. Log in to the SSH server using the account that will be granted remote SSH access (in this example: *radCurtis*):
   b. Locate the account's authorized_keys file in the *~/.ssh* directory:

   ```
   $ ls -la ~/.ssh
   total 12
   drwxrwxr-x 2 radCurtis radCurtis 4096 Aug 10 19:14 .
   drwxr-xr-x 5 radCurtis radCurtis 4096 Aug 10 19:13 ..
   -rw-rw-r-- 1 radCurtis radCurtis  419 Aug 10 19:14 authorized_keys
   ```

   c. If the directory and file do not exist, create the directory:

   ```
   $ mkdir ~/.ssh
   ```

   d. Create an entry containing the following keywords and add them to the authorized_keys file:

   ```
   echo 'cert-authority,principals="radCurtis" ssh-rsa AAAAB3**********JLXlxj3' >>
   authorized_keys
   ```

   Where:

   - `cert-authority` - indicates that this entry is used in certificate authentication by validating the certificate using the public key provided in this entry.

- `principals="radCurtis"` - indicates the user that must match with the username embedded in the SSH certificate.
- `ssh-rsa AAAAB3**********JLXlxj3` - indicates the FortiGate CA's public key that is used to validate the SSH certificate.

5. Restart the sshd service:

```
$ sudo systemctl stop sshd
$ sudo systemctl start sshd
```

The SSH server can now accept SSH connection from *radCurtis@<server IP>*, where the SSH certificate used by the FortiGate to log in contains radCurtis embedded as a principal.

When a user connects from a SSH client using *<username>@<server IP>*, sshd will locate the authorized_keys file in the directory */home/<username>/.ssh/authorized_keys*. If the authorized_keys is not in that directory, authentication will fail on the SSH server side.

If you suspect that authentication is failing on the SSH server, use the following commands to manually start sshd in debug mode to troubleshoot:

```
$ sudo systemctl stop sshd

$ /usr/sbin/sshd -ddd -p 22
```

To configure the FortiGate :

1. Configure a new VIP to allow access to the SSH access proxy over 192.168.2.87:443:

```
config firewall vip
    edit "ZTNA_SSH"
        set type access-proxy
        set extip 192.168.2.87
        set extintf "any"
        set server-type https
        set extport 443
        set ssl-certificate "Fortinet_SSL"
    next
end
```

2. Configure the address object for the SSH server:

```
config firewall address
    edit "SSH_server"
        set subnet 192.168.20.1 255.255.255.255
    next
end
```

3. Configure the host-key that will be used to authenticate the SSH server. The public-key was retrieved when pre-configure the Linux SSH server (step 1b).

```
config firewall ssh host-key
    edit "ed25519"
        set type ECDSA
        set usage access-proxy
        set public-key "AAAAE2**********IpEik="
    next
end
```

4. Configure the access proxy SSH client certificate:

   A CA certificate is assigned to sign the SSH certificate that will be used in the SSH authentication. The SSH certificate will have the username embedded in the certificate principal.

```
config firewall access-proxy-ssh-client-cert
    edit "ssh-access-proxy"
        set source-address enable
        set auth-ca "Fortinet_SSH_CA"
    next
end
```

5. Configure the access-proxy server setting:

```
config firewall access-proxy
    edit "ZTNA_SSH"
        set vip "ZTNA_SSH"
        set client-cert enable
        config api-gateway
            edit 1
                set url-map "tcp"
                set service tcp-forwarding
                config realservers
                    edit 1
                        set address "SSH_server"
                        set type ssh
                        set ssh-client-cert "ssh-access-proxy"
                        set ssh-host-key-validation enable
                        set ssh-host-key "ed25519"
                    next
                end
            next
        end
    next
end
```

6. Configure the RADIUS setting, user setting, and user group to apply user authentication to the access proxy connection using RADIUS:

```
config user radius
    edit "Win2k16-Radius"
        set server "192.168.20.6"
        set secret ENC <secret>
    next
end
config user local
    edit "radCurtis"
        set type radius
        set radius-server "Win2k16-Radius"
    next
end
config user group
        edit "radius_group"
        set member "radCurtis" "Win2k16-Radius"
    next
end
```

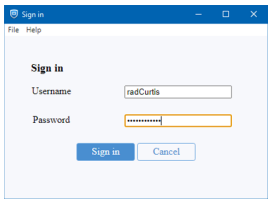
7. Create the authentication scheme and rule to perform the authentication:

```
config authentication scheme
    edit "basic_auth"
        set method basic
        set user-database "Win2k16-Radius"
    next
end
config authentication rule
    edit "ztna-basic"
        set srcaddr "all"
        set ip-based disable
        set active-auth-method "basic_auth"
        set web-auth-cookie enable
    next
end
```

8. Configure the full ZTNA policy to allow traffic to the SSH server, and apply user authentication, posture check, and a security profile where necessary:

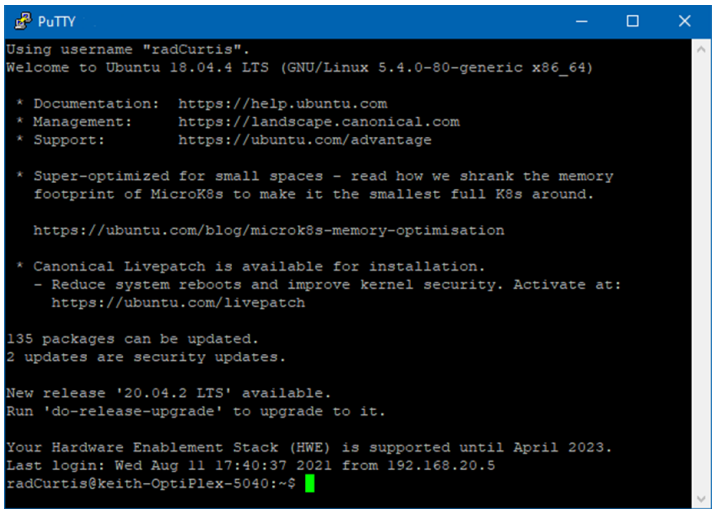
```
config firewall proxy-policy
    edit 5
        set name "SSH-proxy"
        set proxy access-proxy
        set access-proxy "ZTNA_SSH"
        set srcintf "port1"
        set srcaddr "all"
        set dstaddr "all"
        set ztna-ems-tag "FCTEMS8821001056_ems138_av_tag"
        set action accept
        set schedule "always"
        set groups "radius_group"
        set utm-status enable
        set ssl-ssh-profile "custom-deep-inspection"
    next
end
```

To check the results:



1. On the remote client, open FortiClient, go to the *Zero Trust Telemetry* tab, and make sure that it is connected to the EMS server.
2. Go to the *ZTNA Destination* tab and click *Add Destination*.
3. Configure the Destination, then click *Create*:

Rule Name	SSH-Linux
Destination Host	192.168.20.1:22
Proxy Gateway	192.168.2.87:443
Mode	Transparent
Encryption	Disabled (recommended)



When Encryption is disabled, the connection between the client and FortiGate access proxy is not encapsulated in HTTPS after the client and FortiGate connection is established. This allows for less overhead, because SSH is already a secure connection.

4. Open an SSH client, such as PuTTy, and make an SSH connection to *radCurtis@192.168.20.1* on port *22*.

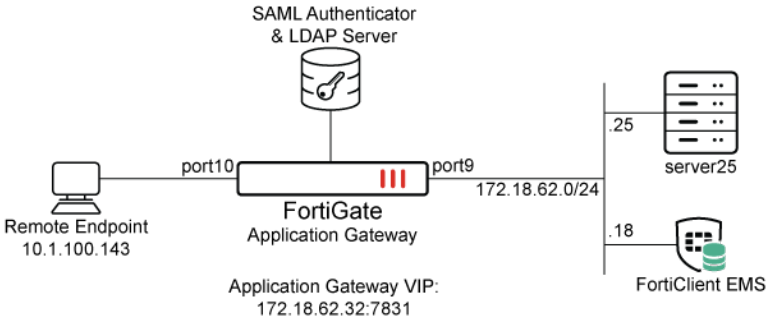
5. After device authentication is performed and passes in the background, FortiClient prompts the user to sign in. Enter the username, *radCurtis*, and password, then click *Sign in*.

After successful user authentication, the SSH connection is established without an additional log in.

6. On the FortiGate, check the logged in user:
   a. Go to *Dashboard* > *Assets & Identities* and expand the *Firewall Users* widget.
   b. Check the WAD proxy user list:

```
# diagnose wad user list
ID: 2, VDOM: root, IPv4: 10.10.10.25
  user name    : radCurtis
  worker       : 0
  duration     : 614
  auth_type    : Session
  auth_method  : Basic
  pol_id       : 5
  g_id         : 12
  user_based   : 0
  expire       : 53
  LAN:
    bytes_in=3403 bytes_out=5699
  WAN:
    bytes_in=3681 bytes_out=3132
```

7. The successful connection is logged in the forward traffic logs after the SSH connection has disconnected:



```
# execute log display
25 logs found.
10 logs returned.

1: date=2021-08-11 time=17:59:56 eventtime=1628729996110159120 tz="-0700"
logid="0000000024" type="traffic" subtype="forward" level="notice" vd="root"
```

```
srcip=10.10.10.25 srcport=50627 srcintf="port1" srcintfrole="wan" dstcountry="Reserved"
srccountry="Reserved" dstip=192.168.20.1 dstport=22 dstintf="root"
dstintfrole="undefined" sessionid=1926338 srcuuid="5445be2e-5d7b-51ea-e2c3-ae6b7855c52f"

```

ZTNA application gateway with SAML authentication example

In this example, an HTTPS access proxy is configured, and SAML authentication is applied to authenticate the client. The FortiGate acts as the SAML SP and a SAML authenticator serves as the IdP. In addition to verifying the user and device identity with the client certificate, the user is also authorized based on user credentials to establish a trust context before granting access to the protected resource.

This example assumes that the FortiGate EMS fabric connector is already successfully connected.

To configure the access proxy VIP:

```
config firewall vip
    edit "ZTNA_server01"
        set type access-proxy
        set extip 172.18.62.32
        set extintf "any"
        set server-type https
        set extport 7831
        set ssl-certificate "Fortinet_CA_SSL"
    next
end
```

To configure access proxy server mappings:

```
config firewall access-proxy
    edit "ZTNA_server01"
        set vip "ZTNA_server01"
        set client-cert enable
        config api-gateway
            edit 1
                set service https
                config realservers
                    edit 1
                        set ip 172.18.62.25
                        set port 443
```

```
                    next
                end
            next
        end
    next
end
```

To configure a SAML server:

```
config user saml
    edit "saml_ztna"
        set cert "Fortinet_CA_SSL"
        set entity-id "https://fgt9.myqalab.local:7831/samlap"
        set single-sign-on-url "https://fgt9.myqalab.local:7831/XX/YY/ZZ/saml/login/"
        set single-logout-url "https://fgt9.myqalab.local:7831/XX/YY/ZZ/saml/logout/"
        set idp-entity-id "http://MYQALAB.LOCAL/adfs/services/trust"
        set idp-single-sign-on-url "https://myqalab.local/adfs/ls"
        set idp-single-logout-url "https://myqalab.local/adfs/ls"
        set idp-cert "REMOTE_Cert_4"
        set digest-method sha256
        set adfs-claim enable
        set user-claim-type upn
        set group-claim-type group-sid
    next
end
```

To map the SAML server into an access proxy configuration:

```
config firewall access-proxy
    edit "ZTNA_server01"
        config api-gateway
             edit 3
                set service samlsp
                set saml-server "saml_ztna"
            next
        end
    next
end
```

To configure an LDAP server and an LDAP server group to verify user groups:

```
config user ldap
    edit "ldap-10.1.100.198"
        set server "10.1.100.198"
        set cnid "cn"
        set dn "dc=myqalab,dc=local"
        set type regular
        set username "cn=fosqa1,cn=users,dc=myqalab,dc=local"
        set password **********
        set group-search-base "dc=myqalab,dc=local"
    next
end
```

```
config user group
    edit "ldap-group-saml"
        set member "ldap-10.1.100.198"
```

```
    next
end
```

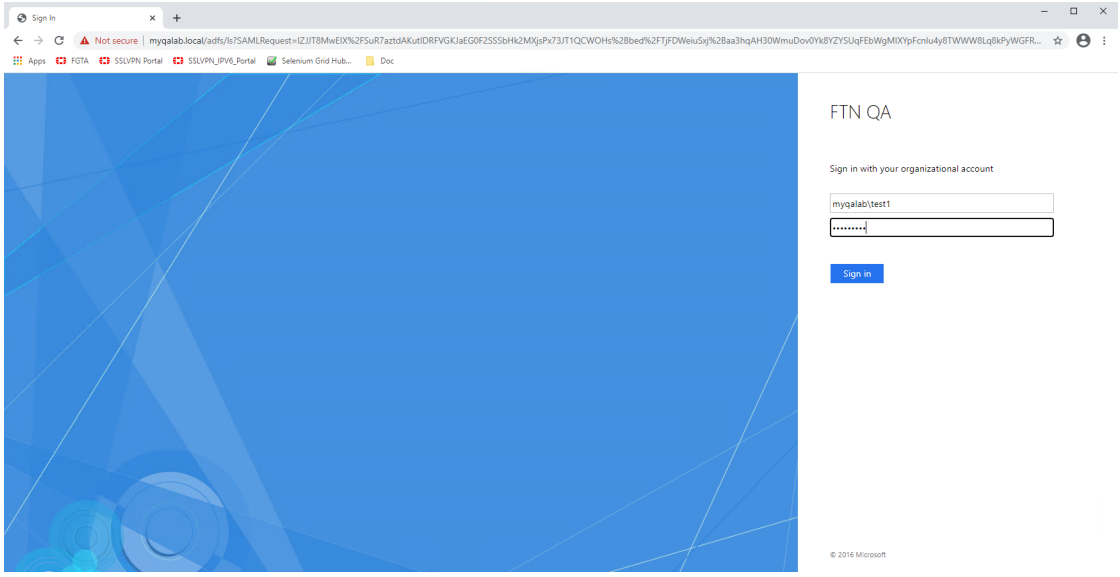
To configure the authentication rule and scheme to match the new SAML server:

```
config authentication rule
    edit "saml_ztna"
        set srcintf "port10"
        set srcaddr "all"
        set ip-based disable
        set active-auth-method "saml_ztna"
        set web-auth-cookie enable
    next
end
config authentication scheme
    edit "saml_ztna"
        set method saml
        set saml-server "saml_ztna"
        set saml-timeout 30
        set user-database "ldap-10.1.100.198"
    next
end
```

To enable user group authentication in an access-proxy type firewall proxy-policy:

```
config firewall proxy-policy
    edit 6
        set name "ZTNA_remote"
        set proxy access-proxy
        set access-proxy "ZTNA_server01"
        set srcintf "any"
        set srcaddr "all"
        set dstaddr "all"
        set action accept
        set schedule "always"
        set groups "ldap-group-saml"
        set utm-status enable
        set ssl-ssh-profile "certificate-inspection"
    next
end
```

Testing the connection



To test the connection:

It is not necessary to configure a *ZTNA Destination* on the FortiClient for the HTTPS access proxy use case. In fact, configuring a *ZTNA Destination* rule for the website may interfere with its operation.

1. On a client PC, try to access the webpage through the HTTPS access proxy. For example, go to http://172.18.62.32:7831 in a browser.

2. The client PC is prompted for a client certificate. After the certificate is validated, you are redirected to a SAML log in portal.

3. Enter your user credentials. The SAML server authenticates and sends a SAML assertion response message to the FortiGate.
4. The FortiGate queries the LDAP server for the user group, and then verifies the user group against the groups or groups defined in the proxy policy.
5. The user is proxied to the webpage on the real web server.

Logs and debugs

Use the following command to check the user information after the user has been authenticated:

```
# diagnose wad user list
ID: 7, VDOM: vdom1, IPv4: 10.1.100.143
  user name    : test1@MYQALAB.local
  worker       : 0
  duration     : 124
  auth_type    : Session
  auth_method  : SAML
  pol_id       : 6
  g_id         : 13
  user_based   : 0
  expire       : no
  LAN:
    bytes_in=25953 bytes_out=14158
  WAN:
    bytes_in=8828 bytes_out=6830
```

Event log:

```
1: date=2021-03-24 time=19:02:21 eventtime=1616637742066893182 tz="-0700" logid="0102043025"

ZTNA application gateway with SAML and MFA using FortiAuthenticator example

ZTNA application gateway supports device verification using device certificates that are issued by EMS. To authenticate users, administrators can use either basic or SAML authentication. An advantage of SAML authentication is that multi-factor authentication (MFA) can be provided by the SAML Identity Provider (IdP).

In these examples, a FortiAuthenticator is used as the IdP, and MFA is applied to user authentication for remote users accessing the web, RDP, and SSH resources over the ZTNA application gateway. It is assumed that the FortiGate EMS fabric connector has already been successfully connected.

- Configuring the FortiAuthenticator on page 988
- Configuring the FortiGate SAML settings on page 992
- Example 1 - Applying SAML and MFA to ZTNA HTTPS access proxy on page 996
- Example 2 - Applying SAML and MFA to a ZTNA TCP forwarding access proxy for RDP connections on page 999
- Example 3 - Applying SAML and MFA to a ZTNA SSH access proxy on page 1001

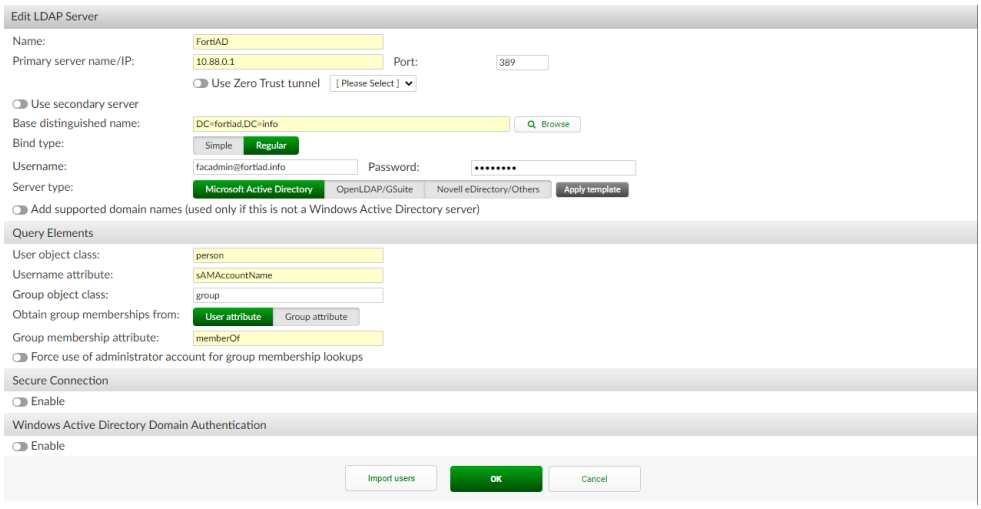
DNS resolutions:

- webserver.ztnademo.com:9443 -> 10.0.3.10:9443
- fac.ztnademo.com -> 10.0.3.7

The FortiAuthenticator (FAC) integrates with Active Directory (AD) on the Windows Domain Controller, which is also acting as the EMS server. Users are synchronized from the AD to the FAC, and remote users are configured with token-based authentication. SAML authentication is configured on the FortiGate, pointing to the FAC as the SAML IdP. The

SAML server is applied to the ZTNA application gateway authentication scheme and rule, to provide the foundation for applying user authentication on individual ZTNA policies.

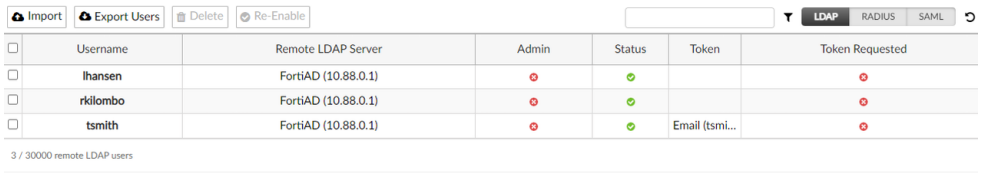
Configuring the FortiAuthenticator



First configure the FortiAuthenticator to synchronize users from AD using LDAP, apply MFA to individual remote users, and be the IdP.

To create a remote authentication server pointing to the Windows AD:

1. Go to *Authentication* > *Remote Auth. Servers* > *LDAP* and click *Create New*.
2. Configure the following:



Name	FortiAD
Primary server name / IP	10.88.0.1
Port	389 (or another port if using LDAPS)
Based distinguished name	DC=fortiad,DC=info
Bind type	Regular
Username	<user account used for LDAP bind>
Password	<password of user>
Server Type	Microsoft Active Directory
User object class	person (default)
Username attribute	sAMAccountName (default)
Group object class	group (default)
Obtain group membership from	User attribute
Group membership attribute	memberOf (default)
Secure connection	Enable if using LDAPS or STARTTLS

3. Click *OK*.
4. Edit the *FortiAD* entry.
5. At the bottom, click *Import users*.

6. On the *Import Remote LDAP User* screen, configure the following settings:
   a. For *Remote LDAP Server*, select *FortiAD*.
   b. For *Action*, select *Import users*.
      i. Click *Go*.
      ii. Select the users to import.
      iii. Click *OK*.

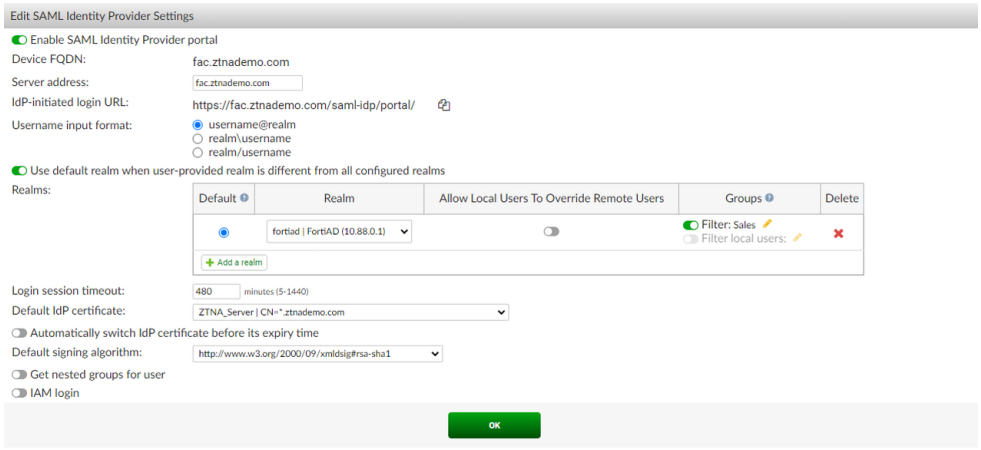
   The screen displays the users that are imported.

   For more details, see LDAP in the FortiAuthenticator Administration Guide.

To configure a remote LDAP user to use MFA:

1. Go to *Authentication* > *User Management* > *Remote Users*, and edit a user.
2. Enable *One-Time Password (OTP) authentication*.
   a. Set *Deliver token codes from*.
   b. Set *Deliver token by*.

   For this example, select *FortiToken* > *Mobile*, select the Token from the drop-down list, and set the *Activation delivery method* to email.
3. In the *User Information* section, add the email address that will be used for the FortiToken activation.



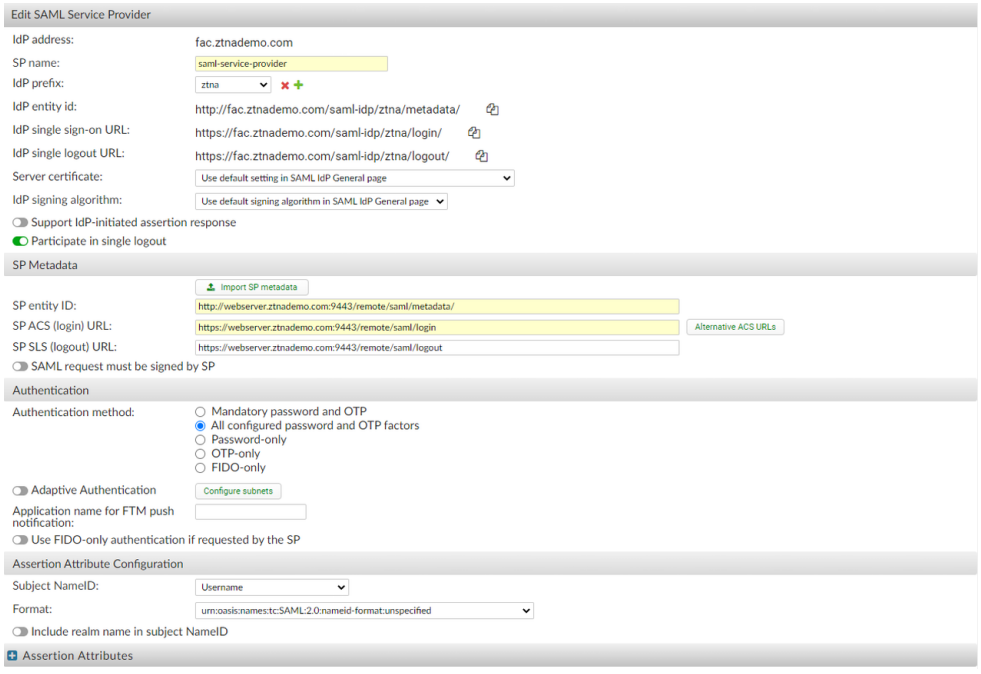
4. Click *OK*.

   An activation email is sent to the user that they can use to install the token to their FortiToken Mobile app.

   For more details, see Remote users in the FortiAuthenticator Administration Guide.

To configure SAML IdP:

1. Go to *Authentication* > *SAML IdP* > *General* and enable *Enable SAML Identity Provider portal*.
2. The *Server address* is the device FQDN or IP address (configured in the System Information widget at *System* > *Dashboard* > *Status*). In this example, it is *fac.ztnademo.com*.
3. Set *Username input format* to *username@realm*.
4. Click *Add a realm* in the *Realms* table:
   a. Set *Realm* to the just created LDAP realm (*FortiAD*).
   b. Optionally, enable *Filter* and select the required users groups. In this example, *Sales* is configured.
5. Set *Default IdP certificate* to the certificate that will be used in the HTTPS connection to the IdP portal.



6. Click *OK*.

7. Go to *Authentication* > *SAML IdP* > *Service Providers*, and click *Create New* to create a service provider (SP) for the FortiGate SP.
8. Configure the following, which must match what will be configured on the FortiGate:

SP name	saml-service-provider
IdP prefix	ztna
Server certificate	Use default setting in *SAML IdP* > *General* page.
SP entity ID	http://webserver.ztnademo.com:9443/remote/saml/metadata/
SP ACS (login) URL	https://webserver.ztnademo.com:9443/remote/saml/login
SP SLS (logout) URL	https://webserver.ztnademo.com:9443/remote/saml/logout
Participate in single logout	Enable

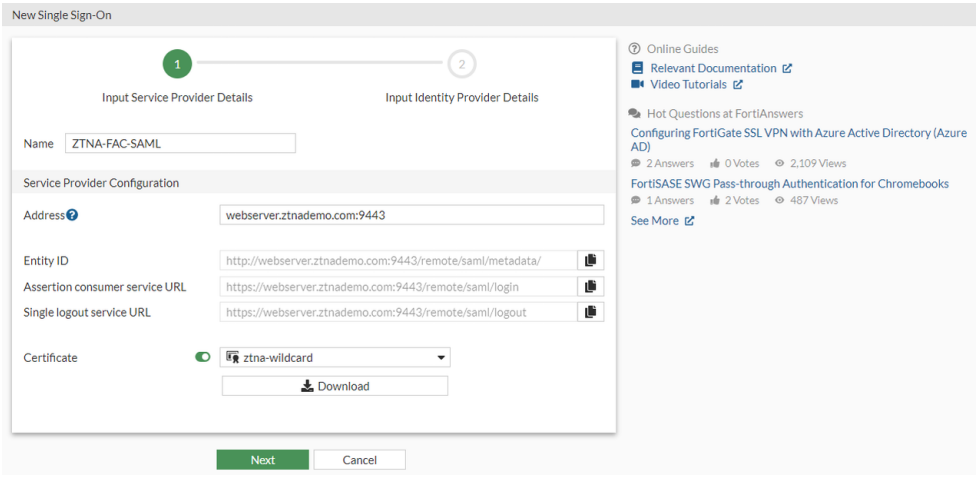
Where the *SP entity ID*, *SP ACS (login) URL*, and *SP SLS (logout) URL* break down as follows:

- *webserver.ztnademo.com* - The FQDN that resolves to the FortiGate SP.
- *9443* - The port that is used to map to the FortiGate's SAML SP service.
- */remote/saml* - The custom, user defined fields.
- */metadata*, */login*, and */logout* - The standard convention used to identify the SP entity, log in portal, and log out portal.

9. Click *OK*.
10. Edit the just created SP object and, under *Assertion Attribute*, click *Add Assertion Attribute*.
11. Set *SAML attribute* to the username and set *User attribute* to *Username*, then click *OK*.
12. Click *OK*.

For more details, see Configuring SAML settings in the SAML Interoperability Guide.

Configuring the FortiGate SAML settings



On the FortiGate, a SAML user is used to define the SAML SP and IdP settings. This user is then applied to the ZTNA proxy using an authentication scheme, rule, and settings. A ZTNA server is then created to allow access to the SAML SP server so that end users can reach the FortiGate SP's captive portal. The SAML user must then be added to a ZTNA policy to trigger authentication when accessing the ZTNA application gateway.

To create a new SAML user/server from the GUI:

1. On the FortiGate, go to *User & Authentication* > *Single Sign-On*.
2. Click *Create New*.
3. Set *Name* to *ZTNA-FAC-SAML*.
4. Set *Address* to *webserver.ztnademo.com:9443*.

   The *Entity ID*, *Assertion consumer service URL* and *Single logout service URL* will be updated. These should be the same URLs you inputted into FAC.
5. Enable *Certificate*, then select the certificate used for the client.

   In this example, the *ztna-wildcard* certificate is a local certificate that is used to sign SAML messages that are exchanged between the client and the FortiGate SP.

6. Click *Next*.
7. Use the settings from the Identity Provider to fill the custom *Identity Provider Details*. In this example, we select *Fortinet Product*, and fill in the fields as follows:

Address	fac.ztnademo.com
Prefix	ztna
IdP certificate	REMOTE_Cert_1

   - Where the `REMOTE_Cert_1` certificate is a remote certificate that is used to identify the IdP; in this example, fac.ztnademo.com.
8. Set *Attribute used to identify users* to *username*. Attributes to identify users and groups are case sensitive.

9. Click *Submit* to save the settings.

To create a new SAML user/server from the CLI:

```
config user saml
    edit "ZTNA-FAC-SAML"
        set cert "ztna-wildcard"
        set entity-id "http://webserver.ztnademo.com:9443/remote/saml/metadata/"
        set single-sign-on-url "https://webserver.ztnademo.com:9443/remote/saml/login"
        set single-logout-url "https://webserver.ztnademo.com:9443/remote/saml/logout"
        set idp-entity-id "http://fac.ztnademo.com/saml-idp/ztna/metadata/"
        set idp-single-sign-on-url "https://fac.ztnademo.com/saml-idp/ztna/login/"
        set idp-single-logout-url "https://fac.ztnademo.com/saml-idp/ztna/logout/"
        set idp-cert "REMOTE_Cert_1"
        set user-name "username"
        set digest-method sha1
    next
end
```

To create a user group for the SAML user object:

1. Under *User & Authentication* > *User Groups*, click *Create New*.
2. Set *Name* to *ztna-saml-users*.
3. Under *Remote Groups*, click *Add*.
4. For *Remote Server*, select *ZTNA-FAC-SAML*.
5. Click *OK*.
6. Click *OK* again to save.

To apply the SAML server to proxy authentication from the GUI:

1. Go to *Policy & Objects* > *Authentication Rules*.
2. Click *Create New* > *Authentication Scheme*.
3. Set the name to *ZTNA-SAML-scheme*.

4. Set *Method* to *SAML*.
5. Set *SAML SSO server* to *ZTNA-FAC-SAML*.
6. Click *OK*.
7. Go to *Policy & Objects* > *Authentication Rules*.
8. Click *Create New* > *Authentication Rule*.
9. Set the *Name* to *ZTNA-SAML-rule*.
10. Set *Source Address* to *all*.
11. Set *Incoming interface* to *port3*.
12. Set *Protocol* to *HTTP*.
13. Enable *Authentication Scheme* and select *ZTNA-SAML-scheme*.
14. Set *IP-based Authentication* to *Disable*.
15. Click *OK*.

To apply the SAML server to proxy authentication from the CLI:

```
config authentication scheme
    edit "ZTNA-SAML-scheme"
        set method saml
        set saml-server "ZTNA-FAC-SAML"
    next
end
config authentication rule
    edit "ZTNA-SAML-rule"
        set srcintf "port3"
        set srcaddr "all"
        set ip-based disable
        set active-auth-method "ZTNA-SAML-scheme"
        set web-auth-cookie enable
    next
end
```

Assign an active authentication scheme and captive portal to serve the log in page for the SAML requests.

To configure the active authentication scheme and captive portal from the GUI:

1. Go to *User & Authentication* > *Authentication Settings*.
2. Enable *Authentication scheme*.
3. Select *ZTNA-SAML-scheme*.
4. Set *Captive portal type* to *FQDN*.
5. Enable *Captive Portal*.
6. Select the firewall address *webserver.ztnademo.com*. If this has not be created, create this firewall address.
7. Click *Apply* to save.

To configure the active authentication scheme and captive portal from the CLI:

```
config firewall address
    edit "webserver.ztnademo.com"
        set type fqdn
        set fqdn "webserver.ztnademo.com"
    next
```

```
end
config authentication setting
    set active-auth-scheme "ZTNA-SAML-scheme"
    set captive-portal "webserver.ztnademo.com"
end
```

To configure a ZTNA application gateway to allow SAML authentication requests to the SP:

1. Configure the ZTNA server:
   a. Go to *Policy & Objects* > *ZTNA*, select the *ZTNA Servers* tab, and click *Create New*.
   b. Configure the following:

Name	ZTNA-access
External interface	Any
External IP	10.0.3.10
External port	9443
SAML	Enabled
SAML SSO Server	ZTNA-FAC-SAML
Default certificate	ztna-wildcard

   c. Click *OK*.
2. Define the full ZTNA policy to allow access to the ZTNA server:
   a. Go to *Policy & Objects* > *Proxy policy* and click *Create New*.
   b. Configure the following:

Name	ZTNA-Rule
Type	ZTNA
Incoming Interface	port3
Source (Address)	all
Source (User)	ztna-saml-users
Destination	all
ZTNA Server	ZTNA-access
Action	Accept
Log Allowed Traffic	All Sessions

   c. Click *OK*.

To configure a VIP and a firewall policy to forward IdP authentication traffic to the FortiAuthenticator:

Remote clients connect to the FortiAuthenticator IdP behind the FortiGate using a VIP. In this example, users connect to the FQDN fac.ztnademo.com that resolves to the VIP's external IP address.

1. Configure the VIP to forward traffic to the FortiAuthenticator:
   a. Go to *Policy & Objects* > *Virtual IPs* and click *Create New* > *Virtual IP*.
   b. Configure the following:

Name	FAC-VIP
Interface	Any
External IP address	10.0.3.7
Map to > IPv4 address/range	10.88.0.7
Port Forwarding	Enabled
Protocol	TCP
External service port	443
Map to IPv4 port	443

   c. Click *OK*.
2. Configure a firewall policy to allow VIP:
   a. Go to *Policy & Objects* > *Firewall Policy* and click *Create New*.
   b. Configure the following:

Name	WAN_to_FAC
Type	Standard
Incoming Interface	port3
Outgoing Interface	port2
Source	All
ZTNA Server	FAC-VIP
Schedule	Always
Service	HTTP. HTTPS
Action	Accept
NAT	disabled

   c. Click *OK*.

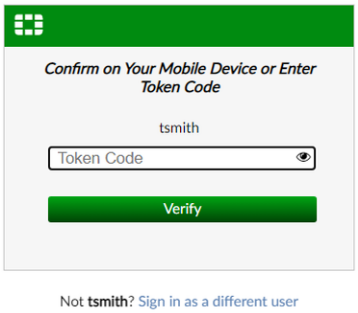
Example 1 - Applying SAML and MFA to ZTNA HTTPS access proxy

In this HTTPS access proxy example, two real servers are implemented with round robin load balancing performed between them. The HTTPS access proxy is configured on the same ZTNA server as was configured in the authentication step. The same ZTNA rule and firewall policy also apply.

To configure the ZTNA server for HTTPS access proxy with load balancing:

1. Go to *Policy & Objects* > *ZTNA* and select the *ZTNA Servers* tab.
2. Edit the ZTNA-access server.
3. In the *Service/server mapping* table, click *Create New*:
   a. Set *Service* to *HTTPS*.
   b. Set *Virtual Host* to *Any Host*.
   c. In the *Servers* table click *Create New*:
      i. Set *IP* to *10.88.0.3*.
      ii. Set *Port* to *9443*.
      iii. Set *Status* to *Active*.
      iv. Click *OK*.
   d. Create a second server with *IP 10.88.0.4*.
   e. Click *OK*.
4. Enable *Load balancing*, and select the *Round Robin* algorithm.
5. Click *OK*.
6. Click *OK* again to finish.

Testing and verification:



From the remote endpoint, user Tom Smith attempts to connect to the web server over ZTNA:

1. On the remote Windows computer, open FortiClient and register to the EMS server.

It is not necessary to configure a *ZTNA Destination* on the FortiClient for the HTTPS access proxy use case. In fact, configuring a *ZTNA Destination* rule for the website may interfere with its operation.

2. Open a browser and attempt to connect to the web server at *https://webserver.ztnademo.com:9443*.
3. Device authentication prompts the user for their device certificate. Select the certificate issued by EMS and click *OK*.
4. FortiGate receives the SAML request and redirects the user to the IdP login screen. Enter the username and password for Tom Smith and click *Login*.
5. A second prompt opens asking for the *Token Code*. Enter the code then click *Verify*.

6. The FortiAuthenticator IdP verifies the login, then sends the SAML assertion back to the user.
7. The browser redirects the assertion to the FortiGate SP, which decides if the user is allowed access.
8. On a successful log in, FortiGate redirects the user to the web page that they are trying to access.

Logs and debugs:

On the FortiGate, a successful connection can be seen in *Log & Report* > *Forward Traffic log*, or by using the CLI:

```
# execute log filter category 0
# execute log filter field subtype srcip
# execute log display
...
2: date=2023-05-09 time=00:47:56 eventtime=1683618475812847145 tz="-0700" logid="0005000024"

```

Log number ten shows that authentication first passes through the WAN_to_FAC policy. Log numbers two and eight show the traffic allowed through the ZTNA proxy-policy over two successive sessions. Note that they have different destination IP addresses (`dstip`), indicating that ZTNA was performing server load balancing.

Use the following command to show if the FortiGate's WAD process has an active record of the SAML user login:

```
# diagnose wad user list

ID: 8, VDOM: root, IPv4: 10.0.3.2
  user name   : tsmith
  worker      : 1
  duration    : 332
  auth_type   : Session
  auth_method : SAML
  pol_id      : 1
  g_id        : 4
  user_based  : 0
  expire      : 390
  LAN:
    bytes_in=29519 bytes_out=629987
```

```
WAN:
  bytes_in=958636 bytes_out=19201
```

Example 2 - Applying SAML and MFA to a ZTNA TCP forwarding access proxy for RDP connections

In this TCP forwarding access proxy example, RDP connections are allowed to be forwarded to the Windows/EMS server. Traffic to TCP/3389 is allowed through the ZTNA proxy.

To configure the ZTNA server for TCP forwarding on TCP/3389:

1. Create a firewall address for the Windows/EMS server:
   a. Go to *Policy & Objects* > *Addresses* and click *Create New* > *Address*.
   b. Configure the following:

Name	winserver
Type	Subnet
IP/Netmask	10.88.0.1/32
Interface	any

   c. Click *OK*.
2. Go to *Policy & Objects* > *ZTNA* and select the *ZTNA Servers* tab.
3. Edit the ZTNA-access server.
4. In the *Service/server mapping* table, click *Create New*:
   a. Set *Service* to *TCP Forwarding*.
   b. In the *Servers* table click *Create New*:
      i. Set *Address* to *winserver*.
      ii. Set *Ports* to *3389*.
      iii. Click *OK*.
   c. Click *OK*.
5. Click *OK*.

Testing and verification:

On the remote endpoint, manually configure a ZTNA destination to forward RDP traffic to the ZTNA application gateway. The rules can also be pushed from the EMS server; for details see Provisioning ZTNA TCP forwarding rules via EMS.

Configure the ZTNA Destination:

1. On the remote Windows computer, open FortiClient.
2. Register to the EMS server.
3. On the *ZTNA Destination* tab, click *Add Destination* to add a TCP forwarding rule.

4. Configure the following:

Rule Name	RDP-server
Destination Host	10.88.0.1:3389
Proxy Gateway	10.0.3.10:9443
Mode	Transparent
Encryption	Disabled *Encryption* can be enabled or disabled. When it is disabled, the client to access proxy connection is not encrypted in HTTPS. Because RDP is encrypted by default, disabling *Encryption* does not reduce security.

5. Click *Create*.

Connect over RDP:

1. On the remote PC, open a new RDP connection.
2. Enter the IP address 10.88.0.1. By default, RDP session use port 3389.

   When the connection to the ZTNA application gateway is established, FortiGate will redirect the SAML login request to the FortiAuthenticator IdP.

   A FortiClient prompt will open with the FortiAuthenticator login screen.
3. Enter the username and password then click *Login*.
4. A second prompt opens asking for the *Token Code*. Enter the code from your FortiToken app, then click *Verify*.
5. FortiAuthenticator verifies the token code, determines if the login is successful, then sends the SAML assertion back to the client.
6. The client redirects the response back to the FortiGate SP.
7. If the log in was successful, the user can now log on to the RDP session.

Logs and debugs:

On the FortiGate, a successful connection can be seen in *Log & Report* > *Forward Traffic log*, or by using the CLI:

```
# execute log filter category 0
# execute log filter field srcip 10.0.3.2
# execute log display
...
8: date=2023-05-09 time=01:14:34 eventtime=1683620074907124357 tz="-0700" logid="0005000024"

```
tranport=443 duration=10 sentbyte=3368 rcvdbyte=4376 sentpkt=13 rcvdpkt=13
appcat="unscanned"
```

Use the following command to show if the FortiGate's WAD process has an active record of the SAML user login:

```
# diagnose wad user list

ID: 9, VDOM: root, IPv4: 10.0.3.2
  user name    : tsmith
  worker       : 1
  duration     : 164
  auth_type    : Session
  auth_method : SAML
  pol_id       : 1
  g_id         : 4
  user_based   : 0
  expire       : no
  LAN:
    bytes_in=80950 bytes_out=233010
  WAN:
    bytes_in=219973 bytes_out=58315
```

Example 3 - Applying SAML and MFA to a ZTNA SSH access proxy

In this SSH access proxy example, SSH connections can be forwarded to the FortiAnalyzer (10.88.0.2).

To configure the ZTNA server for SSH access proxy:

1. Create a firewall address for the web server:
   a. Go to *Policy & Objects* > *Addresses* and click *Create New* > *Address*.
   b. Configure the following:

Name	FAZ
Type	Subnet
IP/Netmask	10.88.0.2/32
Interface	any

   c. Click *OK*.
2. Go to *Policy & Objects* > *ZTNA* and select the *ZTNA Servers* tab.
3. Edit the ZTNA-access server.
4. In the *Service/server mapping* table, edit the *TCP Forwarding* entry:
   a. In the *Servers* table click *Create New*:
      i. Set *Address* to *FAZ*.
      ii. Set *Ports* to *22*.
      iii. Optionally, enable *Additional SSH Options* to configure other SSH options as needed.
      iv. Click *OK*.
   b. Click *OK*.
5. Click *OK*.

Testing and verification:

On the remote endpoint, manually configure ZTNA destination to forward SSH traffic to the ZTNA access proxy. The destination can also be pushed from the EMS server; for details see Provisioning ZTNA TCP forwarding rules via EMS.

Configure the ZTNA Destination:

1. On the remote Windows computer, open FortiClient.
2. Register to the EMS server.
3. On the *ZTNA Destination* tab, click *Add Destination* to add a TCP forwarding rule.
4. Configure the following:

Rule Name	SSH-FAZ
Destination Host	10.88.0.2:22
Proxy Gateway	10.0.3.10:9443
Mode	Transparent
Encryption	Disabled

5. Click *Create*.

Connect over SSH:

1. On the remote PC, open a new SSH connection.
2. Enter the host admin@10.88.0.2 on port 22.

   When the connection to the ZTNA application is established, FortiGate will redirect the SAML login request to the FortiAuthenticator IdP.

   A FortiClient prompt will open with the FortiAuthenticator login screen.
3. Enter the username and password then click *Login*.
4. A second prompt opens asking for the *Token Code*. Enter the code from your FortiToken app, then click *Verify*.
5. FortiAuthenticator verifies the token code, determines if the login is successful, then sends the SAML assertion back to the client.
6. The client redirects the response back to the FortiGate SP.
7. If the log in was successful, the user can now log on to the SSH session.

Logs and debugs:

On the FortiGate, a successful connection can be seen in *Log & Report* > *Forward Traffic log*, or by using the CLI:

```
# execute log filter category 0
# execute log filter field srcip 10.0.3.2
# execute log display
...
5: date=2023-05-09 time=10:06:04 eventtime=1683651963820802005 tz="-0700" logid="0005000024"
type="traffic" subtype="ztna" level="notice" vd="root" srcip=10.0.3.2 srcport=22536
srcintf="port3" srcintfrole="wan" dstcountry="Reserved" srccountry="Reserved"

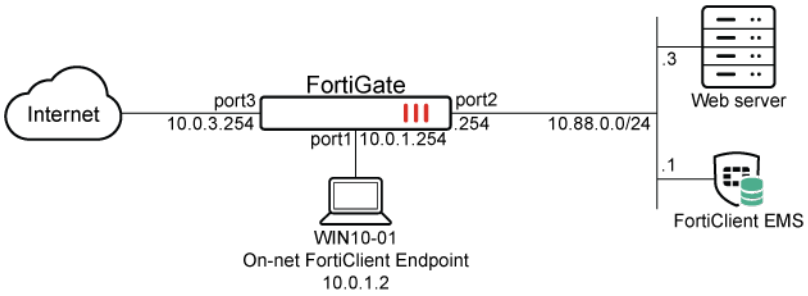
rcvdbyte=2981 wanout=2753 lanin=4663 sentbyte=4663 lanout=5247 appcat="unscanned"
```

Use the following command to show if the FortiGate's WAD process has an active record of the SAML user login:

```
# diagnose wad user list



ID: 10, VDOM: root, IPv4: 10.0.3.2
  user name    : tsmith
  worker       : 1
  duration     : 387
  auth_type    : Session
  auth_method  : SAML
  pol_id       : 1
  g_id         : 4
  user_based   : 0
  expire       : no
  LAN:
    bytes_in=23261 bytes_out=14024
  WAN:
    bytes_in=3242 bytes_out=2541
```

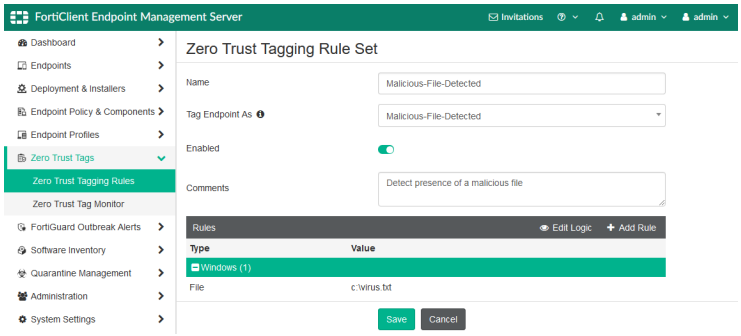
ZTNA IP MAC based access control example

In this example, firewall policies are configured that use ZTNA tags to control access between on-net devices and an internal web server. This mode does not require the use of the access proxy, and only uses ZTNA tags for access control. Traffic is passed when the FortiClient endpoint meets two conditions.

1. It is tagged with the *Domain-Users* ZTNA tag, identifying the device as logged on to the Domain.
2. It has the *High* importance classification tag indicating the device is High importance and low risk.

Traffic is denied when the FortiClient endpoint is tagged with *Malicious-File-Detected*.

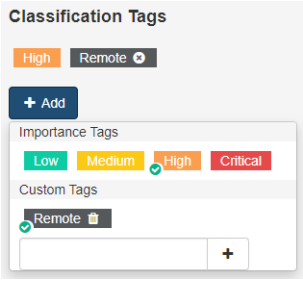
This example assumes that the FortiGate EMS fabric connector is already successfully connected.



To configure ZTNA in the GUI, go to *System* > *Feature Visibility* and enable *Zero Trust Network Access*.

To configure Zero Trust tagging rules on the FortiClient EMS:

1. Log in to the FortiClient EMS.
2. Go to *Zero Trust Tags* > *Zero Trust Tagging Rules*, and click *Add*.
3. In the *Name* field, enter *Malicious-File-Detected*.
4. In the *Tag Endpoint As* dropdown list, select *Malicious-File-Detected*.
5. Click *Add Rule* then configure the rule:



a. For *OS*, select *Windows*.
b. From the *Rule Type* dropdown list, select *File* and click the + button.
c. Enter a file name, such as *C:\virus.txt*.
d. Click *Save*.

6. Click *Save*.
7. Click *Add* again to add another rule.
8. In the *Name* field, enter *Domain-Users*.
9. In the *Tag Endpoint As* dropdown list, enter *Domain-Users* and press `Enter`.
10. Click *Add Rule*, then configure the rule:
    a. For *OS*, select *Windows*.
    b. From the *Rule Type* dropdown list, select *User in AD Group*.
    c. For *AD Group*, select the *Domain-Users* AD group.
    d. Click *Save*.

To configure a classification tag on the FortiClient EMS:

1. Go to *Endpoint* > *All Endpoints*.
2. Select the WIN10-01 computer that will be granted access. This computer should be already registered to FortiClient EMS.
3. In the *Summary* tab, under *Classification Tags*, click *Add* and then set to High Importance.

4. Go to *Administration* > *Fabric Devices*.
5. Select the connecting FortiGate, then click *Edit*.
6. Under *Tag Types Being Shared*, add *Classification Tags*.
7. Click *Save*.

To configure a firewall policy with IP/MAC based access control to deny traffic in the GUI:

1. Go to *Policy & Objects* > *Firewall Policy* and click *Create New*.
2. Set *Name* to *block-internal-malicious-access*.
3. Set *Type* to *Standard*.
4. Set *Incoming Interface* to *port1*.
5. Set *Outgoing Interface* to *port2*.
6. Set *Source* to *all*.
7. Set *IP/MAC Based Access Control* to the *Malicious-File-Detected* tag.
8. Set *Destination* to the address of the Web server. If no address is created, create a new address object for 10.88.0.3/32.
9. Set *Service* to *ALL*.
10. Set *Action* to *DENY*.
11. Enable *Log Violation Traffic*.
12. Configuring the remaining settings as needed.
13. Click *OK*.

To configure a firewall policy with IP/MAC based access control to allow access in the GUI:

1. Go to *Policy & Objects* > *Firewall Policy* and click *Create New*.
2. Set *Name* to *allow-internal-access*.
3. Set *Type* to *Standard*.
4. Set *Incoming Interface* to *port1*.
5. Set *Outgoing Interface* to *port2*.
6. Set *Source* to *all*.
7. Set *IP/MAC Based Access Control* to the *Domain-Users* ZTNA IP tag.
8. Set *Logical And With Secondary Tags* to *Specify*. This option allows for a second group of tags to be used with a logical And operator.
9. Set *Secondary Tags* as the *High* Class IP tag.
10. Set *Destination* to the address of the Web server.
11. Set *Service* to *ALL*.
12. Set *Action* to *ACCEPT*.
13. Enable *Log Allowed Traffic* and set it to *All Sessions*.
14. Configuring the remaining settings as needed.
15. Click *OK*.

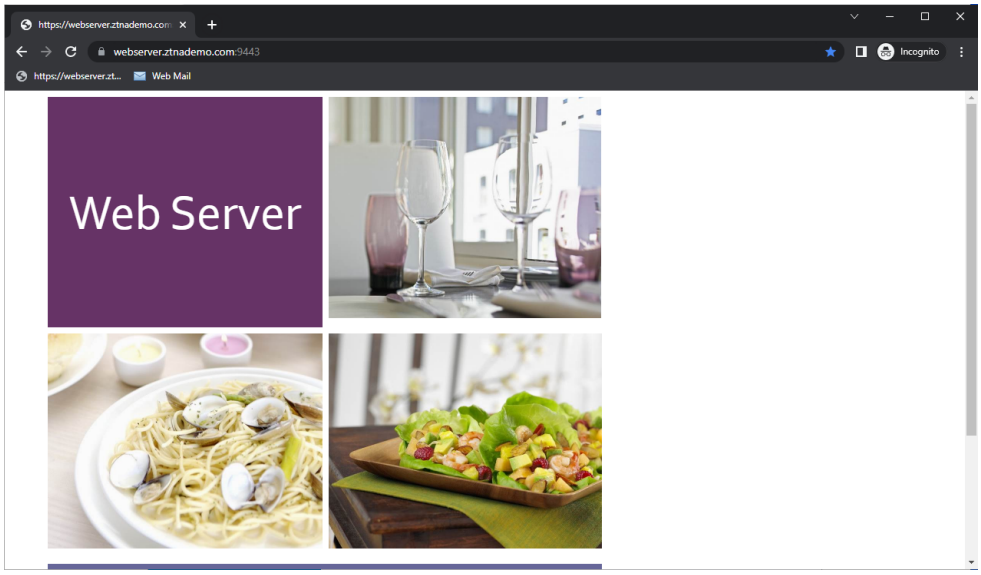
To configure firewall policies with IP/MAC based access control to block and allow access in the CLI:

```
config firewall policy
    edit 10
        set name "block-internal-malicious-access"
        set srcintf "port1"
        set dstintf "port2"
        set ztna-status enable
        set srcaddr "all"
        set dstaddr "Webserver"
        set ztna-ems-tag "EMS1_ZTNA_Malicious-File-Detected"
```

```
        set schedule "always"
        set service "ALL"
        set logtraffic all
    next
    edit 12
        set name "allow-internal-access"
        set srcintf "port1"
        set dstintf "port2"
        set action accept
        set ztna-status enable
        set srcaddr "all"
        set dstaddr "Webserver"
        set ztna-ems-tag "EMS1_ZTNA_Domain-Users"
        set ztna-ems-tag-secondary "EMS1_CLASS_High"
        set schedule "always"
        set service "ALL"
        set logtraffic all
    next
end
```

When multiple tags are selected with `set ztna-ems-tag <tags>`, matching occurs using a logical OR operator. Therefore any single tag that match will return true.

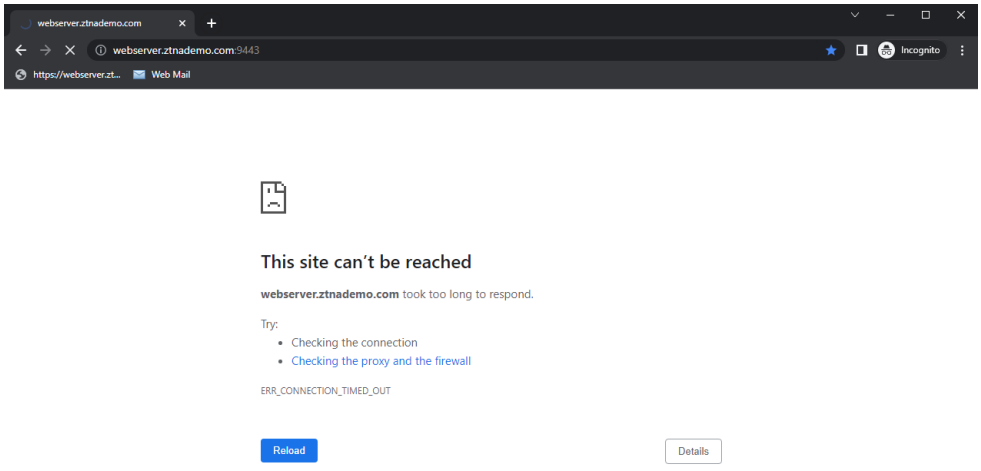
The `set ztna-tags-match-logic {and | or}` option cannot be used to change the logical operator. This option is applied by wad to tags selected for ZTNA proxy-policy.



The `set ztna-ems-tag-secondary <tags>` option by default allows a second group of tags to be specified. This group and the primary group are joined by the logical and operator.

Testing the access to the web server from the on-net client endpoint

Access allowed:



1. On the WIN10-01 PC, open FortiClient.
2. On the *Zero Trust Telemetry* tab, make sure that you are connected to the EMS server.
3. Open a browser and enter the address of the server.
4. The FortiGate matches your security posture by verifying your ZTNA tags and matching the corresponding `allow-`

`internal-access` firewall policy, and you are allowed access to the web server.

Access denied:

1. On the WIN10-01 PC, trigger the Zero Trust Tagging Rule by creating the file in C:\virus.txt.
2. Open a browser and enter the address of the server.
3. FortiGate checks your security posture. Because EMS has tagged the PC with the *Malicious-File-Detected* tag, it matches the *block-internal-malicious-access* firewall policy.
4. You are denied access to the web server.

Logs and debugs

Access allowed:

```

ZTNA IPv6 examples

IPv6 can be configured in ZTNA in several scenarios:

- IPv6 Client — IPv6 Access Proxy — IPv6 Server
- IPv6 Client — IPv6 Access Proxy — IPv4 Server
- IPv4 Client — IPv4 Access Proxy — IPv6 Server

These examples show the basic configuration for each scenario. It is assumed that the EMS fabric connector is already successfully connected.

Example 1: IPv6 Client — IPv6 Access Proxy — IPv6 Server

To configure the FortiGate:

1. Configure the IPv6 access proxy VIP:

```
config firewall vip6
    edit "zv6"
        set type access-proxy
        set extip 2000:172:18:62::66
        set server-type https
        set extport 6443
        set ssl-certificate "cert"
    next
end
```

2. Configure a virtual host:

```
config firewall access-proxy-virtual-host
    edit "vhost_ipv6"
        set ssl-certificate "cert"
        set host "qa6.test.com"
    next
end
```

   The client uses this address to connect to the access proxy.

3. Configure an IPv6 access proxy and IPv6 api-gateway, apply the VIP6 and virtual host to it, and assign an IPv6 address to the realserver:

```
config firewall access-proxy6
    edit "zs6"
        set vip "zv6"
        config api-gateway6
            edit 1
                set virtual-host "vhost_ipv6"
                config realservers
                    edit 1
                        set ip 2000:172:16:200::209
                    next
                end
            next
```

```
        end
    next
end
```

4. Apply the IPv6 access proxy to a proxy policy:

```
config firewall proxy-policy
    edit 1
        set name "ztna_rule"
        set proxy access-proxy
        set access-proxy6 "zs6"
        set srcintf "port2"
        set action accept
        set schedule "always"
        set logtraffic all
        set srcaddr6 "all"
        set dstaddr6 "all"
        set utm-status enable
        set ssl-ssh-profile "custom-deep-inspection"
        set webfilter-profile "monitor-all"
    next
end
```

5. Apply the IPv6 VIP to a firewall policy:

```
config firewall policy
    edit 4
        set name "ZTNA"
        set srcintf "port2"
        set dstintf "any"
        set action accept
        set srcaddr6 "all"
        set dstaddr6 "zv6"
        set schedule "always"
        set service "ALL"
        set inspection-mode proxy
        set logtraffic all
        set nat enable
    next
end
```

To test the configuration:

1. On an IPv6 client, ensure that the address qa6.test.com resolves to the IPv6 VIP address of 2000:172:18:62::66.
2. In a browser, connect to https://qa6.test.com:6443.
3. After device certificate verification, the browser will open up the webpage on the IPv6 real server.
4. In the Forward Traffic Log, the following log is available:

```
3: date=2021-06-25 time=13:38:18 eventtime=1624653498459580215 tz="-0700"
logid="0000000024" type="traffic" subtype="forward" level="notice" vd="root"
srcip=2000:10:1:100::214 srcport=55957 srcintf="port2" srcintfrole="undefined"
dstcountry="Reserved" srccountry="Reserved" dstip=2000:172:16:200::209 dstport=443
dstintf="root" dstintfrole="undefined" sessionid=92406 service="HTTPS" proto=6
action="accept" policyid=1 policytype="proxy-policy" poluuid="7afdac8c-d5db-51eb-dfc6-

lanin=1247 sentbyte=1247 lanout=950 appcat="unscanned" utmaction="allow" countweb=1
utmref=65445-0
```

Example 2: IPv6 Client — IPv6 Access Proxy — IPv4 Server

To configure the FortiGate:

1. Configure the IPv6 access proxy VIP:

```
config firewall vip6
    edit "zv6"
        set type access-proxy
        set extip 2000:172:18:62::66
        set server-type https
        set extport 6443
        set ssl-certificate "cert"
    next
end
```

2. Configure a virtual host:

```
config firewall access-proxy-virtual-host
    edit "vhost_ipv6"
        set ssl-certificate "cert"
        set host "qa6.test.com"
    next
end
```

   The client uses this address to connect to the access proxy.

3. Configure an IPv6 access proxy and IPv6 api-gateway, apply the VIP6 and virtual host to it, and assign an IPv4 address to the realserver:

```
config firewall access-proxy6
    edit "zs6"
        set vip "zv6"
        config api-gateway6
            edit 1
                set virtual-host "vhost_ipv6"
                config realservers
                    edit 1
                        set ip 172.16.200.209
                    next
                end
            next
        end
    next
end
```

4. Apply the IPv6 access proxy to a proxy policy:

```
config firewall proxy-policy
    edit 1
        set name "ztna_rule"
        set proxy access-proxy
        set access-proxy6 "zs6"
        set srcintf "port2"
        set srcaddr "all"
        set dstaddr "all"
        set action accept
        set schedule "always"
```

```
        set logtraffic all
        set srcaddr6 "all"
        set dstaddr6 "all"
        set utm-status enable
        set ssl-ssh-profile "custom-deep-inspection"
        set webfilter-profile "monitor-all"
    next
end
```

5. Apply the IPv6 VIP to a firewall policy:

```
config firewall policy
    edit 4
        set name "ZTNA"
        set srcintf "port2"
        set dstintf "any"
        set action accept
        set srcaddr6 "all"
        set dstaddr6 "zv6"
        set schedule "always"
        set service "ALL"
        set inspection-mode proxy
        set logtraffic all
        set nat enable
    next
end
```

To test the configuration:

1. On an IPv6 client, ensure that the address qa6.test.com resolves to the IPv6 VIP address of 2000:172:18:62::66.
2. In a browser, connect to https://qa6.test.com:6443.
3. After device certificate verification, the browser will open up the webpage on the IPv4 real server.
4. In the Forward Traffic Log, the following log is available:

```
2: date=2021-06-25 time=13:46:54 eventtime=1624654014129553521 tz="-0700"
logid="0000000024" type="traffic" subtype="forward" level="notice" vd="root"
srcip=2000:10:1:100::214 srcport=60530 srcintf="port2" srcintfrole="undefined"
dstcountry="Reserved" srccountry="Reserved" dstip=172.16.200.209 dstport=443
dstintf="root" dstintfrole="undefined" sessionid=219 service="HTTPS" proto=6
action="accept" policyid=1 policytype="proxy-policy" poluuid="7afdac8c-d5db-51eb-dfc6-
67bb86e4bdcf" policyname="ztna_rule" duration=5 wanin=2028 rcvdbyte=2028 wanout=1321
lanin=1236 sentbyte=1236 lanout=947 appcat="unscanned" utmaction="allow" countweb=1
utmref=65443-14
```

Example 3: IPv4 Client — IPv4 Access Proxy — IPv6 Server

To configure the FortiGate:

1. Configure the IPv4 access proxy VIP:

```
config firewall vip
    edit "zv4"
        set type access-proxy
        set extip 172.18.62.66
        set extintf "any"
```

```
        set server-type https
        set extport 4443
        set ssl-certificate "cert"
    next
end
```

2. Configure a virtual host:

```
config firewall access-proxy-virtual-host
    edit "vhost_ipv4"
        set ssl-certificate "cert"
        set host "qa.test.com"
    next
end
```

   The client uses this address to connect to the access proxy.

3. Configure an IPv4 access proxy and IPv6 api-gateway, apply the VIP and virtual host to it, and assign an IPv6 address to the realserver:

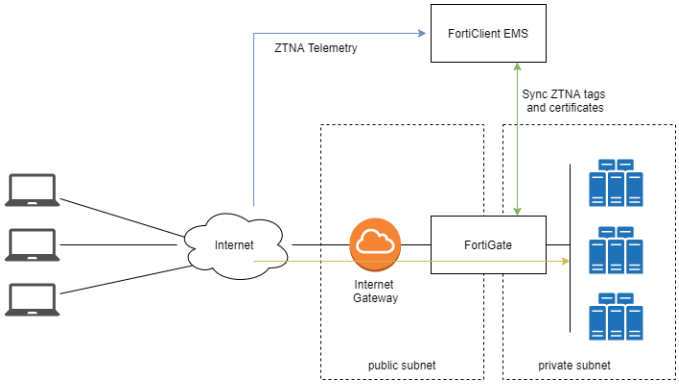
```
config firewall access-proxy
    edit "zs4"
        set vip "zv4"
        config api-gateway6
            edit 1
                set virtual-host "vhost_ipv4"
                config realservers
                    edit 1
                        set ip 2000:172:16:200::209
                    next
                end
            next
        end
    next
end
```

4. Apply the IPv4 access proxy to a proxy policy:

```
config firewall proxy-policy
    edit 1
        set name "ztna_rule"
        set proxy access-proxy
        set access-proxy "zs4"
        set srcintf "port2"
        set srcaddr "all"
        set dstaddr "all"
        set action accept
        set schedule "always"
        set logtraffic all
        set srcaddr6 "all"
        set dstaddr6 "all"
        set utm-status enable
        set ssl-ssh-profile "custom-deep-inspection"
        set webfilter-profile "monitor-all"
    next
end
```

5. Apply the IPv4 VIP to a firewall policy:

```
config firewall policy
    edit 4
        set name "ZTNA"
        set srcintf "port2"
        set dstintf "any"
        set action accept
        set srcaddr "all"
        set dstaddr "zv4"
        set schedule "always"
        set service "ALL"
        set inspection-mode proxy
        set logtraffic all
        set nat enable
    next
end
```



To test the configuration:

1. On an IPv4 client, ensure that the address qa6.test.com resolves to the IPv4 VIP address of 172.18.62.66.
2. In a browser, connect to https://qa6.test.com:6443.
3. After device certificate verification, the browser will open up the webpage on the IPv6 real server.
4. In the Forward Traffic Log, the following log is available:

```
1: date=2021-06-25 time=13:52:30 eventtime=1624654350689576485 tz="-0700"
logid="0000000024" type="traffic" subtype="forward" level="notice" vd="root"
srcip=10.1.100.206 srcport=53492 srcintf="port2" srcintfrole="undefined"
dstcountry="Reserved" srccountry="Reserved" dstip=2000:172:16:200::209 dstport=443
dstintf="root" dstintfrole="undefined" sessionid=726 service="HTTPS" proto=6
action="accept" policyid=1 policytype="proxy-policy" poluuid="7afdac8c-d5db-51eb-dfc6-
67bb86e4bdcf" policyname="ztna_rule" duration=0 wanin=1901 rcvdbyte=1901 wanout=736
lanin=569 sentbyte=569 lanout=3040 appcat="unscanned" utmaction="allow" countweb=1
utmref=65443-28
```

ZTNA Zero Trust application gateway example

The Zero Trust application gateway (ZTAG) for SaaS applications delivers Zero Trust Network Access (ZTNA) to companies that deploy SaaS applications and services in the cloud. A Zero Trust application gateway is deployed in the cloud, protecting resources on the private subnets by enforcing security and access control.

A Zero Trust application gateway can be deployed directly on AWS and Azure. The deployment template can configure the necessary ZTNA settings to get the ZTNA configurations started.

For more information, see the Zero Trust Application Gateway Admin Guide.

ZTNA access proxy with KDC to access shared drives

Fortinet technical support cannot troubleshoot third-party applications involved in this solution.

Kerberos Key Distribution Center (KDC) proxy protocol can be used to remotely authenticate domain users and issue Kerberos tickets. A remote user can use the same Kerberos ticket to authenticate when remotely accessing shared drives through ZTNA access proxy.

The following options are available when setting up ZTNA access proxy on TCP 445 for remote access to mapped drives:

- Create the mapped drive using the server's IP address, which uses Windows NT LAN Manager (NTLM) to authenticate users.
- Create the mapped drive using the server's FQDN (or DNS name), which requires Kerberos authentication.

The preferred way to create mapped drives is using the server's DNS name. KDC proxy protocol can be a reliable way to initiate Kerberos authentication for remote users to seamlessly access mapped drives and requires the following steps:

1. Set up the KDC proxy service on a server.
2. Set up the ZTNA access proxy for mapped drives.

The KDC Proxy only works for domain-joined workstations.

Setting up the KDC proxy service

The following steps are required to set up the KDC proxy service on a server:

1. Deploy a server that is joined to the domain and create a trusted certificate.
2. Configure the KDC proxy service on the server.
3. Configure clients to use the KDC proxy.
4. If client machines cannot retrieve group policy updates, configure registry keys on the clients.

Deploying a server and creating a certificate

Deploy a server that is joined to the domain. At a minimum, the server must have a public network interface with a domain name pointed to it. Clients will connect to the server over the internet. For networking, you can forward port 443 if necessary.

Create a trusted certificate for the public domain name of the proxy endpoint:

- Domain: fortitest.net
- KDC proxy: kdcproxy.fortitest.net

The KDC proxy service is present on the server, but not configured.

Configuring the KDC proxy service on the server

The KDC proxy service must be configured before it can be started.

To configure the server:

1. Start an elevated command prompt, and configure a URL ACL for the endpoint:

   ```
   netsh http add urlacl url=https://+:443/KdcProxy user="NT authority\Network Service"
   ```

2. Associate the certificate created previously with the endpoint:

   ```
   netsh http add sslcert ipport=0.0.0.0:443 certhash=<thumbprint of your certificate>
   appid={generated Guid}
   ```

   This association instructs `HTTP.SYS` to use the certificate when connections occur over HTTPS.

   For example: `netsh http add sslcert ipport=0.0.0.0:443 certhash=aaaabbbbccccddddeeeeffff0000111122223333 appid={aaaaaaaa-bbbb-cccc-dddd-aaaabbbbcccc}`

   For `appid` you should generate a random GUID here. From PowerShell try `[Guid]::NewGuid()`. The `certhash` is the thumbprint of your certificate.

   If the certificate contains extensions for CRL or AIA, those URLs should be reachable from the remote client.

3. If not using smart card certificates (or Windows Hello) for authentication, disable the certificate authentication requirement:

   ```
   REG ADD "HKLM\SYSTEM\CurrentControlSet\Services\KPSSVC\Settings" /v HttpsClientAuth /t
   REG_DWORD /d 0x0 /f
   ```

4. Additionally if not using certificates, enable password authentication:

   ```
   REG ADD "HKLM\SYSTEM\CurrentControlSet\Services\KPSSVC\Settings" /v
   DisallowUnprotectedPasswordAuth /t REG_DWORD /d 0x0 /f
   ```

5. Configure the KDC Proxy Service (KPSSVC) to start automatically:

   ```
   sc config kpssvc start=auto
   ```

6. Start the service:

   ```
   net start kpssvc
   ```

Configuring clients to use a KDC proxy

Clients must be configured to use a KDC proxy. This can be done through GPO or through modifying the registry directly. The GPO path is:

```
Computer Configuration\Policies\Administrative Templates\System\Kerberos\Specify KDC proxy
servers for Kerberos clients
```

Enabling this policy requires setting a realm-to-value mapping. The realm is your domain name, starting with a period (for example ".fortitest.net"), or a "*" to include all domains in a wildcard format. The value is specially crafted:

```
<kdcproxy.fortitest.net:kdcproxy />
```

Deploy the policy, and reboot the client. Wait a while for caching to complete, and then log in. You should find users are now authenticating over the KDC proxy endpoint.

To verify from a logged in session, launch a command prompt and try the following command:

```
klist get krbtgt
```

Configuring registry keys on clients

If you are trying to deploy these settings on a client machine that cannot retrieve group policy updates, manually configure the registry keys for the client:

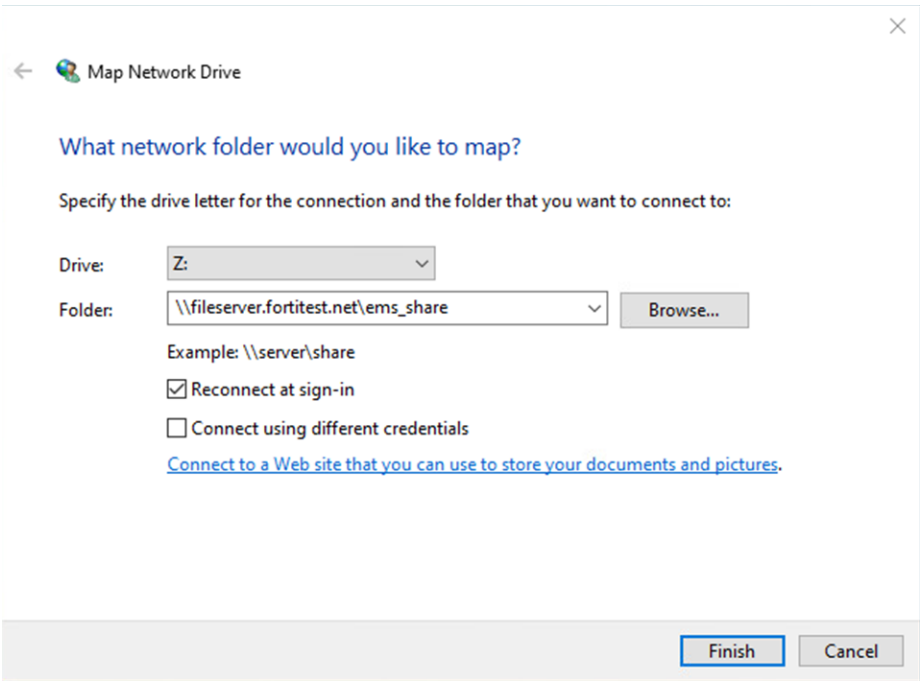
```
[HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\Windows\CurrentVersion\Policies\System\Kerberos]
"KdcProxyServer_Enabled"=dword:00000001
```

```
[HKEY_LOCAL_
MACHINE\SOFTWARE\Microsoft\Windows\CurrentVersion\Policies\System\Kerberos\KdcProxy\ProxySer
vers]
"*"="<https kdcproxy.fortitest.net />" or ".fortitest.net"="<https kdcproxy.fortitest.net
/>"
```

```
[HKEY_LOCAL_
MACHINE\SOFTWARE\Microsoft\Windows\CurrentVersion\Policies\System\Kerberos\Parameters]
"NoRevocationCheck"=dword:00000000
```

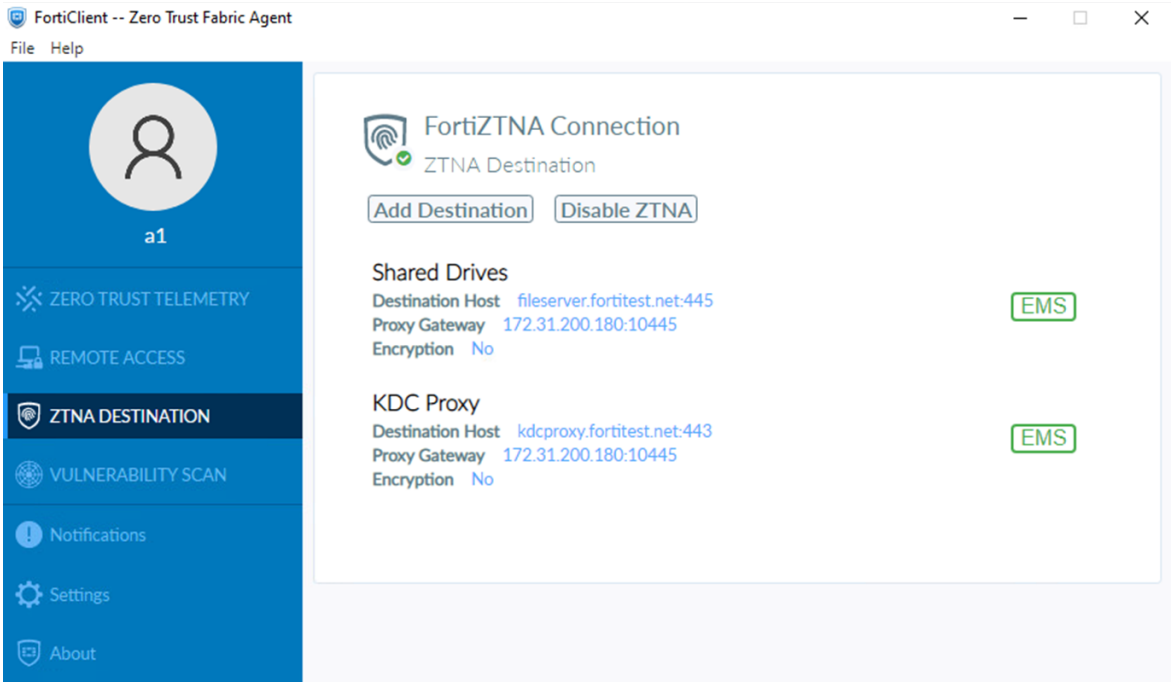
Setting up the ZTNA access proxy for mapped drives

The following steps are required to set up ZTNA access proxy for mapped drives on the FortiGate:



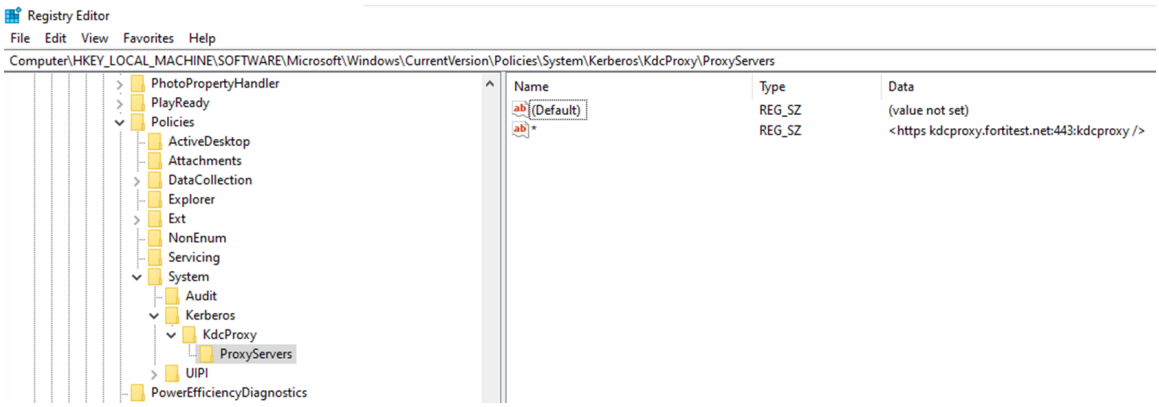
1. Configure FortiClient to have the ZTNA destination rule.
2. Configure a ZTNA server and proxy policy on FortiGate.

Configuring a ZTNA destination rule on FortiClient



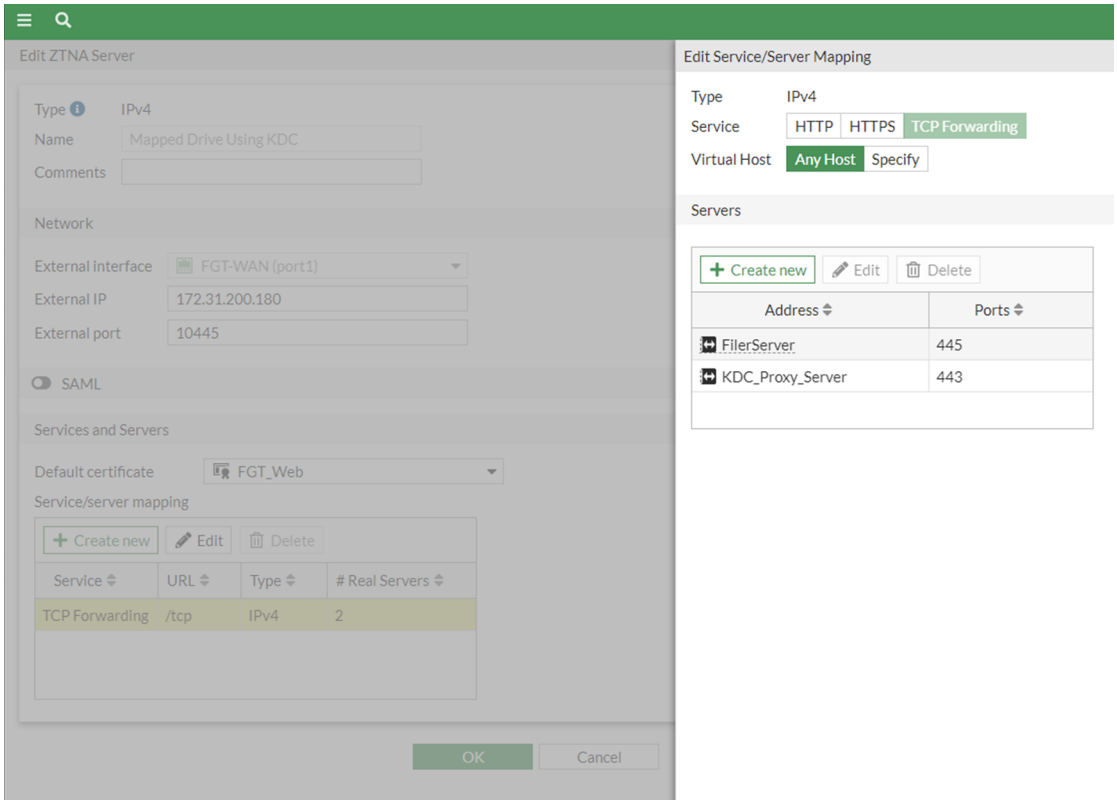
The ZTNA destination rule can be configured by using FortiClient EMS or by manually configuring FortiClient. The destination host matches the server's FQDN on port 445, and the proxy gateway should be the FortiGate WAN port on the chosen external port.

Another rule is required for the KDC proxy communication with the destination host defined as the FQDN of the KDC proxy server and port 443.

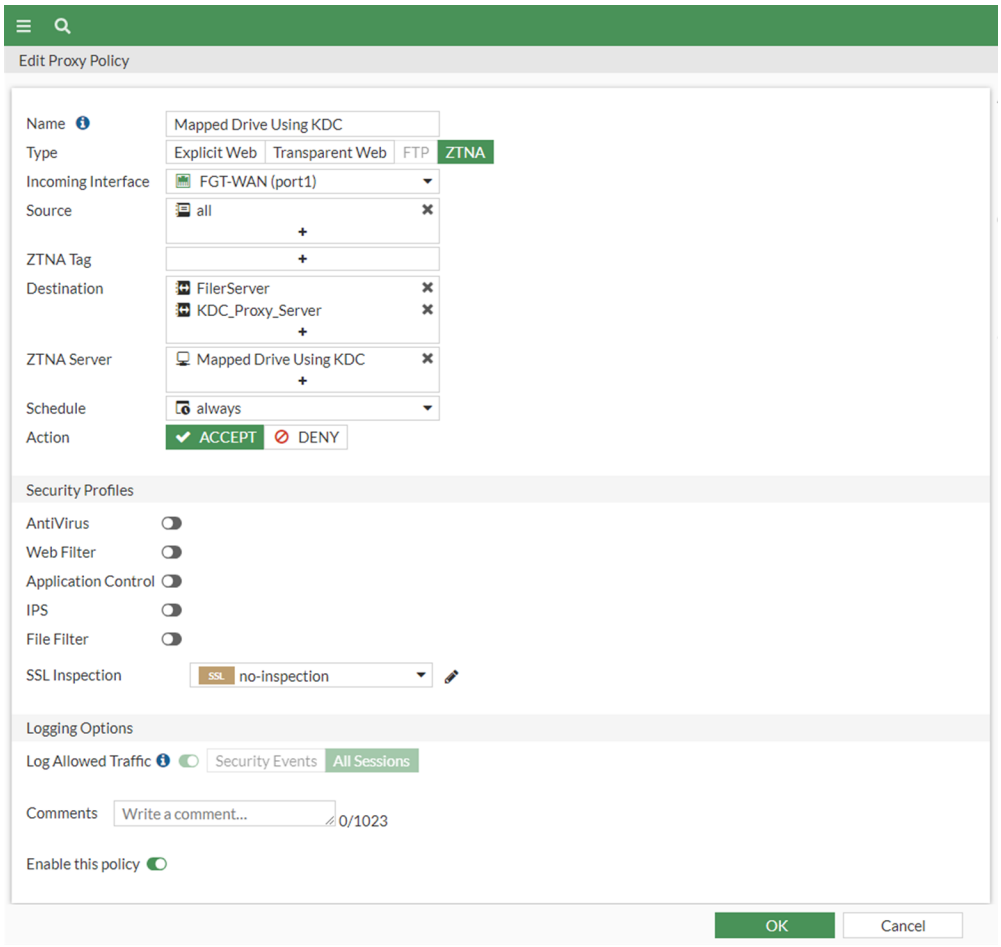


The map network drive configuration should be the last step after configuring the FortiGate. The following example shows the mapped drive:

The following example shows a ZTNA destination configured in FortiClient with the *Proxy Gateway*:



The following example shows the registry settings:



Configuring FortiGate

A ZTNA server and a proxy policy are required to verify and forward the incoming requests on port 10445 to the file server on port 445 as well as to the KDC proxy server on port 443.

The following example shows the ZTNA server:

The following example shows the proxy policy:

ZTNA troubleshooting and debugging commands

The following debug commands can be used to troubleshoot ZTNA issues:

Command	Description
`# diagnose endpoint fctems test-connectivity <EMS>`	Verify FortiGate to FortiClient EMS connectivity.
`# execute fctems verify <EMS>`	Verify the FortiClient EMS's certificate.
`# diagnose test application fcnacd 2`	Dump the EMS connectivity information.
`# diagnose debug app fcnacd -1` `# diagnose debug enable`	Run real-time FortiClient NAC daemon debugs.
`# diagnose endpoint record list <ip>`	Show the endpoint record list. Optionally, filter by the endpoint IP address.

Command	Description
`# diagnose endpoint lls-comm send ztna find-uid <uid> <EMS_serial_number> <EMS_tenant_id>`	Query endpoints by client UID, EMS serial number, and EMS tenant ID.
`# diagnose endpoint lls-comm send ztna find-ip-vdom <ip> <vdom>`	Query endpoints by the client IP-VDOM pair.
`# diagnose wad dev query-by uid <uid> <EMS_serial_number> <EMS_tenant_id>`	Query from WAD diagnose command by UID, EMS serial number, and EMS tenant ID.
`# diagnose wad dev query-by ipv4 <ip>`	Query from WAD diagnose command by IP address.
`# diagnose firewall dynamic list`	List EMS ZTNA tags and all dynamic IP and MAC addresses.
`# diagnose test application fcnacd 7` `# diagnose test application fcnacd 8`	Check the FortiClient NAC daemon ZTNA and route cache.
`# diagnose wad worker policy list`	Display statistics associated with access proxy rules.

`# diagnose wad debug enable category all`
`# diagnose wad debug enable level verbose`
`# diagnose debug enable`
	Run real-time WAD debugs.

`# diagnose debug reset`	Reset debugs when completed

The WAD daemon handles proxy related processing. The FortiClient NAC daemon (fcnacd) handles FortiGate to EMS connectivity.

Troubleshooting usage and output

1. Verify the FortiGate to EMS connectivity and EMS certificate:

```
# diagnose endpoint fctems test-connectivity WIN10-EMS
Connection test was successful:
```

```
# execute fctems verify WIN10-EMS
Server certificate already verified.
```

```
# diagnose test application fcnacd 2
EMS context status:
FortiClient EMS number 1:
        name: WIN10-EMS confirmed: yes
        fetched-serial-number: FCTEMS0000109188
Websocket status: connected
```

2. If fcnacd does not report the proper status, run real-time fcnacd debugs:

```
# diagnose debug app fcnacd -1
# diagnose debug enable
```

3. Verify the following information about an endpoint:

- Network information
- Registration information
- Client certificate information
- Device information
- Vulnerability status
- Relative position with the FortiGate

```
# diagnose endpoint record list 10.6.30.214
Record #1:
                IP Address = 10.6.30.214
                MAC Address = 00:0c:29:ba:1e:61
                MAC list = 00:0c:29:ba:1e:61;00:0c:29:ba:1e:6b;
                VDOM = root (0)
                EMS serial number: FCTEMS8821001322
                EMS tenant id: 00000000000000000000000000000000
                Client cert SN: 17FF6595600A1AF53B87627AB4EBEDD032593E64
                Quarantined: no
                Online status: online
                Registration status: registered
                On-net status: on-net
                Gateway Interface: port2
                FortiClient version: 7.0.0
                AVDB version: 84.778
                FortiClient app signature version: 18.43
                FortiClient vulnerability scan engine version: 2.30
                FortiClient UID: 5FCFA3ECDE4D478C911D9232EC9299FD
                Host Name: ADPC
    …
                Number of Routes: (1)
                        Gateway Route #0:
                                - IP:10.1.100.214, MAC: 00:0c:29:ba:1e:6b, Indirect: no
                                - Interface:port2, VFID:0, SN: FG5H1E5819902474
online records: 1; offline records: 0; quarantined records: 0
```

4. Query the endpoint information, include ZTNA tags, by UID or IP address:

```
# diagnose endpoint lls-comm send ztna find-uid 5FCFA3ECDE4D478C911D9232EC9299FD
FCTEMS8821001322 00000000000000000000000000000000

6. List all the dynamic ZTNA IP and MAC addresses learned from EMS:

```
# diagnose firewall dynamic list
List all dynamic addresses:
FCTEMS0000109188_all_registered_clients: ID(51)
        ADDR(172.17.194.209)
        ADDR(192.168.40.8)
…
FCTEMS0000109188_Low: ID(78)
        ADDR(172.17.194.209)
        ADDR(192.168.40.8)
…
FCTEMS0000109188_Malicious-File-Detected: ID(190)
        ADDR(172.17.194.209)
        ADDR(192.168.40.8)
…
```

7. Check the FortiClient NAC daemon ZTNA and route cache:

```
# diagnose test application fcnacd 7
ZTNA Cache:
-uid 5FCFA3ECDE4D478C911D9232EC9299FD: { "tags": [ "ZT_OS_WIN", "all_registered_
clients", "Medium" ], "domain": "qa.wangd.com", "user_name": "user1", "client_cert_sn":
```

```
"17FF6595600A1AF53B87627AB4EBEDD032593E64", "owner": "FOSQA@qa.wangd.com", "gateway_
route_list": [ { "gateway_info": { "fgt_sn": "FG5H1E5819902474", "interface": "port2",
"vdom": "root" }, "route_info": [ { "ip": "10.1.100.214", "mac": "00-0c-29-ba-1e-6b",
"route_type": "direct" } ] } ], "ems_sn": "FCTEMS8821001322" }

# diagnose test application fcnacd 8
IP-VfID Cache:
IP: 10.1.100.206, vfid: 0, uid: 3DED29B54386416E9888F2DCBD2B9D21
IP: 10.1.100.214, vfid: 0, uid: 5FCFA3ECDE4D478C911D9232EC9299FD
```

8. Troubleshoot WAD with real-time debugs to understand how the proxy handled a client request:

```
# diagnose wad debug enable category all
# diagnose wad debug enable level verbose
# diagnose debug enable

[0x7fbd7a46bb60] Received request from client: 10.10.10.20:56312

```

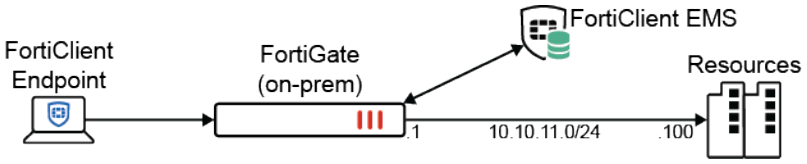
Always reset the debugs after using them:

```
# diagnose debug reset
```



ZTNA troubleshooting scenarios

This topic describes how to troubleshoot common FortiClient endpoint IP/MAC access control issues for the following topologies:

- ZTNA access control on page 1027
- IP/MAC based access control on page 1029

ZTNA access control

In this topology, FortiClient endpoints use an SSL encrypted connection to the FortiGate access proxy to access protected resources. FortiGate works with FortiClient EMS to use a combination of IP/MAC addresses and ZTNA tags to control FortiClient endpoint access to resources.

This section describes how to handle the following errors:

- Invalid ZTNA certificate on page 1028
- ZTNA policy mismatch on page 1028

Invalid ZTNA certificate

When FortiClient attempts to access a server protected by ZTNA, an *Invalid ZTNA certificate* error is shown. This error often appears when the serial number for the ZTNA certificate differs between the endpoint and the FortiGate.

1. Check the serial number for the ZTNA certificate on the endpoint and the FortiGate:
   a. On the endpoint, check the serial number for the certificate.
   b. On the FortiGate, check the serial number for the client certificate by running the following command:

   ```
   # diagnose endpoint record list
   ```
2. If the serial number for the ZTNA certificate differs between the endpoint and the FortiGate, and the serial number on the FortiGate is comprised of zeros, check the following:
   a. For FortiClient, make sure that the endpoint is running FortiClient 7.0 or later. FortiClient versions earlier than 7.0 do not support ZTNA.
   b. For FortiClient EMS, make sure that ZTNA is enabled. Check the profile on EMS and the endpoint's summary information.
   c. For licensing, make sure that you have a ZTNA agent license entitlement. Only some license types support ZTNA.
3. If the serial numbers still do not match, deregister FortiClient from EMS, and then connect FortiClient to EMS again to trigger a new certificate signing request.

ZTNA policy mismatch

In most cases, FortiGate denies incoming ZTNA requests because the endpoint FortiClient does not meet the tagging criteria configured in the ZTNA rule and is considered a policy mismatch.

1. On the FortiGate, look at the ZTNA event logs and the forwarded logs.
2. Run the following commands on the ZTNA server:

   ```
   # diagnose wad debug enable category policy
   # diagnose wad debug enable level verbose
   # diagnose debug enable
   ```

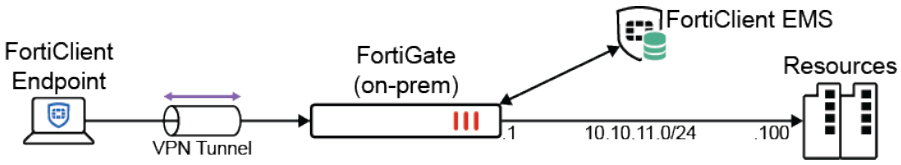
   The command output contains incoming ZTNA requests and the FortiGate process for matching the connection to a ZTNA rule.
3. Verify the zero trust tags for the endpoint:
   - On FortiClient, verify the applied tags. Click the avatar to view the zero trust tags.
   - On FortiClient EMS, verify the endpoint's tags. Go to the endpoint list and click the endpoint.

- On FortiGate, verify the tags using the following commands:
  - Display ZTNA cache data for all endpoints:

    ```
    # diagnose test application fcnacd 7
    ```

  - Display ZTNA cache data for an individual endpoint:

    ```
    # diagnose wad dev query-by uid <UID> <EMS S/N> <tenant ID>
    ```



4. If the tagging information differs between FortiGate and EMS, examine the EMS tag exchange communication between FortiGate and EMS by looking at the cmNotify and python logs in the debug diagnostics for EMS.

   For more information about FortiClient EMS diagnostics, see Generate Diagnostic Log in the FortiClient EMS Administration Guide.

IP/MAC based access control

In the following ZTNA topology, FortiClient endpoints use VPN to access resources. FortiGate works with FortiClient EMS to use a combination of IP/MAC addresses and ZTNA tags to control FortiClient endpoint access to resources.

For more information, see ZTNA IP MAC based access control example on page 1003.

ZTNA tag information missing on the FortiGate

If the IP address for the FortiClient endpoint is not associated with a ZTNA tag on the FortiGate, a firewall policy mismatch occurs, and the FortiGate denies network access to the FortiClient endpoint.

The following workflow summarizes how FortiGate retrieves the IP address and tags for the FortiClient endpoint to help you better understand how to troubleshoot the situation:

1. FortiClient establishes a VPN connection to the FortiGate.
2. FortiGate uses the API to pass FortiClient's UUID and VPN IP address to FortiClient EMS.
3. FortiGate requests system information and tags from FortiClient based on the response from EMS.

Based on the workflow, start troubleshooting before the FortiClient endpoint attempts to establish a VPN connection to FortiGate. On FortiGate, run the following commands:

```
# diagnose debug application fcnacd -1
# diagnose debug console timestamp enable
# diagnose endpoint filter show-large-data yes
# diagnose debug enable
```

The following outputs illustrate how to examine the command output. The output can differ between environments. The outputs help illustrate how to understand the communication between FortiGate and FortiClient EMS.

In the following output, FortiGate's VPN daemon sends FortiClient's UUID and the VPN IP address to FortiClient EMS using the API. The NAC daemon makes the API call to send the details to FortiClient EMS:

```
2022-10-17 08:50:41 [fcems_call_vpn_client_gateway_call:1147] VPN act connect (UID:
3358095CFDCB414B9EDA49ADE79AF428, Interface: port1, IP: 10.212.134.200, VDom: root,

"""
```

The following example from the fcmNotify.log file on FortiClient EMS shows how FortiClient EMS interprets the information sent from FortiGate:

```
2022-10-26 11:59:37,817 DEBUG ems_logger 6 7 [VPN Gateway Details]: Request made with
params: {'is_snapshot': False, 'sn_list': ['FG10E0TB20903081', 'FG10E0TB20903034'], 'uid_
list': [{'uid': 'D997B2A7A78E4E6F832309FF97FC2215', 'vdom': 'root', 'interface': 'EXT',
'sn': 'FG10E0TB20903081', 'ip': '10.1.18.61', 'is_delete': False}]}.
2022-10-26 11:59:38,281 DEBUG ems_logger 6 7 [Sysinfo c44cc74b1185431491f71c133c097f00
Certificate user: FG10E0TB20903081]: Request with SN [FG10E0TB20903034,FG10E0TB20903081]
success. Returned 1 endpoints. uid_offset: D997B2A7A78E4E6F832309FF97FC2215, updated_after:
2022-10-26 15:59:37.8237471, is_final: True
2022-10-26 11:59:38,543 DEBUG ems_logger 6 7 [UID-Tags e6ecc42c058e48b2b71cf7d65ecd432c
Certificate user: FG10E0TB20903081]: Request with SN [FG10E0TB20903034,FG10E0TB20903081]
success. uid_offset: D997B2A7A78E4E6F832309FF97FC2215, updated_after: 2022-10-26
15:59:37.8227461, is_final: True
```

FortiGate uses the information from FortiClient EMS to make a targeted API call to FortiClient EMS to retrieve both system information and tag information (with the means of uid_offset and updated_after parameters) for the endpoint. The following is the API call to retrieve the tags from FortiClient EMS:

```
https://172.31.200.182/api/v1/report/fct/uid_tags?sn_list[]=FGVM02TM22018374&updated_
after=2022-10-17 15:59:37.8227461&uid_offset=3358095CFDCB414B9EDA49ADE79AF428
```

The following in an example of the API call and subsequent communication between FortiGate and FortiClient EMS to retrieve tags for the FortiClient endpoint IP address:

```
2022-10-17 08:50:42 [ec_ez_worker_base_prep_resolver:373] Outgoing interface index 0 for 2
(FortiClientEMS).
2022-10-17 08:50:42 [ec_ez_worker_prep_data_url:98] request (26):
"""
sn_list[]=FGVM02TM22018374

"""
```

Other useful CLI commands

Output the JSON-formatted list of FortiGate interfaces (gateways) with IP and MAC addresses. This is the list that FortiGate sends to EMS so that EMS can identify the endpoints that are directly connected to the firewall:

```
# diagnose endpoint fctems json gateway-mac-request
```

Makes EMS execute API calls to the EMS API endpoints on demand:

```
# diagnose test application fcnacd 5
```

Send the gateway list to EMS on demand. It could be useful to execute `diagnose test application fcnacd 5` right after command during troubleshooting, as EMS will have an updated list of firewall interfaces:

```
# diagnose test application fcnacd 99
```

For more commands, see ZTNA troubleshooting and debugging commands on page 1022.

Policy and Objects

This section contains topics on configuring policies and traffic shaping:

- Policies on page 1032
- Address objects on page 1152
- Protocol options on page 1187
- Traffic shaping on page 1189
- Internet Services on page 1240

Policies

The firewall policy is the axis around which most features of the FortiGate revolve. Many firewall settings end up relating to or being associated with the firewall policies and the traffic they govern. Any traffic going through a FortiGate has to be associated with a policy. These policies are essentially discrete compartmentalized sets of instructions that control the traffic flow going through the firewall. These instructions control where the traffic goes, how it is processed, if it is processed, and whether or not it is allowed to pass through the FortiGate.

When the firewall receives a connection packet, it analyzes the source address, destination address, and service (by port number). It also registers the incoming interface, the outgoing interface it needs to use, and the time of day. Using this information, the FortiGate firewall attempts to locate a security policy that matches the packet. If a policy matches the parameters, then the FortiGate takes the required action for that policy. If it is *Accept*, the traffic is allowed to proceed to the next step. If the action is *Deny* or a match cannot be found, the traffic is not allowed to proceed.

The two basic actions at the initial connection are either *Accept* or *Deny*:

- If the action is *Accept*, the policy permits communication sessions. There may be other packet processing instructions, such as requiring authentication to use the policy or restrictions on the source and destination of the traffic.
- If the action is *Deny*, the policy blocks communication sessions, and you can optionally log the denied traffic. If no security policy matches the traffic, the packets are dropped. A *Deny* security policy is needed when it is required to log the denied traffic, also called *violation traffic*.

One other action can be associated with the policy:

- *IPsec*: this is an *Accept* action that is specifically for IPsec VPNs.

Each field in a firewall policy that accepts multiple inputs, such as srcaddr and dstaddr, can accept as many inputs as there are unique objects created. The maximum number of objects depends on the model. See the Maximum Values Table for more details.

The following topics provide information on the available types of policies and configuration instructions:

- Firewall policy on page 1033
- NGFW policy on page 1046
- Local-in policy on page 1062

- DoS policy on page 1066
- Access control lists on page 1073
- Interface policies on page 1074

The following topics provide instructions on configuring policies:

- Source NAT on page 1075
- Destination NAT on page 1095
- Examples and policy actions on page 1119

Firewall policy

The firewall policy is the axis around which most of the other features of the FortiGate firewall revolve. A large portion of the settings in the firewall at some point will end up relating to or being associated with the firewall policies and the traffic that they govern. Any traffic going through a FortiGate unit has to be associated with a policy. These policies are essentially discrete compartmentalized sets of instructions that control the traffic flow going through the firewall. These instructions control where the traffic goes, how it's processed, if it's processed, and even whether or not it's allowed to pass through the FortiGate.

The following topics provide information on the firewall policy and configuration:

- Firewall policy parameters on page 1033
- Configurations in the GUI on page 1034
- Configurations in the CLI on page 1039
- Policy views on page 1044
- Policy lookup on page 1046

Firewall policy parameters

For traffic to flow through the FortiGate firewall, there must be a policy that matches its parameters:

- Incoming interface(s)
- Outgoing interface(s)
- Source address(es)
- User(s) identity
- Destination address(es)
- Internet service(s)
- Schedule
- Service

Traffic parameters are checked against the configured policies for a match. If the parameters do not match any configured policies, the traffic is denied.

Traffic flow initiated from each direction requires a policy, that is, if sessions can be initiated from both directions, each direction requires a policy.

Just because packets can go from point A to point B on port X does not mean that the traffic can flow from point B to point A on port X. A policy must be configured for each direction.

When designing a policy, there is often reference to the traffic flow, but most communication is two-way so trying to determine the direction of the flow might be confusing. If traffic is HTTP web traffic, the user sends a request to the

website, but most of the traffic flow will be coming from the website to the user or in both directions? For the purposes of determining the direction for a policy, the important factor is the direction of the initiating communication. The user is sending a request to the website, so this is the initial communication; the website is responding so the traffic is from the user's network to the Internet.

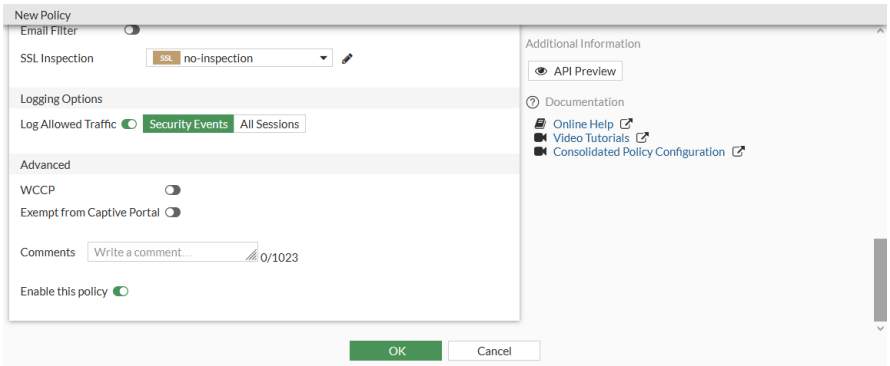
FortiOS does not perform a reverse-path check on reply traffic that matches an allowed session based on the IP tuple. The request traffic can be sent on one interface and the reply traffic could return on another interface.

Configurations in the GUI

Firewall policies can be created in the GUI by configuring the necessary parameters.

Incoming interface(s)	This is the interface or interfaces by which the traffic is first connected to the FortiGate unit. The exception being traffic that the FortiGate generates itself. This is not limited to the physical Ethernet ports found on the device. The incoming interface can also be a logical or virtual interface such as a VPN tunnel, a Virtual WAN link, or a wireless interface.
Outgoing interface(s)	This is the interface or interfaces used by traffic leaving a port once it has been processed by the firewall. Similar to incoming interfaces, it is not limited to only physical interfaces.
Source address(es)	The addresses that a policy can receive traffic from can be wide open or tightly controlled. For a public web server that the world at large should be able to access, the best choice will be *all*. If the destination is a private web server that only the branch offices of a company should be able to access, or a list of internal computers that are the only ones allowed to access an external resource, then a group of preconfigured addresses is the better strategy
User(s) identity	This parameter is based on a user identity that can be from a number of authentication authorities. It will be an account or group that has been set up in advance that can be selected from the drop down menu. The exception to this is the feature that allows the importing of LDAP Users. When the feature is used, a small wizard window will appear to guide the user through the setup. The caveat is that the LDAP server object in the *User & Authentication* > *LDAP Servers* section has to be already configured to allow the use of this import feature.
Destination address(es)	In the same way that the source address may need to be limited, the destination address can be used as a traffic filter. When the traffic is destined for internal resources, the specific address of the resource can be defined to better protect the other resources on the network. One of the specialized destination address options is to use a Virtual IP address. If the destination address doesn't need to be internal, you can define policies that are only for connecting to specific addresses on the Internet.
Internet service(s)	In this context, an Internet service is a combination of one or more addresses and one or more services associated with a service found on the Internet such as an update service for software.

Schedule	The time frame that is applied to the policy. This can be something as simple as a time range that the sessions are allowed to start, such as between 8:00 am and 5:00 pm. Something more complex like business hours that include a break for lunch and time of the session's initiation may need a schedule group because it will require multiple time ranges to make up the schedule.
Service	The services chosen represent the TCP/IP suite port numbers that will most commonly be used to transport the named protocols or groups of protocols. This is different than *Application Control* which looks more closely at the packets to determine the actual protocol used to create them. A case where either side can initiate the communication, like between two internal interfaces on the FortiGate unit, would be a more likely situation to require a policy for each direction.

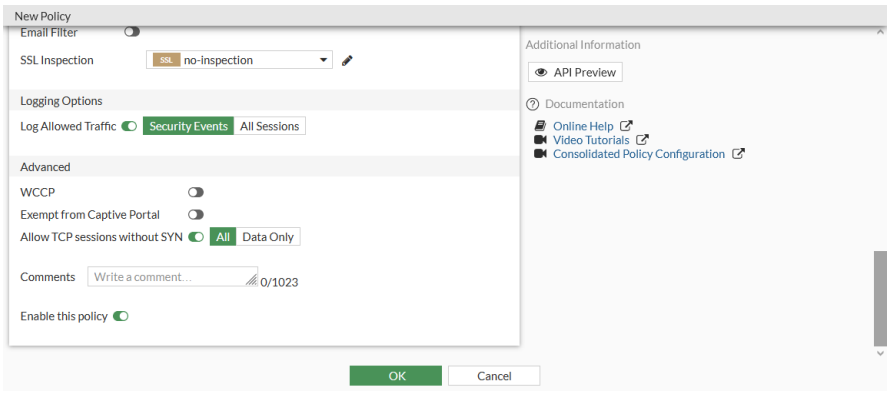


Enabling advanced policy options in the GUI

Advanced policy options can be enabled so that you can configure the options in the GUI.

To enable advanced policy options:

```
config system settings
    set gui-advanced-policy enable
end
```



Advanced policy options are now available when creating or editing a policy in the GUI:

To enable configuring TCP sessions without SYN:

```
config system settings
    set tcp-session-without-syn enable
end
```

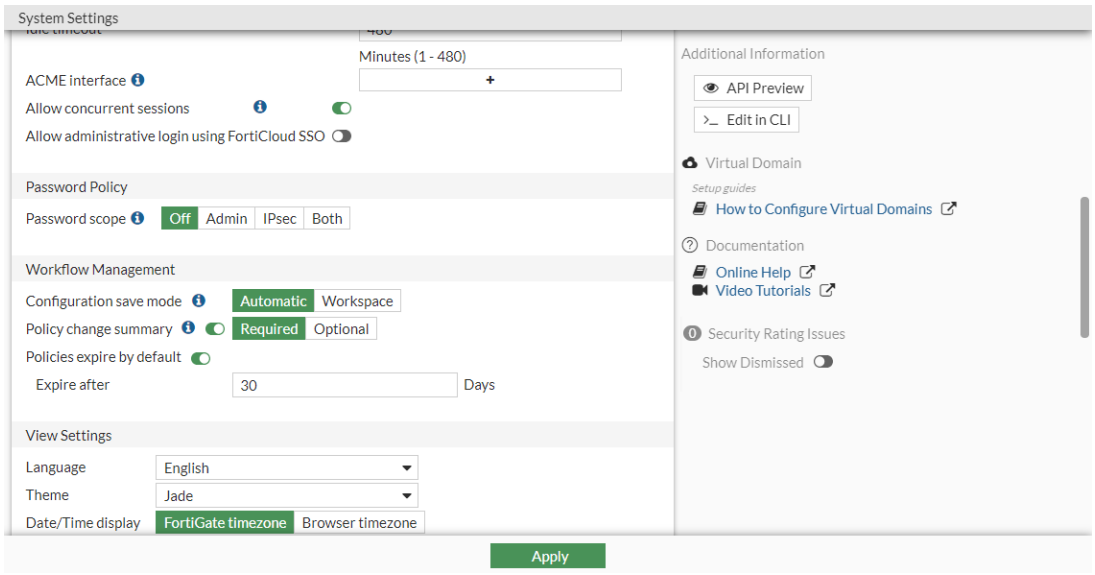
TCP sessions without SYN can now be configured when creating or editing a policy in the GUI:

Add Policy change summary and Policy expiration to Workflow Management

Two options, *Policy change summary* and *Policy expiration*, are included in *Workflow Management*. *Policy change summary* enforces an audit trail for changes to firewall policies. *Policy expiration* allows administrators to set a date for the firewall policy to be disabled.

There are three states for the *Policy change summary*:

- *Disable*: users will not be prompted to add a summary when editing a policy.
- *Required*: the *Policy change summary* will be enabled and will require users to add a summary when editing or creating a firewall policy.
- *Optional*: the *Policy change summary* will be enabled but users can leave the summary empty, if preferred, when editing or creating a firewall policy.

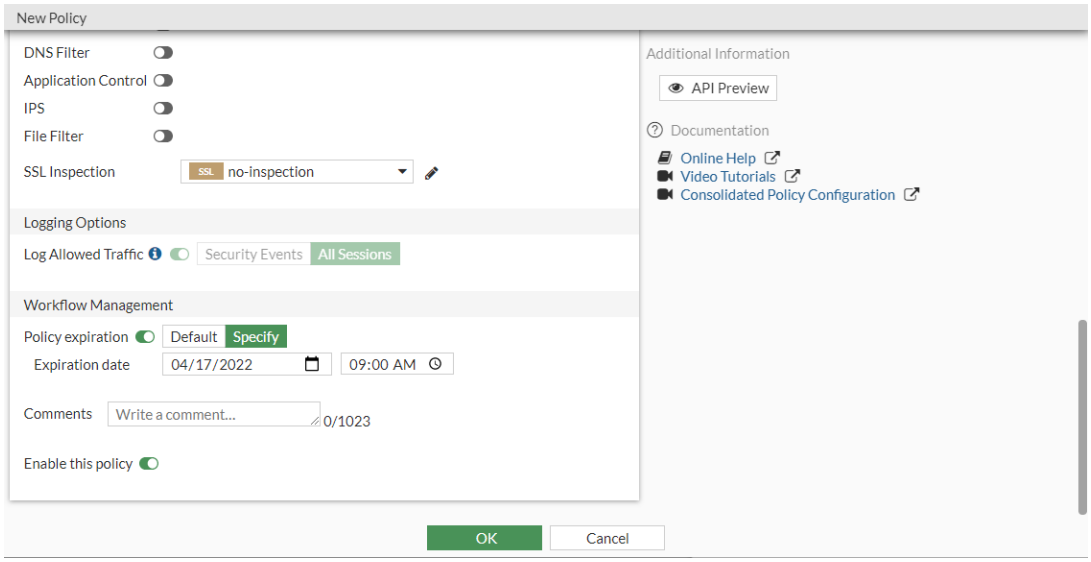


There are three states for *Policy expiration*:

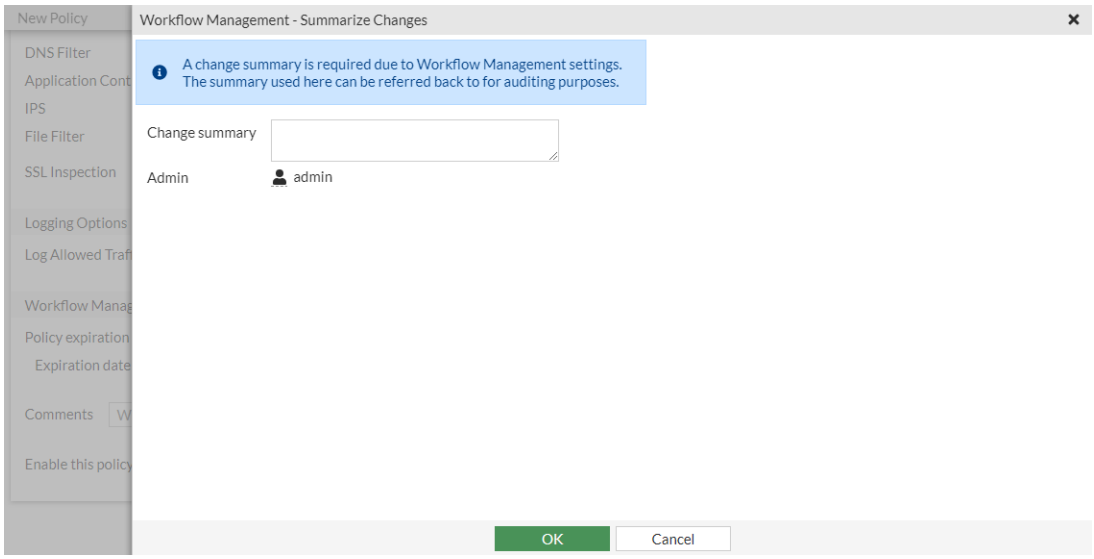
- *Disable*: the firewall policy will not expire. This is the default setting for *Policy expiration*.
- *Default*: the firewall policy will expire after the default number of days.
- *Specify*: the firewall policy will expire at a set date and time.

The default value for *Policy expiration* is 30 days. This number can be changed in the CLI or in *System* > *Settings* in the GUI to any value between zero and 365 days. If the default value is set to zero, the *Default* state will disable the *Policy expiration*.

To configure the firewall policy change summary and default expiration in the GUI:



1. Go to *System* > *Feature Visibility*.
2. Enable *Workflow Management*.
3. Click *Apply*.
4. Go to *System* > *Settings*.
5. In the *Workflow Management* section, set *Policy change summary* to *Required*. *Policies expire by default* is enabled by default with an *Expire after* value of *30*.



6. Click *Apply*.

To configure firewall policy expiration in the GUI:

1. Go to *Policy & Objects* > *Firewall Policy* and click *Create New*.
2. Name the policy and configure the necessary parameters.
3. Set *Policy expiration* to *Specify*. The *Expiration date* fields appears with the current date and time.

4. Select the date and time for the policy to expire from the *Expiration date* fields.
5. Click *OK*. The *Workflow Management - Summarize Changes* pane opens.

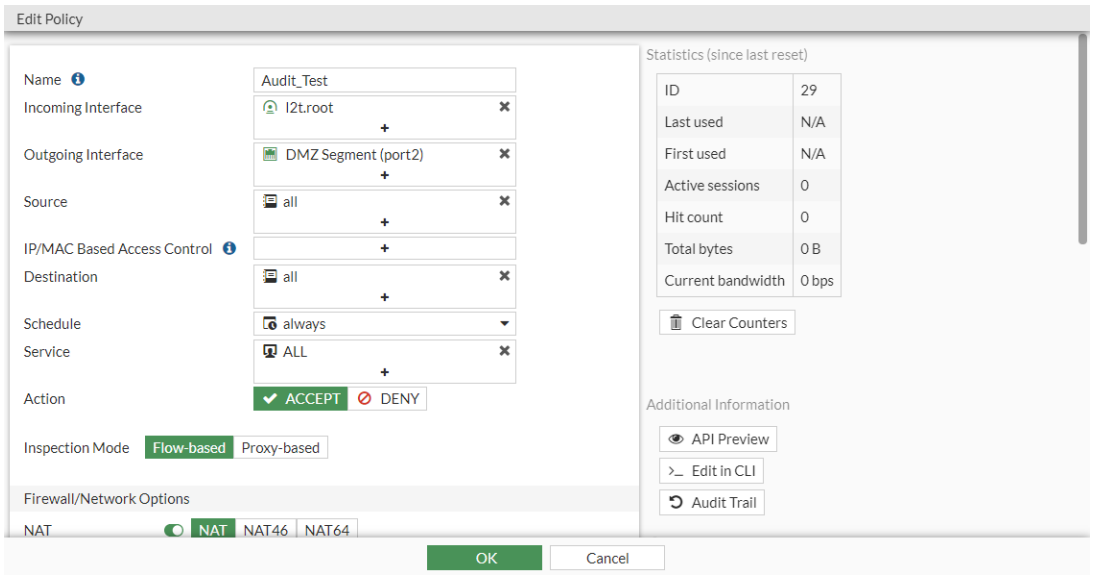
6. In the *Change summary* field, enter details about the changes made to the policy. These details can be referred to later for auditing purposes.
7. Click *OK*.

To configure the firewall policy change summary in the CLI:

```
config system settings
    set gui-enforce-change-summary {disable | require | optional}
end
```

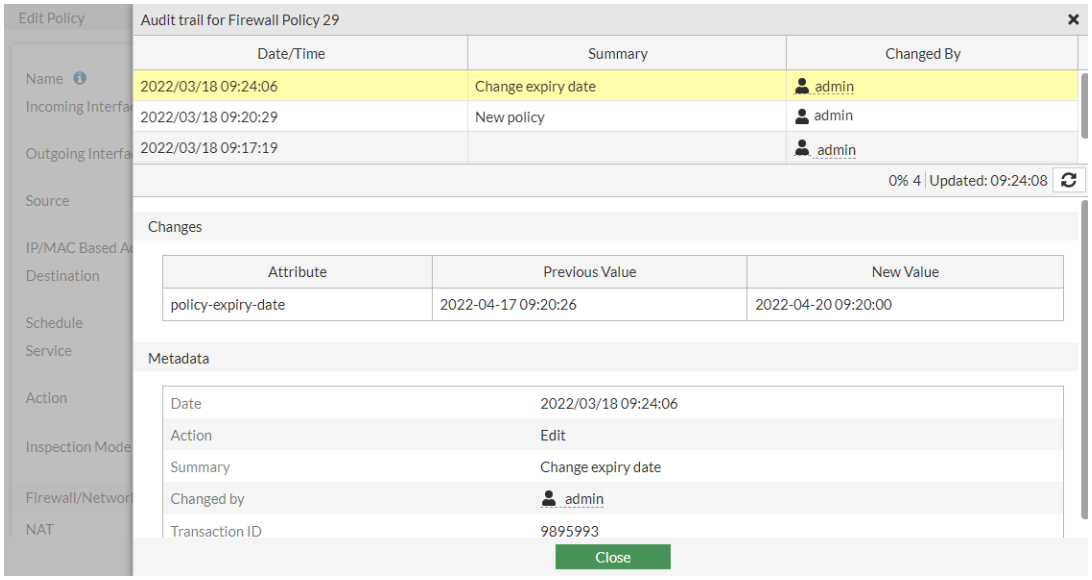
To configure the policy expiration default value in the CLI:

```
config system settings
    set default-policy-expiry-days <integer>
end
```



To configure firewall policy expiration in the CLI:

```
config firewall policy
    edit <id>
        set policy-expiry {enable | disable}
        set policy-expiry-date <YYYY-MM-DD HH:MM:SS>
    next
end
```



Policy change summaries are used to track changes made to a firewall policy. The *Audit trail* allow users to review the policy change summaries, including the date and time of the change and which user made the change.

To review the audit trail in the GUI:

1. Go to *Policy & Objects* > *Firewall Policy*.
2. Select the policy you want to review and click *Edit*.

3. In the right-side banner, click *Audit Trail*. The *Audit trail for Firewall Policy* pane opens and displays the policy change summaries for the selected policy.

4. Select an entry to review the details of the change made.
5. When you are done reviewing the *Audit Trail*, click *Close*.
6. Click *Cancel* to exit the *Edit Policy* page.

Configurations in the CLI

Firewall policies can be created in the CLI by configuring the necessary parameters. See Configurations in the GUI on page 1034 for more information on the various parameters.

Parameter	Definition
srcintf	Incoming (ingress) interface.
dstintf	Outgoing (egress) interface.
srcaddr	Source IPv4 address and address group names.
dstaddr	Destination IPv4 address and address group names.
internet-service	Enable/disable use of Internet Services for this policy. If enabled, destination address and service are not used.
schedule	Schedule name.
service	Service and service group names.
anti-replay	Enable/disable checking of TCP flags per policy.
match-vip	Enable/disable matching of VIPs when used in a policy with a deny action.
auto-asic-offload	Enable/disable hardware acceleration. Available on select FortiGate models with Secure Processing Unit (SPU) hardware only.
tcp-mss-sender	Sender TCP maximum segment size (MSS).
tcp-mss-receiver	Receiver TCP maximum segment size (MSS).
session-ttl	Time-to-live (TTL) in seconds for session accepted by this policy.

Firewall anti-replay option per policy

When the global anti-replay option is disabled, the FortiGate does not check TCP flags in packets. The per policy anti-replay option overrides the global setting. This allows you to control whether or not TCP flags are checked per policy.

To enable the anti-replay option so TCP flags are checked using the CLI:

```
config firewall policy
    edit 1
        set name "policyid-1"
        set srcintf "wan2"
        set dstintf "wan1"
        set srcaddr "all"
        set dstaddr "all"
        set action accept
        set schedule "always"
        set service "ALL"
        set anti-replay enable
        set logtraffic all
        set nat enable
    next
end
```

Deny matching with a policy with a virtual IP applied

Preventing hosts with specific source addresses from accessing a server behind the FortiGate may be required in some cases. For this scenario, you should have previously configured a firewall policy with a virtual IP (VIP) object applied to it

to allow such access. See Destination NAT on page 1095 for details.

When denying traffic destined for a typical firewall policy without a VIP applied, you would simply configure a new firewall policy with an action of `deny` and with specific source addresses above the firewall policy that you want to prevent these hosts from accessing. However, the FortiGate matches firewall policies with VIPs applied differently than typical firewall policies. Policies with VIPs applied have priority over typical firewall policies.

Therefore, to block specific source traffic destined for a firewall policy specified with an action of `accept` and with a VIP applied, you should configure `set match-vip enable` on the firewall policy with a `deny` action that has been configured to match traffic before the firewall policy with the VIP applied. By default, new `deny` action firewall policies have `match-vip` enabled.

If the policy action is set to `accept`, `match-vip` cannot be enabled.

To block VIP traffic in a deny policy:

```
config firewall policy
    edit 1
        set name "deny-policy-1"
        set srcintf "wan1"
        set dstintf "lan1"
        set srcaddr "src-hosts-to-deny-access"
        set dstaddr "all"
        set action "deny"
        set schedule "always"
        set service "all"
        set match-vip enable
    next
    edit 2
        set name "vip-policy-1"
        set srcintf "wan1"
        set dstintf "lan1"
        set srcaddr "all"
        set dstaddr "vip-object-1"
        set action "accept"
        set schedule "always"
        set service "ALL"
    next
end
```

Alternatively, to block access to a firewall policy with a VIP applied, you can configure a new VIP object configured with `set src-filter <range>`. Configure a new firewall policy with a `deny` action and with this new VIP applied, and then configure this policy to match traffic before the firewall policy with the same VIP applied with an action of `accept`. In this case, the firewall policy can simply have `set match-vip disable`.

To specify a VIP with source addresses specified with a deny policy:

```
config firewall vip
    edit "vip-with-srcaddr-to-deny"
        set extip "10.1.100.199"
        set extintf "wan1"
        set mappedip "172.16.200.55"
```

```
        set src-filter "1.1.1.1/24"
    next
end
config firewall policy
    edit 3
        set name "deny-policy-3"
        set srcintf "wan1"
        set dstintf "lan1"
        set srcaddr "all"
        set dstaddr "vip-with-srcaddr-to-deny"
        set action "deny"
        set match-vip disable
        set schedule "always"
        set service "ALL"
    next
    edit 2
        set name "vip-policy-1"
        set srcintf "wan1"
        set dstintf "lan1"
        set srcaddr "all"
        set dstaddr "vip-object-1"
        set action "accept"
        set match-vip disable
        set schedule "always"
        set service "ALL"
    next
end
```

Hardware acceleration

Hardware acceleration is supported on select FortiGate devices and is enabled by default on all firewall policies to ensure optimal performance when processing network traffic traversing the FortiGate. See the Hardware Acceleration Reference Manual for details.

Typically, hardware acceleration on a specific firewall policy is disabled for one of two purposes:

- To allow CLI commands such as the packet sniffer and debug flow to display all traffic matching the policy since traffic offloaded by SPU hardware on a FortiGate device is not visible by those CLI tools.
- To troubleshoot any possible issues arising by using hardware acceleration.

To disable hardware acceleration in an IPv4 firewall policy:

```
config firewall policy
    edit 1
        set auto-asic-offload disable
    next
end
```

To disable hardware acceleration in an IPv6 firewall policy:

```
config firewall policy6
    edit 1
        set auto-asic-offload disable
    next
end
```

To disable hardware acceleration in a multicast firewall policy:

```
config firewall multicast-policy
    edit 1
        set auto-asic-offload disable
    next
end
```

TCP Maximum Segment Size (MSS)

The TCP maximum segment size (MSS) is the maximum amount of data that can be sent in a TCP segment. The MSS is the MTU size of the interface minus the 20 byte IP header and 20 byte TCP header. By reducing the TCP MSS, you can effectively reduce the MTU size of the packet.

The TCP MSS can be configured in a firewall policy, or directly on an interface. See Interface MTU packet size on page 163 for details on configuring TCP MSS directly on an interface.

To configure TCP MSS in a firewall policy:

```
config firewall policy
    edit <policy ID>
        set srcintf "internal"
        set dstintf "wan1"
        set srcaddr "10.10.10.6"
        set dstaddr "all"
        set schedule "always"
        set service "ALL"
        set tcp-mss-sender 1448
        set tcp-mss-receiver 1448
    next
end
```

Adjusting session time-to-live (TTL)

A session is a communication channel between two devices or applications across the network. Sessions allow FortiOS to inspect and act on a sequential group of packets in a session all at once instead of inspecting each packet individually. Each session has an entry in the session table that includes important information about the session.

The session time-to-live (TTL) parameter determines how long a session of a particular protocol such as TCP, UDP, or ICMP remains in the session table. To ensure proper operation of some devices or applications, the session TTL parameter may need to be increased or decreased to allow sessions to remain active in the session table for a longer or shorter duration, respectively.

To configure a modified session TTL in a firewall policy:

```
config firewall policy
    edit <policy ID>
        set srcintf "internal"
        set dstintf "wan1"
        set srcaddr "10.10.10.6"
        set dstaddr "all"
        set schedule "always"
        set service "ALL"
        set session-ttl 1800
```

```
    next
end
```

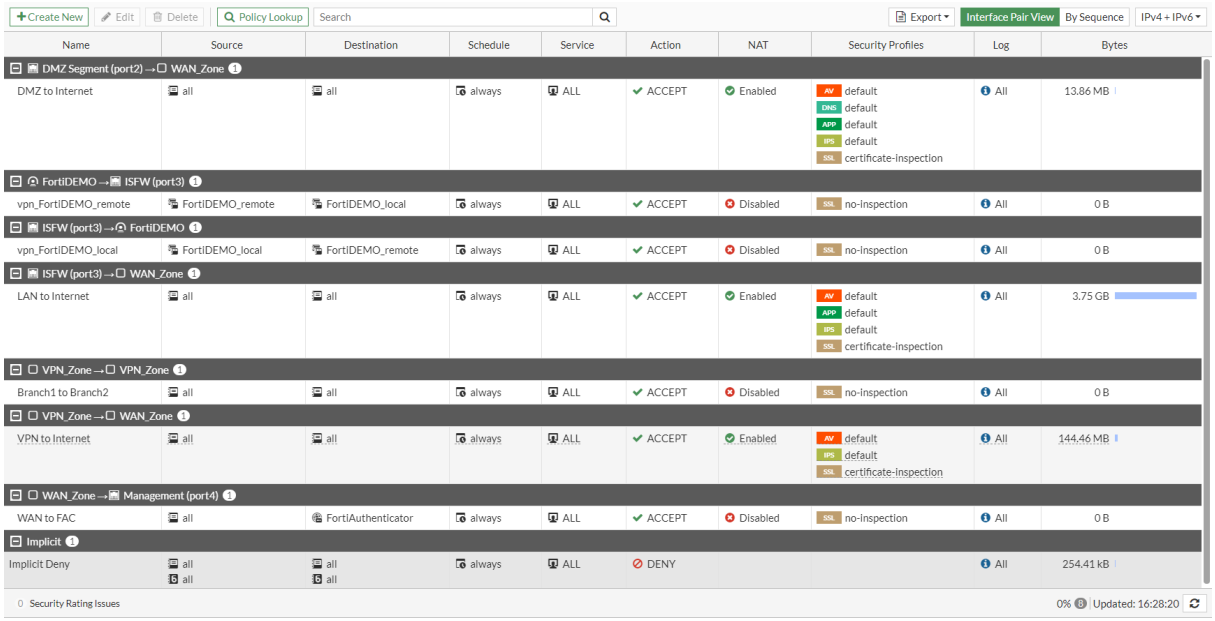
The session TTL can be set to zero or `never` to ensure a session never times out. See No session timeout on page 1141 for details.

Session TTL should only be set to zero or `never` after careful consideration of:

- The connected device's or application's requirements for sessions to always stay alive
- The expectation that a connected device or application will use the same session determined by traffic using a fixed source port, fixed destination port, fixed source IP address, and fixed destination IP address.

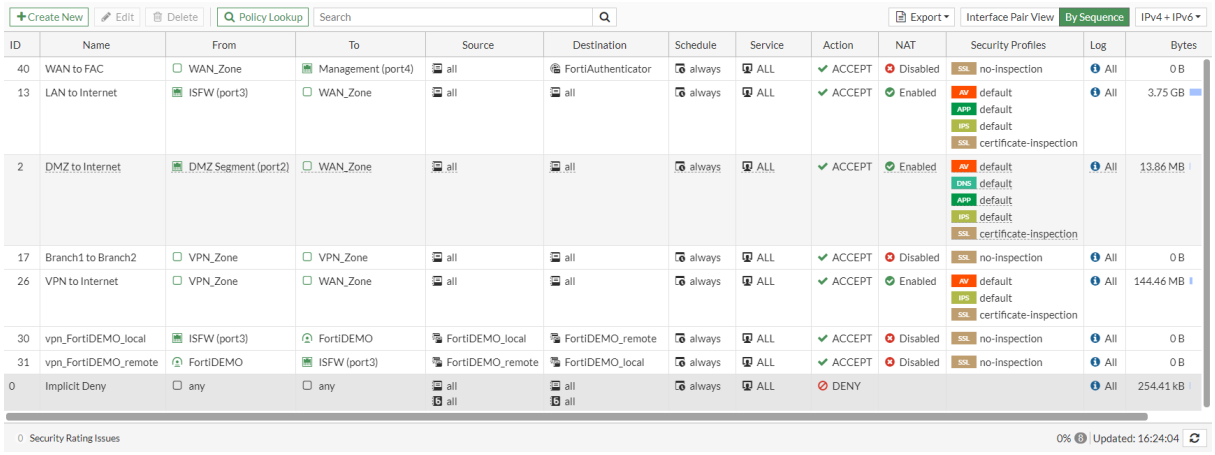
When session TTL is set to zero or `never`, then sessions will not be cleared from the session table or expire after a specified time unless the CLI commands `diagnose system session filter <filter>` and `diagnose system session clear` are used.

If this setting is used in the case when traffic through a firewall policy can generate numerous unique sessions, then this may have unintended consequences to the FortiGate's memory usage and performance due to the session table constantly growing and not clearing out idle sessions.



To disable session TTL in a firewall policy:

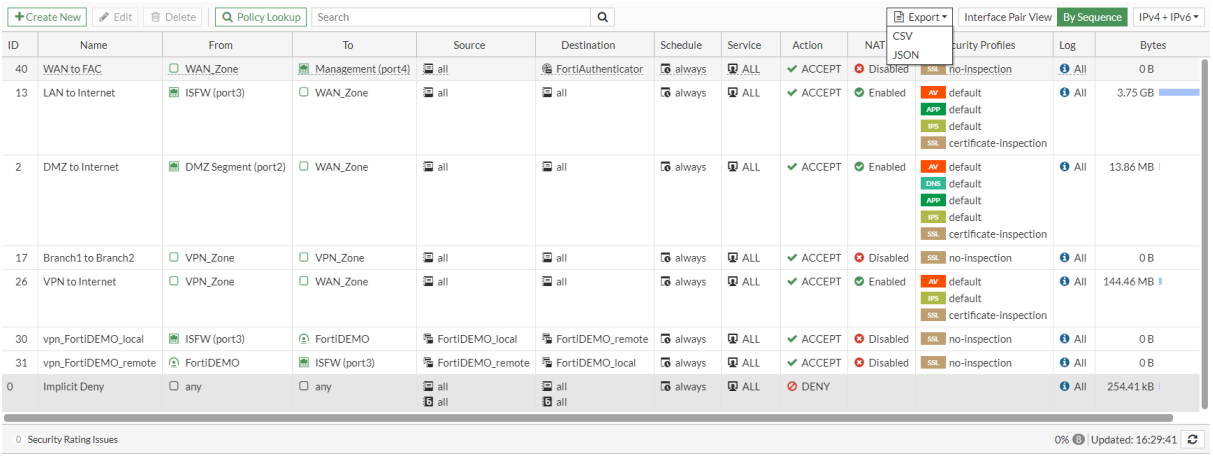
```
config firewall policy
    edit <policy ID>
        set srcintf "internal"
        set dstintf "wan1"
        set srcaddr "10.10.10.6"
        set dstaddr "all"
        set schedule "always"
        set service "ALL"
        set session-ttl never
    next
end
```



Policy views

In *Policy & Objects* policy list pages, there are two policy views: *Interface Pair View* and *By Sequence* view.

Interface Pair View displays the policies in the order that they are checked for matching traffic, grouped by the pairs of incoming and outgoing interfaces in collapsible sections.



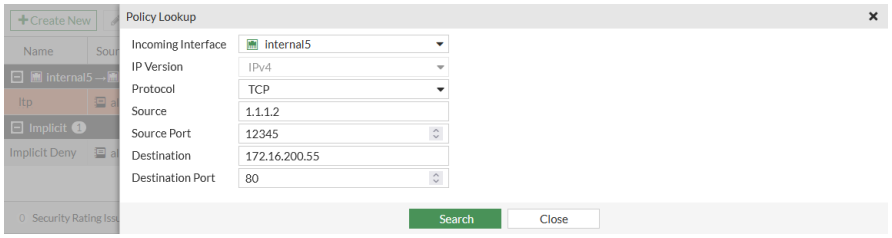
By Sequence displays policies in the order that they are checked for matching traffic without any grouping.

The default display is *Interface Pair View*. You can switch between the two views except if *any* or multiple interfaces are applied in the policy. The FortiGate automatically changes the view on the policy list page to *By Sequence* whenever there is a policy containing *any* or multiple interfaces as the *Source* or *Destination* interface. If the *Interface Pair View* is grayed out, it is likely that one or more policies have used the *any* or multiple interfaces.

You can export the current view to CSV and JSON formats by clicking *Export* and selecting *CSV* or *JSON*. The file is automatically downloaded.

Policy lookup

Firewall policy lookup is based on the `Source_interfaces/Protocol/Source_Address/Destination_Address` that matches the `source-port` and `dst-port` of the protocol. Use this tool to find out which policy matches specific traffic from a number of policies. After completing the lookup, the matching firewall policy is highlighted on the policy list page.



The *Policy Lookup* tool has the following requirements:

- Transparent mode does not support policy lookup function.
- When executing the policy lookup, you need to confirm whether the relevant route required for the policy work already exists.

Sample configuration

This example uses the TCP protocol to show how policy lookup works:

1. On a *Policy & Objects* policy list page, click *Policy Lookup* and enter the traffic parameters.

2. Click *Search* to display the policy lookup results.

NGFW policy

Profile-based next-generation firewall (NGFW) mode is the traditional mode where you create a profile (antivirus, web filter, and so on) and then apply the profile to a policy.

In policy-based NGFW mode, you allow applications and URL categories to be used directly in security policies, without requiring web filter or application control profiles. However, it is possible to select and apply web filter URL categories and groups.

In policy-based mode:

- Central NAT is always enabled. If no Central SNAT policy exists, you must create one. See Central SNAT on page 1086 for more information.
- Pre-match rules are defined separately from security policies, and define broader rules, such as SSL inspection and user authentication.
- The IPsec wizard is not supported.

If your FortiGate operates in NAT mode, rather than enabling source NAT in individual NGFW policies, go to *Policy & Objects* > *Central SNAT* and add source NAT policies that apply to all matching traffic. In many cases, you may only need one SNAT policy for each interface pair.

The NGFW mode is set per VDOM, and it is only available when the VDOM inspection mode is flow-based. You can operate your entire FortiGate or individual VDOMs in NGFW policy mode. The application default port can be set as a service port in the NGFW mode using the `default-app-port-as-service` option.

In NGFW mode, administrators can configure a security policy in learn mode to monitor traffic. See Learn mode in security policies in NGFW mode on page 1058 for more information.

Enabling policy-based NGFW mode

To enable policy-based NGFW mode without VDOMs in the GUI:

1. Go to *System* > *Settings*.
2. In *NGFW Mode*, select *Policy-based*.
3. Click *Apply*.

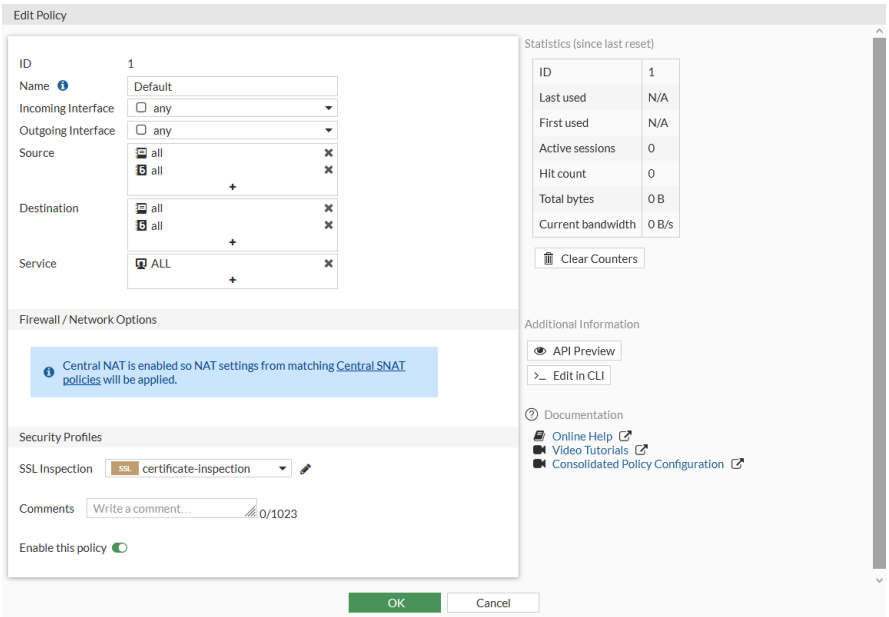
To enable policy-based NGFW mode with VDOMs in the GUI:

1. Go to *System* > *VDOM* .
2. Double-click a VDOM to edit the settings.
3. In *NGFW Mode*, select *Policy-based*.
4. Click *OK*.

To enable policy-based NGFW mode without VDOMs in the CLI:

```
config system settings
    set ngfw-mode policy-based
end
```

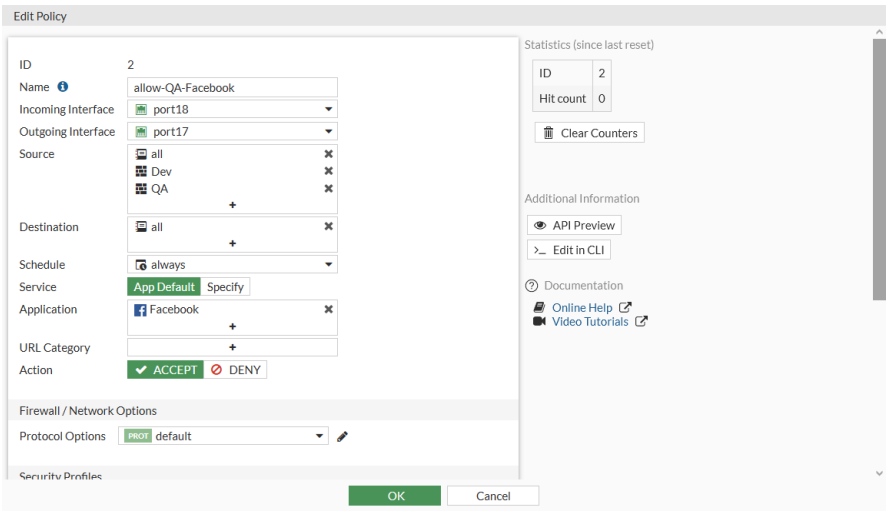
To enable policy-based NGFW mode with VDOMs in the CLI:



```
config vdom
    edit <vdom>
        config system settings
            set ngfw-mode policy-based
        end
    next
end
```

Security and SSL Inspection & Authentication policies

Security policies work with SSL Inspection & Authentication policies to inspect traffic. To allow traffic from a specific user or user group, both Security and SSL Inspection & Authentication policies must be configured. A default SSL Inspection & Authentication policy with the certificate-inspection SSL Inspection profile is preconfigured. Traffic will match the SSL Inspection & Authentication policy first. If the traffic is allowed, packets are sent to the IPS engine for application, URL category, user, and user group match, and then, if enabled, UTM inspection (antivirus, IPS, DLP, and email filter) is performed.



SSL Inspection & Authentication policies are used to pre-match traffic before sending the packets to the IPS engine:

- There are no schedule or action options; traffic matching the policy is always redirected to the IPS engine.
- SSL inspection, formerly configured in the VDOM settings, is configured in an SSL Inspection & Authentication policy.
- Users and user groups that require authentication must be configured in an SSL Inspection & Authentication policy.

Security policies work with SSL Inspection & Authentication policies to inspect traffic:

- Applications and URL categories can be configured directly in the policy.
- Users and user groups that require authentication must also be configured in a security policy.
- The available actions are *Accept* or *Deny*.
- The *Service* option can be used to enforce the standard port for the selected applications.
- UTM inspection is configured in a security policy.

To configure policies for Facebook and Gmail access in the CLI:

1. Configure an SSL Inspection & Authentication policy:

```
config firewall policy
    edit 1
        set name "Policy-1"
        set srcintf "port18"
        set dstintf "port17"
        set srcaddr "all"
        set dstaddr "all"
        set service "ALL"
        set ssl-ssh-profile "new-deep-inspection"
        set groups "Dev" "HR" "QA" "SYS"
    next
end
```

2. Configure security policies:

```
config firewall security-policy
    edit 2
        set name "allow-QA-Facebook"
        set srcintf "port18"
        set dstintf "port17"
        set srcaddr "all"
        set dstaddr "all"
        set action accept
        set schedule "always"

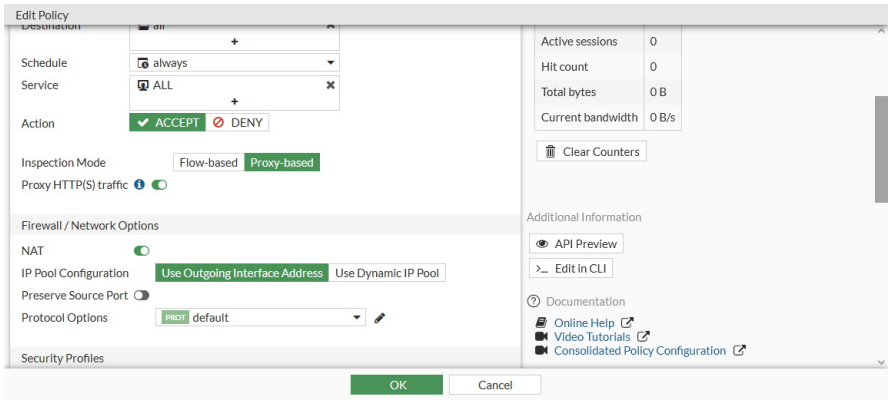
Other NGFW policy-based mode options

You can combine *Application Control* and *Web Filter* in the same NGFW mode policy.

The following security profiles can be used in NGFW policy-based mode:

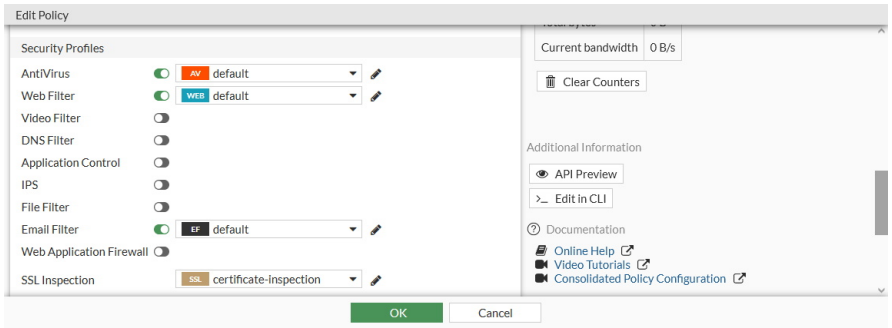
- AntiVirus
- Web Filter
- Intrusion Prevention
- File Filter
- Email Filter

Logging can also be enabled in security policies.



Inspection mode per policy

Inspection mode is configured on a per-policy basis in NGFW mode. This gives you more flexibility when setting up different policies.



When configuring a firewall policy, you can select a *Flow-based* or *Proxy-basedInspection Mode*. The default setting is *Flow-based*.

To configure inspection mode in a policy:

1. Go to *Policy & Objects* > *Firewall Policy*.
2. Create a new policy, or edit an existing policy.
3. Configure the policy as needed.
   a. If you change the *Inspection Mode* to *Proxy-based*, the *Proxy HTTP(S) traffic* option displays.

   b. In the *Security Profiles* section, if no security profiles are enabled, the default *SSL Inspection* is *no-inspection*.
   c. In the *Security Profiles* section, if you enable any security profile, the *SSL Inspection* changes to *certificate-inspection*.

To see the inspection mode changes using the CLI:

```
config firewall policy
    edit 1
        set srcintf "wan2"
        set dstintf "wan1"
        set srcaddr "all"
        set dstaddr "all"
        set action accept
        set schedule "always"
        set service "ALL"
        set inspection-mode proxy
        set nat enable
    next
end
```

To see the HTTP and SSH policy redirect settings when inspection mode is set to proxy using the CLI:

```
config firewall policy
    edit 1
        set srcintf "wan2"
        set dstintf "wan1"
        set srcaddr "all"
        set dstaddr "all"
        set action accept
        set schedule "always"
        set service "ALL"
        set inspection-mode proxy
        set http-policy-redirect enable
        set ssh-policy-redirect enable
        set nat enable
    next
end
```

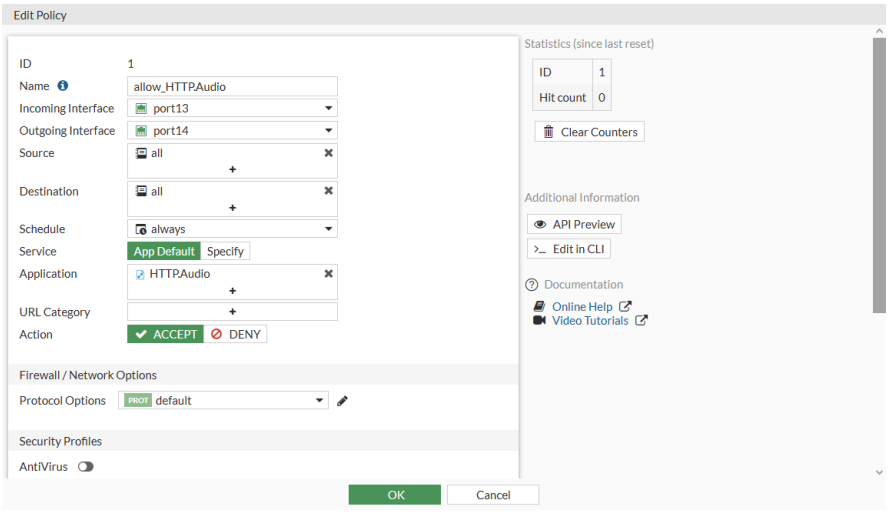
To see the default SSL-SSH policy set to no inspection using the CLI:

```
config firewall policy
    edit 1
       show fu | grep ssl-ssh-profile
        set ssl-ssh-profile "no-inspection"
    next
end
```

NGFW policy mode application default service

In NGFW policy-based mode, the application default service enforces applications running only on their default service port. The applications specified in the policy are monitored, and if traffic is detected from a nonstandard port, it is blocked, and a log entry is recorded with a *port-violation* event type.

If you are not using the default ports, and need to pick specific services, select *Specify* to select the required services.



Example

In this example, the standard port is enforced for HTTPS traffic using the HTTP.Audio application.

First, an SSL Inspection & Authentication policy is created do to traffic pre-match, and then a security policy is created to allow the HTTP.Audio application when using the default port. Fetching an MP3 file from an HTTP server using port 443 is allowed, but is blocked when using a nonstandard port, such as 8443.

To enforce the HTTP.Audio application using the default port in the GUI:

1. Create a new SSL Inspection & Authentication policy, or use the default policy.
2. Go to *Policy & Objects* > *Security Policy*, and click *Create New*.
3. Enter a name for the policy, such as *allow_HTTP.Audio*.
4. Configure the ports as needed.
5. Set *Service* to *App Default*.
6. In the *Application* field, select *HTTP.Audio*.
7. Set the *Action* to *Accept*.

8. Click *OK*.

To enforce the HTTP.Audio application using the default port in the CLI:

1. Create a firewall policy:

```
config firewall policy
    edit 1
        set name "consolidated_all"
        set srcintf "port13"
        set dstintf "port14"
        set srcaddr "all"
        set dstaddr "all"
        set service "ALL"
        set ssl-ssh-profile "new-deep-inspection"
    next
end
```

2. Create a security policy:

```
config firewall security-policy
    edit 1
```

```
            set name "allow_HTTP.Audio"
            set srcintf "port13"
            set dstintf "port14"
            set srcaddr "all"
            set enforce-default-app-port enable
            set action accept
            set schedule "always"
            set logtraffic all
            set application 15879
        next
    end
```

Logs

The application logs show logs with an event type of `port-violation` for traffic on port 8443 that is blocked, and an event type of `signature` for traffic on port 443 that is allowed.

Blocked:

```
2: date=2019-06-18 time=16:15:40 logid="1060028736" type="utm" subtype="app-ctrl"
eventtype="port-violation" level="warning" vd="vd1" eventtime=1560899740218875746 tz="-0700"
appid=15879 srcip=10.1.100.22 dstip=172.16.200.216 srcport=52680 dstport=8443
srcintf="port13" srcintfrole="undefined" dstintf="port14" dstintfrole="undefined" proto=6
service="HTTPS" direction="incoming" policyid=1 sessionid=5041 appcat="Video/Audio"
app="HTTP.Audio" action="block" hostname="172.16.200.216" incidentserialno=1906780850
url="/app_data/story.mp3" securityid=2 msg="Video/Audio: HTTP.Audio," apprisk="elevated"
```

Allowed:

```
1: date=2019-06-18 time=16:15:49 logid="1059028704" type="utm" subtype="app-ctrl"
eventtype="signature" level="information" vd="vd1" eventtime=1560899749258579372 tz="-0700"
appid=15879 srcip=10.1.100.22 dstip=172.16.200.216 srcport=54527 dstport=443
srcintf="port13" srcintfrole="undefined" dstintf="port14" dstintfrole="undefined" proto=6

url="/app_data/story.mp3" securityid=2 msg="Video/Audio: HTTP.Audio," apprisk="elevated"
```

Add option to set application default port as a service port

The `default-app-port-as-service` option can be used in NGFW mode to set the application default port as a service port. This allows applications to match the policy and be blocked immediately the first time that traffic hits the firewall. When this option is enabled, the NGFW policy aggregates the ports used by the applications in the policy and performs a pre-match on the traffic.

```
config system settings
    set default-app-port-as-service {enable | disable}
end
```

This option can be configured on a per-VDOM level.

This setting is enabled by default on new installations. When upgrading, the setting is disabled to retain the previous behavior.

To configure the application default port as service port:

1. Configure the VDOM settings:

```
config system settings
    set vdom-type traffic
    set opmode nat
    set ngfw-mode policy-based
    set block-land-attack disable
    set default-app-port-as-service enable
    set application-bandwidth-tracking disable
end
```

2. Configure the NGFW policy:

```
config firewall security-policy
    edit 1
        set name "test"
        set srcintf "port2"
        set dstintf "port1"
        set srcaddr "all"
        set dstaddr "all"
        set internet-service-src disable
        set enforce-default-app-port enable
        set action accept
    next
end
```

Sample logs

The following logging behavior occurs in NGFW mode with `default-app-port-as-service`:

- When `default-app-port-as-service` and `enforce-default-app-port` are enabled, traffic that does not match the default port is blocked immediately. Only a traffic log is generated.

Log with SSH and FTP traffic:

```
1: date=2022-02-24 time=11:16:36 eventtime=1645730197145603994 tz="-0800"

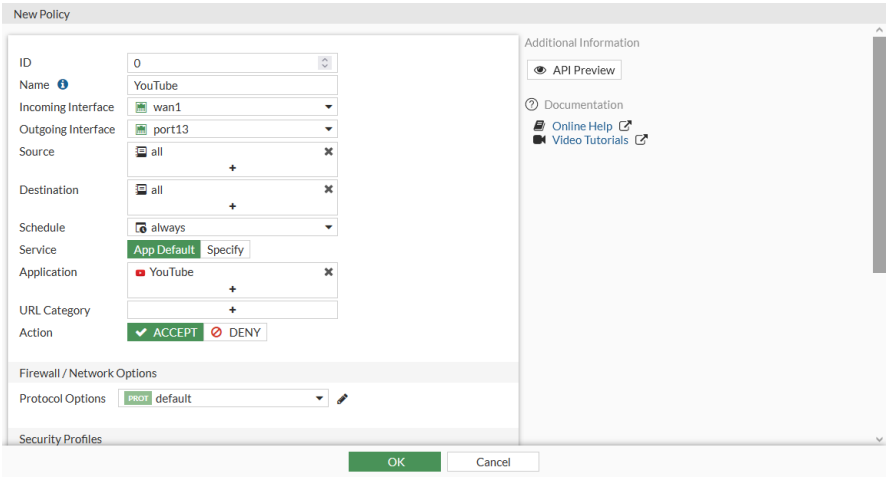
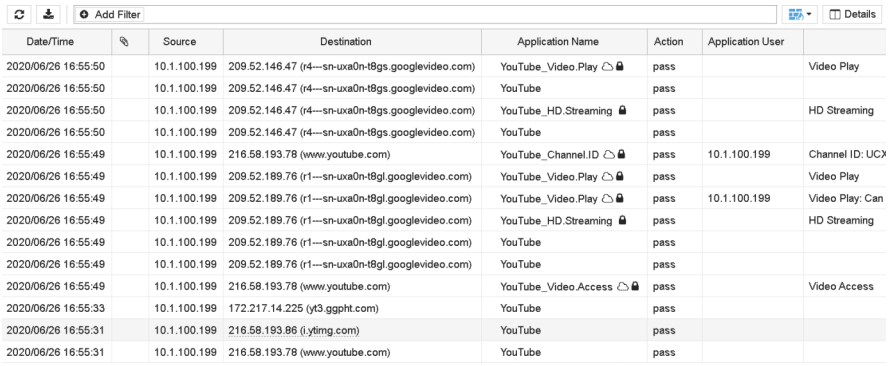
Application logging in NGFW policy mode



In NGFW policy mode, if an application, application category, or application group is selected on a security policy, and traffic logging is set to *UTM* or *All*, then application control logs will be generated. In addition, when a signature is set to the *ACCEPT* action under a security policy, all corresponding child signatures will be assessed and logged as well.

Under NGFW, with `default-app-port-as-service` enabled, enable APP Default. The traffic which doesn't match the default port will be blocked immediately, and there is only traffic log generated.



Under NGFW, with `default-app-port-as-service` disabled, enable APP Default. The traffic which doesn't match the default port will not be blocked immediately, and there is app and traffic logs generated.

To verify application logging:

1. Go to *Policy & Objects* > *Security Policy* and configure a new policy for YouTube.
2. Set *Action* to *ACCEPT* and *Log Allowed Traffic* to *Security Events*.

3. Configure the remaining settings as required, then click *OK*.
4. On a client system, play some YouTube videos.
5. On FortiOS, go to *Log & Report* > *Security Events* and view the *Application Control* logs.
   There are logs not only for *YouTube*, but also for *YouTube_Video.Play*, *YouTube_Video.Access*, and so on, as verified from the *Application Name* column.

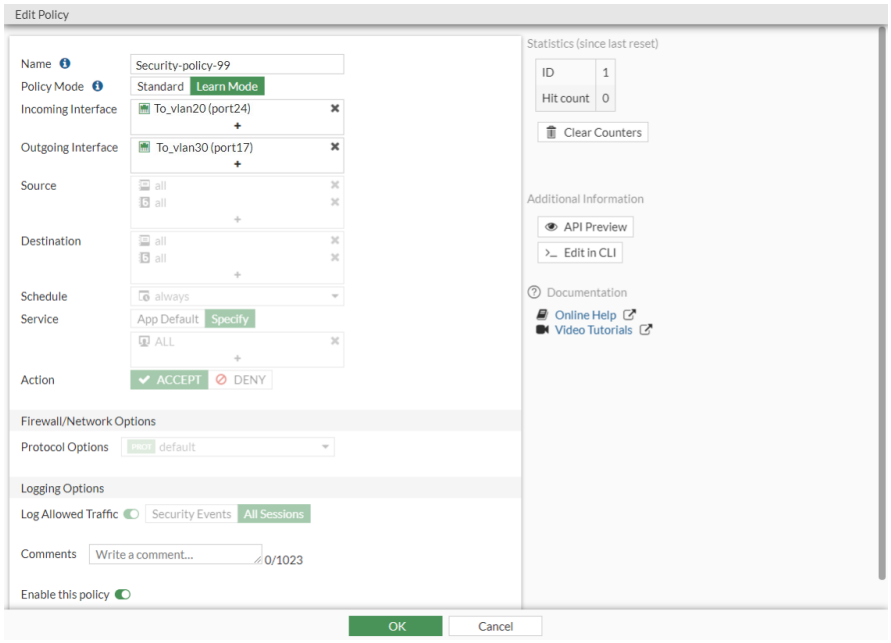
Learn mode in security policies in NGFW mode

In NGFW mode, administrators can configure a security policy in learn mode to monitor traffic that passes through the source and destination interfaces. The learn mode uses a special prefix in the `policymode` and `profile` fields in traffic and UTM logs for use by FortiAnalyzer and the Policy Analyzer Management Extension Application (MEA) that is available with FortiManager.



When enabled on FortiManager, Policy Analyzer MEA works with security policies in learning mode to analyze logs sent from a managed FortiGate to FortiAnalyzer. Based on the analyzed traffic, FortiManager administrators can choose to automatically create a policy in FortiManager for the managed FortiGate. For more information about Policy Analyzer MEA, see the Policy Analyzer Administration Guide.

The following limitations apply when learn mode is enabled in a security policy:

- Only interfaces with `device-identification enable` can be used as source interfaces in a security policy with learning mode enabled.
- Incoming and outgoing interfaces do not support `any`.
- Internet service is not supported.
- NAT46 and NAT64 are not supported.
- Users and groups are not supported.
- Some negate options are not supported.

To enable learn mode in the GUI:

1. Enable policy-based NGFW mode:
   a. Go to *System* > *Settings*.
   b. Set the *NGFW Mode* to *Policy-based* and click *Apply*.
2. Go to *Policy & Objects* > *Security Policy*, and open a security policy for editing.
3. Set the *Policy Mode* to *Learn Mode*.

4. Select an *Incoming Interface*.
5. Select an *Outgoing Interface*.
6. (Optional) Type a comment in the *Comments* box.
7. Toggle on *Enable this policy*.
8. Click *OK* to save the security policy.

To enable learn mode in the CLI:

1. Enable policy-based NGFW mode:

```
config system settings
    set ngfw-mode policy-based
end
```

2. Enable learn mode in a security policy:

```
config firewall security-policy
    edit <id>
        set learning-mode enable
    next
end
```

To view learn mode fields in logs in the CLI:

1. Filter and view fields in traffic logs:

```
# execute log filter category 0

# execute log display

1 logs found.

1 logs returned.

Local-in policy

While security profiles control traffic flowing through the FortiGate, local-in policies control inbound traffic that is going to a FortiGate interface.

Administrative access traffic (HTTPS, PING, SSH, and others) can be controlled by allowing or denying the service in the interface settings. Trusted hosts can be configured under an administrator to restrict the hosts that can access the administrative service.

Local-in policies allow administrators to granularly define the source and destination addresses, interface, and services. Traffic destined for the FortiGate interface specified in the policy that meets the other criteria is subject to the policies action.

Local-in policies can be used to restrict administrative access or other services, such as VPN, that can be specified as services. You can define source addresses or address groups to restrict access from. For example, by using a geographic type address you can restrict a certain geographic set of IP addresses from accessing the FortiGate. An IP Address threat feed can also be used as either a source or destination address; see Applying an IP address threat feed in a local-in policy on page 2938 for more information.

Local-in policies can only be created or edited in the CLI. You can view the existing local-in policies in the GUI by enabling it in *System* > *Feature Visibility* under the *Additional Features* section. This page does not list the custom local-in policies.

To configure a local-in policy using the CLI:

```
config firewall {local-in-policy | local-in-policy6}
    edit <policy_number>
        set intf <interface>
        set srcaddr <source_address> [source_address] ...
        set dstaddr <destination_address> [destination_address] ...
        set action {accept | deny}
        set service <service_name> [service_name] ...
        set schedule <schedule_name>
        set comments <string>
    next
end
```

For example, to prevent the source subnet 10.10.10.0/24 from pinging port1, but allow administrative access for PING on port1:

```
config firewall address
    edit "10.10.10.0"
        set subnet 10.10.10.0 255.255.255.0
    next
```

```
end
config firewall local-in-policy
    edit 1
        set intf "port1"
        set srcaddr "10.10.10.0"
        set dstaddr "all"
        set service "PING"
        set schedule "always"
    next
end
```

To test the configuration:

1. From the PC at 10.10.10.12, start a continuous ping to port1:

   ```
   ping 192.168.2.5 -t
   ```

2. On the FortiGate, enable debug flow:

   ```
   # diagnose debug flow filter addr 10.10.10.12
   # diagnose debug flow filter proto 1
   # diagnose debug enable
   # diagnose debug flow trace start 10
   ```

3. The output of the debug flow shows that traffic is dropped by local-in policy 1:

   ```
   # id=20085 trace_id=1 func=print_pkt_detail line=5746 msg="vd-root:0 received a packet
   (proto=1, 10.10.10.12:1->192.168.2.5:2048) from port1. type=8, code=0, id=1, seq=128."
   id=20085 trace_id=1 func=init_ip_session_common line=5918 msg="allocate a new session-
   0017c5ad"
   id=20085 trace_id=1 func=vf_ip_route_input_common line=2615 msg="find a route:
   flag=80000000 gw-192.168.2.5 via root"
   id=20085 trace_id=1 func=fw_local_in_handler line=474 msg="iprope_in_check() check
   failed on policy 1, drop"
   ```

Implicit deny rule

If a local-in-policy is not functioning correctly and traffic that should be blocked is being allowed through, the issue may be that the implicit deny local-in-policy has not been created. Unlike IPv4 policies, there is no default implicit deny policy. The implicit deny policy should be placed at the bottom of the list of local-in-policies. Local-in-policies are created for each interface, but if you want to create a general implicit deny rule for all interfaces for a specific service, source, address, or destination address, use the `any` interface.

By default, no local-in policies are defined, so there are no restrictions on local-in traffic. When you define a local-in policy, if no action is set manually, then the action will default to `deny`.

For example, to allow only the source subnet 172.16.200.0/24 to ping port1:

```
config firewall address
    edit "172.16.200.0"
        set subnet 172.16.200.0 255.255.255.0
    next
end
config firewall local-in-policy
```

```
    edit 2
        set intf "port1"
        set srcaddr "172.16.200.0"
        set dstaddr "all"
        set action accept
        set service "PING"
        set schedule "always"
    next
    edit 3
        set intf "port1"
        set srcaddr "all"
        set dstaddr "all"
        set service "PING"
        set schedule "always"
    next
end
```

To test the configuration:

1. From the PC at 172.16.200.2, start a continuous ping to port1:

   ```
   ping 172.16.200.1 -t
   ```

2. On the FortiGate, enable debug flow:

   ```
   # diagnose debug flow filter proto 1
   # diagnose debug enable
   # diagnose debug flow trace start 10
   ```

3. The output of the debug flow shows that ping traffic coming from the 172.16.200.0 subnet is allowed:

   ```
   # id=65308 trace_id=25 func=print_pkt_detail line=5939 msg="vd-root:0 received a packet
   (proto=1, 172.16.200.2:5->172.16.200.1:2048) tun_id=0.0.0.0 from port1. type=8, code=0,
   id=5, seq=0."
   id=65308 trace_id=25 func=init_ip_session_common line=6121 msg="allocate a new session-

   id=5, seq=1."
   id=65308 trace_id=27 func=resolve_ip_tuple_fast line=6027 msg="Find an existing session,
   id-00029409, original direction"
   id=65308 trace_id=28 func=print_pkt_detail line=5939 msg="vd-root:0 received a packet
   (proto=1, 172.16.200.1:5->172.16.200.2:0) tun_id=0.0.0.0 from local. type=0, code=0,
   id=5, seq=1."
   ```

4. From the PC at 172.20.120.13, start a continuous ping to port1:

   ```
   ping 172.16.200.1 -t
   ```

5. The output of the debug flow shows that ping traffic coming from subnets other than 172.16.200.0 is dropped by local-in policy 3:

```
# id=65308 trace_id=21 func=print_pkt_detail line=5939 msg="vd-root:0 received a packet
(proto=1, 172.20.120.13:1->172.16.200.1:2048) tun_id=0.0.0.0 from port2. type=8, code=0,
id=1, seq=8."
id=65308 trace_id=21 func=init_ip_session_common line=6121 msg="allocate a new session-
0002929d, tun_id=0.0.0.0"
id=65308 trace_id=21 func=__vf_ip_route_input_rcu line=2012 msg="find a route:
flag=80000000 gw-0.0.0.0 via root"
id=65308 trace_id=21 func=__iprope_tree_check line=520 msg="gnum-100004, use int hash,
slot=51, len=2"
id=65308 trace_id=21 func=fw_local_in_handler line=545 msg="iprope_in_check() check
failed on policy 3, drop"
```

Additional options

To disable or re-enable the local-in policy, use the `set status {enable | disable}` command.

To dedicate the interface as an HA management interface, use the `set ha-mgmt-intf-only enable` command.

Example:

```
config firewall local-in-policy
    edit 1
        set ha-mgmt-intf-only enable
        set intf port4
        set srcaddr all
        set dstaddr all
        set service ALL
        set schedule always
        set action accept
        set status enable
    next
end
```

If a user tries to set the HA reserved management interface during the local-in policy an error is generated. Use the `set ha-mgmt-intf-only enable` command to avoid the error.

TTL policies

You can configure a time-to-live (TTL) policy to block attack traffic with high TTLs. This feature only applies to local-in traffic and does not apply to traffic passing through the FortiGate. You can use `srcintf` to set the interface that the local-in traffic hits. See config firewall ttl-policy.

To configure a TTL policy using the CLI:

```
config firewall ttl-policy
    edit <id>
        set status {enable | disable}
        set action {accept | deny}
        set srcintf <interface>
        set srcaddr <source_address> [source_address] ...
```

```
        set service <service_name> [service_name] ...
        set schedule <schedule_name>
        set ttl <value/range>
    next
end
```

DoS policy

A Denial of Service (DoS) policy examines network traffic arriving at a FortiGate interface for anomalous patterns, which usually indicates an attack.

A denial of service occurs when an attacking system starts an abnormally large number of sessions with a target system. The large number of sessions slows down or disables the target system, preventing legitimate users from using it.

DoS policies are checked before security policies, preventing attacks from triggering more resource intensive security protection and slowing down the FortiGate.

DoS anomalies

Predefined sensors are setup for specific anomalous traffic patterns. New DoS anomalies cannot be added by the user.

The predefined anomalies that can be used in DoS policies are:

Anomaly	Description	Recommended Threshold
tcp_syn_flood	If the SYN packet rate of new TCP connections, including retransmission, to one destination IP address exceeds the configured threshold value, the action is executed.	2000 packets per second.
tcp_port_scan	If the SYN packet rate of new TCP connections, including retransmission, from one source IP address exceeds the configured threshold value, the action is executed.	1000 packets per second.
tcp_src_session	If the number of concurrent TCP connections from one source IP address exceeds the configured threshold value, the action is executed.	5000 concurrent sessions.
tcp_dst_session	If the number of concurrent TCP connections to one destination IP address exceeds the configured threshold value, the action is executed.	5000 concurrent sessions.
udp_flood	If the UDP traffic to one destination IP address exceeds the configured threshold value, the action is executed.	2000 packets per second.
udp_scan	If the UDP sessions setup rate originating from one source IP address exceeds the configured threshold value, the action is executed.	2000 sessions per second.
udp_src_session	If the number of concurrent UDP connections from one source IP address exceeds the configured threshold value, the action is executed.	5000 concurrent sessions.

Anomaly	Description	Recommended Threshold
udp_dst_session	If the number of concurrent UDP connections to one destination IP address exceeds the configured threshold value, the action is executed.	5000 concurrent sessions.
icmp_flood	If the number of ICMP packets sent to one destination IP address exceeds the configured threshold value, the action is executed.	250 packets per second.
icmp_sweep	If the ICMP sessions setup rate originating from one source IP address exceeds the configured threshold value, the action is executed.	100 sessions per second.
icmp_src_session	If the number of concurrent ICMP connections from one source IP address exceeds the configured threshold value, the action is executed.	300 concurrent sessions
icmp_dst_session	If the number of concurrent ICMP connections to one destination IP address exceeds the configured threshold value, the action is executed.	1000 concurrent sessions
ip_src_session	If the number of concurrent IP connections from one source IP address exceeds the configured threshold value, the action is executed.	5000 concurrent sessions.
ip_dst_session	If the number of concurrent IP connections to one destination IP address exceeds the configured threshold value, the action is executed.	5000 concurrent sessions.
sctp_flood	If the number of SCTP packets sent to one destination IP address exceeds the configured threshold value, the action is executed.	2000 packets per second
sctp_scan	If the number of SCTP sessions originating from one source IP address exceeds the configured threshold value, the action is executed.	1000 packets per second
sctp_src_session	If the number of concurrent SCTP connections from one source IP address exceeds the configured threshold value, the action is executed.	5000 concurrent sessions
sctp_dst_session	If the number of concurrent SCTP connections to one destination IP address exceeds the configured threshold value, the action is executed.	5000 concurrent sessions

For thresholds based on the number of concurrent sessions, blocking the anomaly will not allow more than the number of concurrent sessions to be set as the threshold.

For example, if the period for a particular anomaly is 60 seconds, such as those where the threshold is measured in concurrent sessions, after the 60 second timer has expired the number of allowed sessions that match the anomaly criteria is reset to zero. This means that, if you allow 10 sessions through before blocking, after the 60 seconds has elapsed, another 10 sessions will be allowed. The attrition of sessions from expiration should keep the allowed sessions from reaching the maximum.

For rate based thresholds, where the threshold is measured in packets per second, the *Block* action prevents anomalous traffic from overwhelming the firewall in two ways:

- continuous: Block packets once an anomaly is detected, and continue to block packets while the rate is above the threshold. This is the default setting.
- periodical: After an anomaly is detected, allow the configured number of packets per second.

For example, if a DoS policy is configured to block icmp_flood with a threshold of 10pps, and a continuous ping is started at a rate of 20pps for 1000 packets:

- In continuous mode, the first 10 packets are passed before the DoS sensor if triggered, and then the remaining 990 packets are blocked.
- In periodical mode, 10 packets are allowed to pass per second, so 500 packets are blocked in the 50 seconds during which the ping is occuring.

The actual numbers of passed and blocked packets may not be exact, as fluctuations in the rates can occur, but the numbers should be close to the defined threshold.

To configure the block action for rate based anomaly sensors:

```
config ips global
    set anomaly-mode {continuous | periodical}
end
```

DoS policies

A DoS policy can be configured to use one or more anomalies.

To configure a DoS policy in the GUI:

1. Go to *Policy & Objects* > *IPv4 DoS Policy* or *Policy & Objects* > *IPv6 DoS Policy* and click *Create New*.
   If the option is not visible, enable *DoS Policy* in *Feature Visibility*. See Feature visibility on page 2517 for details.

2. Configure the following:

Name	Enter a name for the policy.
Incoming Interface	Enter the interface that the policy applies to.
Source Address	Enter the source address.
Destination Address	Enter the destination address. This is the address that the traffic is addressed to. In this case, it must be an address that is associated with the firewall interface. For example, it could be an interface address, a secondary IP address, or the address assigned to a VIP address.
Service	Select the services or service groups. The ALL service can used or, to optimize the firewall resources, only the services that will be answered on an interface can be used.
L3 Anomalies **L4 Anomalies**	Configure the anomalies: • *Logging*: Enable/disable logging for specific anomalies or all of them. Anomalous traffic will be logged when the action is *Block* or *Monitor*. • *Action*: Select the action to take when the threshold is reached: • *Disable*: Do not scan for the anomaly. • *Block*: Block the anomalous traffic. • *Monitor*: Allow the anomalous traffic, but record a log message if logging is enabled. • *Threshold*: The number of detected instances that triggers the anomaly action.
Comments	Optionally, enter a comment.

3. Enable the policy, then click *OK*.

The quarantine option is only available in the CLI. See Quarantine on page 1070 for information.

To configure a DoS policy in the GUI:

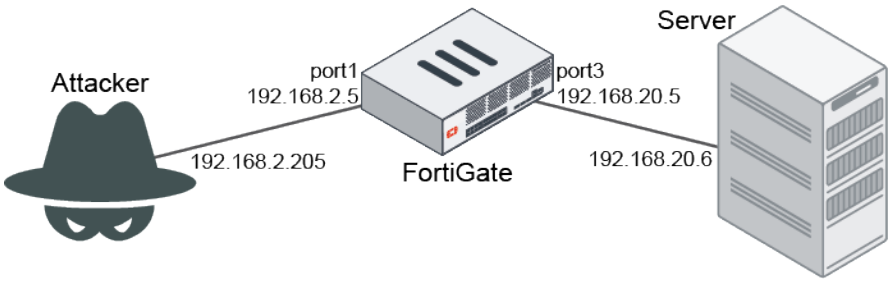
```
config firewall DoS-policy
    edit 1
        set name "Flood"
        set interface "port1"
        set srcaddr "all"
        set dstaddr "all"
        set service "ALL"
        config anomaly
            edit "icmp_flood"
                set status enable
                set log enable
                set action block
                set quarantine attacker
                set quarantine-expiry 1d1h1m
```

```
                set quarantine-log enable
                set threshold 100
            next
        end
    next
end
```

`name <string>`	Enter a name for the policy.
`interface <string>`	Enter the interface that the policy applies to.
`srcaddr <string>`	Enter the source address.
`dstaddr <string>`	Enter the destination address. This is the address that the traffic is addressed to. In this case, it must be an address that is associated with the firewall interface. For example, it could be an interface address, a secondary IP address, or the address assigned to a VIP address.
`service <string>`	Enter the services or service groups. The `ALL` service can used or, to optimize the firewall resources, only the services that will be answered on an interface can be used.
`status {enable | disable}`	Enable/disable this anomaly.
`log {enable | disable}`	Enable/disable anomaly logging. When enabled, a log is generated whenever the anomaly action is triggered, regardless of which action is configured.
`action {pass | block}`	Set the action to take when the threshold is reached: • `pass`: Allow traffic, but record a log message if logging is enabled. • `block`: Block traffic if this anomaly is found.
`quarantine {none | attacker}`	Set the quarantine method (see Quarantine on page 1070): • `none`: Disable quarantine. • `attacker`: Block all traffic from the attacker's IP address, and add the attacker's IP address to the banned user list.
`quarantine-expiry <###d##h##m>`	Set the duration of the quarantine, in days, hours, and minutes (###d##h##m) (1m - 364d23h59m, default = 5m). This option is available if `quarantine` is set `attacker`.
`quarantine-log {enable | disable}`	Enable/disable quarantine logging (default = disable). This option is available if `quarantine` is set `attacker`.
`threshold <integer>`	The number of detected instances - packets per second or concurrent session number - that triggers the anomaly action.

Quarantine

Quarantine is used to block any further traffic from a source IP address that is considered a malicious actor or a source of traffic that is dangerous to the network. Traffic from the source IP address is blocked for the duration of the quarantine, and the source IP address is added to the banned user list.



The banned user list is kept in the kernel, and used by Antivirus, Data Leak Prevention (DLP), DoS, and Intrusion Prevention System (IPS). Any policies that use any of these features will block traffic from the attacker's IP address.

To view the quarantined user list:

```
# diagnose user banned-ip list
src-ip-addr       created                  expires                  cause
192.168.2.205     Wed Nov 25 12:47:54 2020 Wed Nov 25 12:57:54 2020 DOS
```

Troubleshooting DoS attacks

The best way to troubleshoot DoS attacks is with Anomaly logs and IPS anomaly debug messages.

To test an icmp_flood attack:

1. From the Attacker, launch an icmp_flood with 50pps lasting for 3000 packets.
2. On the FortiGate, configure continuous mode and create a DoS policy with an icmp_flood threshold of 30pps:

```
config firewall DoS-policy
    edit 1
        set name icmpFlood
        set interface "port1"
        set srcaddr "all"
        set dstaddr "all"
        set service "ALL"
        config anomaly
            edit "icmp_flood"
                set status enable
                set log enable
                set action block
                set threshold 30
            next
        end
    next
end
```

3. Configure the debugging filter:

```
# diagnose ips anomaly config
DoS sensors in kernel vd 0:
DoS id 1 proxy 0
  0 tcp_syn_flood status 0 log 0 nac 0 action 0 threshold 2000
  ...
  7 udp_dst_session status 0 log 0 nac 0 action 0 threshold 5000
  8 icmp_flood status 1 log 1 nac 0 action 7 threshold 30
  9 icmp_sweep status 0 log 0 nac 0 action 0 threshold 100
  ...
total # DoS sensors: 1.
```

```
# diagnose ips anomaly filter id 8
```

4. Launch the icmp_flood from a Linux machine. This example uses Nmap:

```
$ sudo nping --icmp --rate 50 -c 3000 192.168.2.50
SENT (0.0522s) ICMP [192.168.2.205 > 192.168.2.50 Echo request (type=8/code=0) id=8597
seq=1] IP [ttl=64 id=47459 iplen=28 ]
...
Max rtt: 11.096ms | Min rtt: 0.028ms | Avg rtt: 1.665ms
Raw packets sent: 3000 (84.000KB) | Rcvd: 30 (840B) | Lost: 2970 (99.00%)
Nping done: 1 IP address pinged in 60.35 seconds
```

5. During the attack, check the anomaly list on the FortiGate:

```
# diagnose ips anomaly list
list nids meter:
id=icmp_flood         ip=192.168.2.50 dos_id=1 exp=998 pps=46 freq=50

total # of nids meters: 1.
```

id=icmp_flood	The anomaly name.
ip=192.168.2.50	The IP address of the host that triggered the anomaly. It can be either the client or the server. For icmp_flood, the IP address is the destination IP address. For icmp_sweep, it would be the source IP address.
dos_id=1	The DoS policy ID.
exp=998	The time to be expired, in jiffies (one jiffy = 0.01 seconds).
pps=46	The number of packets that had been received when the diagnose command was executed.
freq=50	For session based anomalies, freq is the number of sessions. For packet rate based anomalies (flood, scan): • In continuous mode: freq is the greater of pps, or the number of packets received in the last second. • In periodic mode: freq is the pps.

6. Go to *Log & Report* > *Security Events* and download the *Anomaly* logs:

```
date=2020-11-20 time=14:38:39 eventtime=1605911919824184594 tz="-0800"
logid="0720018433" type="utm" subtype="anomaly" eventtype="anomaly" level="alert"
vd="root" severity="critical" srcip=192.168.2.205 srccountry="Reserved"
dstip=192.168.2.50 srcintf="port1" srcintfrole="undefined" sessionid=0 action="clear_
session" proto=1 service="PING" count=1307 attack="icmp_flood" icmpid="0x2195"
icmptype="0x08" icmpcode="0x00" attackid=16777316 policyid=1 policytype="DoS-policy"
ref="http://www.fortinet.com/ids/VID16777316" msg="anomaly: icmp_flood, 31 > threshold
30, repeats 28 times" crscore=50 craction=4096 crlevel="critical"

date=2020-11-20 time=14:39:09 eventtime=1605911949826224056 tz="-0800"
logid="0720018433" type="utm" subtype="anomaly" eventtype="anomaly" level="alert"
vd="root" severity="critical" srcip=192.168.2.205 srccountry="Reserved"
dstip=192.168.2.50 srcintf="port1" srcintfrole="undefined" sessionid=0 action="clear_
session" proto=1 service="PING" count=1497 attack="icmp_flood" icmpid="0x2195"
icmptype="0x08" icmpcode="0x00" attackid=16777316 policyid=1 policytype="DoS-policy"
```

```
ref="http://www.fortinet.com/ids/VID16777316" msg="anomaly: icmp_flood, 50 > threshold
30, repeats 1497 times" crscore=50 craction=4096 crlevel="critical"
```

Analysis

In the first log message:

msg="anomaly: icmp_flood, 31 > threshold 30	At the beginning of the attack, a log is recorded when the threshold of 30pps is broken.
repeats 28 times	The number of packets that has exceeded the threshold since the last time a log was recorded.
srcip=192.168.2.205 dstip=192.168.2.50	The source and destination IP addresses of the attack.
action="clear_session"	Equivalent to block. If `action` was set to `monitor` and logging was enabled, this would be `action="detected"`.

In the second log message:

- Because it is an ongoing attack, the FortiGate generates one log message for multiple packets every 30 seconds..
- It will not generate a log message if:
  - The same attack ID happened more than once in a five second period, or
  - The same attack ID happened more than once in a 30 second period and the actions are the same and have the same source and destination IP addresses.

msg="anomaly: icmp_flood, 50 > threshold 30	In the second before the log was recorded, 50 packets were detected, exceeding the configured threshold.
repeats 1497 times	The number of packets that has exceeded the threshold since the last time a log was recorded

Access control lists

An access control list (ACL) is a granular, targeted blocklist that is used to block IPv4 and IPv6 packets on a specified interface based on the criteria configured in the ACL policy.

On FortiGate models with ports that are connected through an internal switch fabric with TCAM capabilities, ACL processing is offloaded to the switch fabric and does not use CPU resources. VLAN interfaces that are based on physical switch fabric interfaces are also supported. Interfaces that are connected through an internal switch fabric usually have names prefixed with *port* or *lan*, such as *port1* or *lan2*; other interfaces are not supported.

The packets will be processed by the CPU when offloading is disabled or not possible, such as when a port on a supported model does not connect to the internal fabric switch.

ACL is supported on the following FortiGate models:

- 100D, 100E, 100EF, 101E
- 140D, 140D-POE, 140E, 140E-POE
- 1500D, 1500DT

- 3000D, 3100D, 3200D, 3700D, 3800D
- All 300E and larger E-series models
- All 100F and larger F-series models

Example

To block all IPv4 and IPv6 telnet traffic from port2 to Company_Servers:

```
config firewall acl
    edit 1
       set interface "port2"
       set srcaddr "all"
       set dstaddr "Company_Servers"
       set service "TELNET"
    next
end
config firewall acl6
    edit 1
        set interface "port2"
        set srcaddr "all"
        set dstaddr "Company_Servers_v6"
        set service "TELNET"
    next
end
```

Diagnose commands

To check the number of packets dropped by an ACL:

```
# diagnose firewall acl counter
ACL id 1 dropped 0 packets
```

```
# diagnose firewall acl counter6
ACL id 2 dropped 0 packets
```

To clear the packet drop counters:

```
# diagnose firewall acl clearcounter
```

```
# diagnose firewall acl clearcounter6
```

Interface policies

Interface policies are implemented before the security policies and are only flow-based. They are configured in the CLI.

This feature allows you to attach a set of IPS policies with the interface instead of the forwarding path, so packets can be delivered to IPS before entering the firewall. This feature is used for following IPS deployments:

- One-Arm: By defining interface policies with IPS and DoS anomaly checks and enabling sniff-mode on the interface, the interface can be used for one-arm IDS.
- IPv6 IPS: IPS inspection can be enabled through interface IPv6 policy.

- Scan traffic that is destined to the FortiGate.
- Scan and log traffic that are silently dropped or flooded by Firewall or Multicast traffic.

IPS sensors can be assigned to an interface policy. Both incoming and outgoing packets are inspected by IPS sensor (signature).

To configure an interface policy:

```
config firewall interface-policy
    edit 1
        set status enable
        set comments 'test interface policy #1'
        set logtraffic utm
        set interface "port2"
        set srcaddr all
        set dstaddr all
        set service "ALL"
        set application-list-status disable
        set ips-sensor-status disable
        set dsri disable
        set av-profile-status enable
        set av-profile default
        set webfilter-profile-status disable
    next
end
```

Source NAT

The following topics provide instructions on configuring policies with source NAT:

- Static SNAT on page 1075
- Dynamic SNAT on page 1076
- Central SNAT on page 1086
- Configuring an IPv6 SNAT policy on page 1091
- SNAT policies with virtual wire pairs on page 1093

Static SNAT

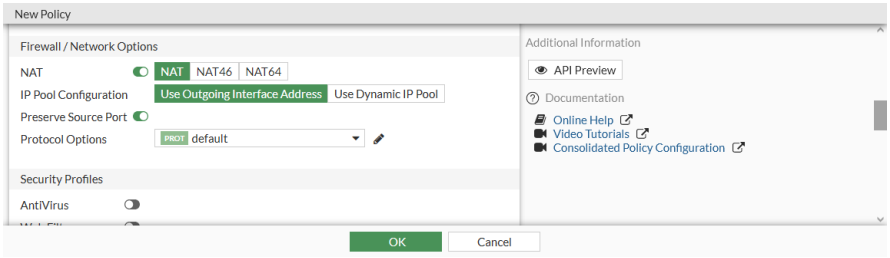
Network Address Translation (NAT) is the process that enables a single device such as a router or firewall to act as an agent between the Internet or Public Network and a local or private network. This agent acts in real time to translate the source or destination IP address of a client or server on the network interface. For the source IP translation, this enables a single public address to represent a significantly larger number of private addresses. For the destination IP translation, the firewall can translate a public destination address to a private address. So we don't have to configure a real public IP address for the server deployed in a private network.

We can subdivide NAT into two types: source NAT (SNAT) and destination NAT (DNAT). This topic is about SNAT, We support three NAT working modes: static SNAT, dynamic SNAT, and central SNAT.

In static SNAT all internal IP addresses are always mapped to the same public IP address. This is a port address translation, Since we have 60416 available port numbers, this one public IP address can handle the conversion of 60,416 internal IP addresses to the same service, where a service is defined by a specified protocol, destination IP address, and destination port.

Internal Source IP	Source Port	Translated Source IP	Translated Source Port
10.1.100.1	11110	172.16.200.1	5117
10.1.100.1	11111	172.16.200.1	5118
10.1.100.2	11112	172.16.200.1	5119
.....	.....	172.16.200.1	.....
.....	.....	172.16.200.1	65533

FortiGate firewall configurations commonly use the Outgoing Interface address.



Sample configuration

The following example of static SNAT uses an internal network with subnet 10.1.100.0/24 (vlan20) and an external/ISP network with subnet 172.16.200.0/24 (vlan30).

When the clients in internal network need to access the servers in external network, We need to translate IP addresses from 10.1.100.0/24 to an IP address 172.16.200.0/24, In this example, we implement static SNAT by creating a firewall policy.

To configure static NAT:

1. Go to *Policy & Objects* > *Firewall Policy* and click *Create New*.
2. Configure the required policy parameters.
3. Enable *NAT* and select *Use Outgoing Interface Address*. For packets that match this policy, its source IP address is translated to the IP address of the outgoing interface.
4. If needed, enable *Preserve Source Port* to keep the same source port for services that expect traffic to come from a specific source port. Disable *Preserve Source Port* to allow more than one connection through the firewall for that service.

5. Click *OK*.

Dynamic SNAT

Dynamic SNAT maps the private IP addresses to the first available public address from a pool of addresses. In the FortiGate firewall, this can be done by using IP pools. IP pools is a mechanism that allows sessions leaving the FortiGate firewall to use NAT. An IP pool defines a single IP address or a range of IP addresses to be used as the source address for the duration of the session. These assigned addresses are used instead of the IP address assigned to that FortiGate interface.

IP pool types

FortiGate uses four types of IPv4 IP pools. This topic focuses on some of the differences between them.

Overload

This type of IP pool is similar to static SNAT mode. We need to define an external IP range that contains one or more IP addresses. When there is only one IP address it is almost the same as static SNAT, the outgoing interface address is used. When it contains multiple IP addresses, it is equivalent to an extended mode of static SNAT.

For instance, if we define an overload type IP pool with two external IP addresses (172.16.200.1—172.16.200.2), since there are 60,416 available port numbers per IP, this IP pool can handle 60,416*2 internal IP addresses to the same service, where a service is defined by a specific protocol, destination IP address, and destination port.

Original Source IP	Original Source Port	Translated Source IP	Translated Source Port
10.1.100.1	11110	172.16.200.1	5117
10.1.100.2	11111	172.16.200.1	5118
.....	.....	172.16.200.1	.....
.....	.....	172.16.200.1	65533
.....	.....	172.16.200.2	5117
.....	.....	.....	.....
.....	.....	172.16.200.2	65533

The mapped IP address can be calculated from the source IP address. The index number of the address in the pool is the remainder of the source IP address, in decimal, divided by the number addresses in the pool.

To calculate the decimal value of the source IP address, either use an online calculator, or use the following equation:

$$a.b.c.d = a * (256)^3 + b * (256)^2 + c * (256) + d$$

For example:

$$192.168.0.1 = 192 * (256)^3 + 168 * (256)^2 + 0 * (256) + 1 = 3232235521$$

If there is one IP pool, where:

- P_1 = the first address in the IP pool
- R_1 = the number of IP addresses in the IP pool
- X = the source IP address as a decimal number
- Y = the mapped IP address

Then the equation to determine the mapped address is:

$$Y = P_1 + X \bmod R_1$$

For example:

IP pool	Source IP address
172.26.73.20 to 172.26.73.90	192.168.1.200

1. Convert the source IP address to a decimal number:

$$192 * (256)^3 + 168 * (256)^2 + 1 * (256) + 200 = 3232235976$$

2. Determine the number of IP addresses in the pool:
   172.26.73.90 - 172.26.73.20 = 71
3. Find the remainder of the source IP address divided by the number of addresses in the pool:
   3232235976 mod 71 = 26
4. Add the remainder to the first IP address in the pool:
   172.26.73.20 + 26 = 172.26.73.46

   So, the mapped IP address is **172.26.73.46**.

If there are multiple IP pools, the calculation is similar to when there is only one pool.

If there are two IP pools, where:

- P_1 = the first address in the first IP pool
- P_2 = the first address in the second IP pool
- R_1 = the number of IP addresses in the first IP pool
- R_2 = the number of IP addresses in the second IP pool
- X = the source IP address as a decimal number
- Y = the mapped IP address

Then the equations to determine the mapped address are:

If $X \bmod (R_1 + R_2) >= R_1$, then $Y = P_2 + X \bmod R_2$

If $X \bmod (R_1 + R_2) < R_1$, then $Y = P_1 + X \bmod R_1$

For example:

IP pools	Source IP address
pool01: 172.26.73.20 to 172.26.73.90	192.168.1.200
pool02: 172.26.75.50 to 172.26.75.150	

1. Convert the source IP address to a decimal number:
   $192 * (256)^3 + 168 * (256)^2 + 1 * (256) + 200 = 3232235976$
2. Determine the total number of IP addresses in the pools:
   (172.26.73.90 - 172.26.73.20) + (172.26.75.50 - 172.26.75.150) = 71 + 101 = 172
3. Find the remainder of the source IP address divided by the number of addresses in the pools:
   3232235976 mod 172 = 108
4. The remainder is greater than the number of addresses in pool01, so the address is selected from pool02 and the remainder is recalculated based only on pool02:
   3232235976 mod 101 = 40
5. Add the new remainder to the first IP address in pool02:
   172.26.75.50 + 40 = 172.26.75.90

   So, the mapped IP address is **172.26.75.90**.

One-to-one

This type of IP pool means that the internal IP address and the external (translated) IP address match one-to-one. The port address translation (PAT) is disabled when using this type of IP pool. For example, if we define a one-to-one type IP pool with two external IP addresses (172.16.200.1 - 172.16.200.2), this IP pool only can handle two internal IP addresses.

Fixed port range

For the overload and one-to-one IP pool types, we do not need to define the internal IP range. For the fixed port range type of IP pool, we can define both internal IP range and external IP range. Since each external IP address and the number of available port numbers is a specific number, if the number of internal IP addresses is also determined, we can calculate the port range for each address translation combination. So we call this type fixed port range. This type of IP pool is a type of port address translation (PAT).

For instance, if we define one external IP address (172.16.200.1) and ten internal IP addresses (10.1.100.1-10.1.100.10), we have translation IP+Port combination like following table:

Original Source IP	Original Source Port	Translated Source IP	Translated Source Port Range
10.1.100.1	.....	172.16.200.1	5117~11157
10.1.100.2	.....	172.16.200.1	11158~17198
10.1.100.3	.....	172.16.200.1	.....
10.1.100.4	.....	172.16.200.1	.....
10.1.100.5	.....	172.16.200.1	.....
10.1.100.6	.....	172.16.200.1	.....
10.1.100.7	.....	172.16.200.1	.....
10.1.100.8	.....	172.16.200.1	.....
10.1.100.9	.....	172.16.200.1	53445~59485
10.1.100.10	.....	172.16.200.1	59486~65526

Port block allocation

This type of IP pool is also a type of port address translation (PAT). It gives users a more flexible way to control the way external IPs and ports are allocated. Users need to define *Block Size/Block Per User* and external IP range. *Block Size* means how many ports each Block contains. *Block per User* means how many blocks each user (internal IP) can use.

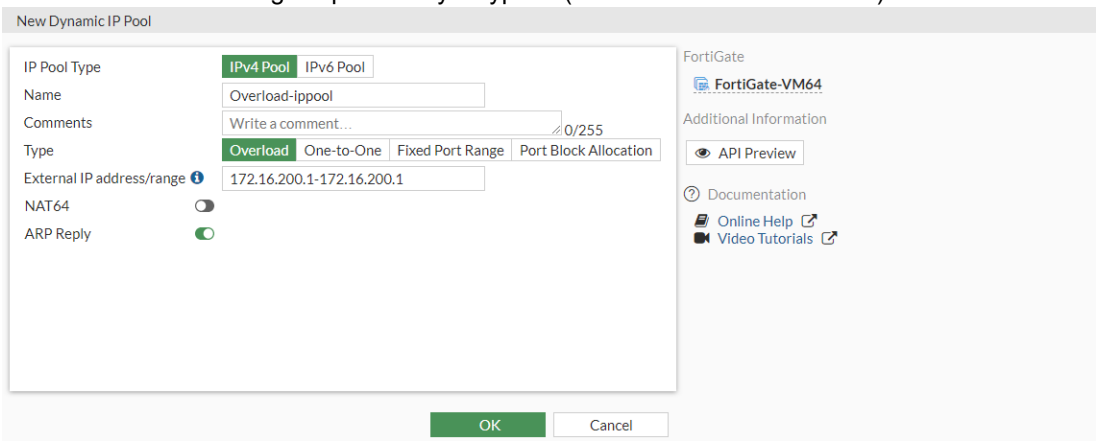
The following is a simple example:

- **External IP Range**: 172.16.200.1—172.16.200.1
- **Block Size**: 128
- **Block Per User**: 8

Result:

- **Total-PBAs**: 472 (60416/128)
- **Maximum ports can be used per User (Internal IP Address)**: 1024 (128*8)
- **How many Internal IP can be handled**: 59 (60416/1024 or 472/8)

Sample configuration

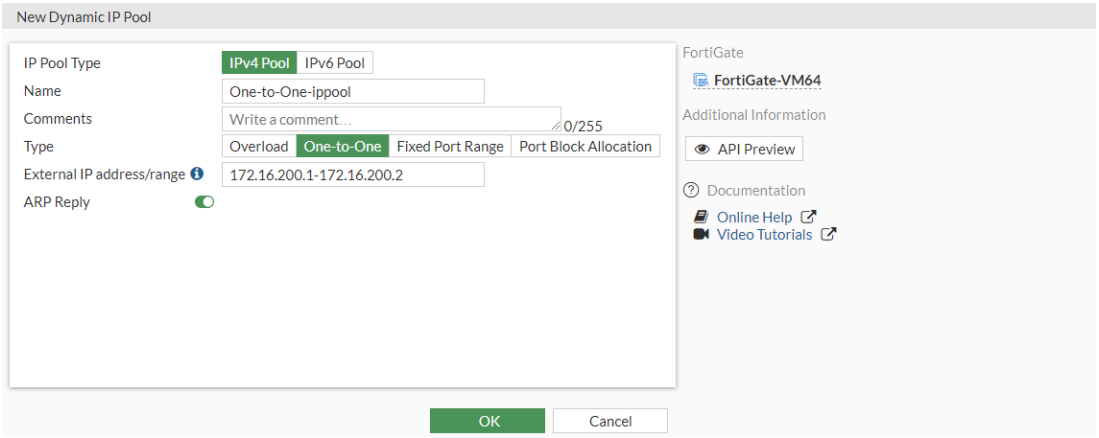


When an IP pool object is created with *ARP Reply* enabled, the object does not need to be referenced in any policies before a FortiGate interface starts responding to ARP requests for the addresses in the IP pool.

To configure overload IP pool in the GUI:

1. In *Policy & Objects* > *IP Pools*, click *Create New*.
2. Select *IPv4 Pool* and then select *Overload*.

3. Enter the external IP range separated by a hyphen (*172.16.200.1-172.16.200.1*).



4. Click *OK*.

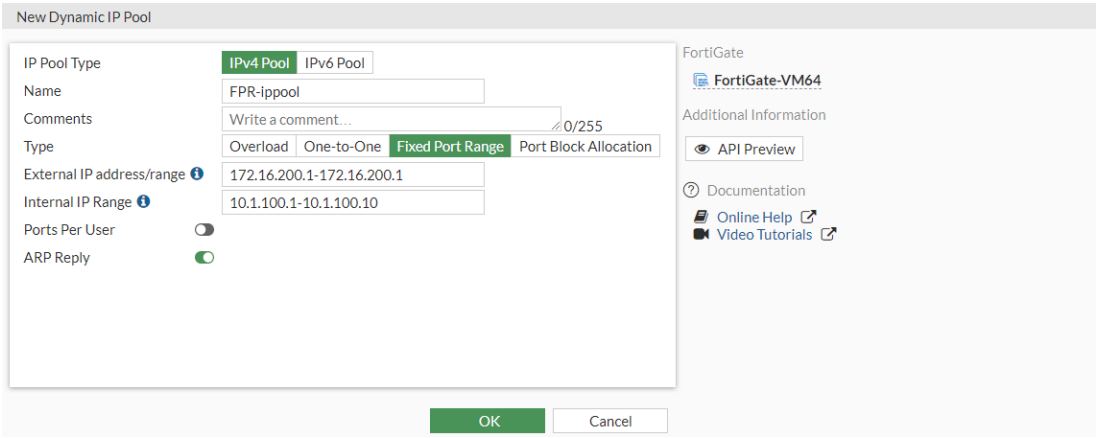
To configure overload IP pool in the CLI:

```
config firewall ippool
    edit "Overload-ippool"
        set startip 172.16.200.1
        set endip 172.16.200.1
    next
end
```

To configure one-to-one IP pool using the GUI:

1. In *Policy & Objects* > *IP Pools*, click *Create New*.
2. Select *IPv4 Pool* and then select *One-to-One*.
3. Enter the external IP range separated by a hyphen (*172.16.200.1-172.16.200.2*).

4. Click *OK*.



To configure one-to-one IP pool in the CLI:

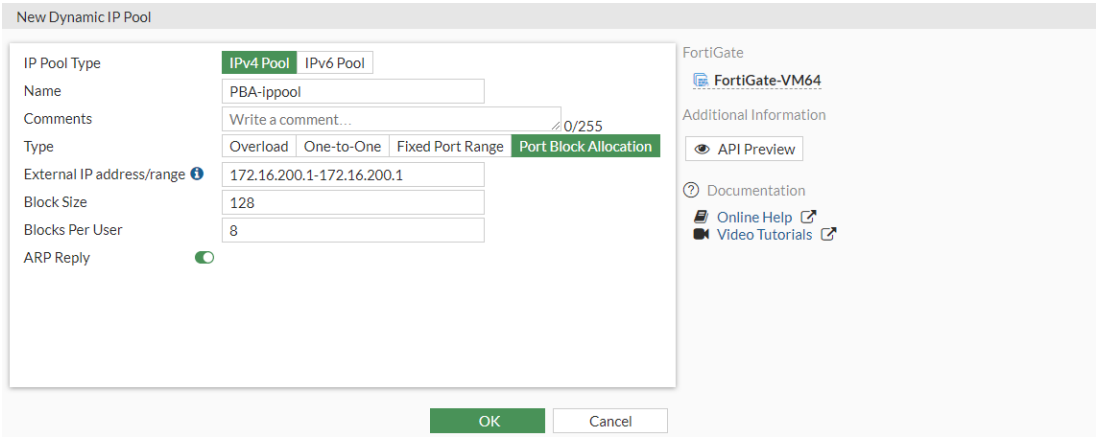
```
config firewall ippool
    edit "One-to-One-ippool"
        set type one-to-one
```

```
        set startip 172.16.200.1
        set endip 172.16.200.2
    next
end
```

To configure fixed port range IP pool in the GUI:

1. In *Policy & Objects* > *IP Pools*, click *Create New*.
2. Select *IPv4 Pool* and then select *Fixed Port Range*.
3. Enter the external IP range separated by a hyphen *172.16.200.1-172.16.200.1*).
4. Enter the internal IP range separated by a hyphen *10.1.100.1-10.1.100.10*).

5. Click *OK*.



To configure fixed port range IP pool in the CLI:

```
config firewall ippool
    edit "FPR-ippool"
        set type fixed-port-range
        set startip 172.16.200.1
        set endip 172.16.200.1
        set source-startip 10.1.100.1
        set source-endip 10.1.100.10
   next
end
```

To configure port block allocation IP pool in the GUI:

1. In *Policy & Objects* > *IP Pools*, click *Create New*.
2. Select *IPv4 Pool* and then select *Port Block Allocation*.

3. Enter the external IP range separated by a hyphen *172.16.200.1-172.16.200.1*).

4. Click *OK*.

To configure port block allocation IP pool in the CLI:

```
config firewall ippool
    edit PBA-ippool
        set type port-block-allocation
        set startip 172.16.200.1
        set endip 172.16.200.1
        set block-size 128
        set num-blocks-per-user 8
    next
end
```

IP pools and blackhole route configuration

In FortiOS 7.0.1 and above, all IP addresses used as IP pools and VIPs are no longer considered local IP addresses if responding to ARP requests on these external IP addresses is enabled (`set arp-reply enable`, by default). In this case, the FortiGate is not considered a destination for those IP addresses and cannot receive reply traffic at the application layer without special handling.

- This behavior affects FortiOS features in the application layer that use an IP pool as its source IP pool including SSL VPN web mode, explicit web proxy, and the Phase 1 local gateway of an interface mode IPsec VPN.
- The FortiGate will not receive reply traffic at the application layer and the corresponding the FortiOS feature will not work as desired.
- Configuring an IP pool as the source NAT IP address in a regular firewall policy works as before.

For explicit proxy setups, one set of these steps is sufficient to avoid the issue:

- Delete the blackhole route and ensure another route is defined that matches traffic for the IP pool reply traffic, or
- Keep the blackhole route and if the IP pool consists of a single IP address, configure this IP address as a secondary IP address on an outgoing FortiGate interface. In this case, the secondary IP address is considered a local address, which allows the FortiGate to be considered a destination that can receive IP pool reply traffic.

For SSL VPN web mode setups, the following steps are sufficient to avoid the issue:

- Configure `set web-mode-snat enable` within `config vpn ssl settings` and configure the first IP address in the IP pool as a secondary IP address on the outgoing FortiGate interface defined in the SSL VPN web mode firewall policy. In this case, the secondary IP address is considered a local address, which allows the FortiGate to be

considered a destination that can receive IP pool reply traffic. `set web-mode-snat enable` was added in FortiOS 7.0.6 and 7.2.0 and then removed in FortiOS 7.2.6, 7.4.0, and future versions after 7.0.12.

For a given VDOM, if different SSL VPN web mode destinations need to go out from different interfaces, then each destination would need to have a different IP pool specified in the corresponding firewall policy.

For interface mode IPsec VPN setups with local gateway configured, the following steps are sufficient to avoid the issue:

- Keep the interface mode IPsec VPN Phase 1 local gateway configured as the IP pool and if the IP pool consists of a single IP address, configure this IP address as a secondary IP address on an outgoing FortiGate interface. In this case, the secondary IP address is considered a local address which allows the FortiGate to be considered a destination that can receive IP pool reply traffic.

Explicit proxy configuration example

In this explicit proxy configuration example, an IP pool with a single IP address is configured with `set arp-reply enable` configured by default along with a blackhole route that matches the reply traffic destined to the IP pool.

```
config firewall ippool
    edit "ippool1"
        set startip 1.1.1.1
        set endip 1.1.1.1
    next
end
config router static
    edit 1
        set dst 1.1.1.0 255.255.255.0
        set blackhole enable
    next
end
```

Suppose the explicit web proxy on the FortiGate has already been enabled and configured using steps described in Explicit web proxy on page 258. In the corresponding proxy policy, configure the IP pool ippool1 as the source IP address.

```
config firewall proxy-policy
    edit 1
        set name "allow_traffic"
        set proxy explicit-web
        set dstintf "port1"
        set srcaddr "all"
        set poolname "ippool1"
        set dstaddr "all"
        set service "webproxy"
        set action accept
        set schedule "always"
    next
end
```

Because the blackhole route matches the reply traffic to the IP pool and drops it, then reply traffic cannot reach the explicit web proxy on the FortiGate.

To resolve the issue caused by the blackhole route configuration, you can consider configuring one of the following settings:

- Delete the blackhole route and ensure another route is defined that matches traffic for the IP pool reply traffic.
  In the example below, a default route for outgoing interface port1 is defined which matches the IP pool reply traffic.

```
config router static
    delete 1
    edit 2
        set dst 0.0.0.0 0.0.0.0
        set device port1
    next
end
```

- Keep the blackhole route and if the IP pool consists of a single IP address as in this example, configure this IP address as a secondary IP address on an outgoing FortiGate interface.
  In the example below, the outgoing interface port1 has a secondary IP of 1.1.1.1/24 defined on it.

```
config system interface
    edit DMZ
        set secondary-IP enable
        config secondaryip
            edit 1
                set ip 1.1.1.1 255.255.255.0
            next
        end
    next
end
```

SSL VPN web mode configuration example

In this SSL VPN web mode configuration example, an IP pool with a single IP address is configured with `set arp-reply enable` configured by default along with a blackhole route that matches the reply traffic destined to the IP pool.

```
config firewall ippool
    edit "ippool1"
        set startip 1.1.1.1
        set endip 1.1.1.1
    next
end
config router static
    edit 1
        set dst 1.1.1.0 255.255.255.0
        set blackhole enable
    next
end
```

Suppose SSL VPN web mode has already been configured on the FortiGate using steps described in SSL VPN web mode for remote user on page 1906. In the corresponding SSL VPN web mode firewall policy, configure the IP pool ippool1 as the source IP address and dynamic SNAT pool.

```
config firewall policy
    edit 1
        set name "SSL_Web_SFTP"
        set srcintf "ssl.root"
        set dstintf "DMZ"
        set action accept
        set srcaddr "all"
        set dstaddr "SFTP_SERVER"
        set schedule "always"
```

```
        set service "ALL"
        set logtraffic all
        set nat enable
        set fixedport enable
        set ippool enable
        set poolname "SSL_Web_SFTP"
        set groups "SSL_VPN_WEB_SFTP"
    next
end
```

Because the blackhole route matches the reply traffic to the IP pool and drops it, then reply traffic from the secure FTP server connected to the FortiGate DMZ interface cannot reach the FortiGate SSL VPN web portal.

To resolve the issue caused by the blackhole route configuration, configure the following settings:

- Keep the blackhole route, configure `set web-mode-snat enable` within `config vpn ssl settings` and if the IP pool consists of a single IP address as in this example, configure this IP address as a secondary IP address on the outgoing FortiGate interface defined in the SSL VPN web mode firewall policy. `set web-mode-snat enable` was added in FortiOS 7.0.6 and 7.2.0 and then removed in FortiOS 7.2.6, 7.4.0, and future versions after 7.0.12.

  For a given VDOM, if different SSL VPN web mode destinations need to go out from different interfaces, then each destination would need to have a different IP pool specified in the corresponding firewall policy.

  In the example below, the `web-mode-snat` option is enabled and the DMZ interface is the outgoing interface used to reach the secure FTP server that requires a secondary IP of 1.1.1.1/24 to be defined on it.

```
config vpn ssl settings
...
    set web-mode-snat enable
...
end
config system interface
    edit DMZ
        set secondary-IP enable
        config secondaryip
            edit 1
                set ip 1.1.1.1 255.255.255.0
            next
        end
    next
end
```

Interface mode IPsec VPN with local gateway configuration example

In this interface mode IPsec VPN with local gateway configuration example, an IP pool with a single IP address is configured with `set arp-reply enable` configured by default and this IP pool is specified with the local gateway setting.

```
config firewall ippool
    edit "ippool2"
        set startip 1.2.3.4
        set endip 1.2.3.4
    next
end
config vpn ipsec phase1-interface
```

```
    edit "VPN1"
        ...
        set local-gw 1.2.3.4
        ...
    next
end
```

Since the local gateway is configured with the IP address that matches an IP pool, this IP address is not considered local. Then, the IPsec VPN Phase 1 negotiation will fail and the IPsec tunnel will not come up as expected.

To resolve the issue caused by the IP pool not being considered a local address for the interface mode IPsec VPN local gateway setting, configure the following settings:

- Keep the interface mode IPsec VPN Phase 1 local gateway configured as the IP pool and if the IP pool consists of a single IP address, configure this IP address as a secondary IP address on the outgoing FortiGate interface used with the interface mode IPsec VPN tunnel. In this case, the secondary IP address is considered a local address, which allows the FortiGate to be considered a destination that can receive IP pool reply traffic.

In the example below, the outgoing interface port2 is the physical interface used for the interface mode IPsec VPN tunnel. Therefore, define a secondary IP of 1.2.3.4/24 on this interface to ensure that IPsec Phase 1 negotiation succeeds and allows the IPsec tunnel to come up.

```
config system interface
    edit port2
        set secondary-IP enable
        config secondaryip
            edit 1
                set ip 1.2.3.4 255.255.255.0
            next
        end
    next
end
```

Central SNAT

The central SNAT table enables you to define and control (with more granularity) the address translation performed by FortiGate. With the NAT table, you can define the rules for the source address or address group, and which IP pool the destination address uses.

FortiGate reads the NAT rules from the top down until it hits a matching rule for the incoming address. This enables you to create multiple NAT policies that dictate which IP pool is used based on source address, destination address, and source port. NAT policies can be rearranged within the policy list. NAT policies are applied to network traffic after a security policy.

The central SNAT table allows you to create, edit, delete, and clone central SNAT entries.

Central SNAT notes

- The central NAT feature is not enabled by default.
- If central NAT is enabled, the NAT option under IPv4 policies is skipped and SNAT must be done via `central-snat-map`. The firewall policy list and dialog boxes have messages and redirection links to show this information.
- If NGFW mode is policy-based, then it is assumed that central NAT (specifically SNAT) is enabled implicitly.

Sample configuration

To enable central SNAT from the GUI:

1. In *System* > *Settings*, under *System Operations Settings*, enable *Central SNAT*.
2. Click *Apply*.

To enable or disable central SNAT using the CLI:

```
config system settings
   set central-nat {enable | disable}
end
```

When central NAT is enabled, *Policy & Objects* displays the Central SNAT section.

The Central SNAT policy has many options:

Field	Description
Type	Specify whether you are performing SNAT on IPv4 or IPv6. This option only appears when IPv6 is enabled under Feature Visibility.
Incoming Interface	Specify one or more interfaces for the ingress traffic.
Outgoing Interface	Specify one or more interfaces for the egress traffic.
Source Address	Specify the address or address group of the source.
Destination Address	Specify the address or address group of the destination.
NAT	Enable or disable to perform NAT. When disabled, no source address translation will occur.
IP Pool Configuration	Use outgoing interface address: • Use the address of the outgoing interfaces as source address. Use Dynamic IP Pool: • Choose an IP Pool to perform source NAT.
Protocol	Choose from any, TCP, UDP, SCTP, or specify the protocol number to match. For example, for ICMP, click *specify* with the protocol number 1.
Explicit port mapping	Enable in order to match this NAT policy only when the following ports are a match: • Choose an original source port from one to 65535. NAT'd port will be chosen by the FortiGate based on the IP Pool configuration. Explicit port mapping cannot apply to some protocols which do not use ports, such as ICMP. When enabling a NAT policy which uses Explicit port mapping, always consider that ICMP traffic will not match this policy. When using IP Pools, only the Overload type IP Pool allows Explicit port mapping. When Explicit port mapping is applied, you must define an original source port range and a translated sort port range. The source port will map one to one with the translated port. Refer to Dynamic SNAT to understand how each IP Pool type works.

Field	Description
Comments	Enter comments for this NAT policy.
Enable this policy	Enable or disable this policy.

To configure central SNAT using the CLI:

```
config firewall central-snat-map
    edit <policyID number>
        set status {enable | disable}
        set orig-addr <valid address object preconfigured on the FortiGate>
        set srcintf <name of interface on the FortiGate>
        set dst-addr <valid address object preconfigured on the FortiGate>
        set dstintf <name of interface on the FortiGate>
        set protocol <integer for protocol number>
        set orig-port <integer for original port number>
        set nat-port <integer for translated port number>
        set comments <string>
    next
end
```

Example one

Apply SNAT to all traffic from port2 to port3.

To configure from the CLI:

```
config firewall central-snat-map
    edit 1
        set srcintf "port3"
        set dstintf "port2"
        set orig-addr "all"
        set dst-addr "all"
    next
end
```

Example two

Apply an IP Pool to all traffic from port3 to port2 that are TCP. NAT all other traffic using the outgoing interface IP.

To configure from the CLI:

```
config firewall ippool
    edit "Overload-IPPOOL"
        set startip 192.168.2.201
        set endip 192.168.2.202
    next
end
config firewall central-snat-map
    edit 1
        set srcintf "port3"
        set dstintf "port2"
        set orig-addr "all"
```

```
        set dst-addr "all"
        set protocol 6
        set nat-ippool "Overload-IPPOOL"
    next
    edit 2
        set srcintf "port3"
        set dstintf "port2"
        set orig-addr "all"
        set dst-addr "all"
    next
end
```

To collect session table output from the CLI:

```
diagnose sys session list
```

The TCP session (protocol 6) is NAT'd with Overload-IPPOOL to 192.168.2.201:

```
session info: proto=6 proto_state=05 duration=14 expire=0 timeout=3600 flags=00000000
socktype=0 sockport=0 av_idx=0 use=3
origin-shaper=
reply-shaper=
per_ip_shaper=
class_id=0 ha_id=0 policy_dir=0 tunnel=/ vlan_cos=0/255
state=may_dirty
statistic(bytes/packets/allow_err): org=860/7/1 reply=555/8/1 tuples=2
tx speed(Bps/kbps): 60/0 rx speed(Bps/kbps): 38/0
orgin->sink: org pre->post, reply pre->post dev=9->6/6->9 gwy=192.168.2.1/192.168.0.10
hook=post dir=org act=snat 192.168.0.10:49531->23.57.57.114:443(192.168.2.201:61776)
hook=pre dir=reply act=dnat 23.57.57.114:443->192.168.2.201:61776(192.168.0.10:49531)
pos/(before,after) 0/(0,0), 0/(0,0)
dst_mac=04:d5:90:5f:a2:2a
misc=0 policy_id=2 auth_info=0 chk_client_info=0 vd=0
serial=00011065 tos=ff/ff app_list=0 app=0 url_cat=0
sdwan_mbr_seq=0 sdwan_service_id=0
rpdb_link_id=00000000 rpdb_svc_id=0 ngfwid=n/a
npu_state=0x040000
```

A UDP session (protocol 17) is NAT'd to the outgoing interface IP address 192.168.2.86:

```
session info: proto=17 proto_state=01 duration=16 expire=163 timeout=0 flags=00000000
socktype=0 sockport=0 av_idx=0 use=3
origin-shaper=
reply-shaper=
per_ip_shaper=
class_id=0 ha_id=0 policy_dir=0 tunnel=/ helper=dns-udp vlan_cos=0/255
state=may_dirty
statistic(bytes/packets/allow_err): org=59/1/1 reply=187/1/1 tuples=2
tx speed(Bps/kbps): 3/0 rx speed(Bps/kbps): 11/0
orgin->sink: org pre->post, reply pre->post dev=9->6/6->9 gwy=192.168.2.1/192.168.0.10
hook=post dir=org act=snat 192.168.0.10:52177->4.2.2.1:53(192.168.2.86:61770)
hook=pre dir=reply act=dnat 4.2.2.1:53->192.168.2.86:61770(192.168.0.10:52177)
dst_mac=04:d5:90:5f:a2:2a
misc=0 policy_id=2 auth_info=0 chk_client_info=0 vd=0
serial=00011061 tos=ff/ff app_list=0 app=0 url_cat=0
sdwan_mbr_seq=0 sdwan_service_id=0
rpdb_link_id=00000000 rpdb_svc_id=0 ngfwid=n/a
npu_state=0x040000
```

Example three

Apply an IP Pool to all traffic from port3 to port2 that have a specific original port range, mapping the ports to the same NAT'd port range. Nat all other traffic using the outgoing interface IP.

To configure from the CLI:

```
config firewall central-snat-map
    edit 1
        set srcintf "port3"
        set dstintf "port2"
        set orig-addr "all"
        set dst-addr "all"
        set orig-port 50000-65535
        set nat-ippool "Overload-IPPOOL"
        set nat-port 50000-65535
    next
    edit 2
        set srcintf "port3"
        set dstintf "port2"
        set orig-addr "all"
        set dst-addr "all"
    next
end
```

To collect session table output from the CLI:

```
diagnose sys session list
```

Traffic with original port in the range between 50000-65535 will be NAT'd with the Overload type IP Pool. The mapped port is in the same port range:

```
session info: proto=17 proto_state=01 duration=3 expire=176 timeout=0 flags=00000000
socktype=0 sockport=0 av_idx=0 use=3
origin-shaper=
reply-shaper=
per_ip_shaper=
class_id=0 ha_id=0 policy_dir=0 tunnel=/ helper=dns-udp vlan_cos=0/255
state=may_dirty
statistic(bytes/packets/allow_err): org=71/1/1 reply=123/1/1 tuples=2
tx speed(Bps/kbps): 23/0 rx speed(Bps/kbps): 40/0
orgin->sink: org pre->post, reply pre->post dev=9->6/6->9 gwy=192.168.2.1/192.168.0.10
hook=post dir=org act=snat 192.168.0.10:52540->4.2.2.1:53(192.168.2.201:52540)
hook=pre dir=reply act=dnat 4.2.2.1:53->192.168.2.201:52540(192.168.0.10:52540)
dst_mac=04:d5:90:5f:a2:2a
misc=0 policy_id=2 auth_info=0 chk_client_info=0 vd=0
serial=00011399 tos=ff/ff app_list=0 app=0 url_cat=0
sdwan_mbr_seq=0 sdwan_service_id=0
rpdb_link_id=00000000 rpdb_svc_id=0 ngfwid=n/a
npu_state=0x040000
```

Traffic with original port outside the range of 50000-65535 will be NAT'd to the outgoing interface IP:

```
session info: proto=6 proto_state=01 duration=3 expire=3597 timeout=3600 flags=00000000
socktype=0 sockport=0 av_idx=0 use=3
origin-shaper=
reply-shaper=
```

```
per_ip_shaper=
class_id=0 ha_id=0 policy_dir=0 tunnel=/ vlan_cos=0/255
state=may_dirty
statistic(bytes/packets/allow_err): org=2262/10/1 reply=2526/11/1 tuples=2
tx speed(Bps/kbps): 741/5 rx speed(Bps/kbps): 828/6
orgin->sink: org pre->post, reply pre->post dev=9->6/6->9 gwy=192.168.2.1/192.168.0.10

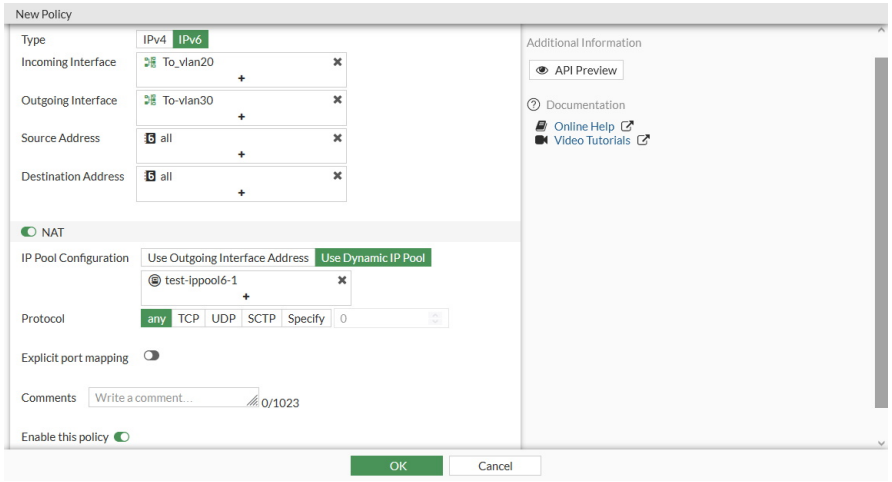
Configuring an IPv6 SNAT policy

IPv4 and IPv6 central SNAT maps are displayed in the same table.



To configure an IPv6 policy with central SNAT in the GUI:

1. Enable central SNAT:
   a. In the Global VDOM, go to *System* > *VDOM*.
   b. Select a VDOM and click *Edit*. The *Edit Virtual Domain Settings* pane opens.
   c. Enable *Central SNAT*.

d. Click *OK*.

2. In the VDOM with central SNAT enabled (FG-traffic in this example), go to *Policy & Objects* > *Central SNAT* and click *Create New*.
3. Configure the policy settings:
   a. For *Type*, select *IPv6*.
   b. Enter the interface, address, and IP pool information.
   c. Configure the remaining settings as needed.

d. Click *OK*.

The matching SNAT traffic will be handled by the IPv6 central SNAT map.

To configure an IPv6 policy with central SNAT in the CLI:

1. Enable central SNAT:

```
config vdom
    edit FG-traffic
        config system settings
            set central-nat enable
        end
    next
end
```

2. Create an IPv6 central SNAT policy:

```
config vdom
    edit FG-traffic
        config firewall central-snat-map
```

```
            edit 2
                set type ipv6
                set srcintf "wan2"
                set dstintf "wan1"
                set orig-addr6 "all"
                set dst-addr6 "all"
                set nat-ippool6 "test-ippool6-1"
            next
        end
    next
end
```

3. Verify the SNAT traffic:

```
(FG-traffic) # diagnose sniffer packet any icmp6 4
interfaces=[any]
filters=[icmp6]
3.602891 wan2 in 2000:10:1:100::41 -> 2000:172:16:200::55: icmp6: echo request seq 0
3.602942 wan1 out 2000:172:16:200::199 -> 2000:172:16:200::55: icmp6: echo request seq 0
3.603236 wan1 in 2000:172:16:200::55 -> 2000:172:16:200::199: icmp6: echo reply seq 0
3.603249 wan2 out 2000:172:16:200::55 -> 2000:10:1:100::41: icmp6: echo reply seq 0
4.602559 wan2 in 2000:10:1:100::41 -> 2000:172:16:200::55: icmp6: echo request seq 1
4.602575 wan1 out 2000:172:16:200::199 -> 2000:172:16:200::55: icmp6: echo request seq 1
4.602956 wan1 in 2000:172:16:200::55 -> 2000:172:16:200::199: icmp6: echo reply seq 1
4.602964 wan2 out 2000:172:16:200::55 -> 2000:10:1:100::41: icmp6: echo reply seq 1
^C
8 packets received by filter
0 packets dropped by kernel
```

SNAT policies with virtual wire pairs

Source NAT (SNAT) can be configured in IPv4 and IPv6 policies with virtual wire pair (VWP) interfaces, and between VWP interfaces when central NAT is enabled.

To configure a policy using SNAT and a VWP interface when central NAT is disabled:

1. Create the VWP interface:

```
config system virtual-wire-pair
    edit "test-vw-1"
        set member "port1" "port4"
    next
end
```

2. Create the IP pool. The IP pool must have a different subnet than the VWP peers.

```
config firewall ippool
    edit "vwp-pool-1"
        set startip 172.16.222.99
        set endip 172.16.222.100
    next
end
```

3. Configure the firewall policy:

```
config firewall policy
    edit 88
```

```
        set srcintf "port4"
        set dstintf "port1"
        set srcaddr "all"
        set dstaddr "all"
        set action accept
        set schedule "always"
        set service "ALL"
        set logtraffic all
        set nat enable
        set ippool enable
        set poolname "vwp-pool-1"
    next
end
```

4. Verify the IP pool functions as expected and traffic passes through:

```
# diagnose sniffer packet any icmp 4
interfaces=[any]
filters=[icmp]
23.438095 port4 in 172.16.200.11 -> 172.16.200.156: icmp: echo request
23.438126 port1 out 172.16.222.100 -> 172.16.200.156: icmp: echo request
23.438492 port1 in 172.16.200.156 -> 172.16.222.100: icmp: echo reply
23.438501 port4 out 172.16.200.156 -> 172.16.200.11: icmp: echo reply
24.439305 port4 in 172.16.200.11 -> 172.16.200.156: icmp: echo request
24.439319 port1 out 172.16.222.100 -> 172.16.200.156: icmp: echo request
24.439684 port1 in 172.16.200.156 -> 172.16.222.100: icmp: echo reply
24.439692 port4 out 172.16.200.156 -> 172.16.200.11: icmp: echo reply

8 packets received by filter
0 packets dropped by kernel
```

To configure a SNAT between VWP interfaces when central NAT is enabled:

1. Enable central NAT:

```
config system settings
    set central-nat enable
end
```

2. Create the VWP interface:

```
config system virtual-wire-pair
    edit "test-vw-1"
        set member "port1" "port4"
    next
end
```

3. Create the IP pool. The IP pool must have a different subnet than the VWP peers.

```
config firewall ippool
    edit "vwp-pool-1"
        set startip 172.16.222.99
        set endip 172.16.222.100
    next
end
```

4. Configure the SNAT policy:

```
config firewall central-snat-map
    edit 2
        set srcintf "port4"
        set dstintf "port1"
        set orig-addr "all"
        set dst-addr "all"
        set nat-ippool "vwp-pool-1"
    next
end
```

5. Configure the firewall policy:

```
config firewall policy
    edit 90
        set srcintf "port4"
        set dstintf "port1"
        set srcaddr "all"
        set dstaddr "all"
        set action accept
        set schedule "always"
        set service "ALL"
        set logtraffic all
    next
end
```

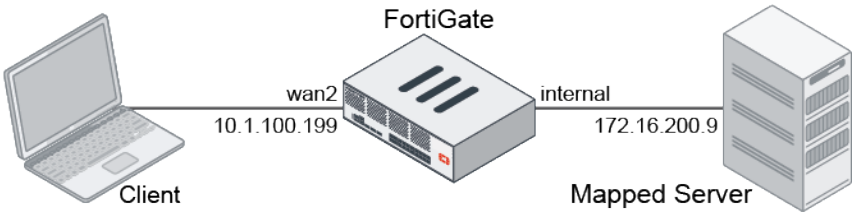
Destination NAT

The following topics provide instructions on configuring policies with destination NAT:

- Static virtual IPs on page 1095
- Virtual IP with services on page 1098
- Virtual IPs with port forwarding on page 1100
- Virtual server load balance on page 1102
- Central DNAT on page 1110
- Configure FQDN-based VIPs on page 1114
- Remove overlap check for VIPs on page 1115
- VIP groups on page 1116
- HTTP2 connection coalescing and concurrent multiplexing for virtual server load balancing on page 1117

Static virtual IPs

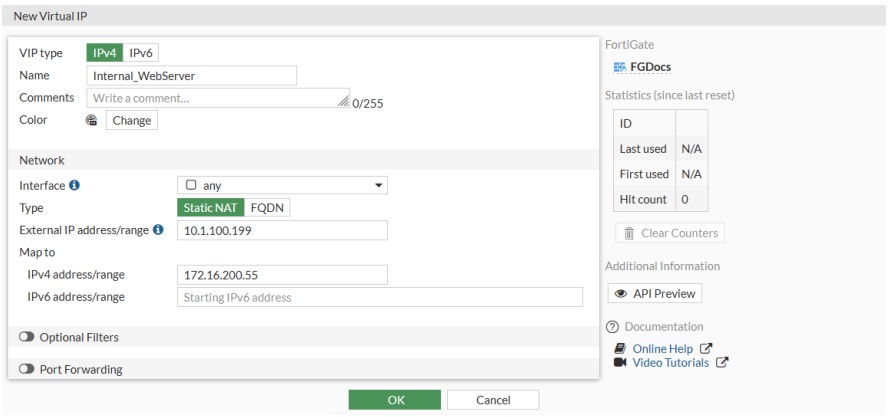
Static Virtual IPs (VIP) are used to map external IP addresses to internal IP addresses. This is also called destination NAT, where a packet's destination is being NAT'd, or mapped, to a different address.



Static VIPs are commonly used to map public IP addresses to resources behind the FortiGate that use private IP addresses. A static one-to-one VIP is when the entire port range is mapped. A port forwarding VIP is when the mapping is configured on a specific port or port range.

Some of the VIP configuration options are:

Setting	Description
VIP Type	• IPv4 (`config firewall vip`) - The source and destination are both IPv4. • IPv6 (`config firewall vip6`) - The source and destination are both IPv6. **Note:** *IPv6* is only available when *IPv6* is enabled in the *Feature Visibility*.
Interface (`extintf`)	The external interface that the firewall policy source interface must match. For example, if the external interface is port1, then the VIP can be used in a policy from port1 to port3, but not in a policy from port2 to port3. If the external interface is *any*, then the VIP can be used in any firewall policy.
Type (`type`)	• Static NAT - Use an external IP address or address range. • FQDN - Use an external IP or FQDN address. • load-balance (CLI only) - Load balance traffic. • server-load-balance - Load balance traffic across multiple servers. SSL processing can be offloaded to the FortiGate. This type of VIP is configure from *Policy & Objects* > *Virtual Servers*. • dns-translation (CLI only) - DNS translation. • access-proxy - Used for ZTNA. See ZTNA HTTPS access proxy example on page 953 for details.
External IP address/range (`extip`)	In a static NAT VIP, the external IP address is the IP address that the FortiGate listens for traffic on. When the external interface is not*any*, 0.0.0.0 can be used to make the external IP address equivalent to the external interface's IP address. The external IP address is also used to perform SNAT for the mapped server when the server outbound traffic with a destination interface that matches the external interface. The firewall policy must also have NAT enabled.
IPv4 address/range (`mappedip`)	The IPv4 address or range that the internal resource is being mapped to.
IPv6 address/range (`ipv6-mappedip`)	The IPv6 address or range that the internal resource is being mapped to.
`srcintf-filter` (CLI only)	Listen for traffic to the external IP address only on the specified interface. While the external interface restricts the policies where the VIP can be used, it does not restrict listening to only the external interface. To restrict listening to only a specific interface, `srcint-filter` must be configured.
`nat-source-vip` (CLI only)	Force all of the traffic from the mapped server to perform SNAT with the external IP address, regardless of the destination interface. If `srcint-filter` is defined, then `nat-source-vip` only forces SNAT to be performed when the destination matches the `srcintf-filter` interface. In both cases, the firewall policy must have NAT enabled.
`arp-reply` (CLI only)	Enable/disable responding to ARP requests on the external IP address (default = enable).



Setting	Description
	When a VIP object is created with `arp-reply` enabled, the object does not need to be referenced in any policies before a FortiGate interface starts responding to ARP requests for the addresses in the VIP.
Source address (`src-filter`)	Restrict the source IP address, address range, or subnet that is allowed to access the VIP.
Services (`service`)	Set the services that are allowed to be mapped.
Port Forwarding (`portforward`)	Enable port forwarding to specify the port (`mappedport`) to map to. If no services are configured, you can configure the protocol (`protocol`) to use when forwarding packets, the external service port range (`extport`) to be mapped to a port range on the destination network, and the mapped port range (`mappedport` and `ipv6-mappedport`) on the destination network.
Port Mapping Type	• One to one - Each external service port is mapped to one port. A range is allowed, but the number of ports should be the same. • Many to Many - The port mapping can be one to one, one to many, or many to one. There are no restrictions on how many external ports must map to internal ports.

Sample configuration

To create a virtual IP in the GUI:

1. In *Policy & Objects* > *Virtual IPs* and click *Create New* > *Virtual IP*.
2. Select a *VIP Type* based on the IP versions used.
3. Enter a unique name for the virtual IP.
4. Enter values for the external IP address/range and map to IPv4/IPv6 address/range fields.

5. Click *OK*.

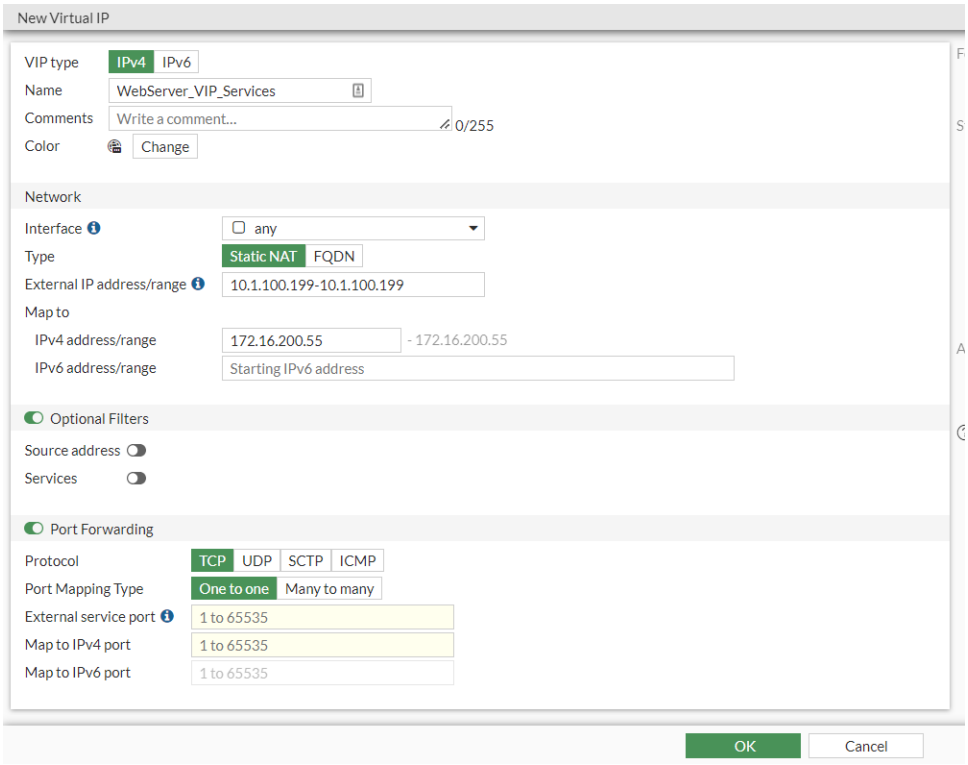
To create a virtual IP in the CLI:

```
config firewall vip
    edit "Internal_WebServer"
        set extip 10.1.100.199
        set extintf "any"
        set mappedip "172.16.200.55"
    next
end
```

To apply a virtual IP to policy in the CLI:

```
config firewall policy
    edit 8
        set name "Example_Virtual_IP_in_Policy"
        set srcintf "wan2"
        set dstintf "internal"
        set srcaddr "all"
        set dstaddr "Internal_WebServer"
        set action accept
        set schedule "always"
        set service "ALL"
        set nat enable
    next
end
```

Virtual IP with services



Virtual IP with services is a more flexible virtual IP mode. This mode allows users to define services to a single port number mapping.

This topic shows how to use virtual IP with services enabled. This example has one public external IP address. We map TCP ports 8080, 8081, and 8082 to an internal WebServer TCP port 80. This allows remote connections to communicate with a server behind the firewall.

Sample configuration

To create a virtual IP with services in the GUI:

1. In *Policy & Objects* > *Virtual IPs* and click *Create New* > *Virtual IP*.
2. Set *VIP Type* to *IPv4*.
3. Enter a unique name for the virtual IP and fill in the other fields.
4. Configure the fields in the *Network* section. For example:
   - Set *Interface* to *any*.
   - Set *External IP Address/Range* to *10.1.100.199*.
   - Set *Mapped IP Address/Range* to *172.16.200.55*.
5. Enable *Optional Filters* and then enable *Services*.
6. In the *Services* field click + to display the *Services* pane.
7. In the *Services* pane select *TCP_8080*, *TCP_8081*, and *TCP_8082*.
8. Enable *Port Forwarding* and set *Map to IPv4 port* to *80*.

9. Click *OK*.

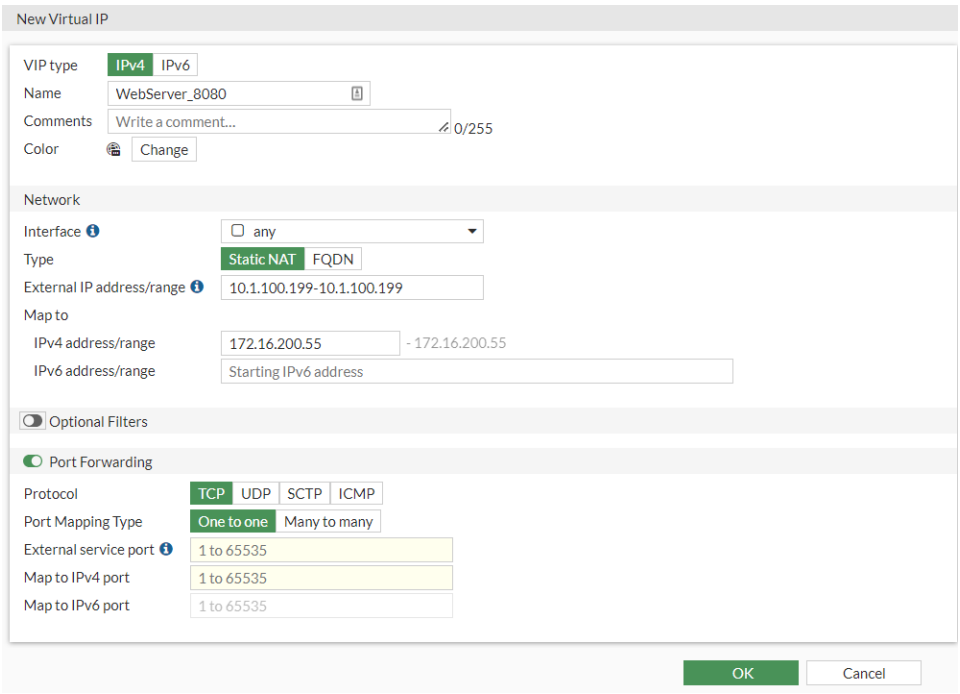
To see the results:

1. Apply the above virtual IP to the firewall policy.
2. The results are:
   - Access 10.1.100.199:8080 from external network and FortiGate maps to 172.16.200.55:80 in internal network.
   - Access 10.1.100.199:8081 from external network and FortiGate maps to 172.16.200.55:80 in internal network.
   - Access 10.1.100.199:8082 from external network and FortiGate maps to 172.16.200.55:80 in internal network.

To create a virtual IP with services in the CLI:

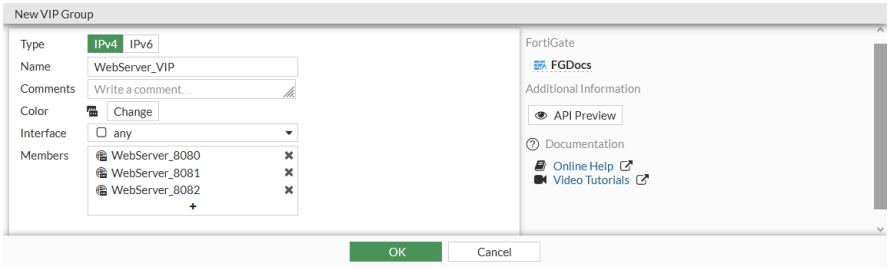
```
config firewall vip
    edit "WebServer_VIP_Services"
        set service "TCP_8080" "TCP_8081" "TCP_8082"
        set extip 10.1.100.199
        set extintf "any"
        set portforward enable
        set mappedip "172.16.200.55"
        set mappedport 80
    next
end
```

Virtual IPs with port forwarding



If you need to hide the internal server port number or need to map several internal servers to the same public IP address, enable port-forwarding for Virtual IP.

This topic shows how to use virtual IPs to configure port forwarding on a FortiGate unit. This example has one public external IP address. We map TCP ports 8080, 8081, and 8082 to different internal WebServers' TCP port 80. This allows remote connections to communicate with a server behind the firewall.



Sample configuration

To create a virtual IP with port forwarding in the GUI:

1. In *Policy & Objects* > *Virtual IPs*.
2. Click *Create New* and select *Virtual IP*.
3. For *VIP Type*, select *IPv4*.
4. Enter a unique name for the virtual IP and fill in the other fields.
5. Configure the fields in the *Network* section. For example:
   - Set *Interface* to *any*.
   - Set *External IP Address/Range* to *10.1.100.199*.
   - Set *Mapped IP Address/Range* to *172.16.200.55*.
6. Leave *Optional Filters* disabled.
7. Enable *Port Forwarding*.
8. Configure the fields in the *Port Forwarding* section. For example:
   - Set *Protocol* to *TCP*.
   - Set *External Service Port* to *8080*.
   - Set *Map to IPv4 port* to *80*.

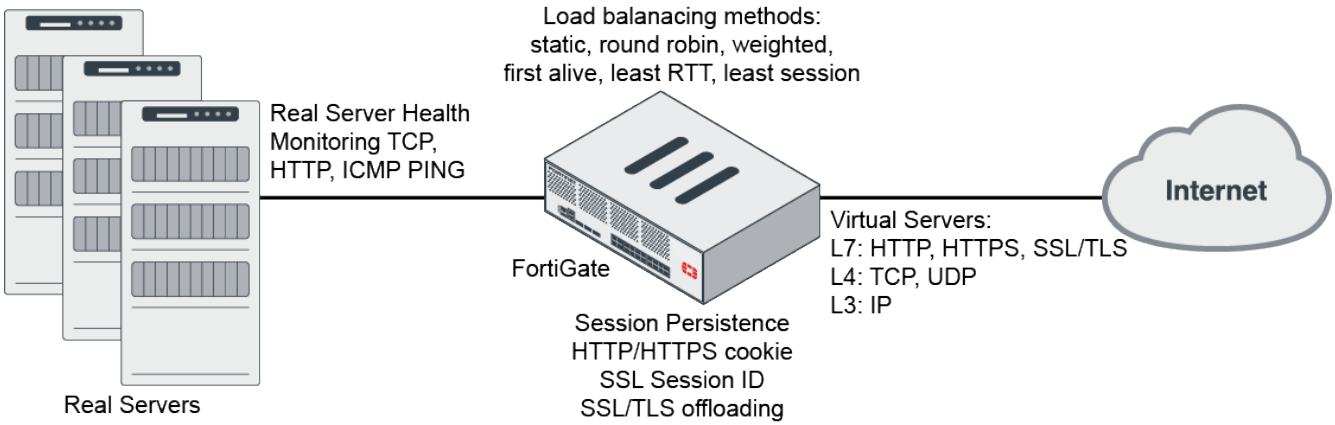
9. Click *OK*.
10. Follow the above steps to create two additional virtual IPs.
    a. For one virtual IP:
        - Use a different *Mapped IP Address/Range*, for example, *172.16.200.56*.
        - Set *External Service Port* to *8081*.
        - Use the same *Map to IPv4 port* number: *80*.
    b. For the other virtual IP:
        - Use a different *Mapped IP Address/Range*, for example, *172.16.200.57*.
        - Set *External Service Port* to *8082*.
        - Use the same *Map to IPv4 port* number: *80*.
11. Create a *Virtual IP Group* and put the above three virtual IPs into that group.

To see the results:

1. Apply the above virtual IP to the Firewall policy.
2. The results are:
    - Access 10.1.100.199:8080 from external network and FortiGate maps to 172.16.200.55:80 in internal network.
    - Access 10.1.100.199:8081 from external network and FortiGate maps to 172.16.200.56:80 in internal network.
    - Access 10.1.100.199:8082 from external network and FortiGate maps to 172.16.200.57:80 in internal network

Virtual server load balance

This topic shows a special virtual IP type: virtual server. Use this type of VIP to implement server load balancing.



The FortiOS server load balancing contains all the features of a server load balancing solution. You can balance traffic across multiple backend servers based on multiple load balancing schedules including:

- Static (failover)
- Round robin
- Weighted (to account for different sized servers or based on the health and performance of the server including round trip time and number of connections)

The load balancer supports HTTP, HTTPS, IMAPS, POP3S, SMTPS, SSL/TLS, and generic TCP/UDP and IP protocols. Session persistence is supported based on the SSL session ID based on an injected HTTP cookie, or based on the HTTP or HTTPS host. SSL/TLS load balancing includes protection from protocol downgrade attacks. Server load balancing is supported on most FortiGate devices and includes up to 10,000 virtual servers on high end systems.

FortiOS HTTP and HTTPS server load balancing does not support load balancing based on URL routing. You can use FortiWeb server pools or FortiADC server load balancing to load balance sessions to two or more URL based routes.

Sample topology

SSL/TLS offloading

FortiGate SSL/TLS offloading is designed for the proliferation of SSL/TLS applications. The key exchange and encryption/decryption tasks are offloaded to the FortiGate unit where they are accelerated using FortiASIC technology which provides significantly more performance than a standard server or load balancer. This frees up valuable resources on the server farm to give better response to business operations. Server load balancing offloads most SSL/TLS versions including SSL 3.0, TLS 1.0, and TLS 1.2, and supports full mode or half mode SSL offloading with DH key sizes up to 4096 bits.

FortiGate SSL offloading allows the application payload to be inspected before it reaches your servers. This prevents intrusion attempts, blocks viruses, stops unwanted applications, and prevents data leakage. SSL/TLS content inspection supports TLS versions 1.0, 1.1, and 1.2 and SSL versions 1.0, 1.1, 1.2, and 3.0.

Virtual server requirements

When creating a new virtual server, you must configure the following options:

- Virtual Server Type.
- Load Balancing Methods.
- Health check monitoring (optional).
- Session persistence (optional).
- Virtual Server IP (External IP Address).
- Virtual Server Port (External Port).
- Real Servers (Mapped IP Address & Port).

Virtual server types

Select the protocol to be load balanced by the virtual server. If you select a general protocol such as IP, TCP, or UDP, the virtual server load balances all IP, TCP, or UDP sessions. If you select specific protocols such as HTTP, HTTPS, or SSL, you can apply additional server load balancing features such as *Persistence* and *HTTP Multiplexing*.

HTTP	Select *HTTP* to load balance only HTTP sessions with the destination port number that matches the *Virtual Server Port* setting. Change *Virtual Server Port* to match the destination port of the sessions to be load balanced (usually port 80 for HTTP sessions). You can enable *HTTP Multiplexing*. You can also set *Persistence* to *HTTP Cookie* to enable cookie-based persistence.
HTTPS	Select *HTTPS* to load balance only HTTPS sessions with the destination port number that matches the *Virtual Server Port* setting. Change *Virtual Server Port* to match the destination port of the sessions to be load balanced (usually port 443 for HTTPS sessions). You can enable *HTTP Multiplexing*. You can also set *Persistence* to *HTTP Cookie* to enable cookie-based persistence, or you can set *Persistence* to *SSL Session ID*.
IMAPS	Select *IMAPS* to load balance only IMAPS sessions with the destination port number that matches the *Virtual Server Port* setting. Change *Virtual Server Port* to match the destination port of the sessions to be load balanced (usually port 993 for IMAPS sessions). You can also set *Persistence* to *SSL Session ID*.
POP3S	Select *POP3S* to load balance only POP3S sessions with the destination port number that matches the *Virtual Server Port* setting. Change *Virtual Server Port* to match the destination port of the sessions to be load balanced (usually port 995 for POP3S sessions). You can also set *Persistence* to *SSL Session ID*.
SMTPS	Select *SMTPS* to load balance only SMTPS sessions with the destination port number that matches the *Virtual Server Port* setting. Change *Virtual Server Port* to match the destination port of the sessions to be load balanced (usually port 465 for SMTPS sessions). You can also set *Persistence* to *SSL Session ID*.
SSL	Select *SSL* to load balance only SSL sessions with the destination port number that matches the *Virtual Server Port* setting. Change *Virtual Server Port* to match the destination port of the sessions to be load balanced. You can also set *Persistence* to *SSL Session ID*.
TCP	Select *TCP* to load balance only TCP sessions with the destination port number that matches the *Virtual Server Port* setting. Change *Virtual Server Port* to match the destination port of the sessions to be load balanced.

UDP	Select *UDP* to load balance only UDP sessions with the destination port number that matches the *Virtual Server Port* setting. Change *Virtual Server Port* to match the destination port of the sessions to be load balanced.
IP	Select *IP* to load balance all sessions accepted by the security policy that contains this virtual server.

Load balancing methods

The load balancing method defines how sessions are load balanced to real servers.

All load balancing methods do not send traffic to real servers that are down or not responding. FortiGate can only determine if a real server is not responding by using a health check monitor. You should always add at least one health check monitor to a virtual server or to real servers; otherwise load balancing might try to distribute sessions to real servers that are not functioning.

Static	The traffic load is statically spread evenly across all real servers. Sessions are not assigned according to how busy individual real servers are. This load balancing method provides some persistence because all sessions from the same source address always go to the same real server. Because the distribution is stateless, so if a real server is added, removed, or goes up or down, the distribution is changed and persistence might be lost.
Round Robin	Directs new requests to the next real server. This method treats all real servers as equals regardless of response time or the number of connections. This method does not direct requests to real servers that down or non responsive.
Weighted	Real servers with a higher weight value receive a larger percentage of connections. Set the real server weight when adding a real server.
Least Session	Directs requests to the real server that has the least number of current connections. This method works best in environments where the real servers or other equipment you are load balancing all have similar capabilities. This load balancing method uses the FortiGate session table to track the number of sessions being processed by each real server. The FortiGate unit cannot detect the number of sessions actually being processed by a real server.
Least RTT	Directs sessions to the real server with the lowest round trip time. The round trip time is determined by a ping health check monitor. The default is 0 if no ping health check monitors are added to the virtual server.
First Alive	Directs sessions to the first live real server. This load balancing schedule provides real server failover protection by sending all sessions to the first live real server. If a real server fails, all sessions are sent to the next live real server. Sessions are not distributed to all real servers so all sessions are processed by the first real server only.
HTTP Host	Load balances HTTP host connections across multiple real servers using the host's HTTP header to guide the connection to the correct real server.

Health check monitoring

In the FortiGate GUI, you can configure health check monitoring so that the FortiGate unit can verify that real servers are able respond to network connection attempts. If a real server responds to connection attempts, the load balancer continues to send sessions to it. If a real server stops responding to connection attempts, the load balancer assumes that the server is down and does not send sessions to it. The health check monitor configuration determines how the

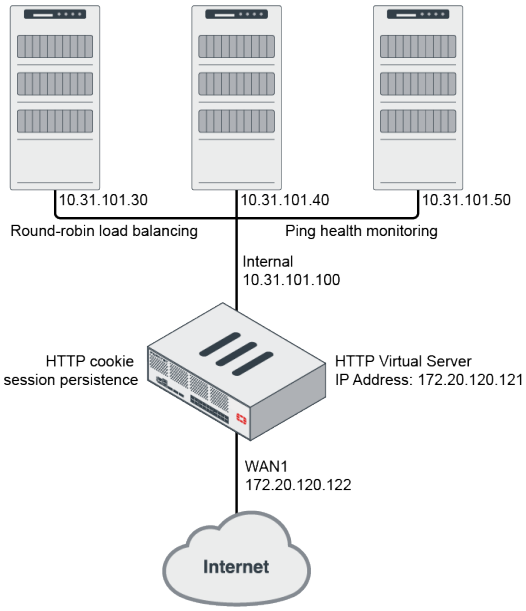
load balancer tests real servers. You can use a single health check monitor for multiple load balancing configurations. You can configure TCP, HTTP, DNS, and ping health check monitors. You usually set the health check monitor to use the same protocol as the traffic being load balanced to it. For example, for an HTTP load balancing configuration, you would normally use an HTTP health check monitor.

Session persistence

Use persistence to ensure a user is connected to the same real server every time the user makes an HTTP, HTTPS, or SSL request that is part of the same user session. For example, if you are load balancing HTTP and HTTPS sessions to a collection of eCommerce web servers, when users make a purchase, they will be starting multiple sessions as they navigate the eCommerce site. In most cases, all the sessions started by this user during one eCommerce session should be processed by the same real server. Typically, the HTTP protocol keeps track of these related sessions using cookies. HTTP cookie persistence ensure all sessions that are part of the same user session are processed by the same real server.

When you configure persistence, the FortiGate unit load balances a new session to a real server according to the load balance method. If the session has an HTTP cookie or an SSL session ID, the FortiGate unit sends all subsequent sessions with the same HTTP cookie or SSL session ID to the same real server.

Real servers



Add real servers to a load balancing virtual server to provide information the virtual server requires to send sessions to the server. A real server configuration includes the IP address of the real server and port number the real server receives sessions on. The FortiGate unit sends sessions to the real server's IP address using the destination port number in the real server configuration.

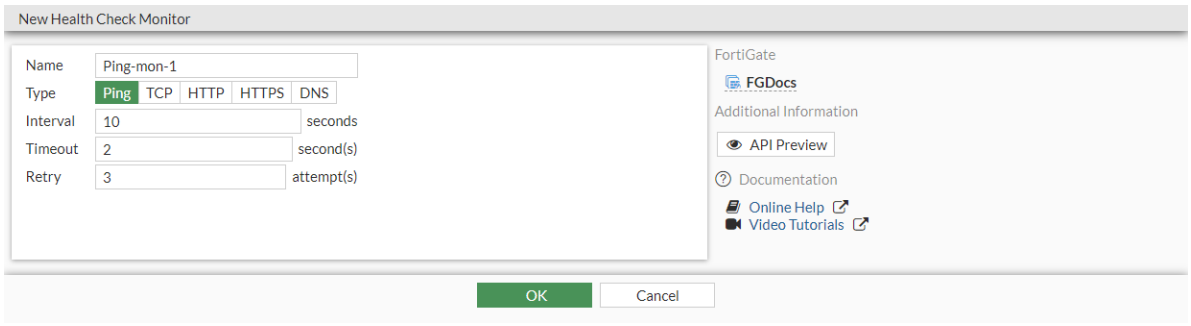
When configuring a real server, you can also specify the weight (if the load balance method is set to *Weighted*) and you can limit the maximum number of open connections between the FortiGate unit and the real server. If the maximum number of connections is reached for the real server, the FortiGate unit automatically switches all further connection requests to other real servers until the connection number drops below the limit. Setting *Maximum Connections* to 0 means that the FortiGate unit does not limit the number of connections to the real server.

Sample of HTTP load balancing to three real web servers

This example describes the steps to configure the load balancing configuration below. In this configuration, a FortiGate unit is load balancing HTTP traffic from the Internet to three HTTP servers on the internal network. HTTP sessions are accepted at the wan1 interface with destination IP address 172.20.120.121 on TCP port 8080, and forwarded from the internal interface to the web servers. When forwarded, the destination address of the session is translated to the IP address of one of the web servers.

This load balancing configuration also includes session persistence using HTTP cookies, round-robin load balancing, and TCP health monitoring for the real servers. Ping health monitoring consists of the FortiGate unit using ICMP ping to ensure the web servers can respond to network traffic.

General steps:

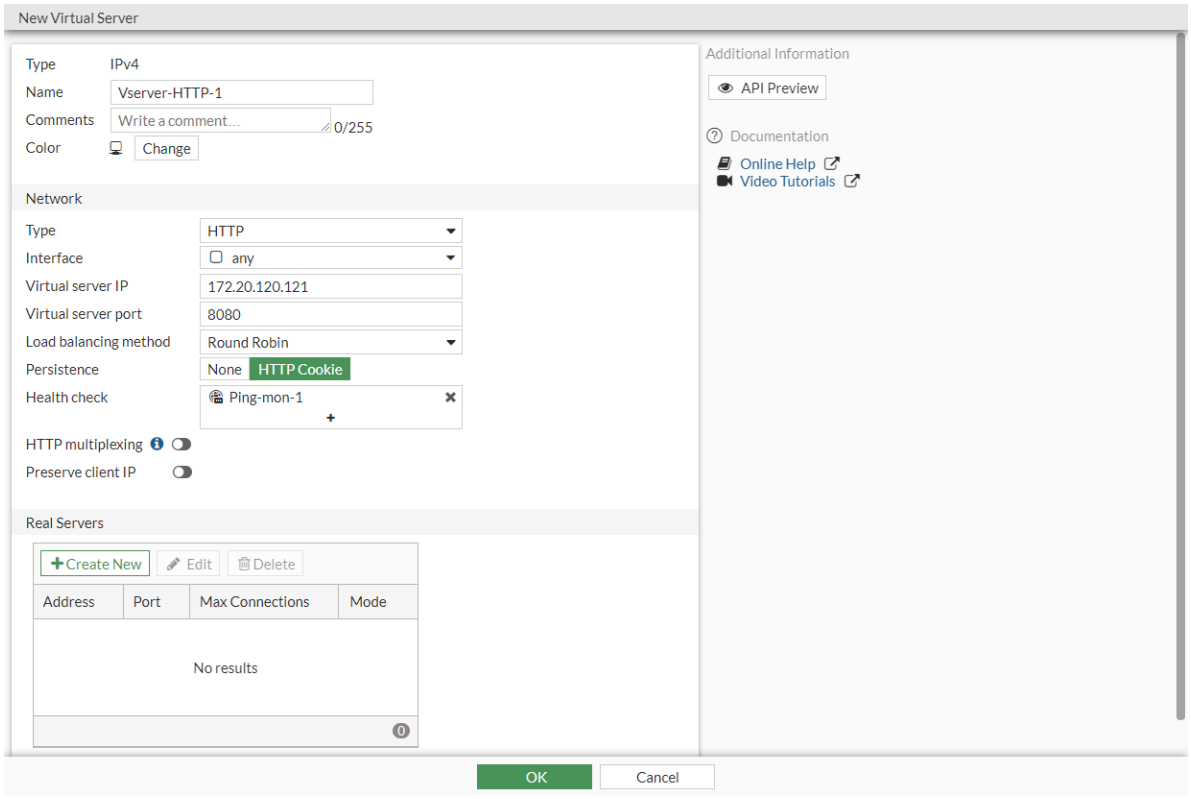


1. Create a health check monitor.
   A ping health check monitor causes the FortiGate to ping the real servers every 10 seconds. If one of the servers does not respond within 2 seconds, the FortiGate unit will retry the ping 3 times before assuming that the HTTP server is not responding.
2. Create a load balance virtual server with three real servers.
3. Add the load balancing virtual server to a policy as the destination address.

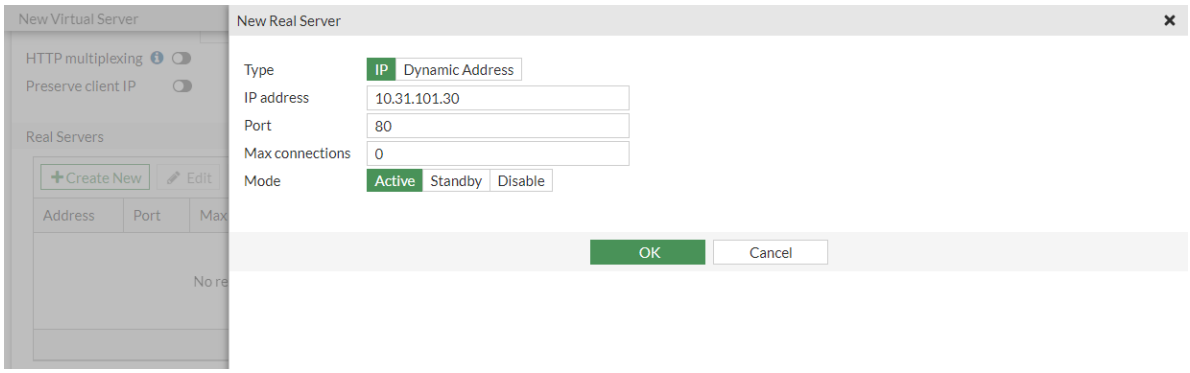
To see the virtual servers and health check monitors options in the GUI, *Load Balance* must be selected in *Feature Visibility* > *Additional Features*. See Feature visibility on page 2517 on page 1 for details.

Configure a load balancing virtual server in the GUI

To create a health check monitor:



1. Go to *Policy & Objects* > *Health Check*.
2. Click *Create New*.
3. Set the following:
   - *Name* to *Ping-mon-1*
   - *Type* to *Ping*
   - *Interval* to *10* seconds
   - *Timeout* to *2* seconds
   - *Retry* to *3* attempt(s)

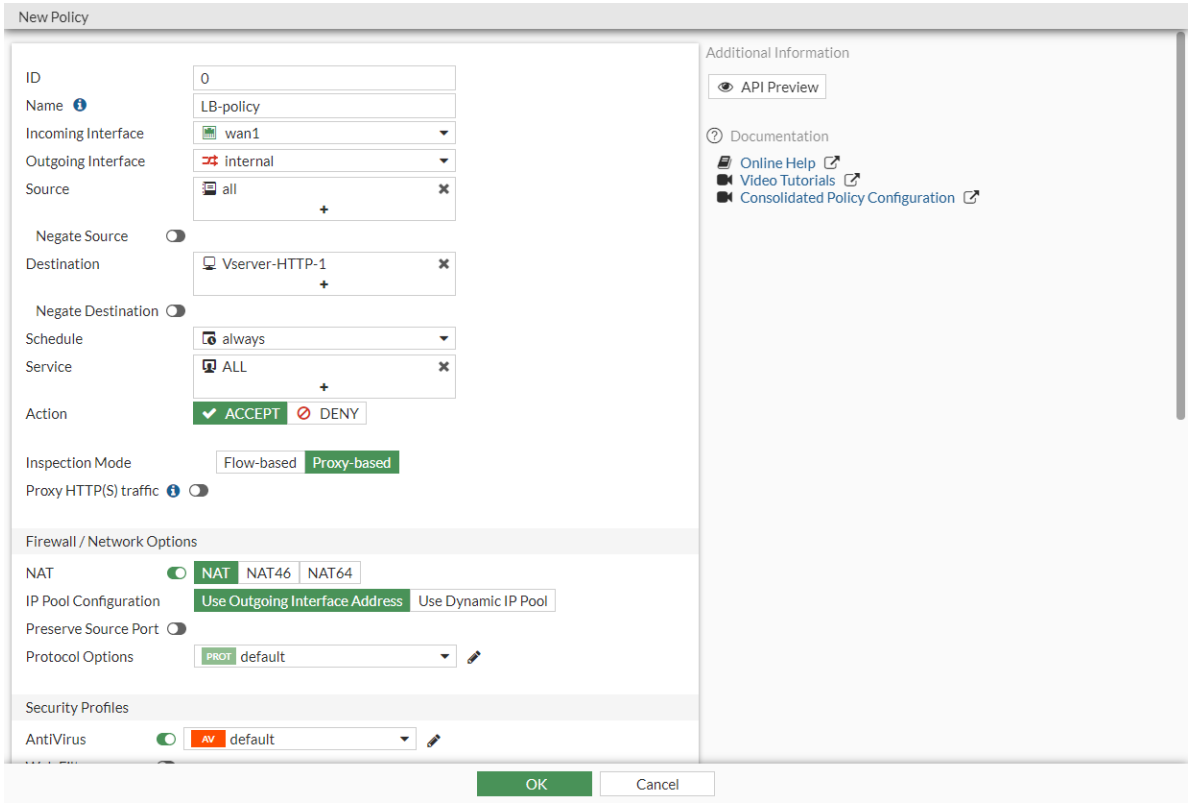


4. Click *OK*.

To create a virtual server:

1. Go to *Policy & Objects* > *Virtual Servers*.
2. Click *Create New*.
3. Set the following:
   - *Name* to *Vserver-HTTP-1*
   - *Type* to *HTTP*
   - *Interface* to *wan1*
   - *Virtual Server IP* to *172.20.120.121*
   - *Virtual Server Port* to *8080*
   - *Load Balance Method* to *Round Robin*
   - *Persistence* to *HTTP Cookie*
   - *Health Check* to *Ping-mon-1*

4. In the *Real Servers* table, click *Create New*.
5. Set the following for the first real server:
   - *Type* to *IP*
   - *IP Address* to *10.31.101.30*
   - *Port* to *80*
   - *Max Connections* to *0*
   - *Mode* to *Active*



6. Click *OK*. Configure two more real servers with IP addresses 10.31.101.40 and 10.31.101.50, and the same settings as the first real server.
7. Click *OK*.

To create a security policy that includes the load balance virtual server as the destination address:

1. Go to *Policy & Objects* > *Firewall Policy*.
2. Click *Create New*.
3. Set the *Inspection Mode* to *Proxy-based*. The new virtual server will not be available if the inspection mode is *Flow-based*.
4. Set the following:
   - *Name* to *LB-policy*
   - *Incoming Interface* to *wan1*
   - *Outgoing Interface* to *internal*
   - *Source* to *all*
   - *Destination* to *Vserver-HTTP-1*
   - *Schedule* to *always*
   - *Service* to *ALL*
   - *Action* to *ACCEPT*
5. Enable *NAT* and set *IP Pool Configuration* to *Use Outgoing Interface Address*.

6. Enable *AntiVirus* and select an antivirus profile.

7. Click *OK*.

Configure a load balancing virtual server in the CLI

To configure HTTP load balancing to three real web servers in the CLI:

1. Create a health check monitor:

```
config firewall ldb-monitor
    edit "Ping-mon-1"
        set type ping
        set interval 10
        set timeout 2
        set retry 3
    next
end
```

2. Create a virtual server:

```
config firewall vip
    edit "Vserver-HTTP-1"
        set type server-load-balance
        set extip 172.20.120.121
        set extintf "any"
        set server-type http
        set monitor "Ping-mon-1"
        set ldb-method round-robin
        set persistence http-cookie
```

```
            set extport 8080
            config realservers
                edit 1
                    set type ip
                    set ip 10.31.101.30
                    set port 80
                next
                edit 2
                    set type ip
                    set ip 10.31.101.40
                    set port 80
                next
                edit 3
                    set type ip
                    set ip 10.31.101.50
                    set port 80
                next
            end
        next
    end
```

3. Add the load balancing virtual server to a policy as the destination address:

```
config firewall policy
    edit 2
        set name "LB-policy"
        set inspection-mode proxy
        set srcintf "wan1"
        set dstintf "internal"
        set srcaddr "all"
        set dstaddr "Vserver-HTTP-1"
        set action accept
        set schedule "always"
        set service "ALL"
        set utm-status enable
        set ssl-ssh-profile "certificate-inspection"
        set av-profile "default"
        set fsso disable
        set nat enable
    next
end
```

Results

Traffic accessing 172.20.120.121:8080 is forwarded in turn to the three real servers.

If the access request has an http-cookie, FortiGate forwards the access to the corresponding real server according to the cookie.

Central DNAT

Central NAT allows for the central configuration of SNAT (source NAT) and DNAT (destination NAT).

To enable central NAT in the GUI:

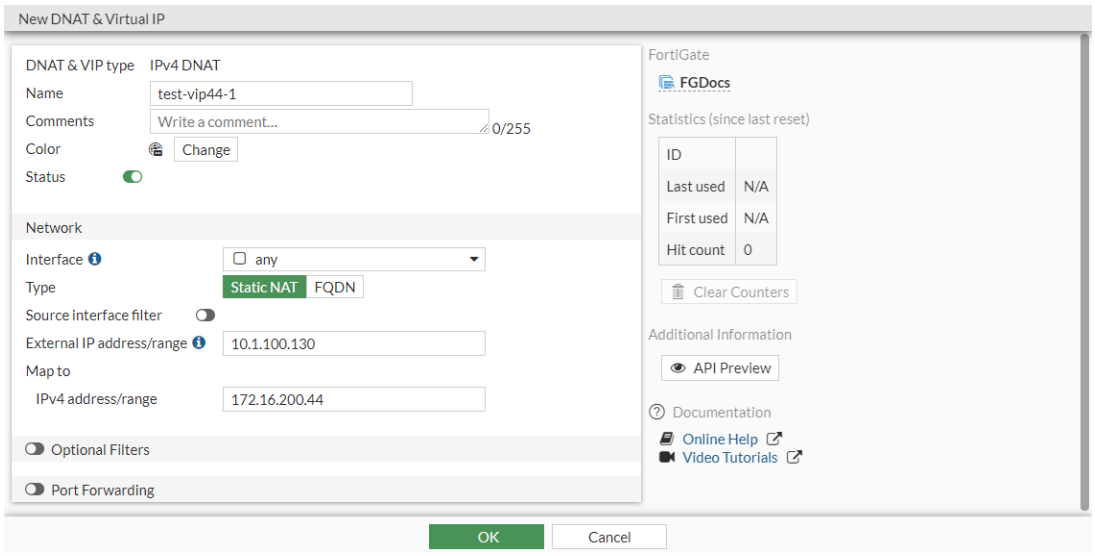
1. Go to *System* > *Settings*.
2. In the *System Operation Settings*, enable *Central SNAT*.
3. Click *Apply*.

To enable central NAT in the CLI:

```
config system settings
    set central-nat {enable | disable}
end
```

When central NAT is enabled, virtual IPs (VIPs) are not configured in the firewall policy. The VIPs are configured as separate objects where their status must be enabled.

This option is only available for IPv4 VIP and VIP46 objects.



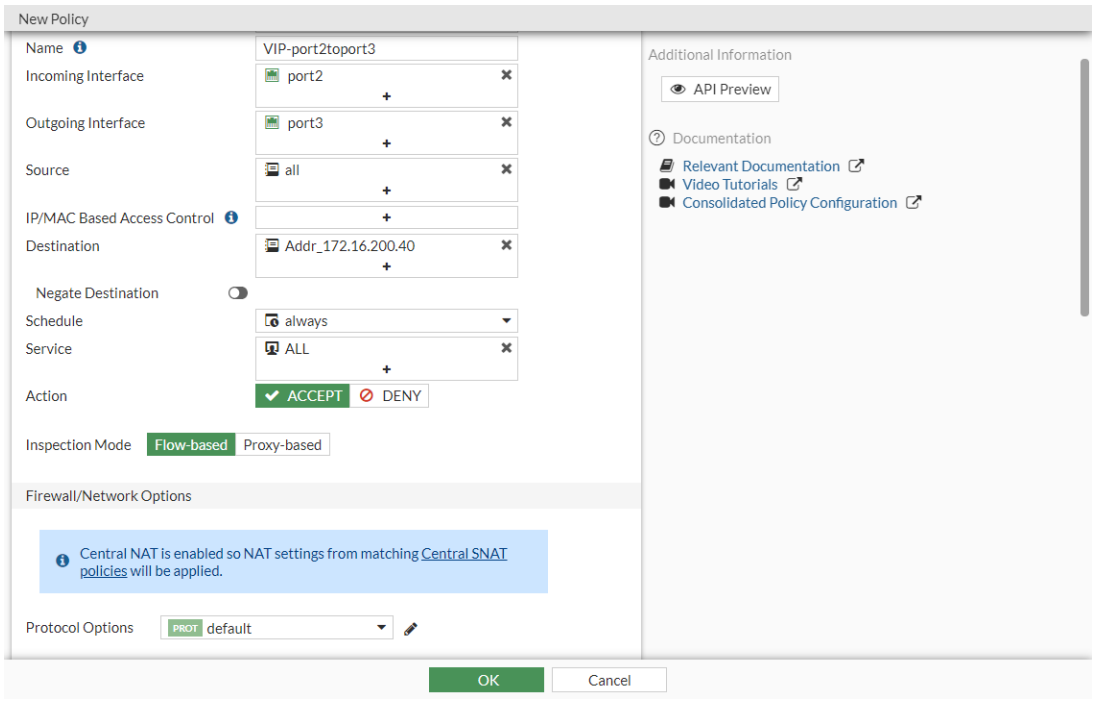
Configuring a DNAT and VIP object in central NAT mode is similar to configuring a VIP when central NAT is disabled. See Static virtual IPs on page 1095 for more information on each setting.

VIP objects can carry over when switching from non-central NAT mode to central NAT mode or vice-versa. However, if a VIP is assigned to a firewall policy in non-central NAT mode, it must be unassigned before switching to central NAT mode.

In this example, a DNAT and VIP are configured to forward traffic from 10.1.100.130 to 172.16.200.44. This example assumes that the firewall address, Addr_172.16.200.44/32, has already been configured.

To configure DNAT and a VIP in the GUI:

1. Configure the VIP:
   a. Go to *Policy & Objects* > *DNAT & Virtual IPs* and click *Create New* > *DNAT & Virtual IP*.
   b. Enter a name (*test-vip44-1*).
   c. Set the *External IP address/range* to *10.1.100.130*.
   d. Set the *Map to IPv4 address/range* to *172.16.200.44*.



e. Click *OK*.

2. Configure a firewall policy that allows traffic in the direction of the VIP:
   a. Go to *Policy & Objects* > *Firewall Policy* and click *Create New*.
   b. Configure the following settings:

Name	*VIP-port2toport3*
Source	*all*
Destination	*Addr_172.16.200.40*
Schedule	*always*
Service	*ALL*
Action	*ACCEPT*

   c. Configure the other settings as needed. There is no SNAT configuration section, so central SNAT policies will be applied.

d. Click *OK*.

To configure DNAT and a VIP in the CLI:

1. Configure the VIP:

```
config firewall vip
    edit "test-vip44-1"
        set extip 10.1.100.130
        set mappedip "172.16.200.44"
        set extintf "any"
        set status enable
    next
end
```

2. Configure a firewall policy that allows traffic in the direction of the VIP:

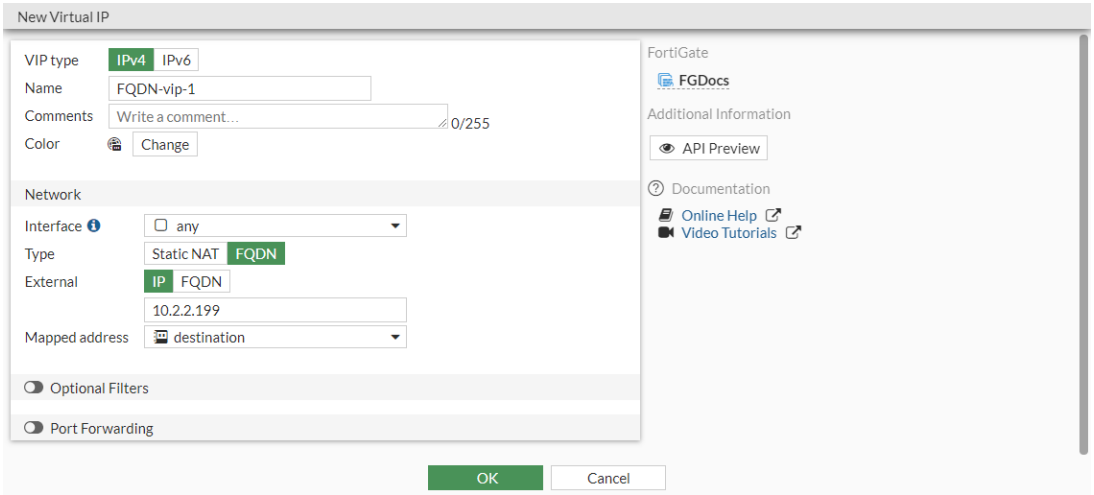
```
config firewall policy
    edit 3
        set name "VIP-port2toport3"
        set srcintf "port2"
        set dstintf "port3"
        set action accept
        set srcaddr "all"
        set dstaddr "Addr_172.16.200.40"
        set schedule "always"
        set service "ALL"
    next
end
```

To verify the DNAT and VIP:

If the VIP status is enabled, it will appear in the VIP table:

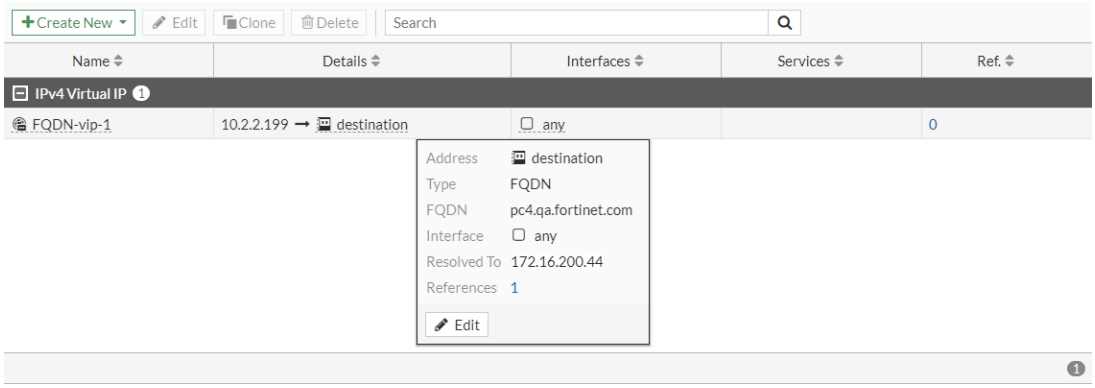
```
# diagnose firewall iprope list 100000
policy index=7 uuid_idx=625 action=accept
flag (8000104): f_p nat pol_stats
cos_fwd=0  cos_rev=0
group=00100000 av=00000000 au=00000000 split=00000000
host=0 chk_client_info=0x0 app_list=0 ips_view=0
misc=0
zone(1): 0 -> zone(1): 0
source(1): 0.0.0.0-255.255.255.255, uuid_idx=0,
dest(1): 10.1.100.130-10.1.100.130, uuid_idx=625,
service(1):
        [0:0x0:0/(0,0)->(0,0)] helper:auto
nat(1): flag=0 base=10.1.100.130:0 172.16.200.44-172.16.200.44(0:0)
```

If the VIP status is disabled, it will not appear in the VIP table.



In this example, a one-to-one static NAT is enabled. Send a ping to 10.1.100.130, and the traffic will be forwarded to the destination 172.16.200.44.

Configure FQDN-based VIPs



In public cloud environments, sometimes it is necessary to map a VIP to an FQDN address.

To configure an FQDN-based VIP in the GUI:

1. Go to *Policy & Objects* > *Virtual IPs* and click *Create New* > *Virtual IP*.
2. Enter a name for the VIP.
3. Select an interface.
4. For *Type*, select *FQDN*.
5. For *External*, select *IP* and enter the external IP address.
6. For *Mapped address*, select an FQDN address.

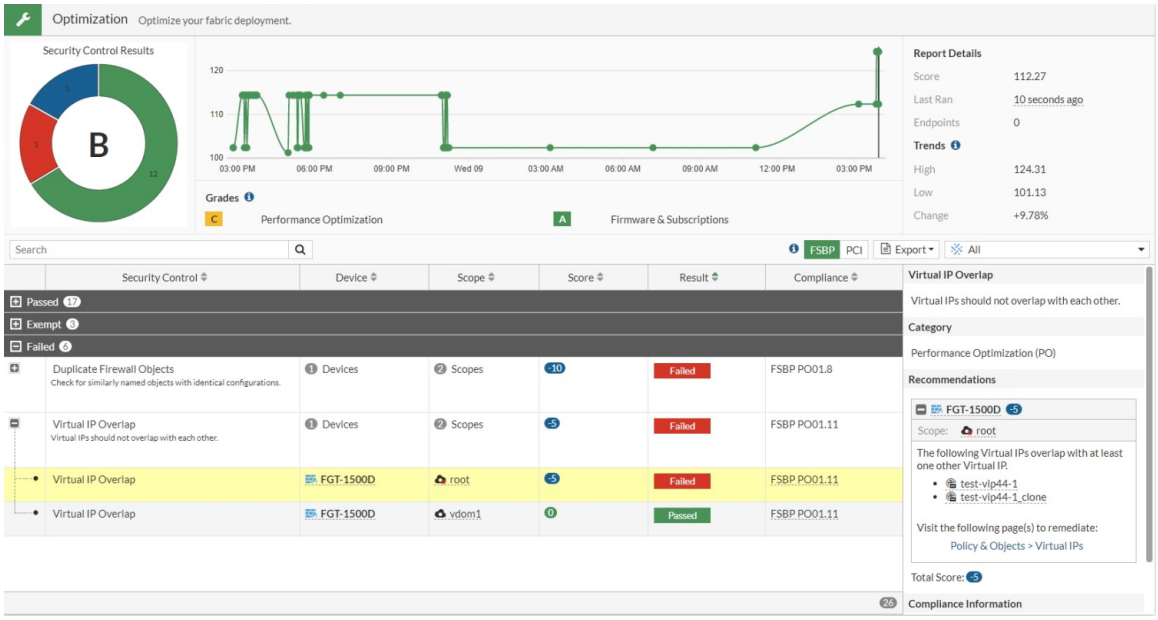
7. Click *OK*.
   In the virtual IP list, hover over the address to view more information.

To configure an FQDN-based VIP in the CLI:

```
config firewall vip
    edit "FQDN-vip-1"
        set type fqdn
        set extip 10.2.2.199
        set extintf "any"
        set mapped-addr "destination"
    next
end
```

Remove overlap check for VIPs

There is no overlap check for VIPs, so there are no constraints when configuring multiple VIPs with the same external interface and IP. A new security rating report alerts users of any VIP overlaps.



To configure two VIPs with the same external interface and IP:

```
config firewall vip
    edit "test-vip44-1"
        set extip 10.1.100.154
        set mappedip "172.16.200.156"
        set extintf "port24"
    next
    edit "test-vip44-1_clone"
        set extip 10.1.100.154
        set mappedip "172.16.200.156"
        set extintf "port24"
        set src-filter 10.1.100.11
    next
end
```

No error message appears regarding the overlapping VIPs.

To view the security rating report:

1. Go to *Security Fabric* > *Security Rating* and click the *Optimization* scorecard.
2. Expand the *Failed* section. The *Virtual IP Overlap* results show an overlap (*test-vip44-1* and *test-vip44-1_clone*) on the root FortiGate.

VIP groups

Virtual IP addresses (VIPs) can be organized into groups. This is useful in scenarios where there are multiple VIPs that are used together in firewall policies. If the VIP group members change, or a group member's settings change (such as the IP address, port, or port mapping type), then those changes are automatically updated in the corresponding firewall policies.

The following table summarizes which VIP types are allowed and not allowed to be members of a VIP group:

Group type	VIP types allowed as members	VIP types not allowed as members
IPv4	• Static NAT • Load balance • DNS translation • FQDN	• Access proxy • Server load balance
IPv6	• Static NAT	• Access proxy • Server load balance

Different VIP types can be added to the same group.

To configure a VIP group in the GUI:

1. Go to *Policy & Objects* > *Virtual IPs* and click *Create New* > *Virtual IP Group*.
2. Set the *Type* to *IPv4* or *IPv6*.
3. Enter a name.

4. Optionally, enter additional information in the *Comments* field.
5. For IPv4 groups, select the *Interface*. Select a specific interface if all of the VIPs are on the same interface; otherwise, select *any*.
6. Click the **+** in the *Members* field and select the members to add to the group.
7. Click *OK*.

To configure an IPv4 VIP group in the CLI:

```
config firewall vipgrp
    edit <name>
        set interface <name>
        set member <vip1> <vip2> ...
    next
end
```

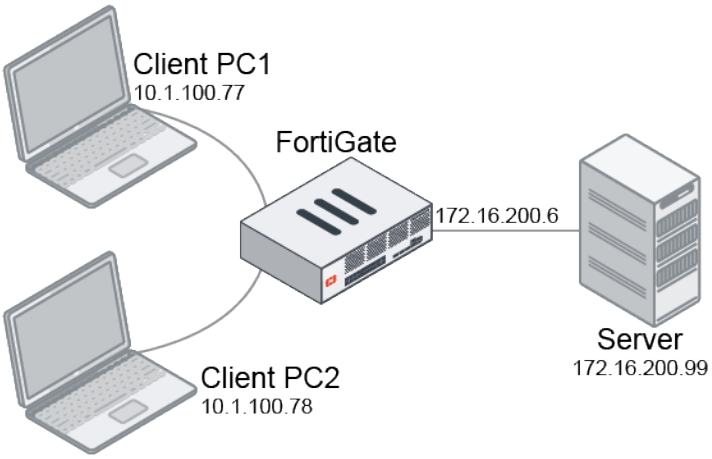
To configure an IPv6 VIP group in the CLI:

```
config firewall vipgrp6
    edit <name>
        set member <vip1> <vip2> ...
    next
end
```

HTTP2 connection coalescing and concurrent multiplexing for virtual server load balancing

HTTP2 connection coalescing and concurrent multiplexing allows multiple HTTP2 requests to share the same TLS connection when the destination IP is the same.

To configure the load balanced virtual server:



```
config firewall vip
    edit <name>
        set type server-load-balance
        set server-type {http | https}
        set http-multiplex {enable | disable}
        set http-multiplex-ttl <integer>
        set http-multiplex-max-request <integer>
        set http-supported-max-version {http1 | http2}
    next
end
```

`http-multiplex {enable | disable}`	Enable/disable HTTP multiplexing.
`http-multiplex-ttl <integer>`	Set the time-to-live for idle connections to servers (in seconds, 0 - 2147483647, default = 15).
`http-multiplex-max-request <integer>`	Set the maximum number of requests that the multiplex server can handle before disconnecting (0 - 2147483647, default = 0).

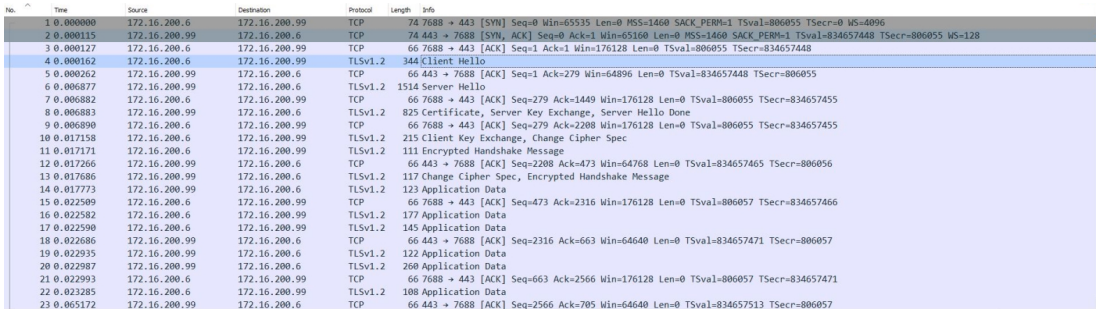
`http-supported-max-version {http1 | http2}`	Set the maximum supported HTTP version: • http1: support HTTP 1.1 and HTTP1. • http2: support HTTP2, HTTP 1.1, and HTTP1 (default).

Example

In this example, multiple clients submit requests in HTTP2. The requests hit the VIP address, and then FortiGate opens a session between itself (172.16.200.6) and the server (172.16.200.99). The coalescing occurs in this session as the multiple streams share the same TLS session to connect to the same destination server.

To configure connection coalescing and concurrent multiplexing with virtual server load balancing:

1. Configure the virtual server:



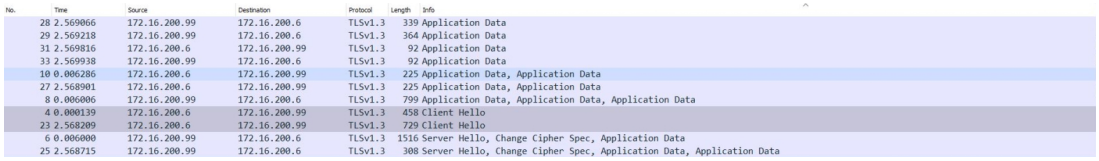
```
config firewall vip
    edit "vip-test"
        set type server-load-balance
        set extip 10.1.100.222
        set extintf "port2"
        set server-type https
        set extport 443
        config realservers
            edit 1
                set ip 172.16.200.99
                set port 443
            next
        end
        set http-multiplex enable
        set ssl-mode full
        set ssl-certificate "Fortinet_SSL"
    next
end
```

2. Configure the firewall policy:

```
config firewall policy
    edit 1
        set srcintf "port2"
        set dstintf "port3"
```

```
        set action accept
        set srcaddr "all"
        set dstaddr "vip-test"
        set schedule "always"
        set service "ALL"
        set utm-status enable
        set inspection-mode proxy
        set ssl-ssh-profile "deep-inspection-clone"
        set av-profile "av"
        set logtraffic all
        set nat enable
    next
end
```

3. Get the clients to access the VIP address (10.1.100.222). The FortiGate shares the first TLS connection with second TLS connection.
4. Verify the sniffer packet capture on the FortiGate server side. There is one client hello.



No.	Time	Source	Destination	Protocol	Length	Info

18	0.022686	172.16.200.99	172.16.200.6	TCP	66	443 → 7688 [ACK] Seq=2316 Ack=663 Win=64640 Len=0 TSval=834657471 TSecr=806057
19	0.022935	172.16.200.99	172.16.200.6	TLSv1.2	122	Application Data
20	0.022987	172.16.200.99	172.16.200.6	TLSv1.2	260	Application Data
21	0.022993	172.16.200.6	172.16.200.99	TCP	66	7688 → 443 [ACK] Seq=663 Ack=2566 Win=176128 Len=0 TSval=806057 TSecr=834657471
22	0.023285	172.16.200.6	172.16.200.99	TLSv1.2	108	Application Data
23	0.065172	172.16.200.99	172.16.200.6	TCP	66	443 → 7688 [ACK] Seq=2566 Ack=705 Win=64640 Len=0 TSval=834657513 TSecr=806057

5. Disable HTTP multiplexing:

```
config firewall vip
    edit "vip-test"
        config realservers
            edit 1
                set type ip
                set ip 172.16.200.99
                set port 443
            next
        end
        set http-multiplex disable
    next
end
```

6. Verify the sniffer packet capture. This time, the FortiGate does reuse the TLS connection, so there are two client hellos sent to the real server.

No.	Time	Source	Destination	Protocol	Length	Info
28	2.569066	172.16.200.99	172.16.200.6	TLSv1.3	339	Application Data

Examples and policy actions

The following topics provide examples and instructions on policy actions:

- NAT46 and NAT64 policy and routing configurations on page 1120
- Mirroring SSL traffic in policies on page 1131
- Recognize anycast addresses in geo-IP blocking on page 1133
- Matching GeoIP by registered and physical location on page 1134
- HTTP to HTTPS redirect for load balancing on page 1136
- Use Active Directory objects directly in policies on page 1137
- No session timeout on page 1141
- MAP-E support on page 1142
- Seven-day rolling counter for policy hit counters on page 1146
- Cisco Security Group Tag as policy matching criteria on page 1148
- Virtual patching on the local-in management interface on page 1150

NAT46 and NAT64 policy and routing configurations

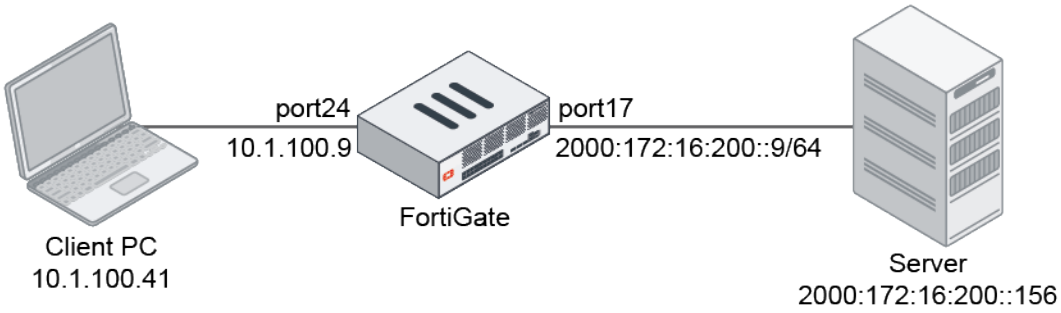
Multiple NAT46 and NAT64 related objects are consolidated into regular objects. A per-VDOM virtual interface, naf.<vdom>, is automatically added to process NAT46/NAT64 traffic. The features include:

- `vip46` and `vip64` settings are consolidated in `vip` and `vip6` configurations.
- `policy46` and `policy64` settings are consolidated in `firewall policy` settings.
- `nat46`/`nat64` are included in `firewall policy` settings.
- `ippool` and `ippool6` support NAT46 and NAT64 (when enabled, the IP pool should match a subnet).
- Central SNAT supports NAT46 and NAT64.
- `add-nat46-route` in `ippool6` and `add-nat64-route` in `ippool` are enabled by default. The FortiGate generates a static route that matches the IP range in `ippool6` or `ippool` for the naf tunnel interface.

Automatic processing of the naf tunnel interface is not supported in security policies.

To configure NAT46/NAT64 translation, use the standard `vip`/`vip6` setting, apply it in a firewall policy, enable NAT46/NAT64, and enter the IP pool to complete the configuration.

The external IP address cannot be the same as the external interface IP address.

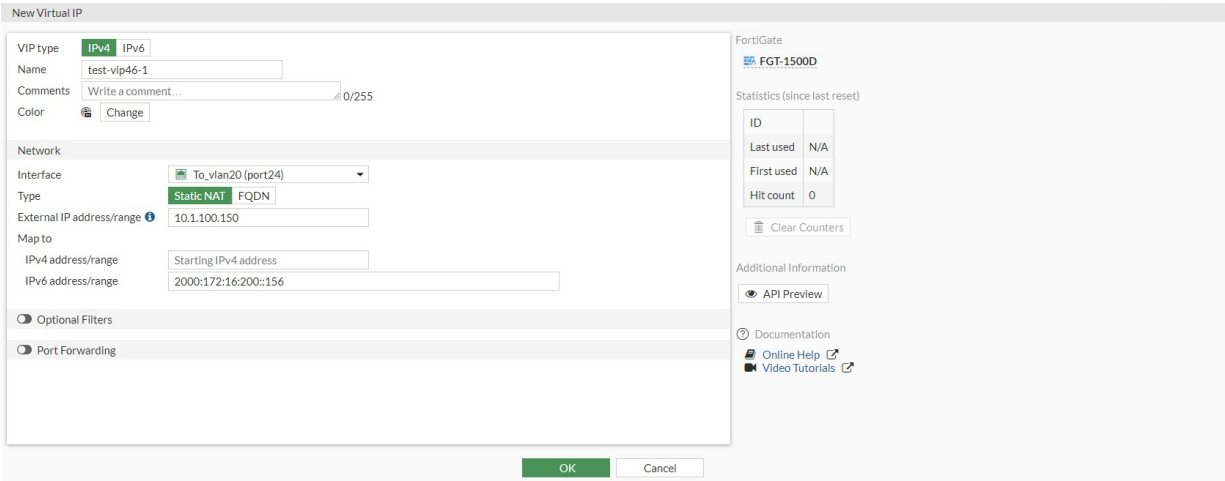


Examples

IPv6 must be enabled to configure these examples. In the GUI, so go to *System* > *Feature Visibility* and enable *IPv6*. In the CLI, enter the following:

```
config system global
    set gui-ipv6 enable
end
```

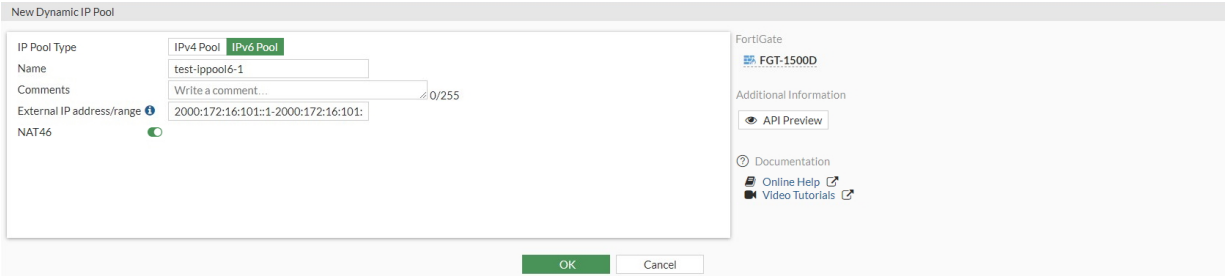
NAT46 policy



In this example, a client PC is using IPv4 and an IPv4 VIP to access a server that is using IPv6. The FortiGate uses NAT46 to translate the request from IPv4 to IPv6 using the virtual interface naf.root. An `ippool6` is applied so that the request is SNATed to the `ippool6` address (2000:172:16:101::1 - 2000:172:16:101::1).

To create a NAT46 policy in the GUI:

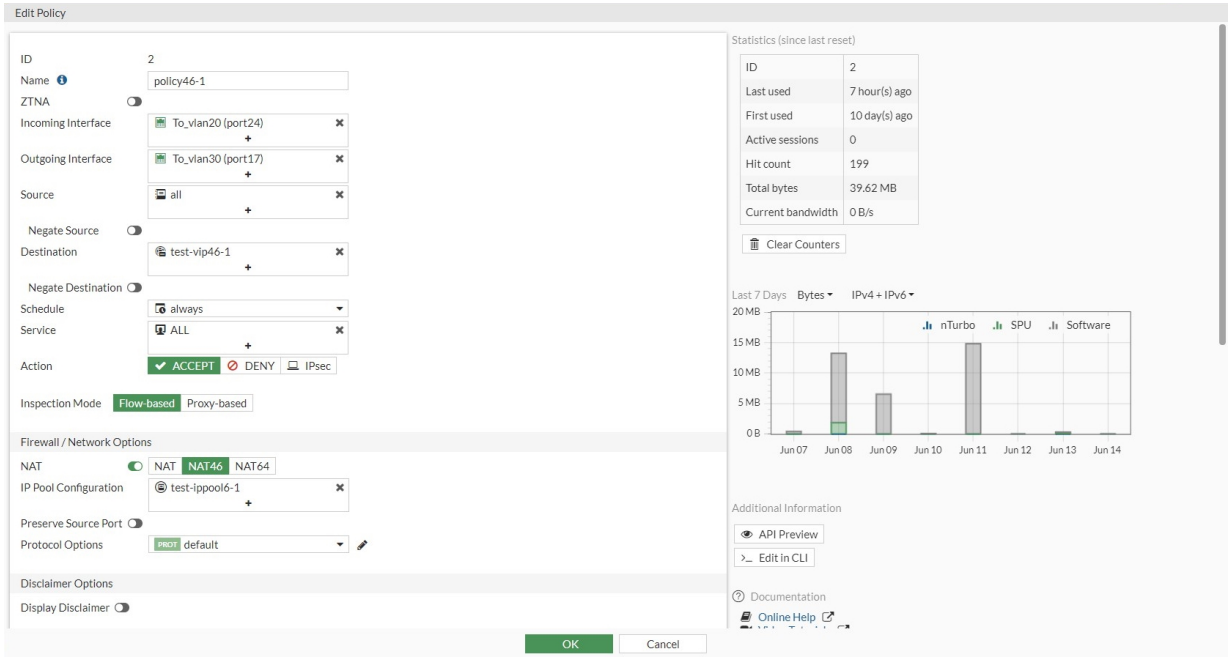
1. Configure the VIP:
   a. Go to *Policy & Objects* > *Virtual IPs* and click *Create New* > *VIP*.
   b. Enter the following:



VIP type	IPv4
Name	test-vip46-1
Interface	To_vlan20
Type	Static NAT
External IP address/range	10.1.100.150
Map to IPv6 address/range	2000:172:16:200::156

   c. Click *OK*.

2. Configure the IPv6 pool:
   a. Go to *Policy & Objects* > *IP Pools* and click *Create New*.
   b. Enter the following:



IP Pool Type	IPv6 Pool
Name	test-ippool6-1
External IP address/range	2000:172:16:101::1-2000:172:16:101::1
NAT46	Enable

   c. Click *OK*.
3. Configure the firewall policy:
   a. Go to *Policy & Objects* > *Firewall Policy* and click *Create New* or edit an existing policy.
   b. Enter the following:

Name	policy46-1
Incoming Interface	To_vlan20
Outgoing Interface	To_vlan30
Source	all
Destination	test-vip46-1
Schedule	always
Service	ALL
Action	ACCEPT
NAT	NAT46
IP Pool Configuration	test-ippool6-1

c. Configure the other settings as needed.

d. Click *OK*.

To create a NAT46 policy in the CLI:

1. Configure the VIP:

```
config firewall vip
    edit "test-vip46-1"
        set extip 10.1.100.150
        set nat44 disable
        set nat46 enable
        set extintf "port24"
        set arp-reply enable
        set ipv6-mappedip 2000:172:16:200::156
    next
end
```

2. Configure the IPv6 pool:

```
config firewall ippool6
    edit "test-ippool6-1"
        set startip 2000:172:16:101::1
        set endip 2000:172:16:101::1
        set nat46 enable
        set add-nat46-route enable
    next
end
```

3. Configure the firewall policy:

```
config firewall policy
    edit 2
        set name "policy46-1"
        set srcintf "port24"
```

```
        set dstintf "port17"
        set action accept
        set nat46 enable
        set srcaddr "all"
        set dstaddr "test-vip46-1"
        set srcaddr6 "all"
        set dstaddr6 "all"
        set schedule "always"
        set service "ALL"
        set logtraffic all
        set auto-asic-offload disable
        set ippool enable
        set poolname6 "test-ippool6-1"
    next
end
```

To verify the traffic and session tables:

1. Verify the traffic by the sniffer packets:

```
(root) # diagnose sniffer packet any 'icmp or icmp6' 4
interfaces=[any]
filters=[icmp or icmp6]
2.593302 port24 in 10.1.100.41 -> 10.1.100.150: icmp: echo request
2.593344 naf.root out 10.1.100.41 -> 10.1.100.150: icmp: echo request
2.593347 naf.root in 2000:172:16:101::1 -> 2000:172:16:200::156: icmp6: echo request seq
1
2.593383 port17 out 2000:172:16:101::1 -> 2000:172:16:200::156: icmp6: echo request seq
1
2.593772 port17 in 2000:172:16:200::156 -> 2000:172:16:101::1: icmp6: echo reply seq 1
2.593788 naf.root out 2000:172:16:200::156 -> 2000:172:16:101::1: icmp6: echo reply seq
1
2.593790 naf.root in 10.1.100.150 -> 10.1.100.41: icmp: echo reply
2.593804 port24 out 10.1.100.150 -> 10.1.100.41: icmp: echo reply
11 packets received by filter
0 packets dropped by kernel
```

2. Verify the session tables for IPv4 and IPv6:

```
(root) # diagnose sys session list
session info: proto=1 proto_state=00 duration=2 expire=59 timeout=0 flags=00000000
socktype=0 sockport=0 av_idx=0 use=3
origin-shaper=

total session 1
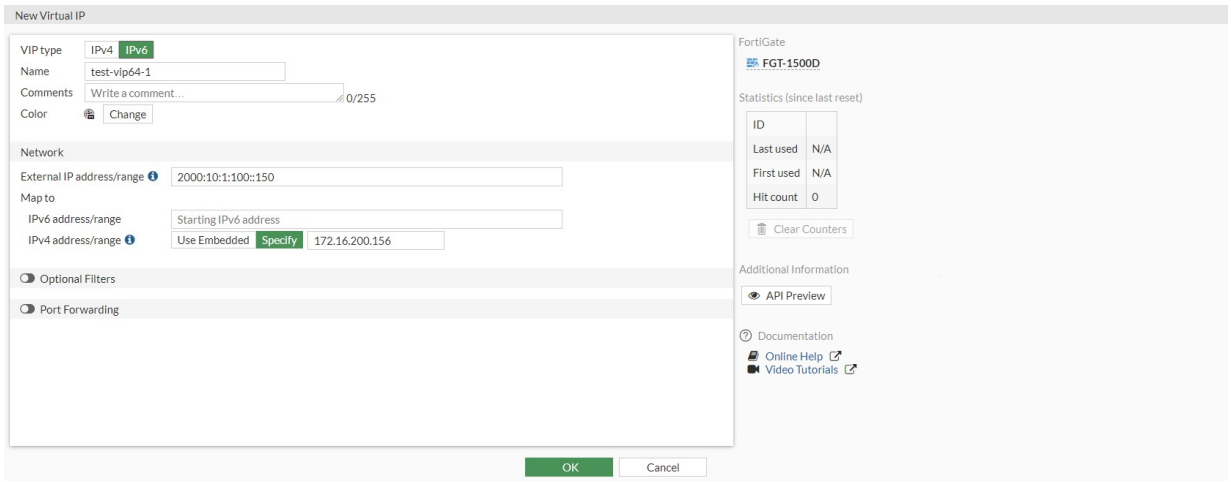
```

The IPv4 session is between the incoming physical interface port24 and naf.root. The IPv6 session is between the naf.root and the outgoing physical interface port17.

NAT64 policy

In this example, a client PC is using IPv6 and an IPv6 VIP to access a server that is using IPv4. The FortiGate uses NAT64 to translate the request from IPv6 to IPv4 using the virtual interface naf.root. An `ippool` is applied so that the request is SNATed to the `ippool` address (172.16.101.2 - 172.16.101.3).



An embedded VIP64 object is used in this configuration so a specific IPv4 mapped IP does not need to be set. The lower 32 bits of the external IPv6 address are used to map to the IPv4 address. Only an IPv6 prefix is defined. In this example, the IPv6 prefix is 2001:10:1:100::, so the IPv6 address 2001:10:1:100::ac10:c89c will be translated to 172.16.200.156.

To create a NAT64 policy in the GUI:
